BLOCK 1 INTRODUCTION TO FOOD SCIENCE AND TECHNOLOGY

The science of food is the study of food components, their behavior under different environmental conditions, process of harvesting, milling, exposure to heat, cold, acid, alkalis etc. It covers all aspects of food raw material production, handling, processing, distribution, marketing and final consumption. For each food the processing methods evolved are based on their composition in terms of carbohydrates, proteins, fat, vitamin and minerals. Now food is a global commodity. Today, the field of food science has progressed from basic physical, chemical and biological reactions that take place during processing to the fields of biotechnology, food engineering, packaging and its effect on the consumer. New processing technologies now aim at not only increasing the shelf life but also retaining maximum organoleptic properties and qualities of fresh foods. The basic knowledge of food, its composition, need, effects of processing etc is essential in order to meet the demands of the market.

Unit 1 deals with **'Introduction to food science'**. After defining the food, its properties, constituents and chemistry are explained. Need of nutrition, digestive process, food spoilage and its effects are also discussed. This unit also covers the recent trends and new processes and equipments coming up in food processing. Food evaluation is discussed in brief.

Unit 2 is about **'Food processing industries'**. This unit explains about the world scenario of food processing, segments of food industries, status of food processing in India. It also covers problems and prospects of Indian food industries. The statuses of major food processing industries like cereal, pulse, horticultural crop, meat and fish industries are discussed. It also gives an overview of National Food Policy.

Unit 3 covers **'Food laws and associated bodies'**. Need pf food laws and standards are discussed. Indian and international food standards and regulatory bodies like PFA, FPO, MPO, BIS, AGMARK, AOAC, USDA, FDA, ISO, Codex Alimentarius are described. Quality assurance systems like HACCP, GMP and TQM are also discussed. This unit also gives an overview of export authorities of India, APEDA, MPEDA, NABL, and MFPI and their role. Product certification and licensing is also discussed in brief.

BPVI-001 FOOD FUNDAMENTALS

UNIT 1 INTRODUCTION TO FOOD SCIENCE

Structure

1.0 OBJECTIVES

After reading this unit, you should be able to:

- know constituents of food and properties;
- explain chemistry of food and nutrition;
- describe food spoilage and its effect; and
- discuss recent advances in food science and food evaluation.

1.1 INTRODUCTION – DEFINITION OF FOOD

Foods are materials, which in their naturally occurring, processed or cooked forms, are consumed by human beings for their nourishment, sustenance and enjoyment. Moreover food items are food grains (cereals: wheat, rice, coarse cereals like sorghum, millets etc.), legumes (pulses: red gram, black gram, green gram, beans), horticultural produce (fruits, vegetables, spices, condiments etc.), livestock produce (meat, egg, milk etc.) and fish (fish, prawns, crabs etc.). Beverages like tea, coffee, cocoa etc are also part of food.

Food sources in their natural form are cultivated, reared, captured or cultured. Some foods can be taken in raw form while most need some kind of processing to introduce desirable characteristics in them to make them acceptable, edible and digestible.

Food, as is known, is the essence of life. It is an exciting subject to study and know its importance and values. In earlier days human started experimenting on various forms and tastes. This led to the development of culinary art. Later on some people who developed special interest, became expert and earned name and fame. Much later it became a huge industry with a trade value of US$ two trillion.

Food Science and Food Technology can be defined as

Food Science: Food Science is the discipline in which the Biological and Physical Sciences and Engineering are used to study the nature of Foods, Causes of their deterioration and the principles underlying Food Processing.

Food Technology: It is the application of Food Science to the selection, preservation, processing, packaging, distribution and use of safe nutritious and wholesome food.

1.2 CONSTITUENTS OF FOOD, PROPERTIES AND THEIR SIGNIFICANCE

There are two important properties of food: nutritional value and taste (hedonic) value. The former is relatively easier to quantify since important nutrients are limited in number and their effects are more or less defined. Defining the taste is more difficult because it must take into account all those properties of food including visual appeal, smell, taste and texture, which interact with our senses. These properties are influenced by a large number of compounds, which in part have not been identified. Besides their nutritional and hedonic values, foods are increasingly being judged according to properties, which determine their handling.

1.2.1 Physical Properties of Foods

In broad sense, the physical properties of foods may be defined as those properties that lend themselves to description and quantification by physical rather than chemical means.

a) **Geometrical properties:** These encompass the properties of size, shape, volume, density and surface area as selected to homogeneous units. The geometrical characteristics of texture refer to structural geometry and structurally heterogeneous foodstuffs.

   Size and shape: The shapes of fruits and vegetables have been classified into 13 categories such as round, oblate, oblong, conic, elliptical, truncated, ribbed etc. the much prevailing method for quantitative shape description involves sphericity which is

   Sphericity = de/dc

   Where, **de** is the diameter of a shape of same as the test object and **dc** is its diameter of smallest circumscribing sphere (usually the longest diameter of the test object).

Size is usually characterized by determining the opening, as in sieve or screen, through which the product will or will not pass and measurement of diameter or length of product.

Volume, density and surface area: Volume and density measurement of liquid foods present no special problem, other than the proper control of temperature at which measurements are made. Standard volumetric methods (graduated cylinder) for volume quantification and pycnometer or commercial density meters for density measurement are simple. Volume of agricultural products, especially those exhibiting an irregular shape, is usually determined by water displacement. Density of solids can be determined by floatation in liquids (usually salt solutions) of different densities. Density of certain agricultural produce (peas, lima beans, potatoes) is an indirect measure of their texture also. Separation by density in floatation is also used with many agricultural commodities to remove defective materials and extraneous matter. Density is measured and defined in various ways like true density, substance density, particle density, apparent density and bulk density.

Surface area values have a meaning in heat transfer. A number of methods have been developed for calculating the surface area of products such as fruits etc based on shape factor measurement (e.g. areas of axial or longitudinal cross sections).

b) **Optical properties:** The most important optical properties from the quality point are colour and surface appearance (gloss) of the produce. These works on reflected light along with some spectrophotometer measuring light in both reflectance and transmittance modes. Transmitted light may be used for detecting defects such as water cores in apple.

Colour: It is one of the most important attributes and can separate a high quality produce (such as the golden yellow of a table orange) or can alert the consumer to a potential psychological danger (such as green processed meat). It also inferences flavour requirements in produce such as beverages and dessert gels and it affects consumer perceptions. Spectrophotometric method for colour description is based on three demarcations reflectance (lightness), dominant wavelength and purity. In this Hunter colour lab equipment colour scales L, a and b are used. L defines the lightness, a, the red-green lines and b the blue-yellow lines.

Gloss: The appearance of a surface, whether it is glossy or dull, is an important physical aspect of food quality detected by human vision. Typical of products where a shiny surface is valued as apples, cucumbers, cherries, on the other hand, oranges, green beans etc have dull surface. Gloss in the psychological attribute of surfaces associated with the spectrum reflects and can vary from surface to surface.

1.2.2 Rheological Properties

The complex nature of foods their variability and their diverse behaviour are some of the reasons for cataloguing separately the flow behaviour of specific foods.

The evaluation of rheological properties of solid foods can be divided into two broad classes. *Fundamental* tests measure properties that are inherent to the material and independent on the geometry of sample, the condition of loading or the apparatus e.g. modulus of elasticity, Poisson ratio, relaxation time, and shear modulus. *Empirical or imitator* tests are used to determine properties such as puncture force and extrusion energy where the mass of the sample, geometry, speed of test etc also determine the parameter estimated. The fundamental tests as applied to solid foods may again be classified into two essentially different groups: those divided under conditions of static (quasi-static) loading and those considered under dynamic conditions. Because foods are visco-elastic both time dependants and time independent measurements are required.

Foods that flow under gravity and do not retain their shape are considered to be fluid foods. Foods may exist as solids at one temperature and as liquid at other temperature (like ice-creams), suspension of solid matter is fluid media or emulsions. Because of wide varieties of their structure and composition, foods exhibit flow behaviour ranging from simple Newtonian to time dependent non-Newtonian and visco-elastic. For example, raw whole egg at 21 C was found to be a Newtonian fluid. However frozen egg was found to be a shear-thinning fluid.

1.2.3 Thermal Properties

Thermal properties are required to understand heat transfer during heating or cooling which foods are often subjected. Variability in composition and physical characteristics is typical for all food products.

The major thermal properties are specific heat, enthalpy, thermal conductivity, thermal diffusivity and heat transfer coefficient. These are much commonly used properties in designing a system for heating/ cooling of foods. These are several other properties that are thermal in value but are much less important to most heat transfer applications: melting/freezing point, latent heat, heat of respiration, heat of adsorption, coefficient of thermal expansion, dielectric constant, emissivity and absorptivity (radiation heat transfer).

1.2.4 Mass Transfer Properties

Mass transfer plays a very important role in basic unit operations of food processing. It is also involved in several physical, chemical and biological food processes such as salting, sugaring, oxygen absorption, de-aeration, and cleaning of process equipment. It is important in food processing and storage, where transfer of moisture; vapours/ gases and flavours components may influence food quality.

1.2.5 Electrical Properties

These properties determine the amount of energy coupled by a food product, its distribution within the product. Electrical properties are of most basic interest in high frequency food processing and their dielectric properties because these determine a number of related electrical properties, which affect energy coupling and its distribution within a food product. Biological material acts as heavy insulators i.e. non-ideal capacitors, in terms of their ability to store and dissipate electrical energy from an applied electromagnetic field by radiation transfer. These properties result form electric charging and less current generally related to materials electrical capacitance and resistance and are defined by fundamental dielectric properties.

1.3 FOOD CHEMISTRY: MOISTURE, CARBOHYDRATES, PROTEINS, LIPIDS, VITAMINS, MINERALS, AND PHYTO-CHEMICALS

Nutrients are naturally occurring chemical substances found in food. There are six categories of nutrients: proteins, lipids, carbohydrates, vitamins, minerals, and water. The chemistry of these nutrients influences the characteristics of our food. Proteins, fats, and carbohydrates in food provide the energy our bodies need to function.

1.3.1 Moisture

Every food material contains moisture. It is found in two forms i.e. free water and bound water. It is one of the most important attributes of the food material that affects processing, preservation and storage of foods. Fifty to 60 percent of human body weight consists of water. The fruits and vegetables contain 90% to 99%, fruit juices 80% to 89%, pasta, legumes, beef, and dairy 10% to 60%, and crackers and cereals contain 1% to 9% water.

1.3.2 Carbohydrates

The carbohydrates in diet come from plant foods. Simple carbohydrates include the different forms of sugar (monosaccharides and disaccharides); complex carbohydrates (polysaccharides) include starches and dietary fiber. Specifically they are composed of carbon and water and have a composition of $C_n (H_2O)_n$. No single carbohydrate is essential, but carbohydrates do participate in many required functions in the body. Carbohydrates may be divided into following categories.

Monosaccharides: It may have 6 carbons (called hexoses), or 5 carbons (called pentoses). Glucose (dextrose), fructose, and galactose are three common hexoses. Ribose and deoxyribose are two common pentoses.

Disaccharides: Two monosaccharides may be linked together to form a disaccharide. Sucrose (sugar) is the most common disaccharide and is made of one molecule each of glucose and fructose. Lactose is the major sugar in milk and is made up of one molecule of glucose and one of galactose. Maltose is a disaccharide made from two molecules of glucose.

Polysaccharides: Combination of more than two sugars is referred to as oligosaccharides, unless they are very large and then they are called polysaccharides. Raffinose and stachyose are two oligosaccharides. Nutritionally, polysaccharides are added to increase the dietary fiber content and functionally to thicken, form gel, bind water and stabilize proteins. Starch, cellulose, gums are main polysaccharides.

1.3.3 Proteins

Amino acids are building blocks of protein. Dietary protein is supplied from plant and animal sources. Proteins are polymers of amino acids. The shape and thus the function of a protein is determined by the sequence of its amino acids. Proteins must be broken down (hydrolyzed) to amino acids before they can be used. Once absorbed, amino acids are utilized to make proteins, converted to energy, or stored as fat. About 20 percent of the human body is made of protein.

Amino acids contain an amino group (-NH2) and an acid group (-COOH). There are twenty amino acids that are found in proteins. Amino acids join by forming peptide bonds. The conformation of a protein molecule in the native state is determined by the primary structure, the secondary structure, a tertiary structure.

Primary: The primary structure is the combination of amino acids in a proper sequence by means of the peptide bonds. No other forces or bonds are implied by this structural level designation.

Secondary: Secondary structure is that which forms a pleated or helix structure. The alpha helix is stabilized by hydrogen bonding between carboxyl and the amide groups of the peptide bonds that generally appear in a regular sequence along the chain of amino acids.

Tertiary: A tertiary structure is the folding of the coiled chain or chains. Covalent, hydrogen, and Vander Waals forces may be involved in the structural organization of protein molecules.

1.3.4 Lipids

Lipids include fats and oils from plants and animals. Lipids are the substances in foods that are soluble in organic solvents. This category includes fatty acids, triglycerides, phospholipids, pigments, vitamins, and cholesterol. Naturally occurring fatty acids have an even number of carbons. Reaction products of long-chain fatty acids are very important to the flavour of foods.

Fatty Acids: Fatty acids may be saturated or unsaturated (contain double bonds). A fatty acid that contains one double bond is called mono-unsaturated and with two or more double bonds is called polyunsaturated. Unsaturated fatty acids can exist in two forms, cis and trans, depending upon the arrangement of the portions of the fatty acid molecules around the double bonds. The double bonds in lipid molecules are highly reactive toward oxygen.

Triglycerides: Food fats are made up of three molecules of fatty acids connected to a molecule of glycerol and are known as triglycerides. The vast majority of foods contain fat in the form of triglycerides. Triglycerides are broken apart by lipases enzymes produces soapy flavour products. Triglycerides molecule that has had one fatty acid removed is called a diglyceride, two fatty acids removed is called a mono glyceride.

Phospholipids: Some fatty acids are connected to glycerol molecules that contain a molecule of phosphorus. These special lipids are known as phospholipids e.g. lecithin. They play important roles in the body but are not essential nutrients because the body can synthesize them in adequate quantities.

Cholesterol: Cholesterol is a compound produced by the body that has received considerable attention due to its reported link to heart disease. Some people have a genetic problem with the system that regulates cholesterol synthesis, and they produce excessive amounts. These people generally have greatly elevated serum cholesterol levels. This is of concern because high serum cholesterol is a risk factor for coronary heart disease.

1.3.5 Vitamins

Vitamins are chemical compounds in our food that are needed in very small amounts (in milligrams and micrograms) which regulate the chemical reactions in our body. The vitamins are divided into fat-soluble and water-soluble vitamins. Fat-soluble vitamins include vitamins A, D, E, and K. The water-soluble vitamins include the B vitamins and vitamin C. B vitamins include: thiamin, riboflavin, niacin, vitamin B_6, pantothenic acid, folic acid, biotin, and cobalamin (vitamin B_{12}).

1.3.6 Minerals

Minerals, which are also needed only in small amounts, have many different functions. Some minerals assist in the body's chemical reactions and others help form body structures. Minerals are important for energy transfer and as an integral part of vitamins, hormones, and amino acids. Depending on the amount in the body, minerals in the diet are classified as macro-minerals or micro-minerals (sometimes called trace minerals) as listed below:

Macro-minerals

Calcium	Chloride
Phosphorous	Magnesium
Potassium	Sulphur
Sodium	

Micro-minerals important in nutrition include:

Chromium	Molybdenum	Iodine
Cobalt	Silicon	Nickel
Copper	Tin	Selenium
Fluorine	Vanadium	Zinc
Manganese	Fluorine	

1.3.7 Phyto-chemicals

Phytochemicals exhibit diversified physiologic and pharmacologic effects. Active derivatives extracted from leaves, stems, roots, flowers, and fruits of plants may be classified into three main categories:

1. Toxic with no discernible therapeutic use; e.g. pyrrolizidine alkaloids, nicotine, and hydrazine derivatives

2. Toxic but useful for treatment of disease when used in controlled amounts; e.g. morphine, digitalis, and vinca alkaloids

3. Chemo preventative, useful against diseases; e.g. arteriosclerosis, cancer, and diverticular disease

Most active chemo preventative phytochemicals are high molecular-weight fibers such as celluloids, pectins, lignins, and low-molecular-weight compounds such as carotenoids, dithiolthiones, flavnoids, indole carbinols, isothiocyanates, mono- and triterpenoids, and thioallyl derivatives.

1.4 NUTRITION AND DIGESTION

1.4.1 Nutrient Needs

The requirement for a nutrient is that the minimum intake will maintain normal functions of the body and health. The main nutrients required by human beings are water, carbohydrates, protein, fat, vitamins and minerals. These are the source of energy. The nutrient needs of human beings are described below.

a) **Water:** Water is essential. About 65 percent of the adult body is made up of water. Lack of water can cause death more quickly than lack of any other nutrient. All the chemical reactions that occur in the body take place in water. Water also reacts during the chemical processes, regulates body temperature, transports nutrients and wastes, and dissolves nutrients. An adult should drink three to five litres of water each day.

b) **Carbohydrates:** Dietary carbohydrates include sugars, complex carbohydrates, starch and fiber. During digestion all carbohydrates except fiber break down into sugars. Sugars and starches occur naturally in many foods that also supply other nutrients. Examples of these foods include milk, fruits, some vegetables, breads, cereals, and grains.

c) **Fiber:** Fiber is found only in plant foods like whole-grain breads and cereals, beans and peas, fruits and vegetables. Eating a variety of fiber-containing plant foods is important for proper bowel function. Some of the health benefits associated with a high-fiber diet may come from other components present in these foods, not just from fiber itself. For this reason, fiber is best obtained from foods rather than supplements.

d) **Protein:** The nitrogen in protein is used for the synthesis of purines, pyrimidines, nucleic acids, adenosine triphosphate (ATP), hemoglobin, and cytochromes.

Depending on age and gender, humans require different levels of protein in their diet. Humans need the amino acids that the body cannot synthesize. These are known as essential amino acids. They include:

Phenylalanine	Methionine
Tryptophan	Valine
Histidine	Leucine
Isoleucine	Threonine
Lysine	Arginine

e) **Lipids:** In food, lipids are a source of essential fatty acids, gives that energy, act as carriers for flavours and fat-soluble vitamins, contributes to texture and mouth feel, is a pre-cursors of flavour, and provides heat transfer medium. The body can produce most of the fatty acids that it requires. It cannot make some fatty acids that contain double bonds. From linoleic acid (18 carbon fatty acid with two double bonds) humans can synthesize all the other fatty acids they require. Thus, linoleic acid is considered as an essential nutrient.

f) **Vitamins:** Table 1.1 lists the fat-and water-soluble vitamins and their functions.

Table 1.1: Functions of some vitamins

Vitamins	Some functions
Fat-Soluble vitamins	
Vitamin A	Growth and development of bone and epithelial cells, vision
Vitamin D	Absorption of dietary calcium and phosphorus
Vitamin E	Antioxidant in tissues
Vitamin K	Aids in blood clotting
Water-Soluble Vitamins	
Thiamin	Coenzyme in energy metabolism
Riboflavin	Coenzyme in many enzyme systems
Niacin	Coenzyme for cell respiration; release of energy from fat, carbohydrates and proteins
Vitamin C	Metabolism of amino acids, fats, lipids, folic acid, and cholesterol control, collagen formation
Vitamin B_{12}	Coenzyme for red blood cell maintenance and nerve tissue; carbohydrate, fat, and protein metabolism

g) **Minerals:** Table 1.2 lists some of the macro minerals and micro minerals and their functions.

Table 1.2: Functions of some minerals

Mineral	Some functions
Calcium	Bone mineral; blood clotting; nerve, muscle, and gland function
Phosphorus	Bone mineral, part of many proteins involved in metabolism
Iron	Part of haemoglobin and some enzymes, oxygen transport
Copper	Iron absorption, haemoglobin synthesis, skin pigments, collagen metabolism
Magnesium	Bone mineral, enzyme activator; energy metabolism
Sodium, Potassium, Chloride	Tissue fluid pressure and acid-base balance, passage of nutrients and water into cells, nerve and muscle function
Zinc	Activator of many enzymes
Iodine	Thyroid function
Manganese	Synthesis of bone and cartilage components, cholesterol metabolism
Selenium	Removal of peroxides from tissues, enzyme activation

1.4.2 Digestive Process

The processing of food takes place in four stages:

a) **Ingestion:** The act of eating. This is the first of the four main stages of food processing.

b) **Digestion:** Digestion breaks down food into molecules small enough to be absorbed. It breaks polymers into monomers that are easier to absorb and that can be used to synthesize new polymers required by the organism.

c) **Absorption:** Cells that line the digestive tract take up the nutrients. Nutrients are transported to the cells where they are incorporated into the cells and converted to energy that may be used immediately or stored until needed.

d) **Elimination:** In the last stage of food processing is elimination in which undigested wastes pass out of the digestive tract.

1.4.3 Components of the Human Digestive System

The following structures are considered parts of digestive system:

Mouth	Gall bladder
Tongue	Pancreas
Pharynx	Small intestine
Salivary glands	Large intestine
Esophagus	Rectum
Stomach	Anus
Liver	

1.4.4 Stability of Nutrients

The nutritive value of food starts with the genetics of the plants or animals. Fertilization, weather, maturity and harvest also influence the composition of the plant or animal being used for food. Storage before processing affects nutrient levels. Then all of the processing steps continue to affect the nutrient levels in a food. Finally, preparation in the home or at the restaurant can reduce the final nutritive value of a food before the digestive process.

Vitamin A is highly sensitive to acid, air, light and heat, vitamin C, D and thiamin to alkalinity, air, light and heat. Because of this sensitiveness, cooking losses of some essential nutrients may be in excess of 75%. A primary goal of food science is to preserve the nutrients through all phases of food harvesting, processing, storage, and preparation. Stability of nutrients under varying conditions of pH, air, light, heat, and cold is different. Nutrient losses are small in most modern food processing operations, but when nutrient losses are unavoidably high, the law allows enrichment.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. What are the major properties of food? Define them.

……………………………………………………………………………

1.5 FOOD SPOILAGE AND ITS EFFECTS

All foods have a time limit of their usefulness that depends on the type of food, the storage conditions, and other factors. Shelf life is the time required for a food product to reach an unacceptable quality. It depends on the food item, the processing method, packaging, and storage conditions. Food spoilage includes changes in organoleptic quality, nutritional value, food safety, aesthetic appeal, colour, texture, and flavour. To some degree, all cause negative changes in the food as much as possible.

1.5.1 Types of Food Deterioration

The three general categories of food deterioration are physical, chemical and biological. Factors that cause food deterioration are many, including light, cold, heat, oxygen, moisture, dryness, other types of radiation, enzymes, microorganisms, time, industrial contaminants, and macro-organisms (insects, mice, etc).

1.5.2 Causes of Food Deterioration

Specific causes of food deterioration include number of factors as described below. These items can cause deterioration individually or in any combination.

Bacteria, Yeast, Mold: Thousands of species of microorganisms exist, and few hundred are associated with foods. Not all are bad because some are desirable in food preservation. Bacteria are single-celled organisms occurring in three shapes: round (cocci), rod (bacilli), and spiral (spirilla and vibrios). Some produce spores, and these spores are resistant to heat, chemicals, and other adverse conditions.

Yeasts are the largest of the microorganisms but are still single cells, and some produce spores. Molds are larger than bacteria. They are often filamentous, and they all produce spores.

In foods, microorganisms attack all the food components-sugars, starches, cellulose, fats, and proteins. Depending on the food and the microorganism, the action on food could be to produce acids, making the food sour, or produce alcohol. Some microorganisms produce gas, making the food foamy; still others produce unwanted pigments or toxins.

Environmental conditions that affect microbial growth include temperature and oxygen. Microbes that prefer cold temperatures are said to be pyschrophilic. Mesophilic microorganisms prefer normal temperatures; thermophilic microorganisms prefer hot temperatures. Bacteria or moulds that require atmospheric oxygen are said to be aerobic, and those yeast and bacteria that do not require atmospheric oxygen are called anaerobic. Facultative microorganisms are both aerobic and anaerobic; obligative microorganisms are either.

Insects: Insect damage can be minor, but the wounds facilitate additional damage by microorganisms. Insect damage and infestation can also be so much that it can make the food inedible.

Food Enzymes: All foods from living tissues have enzymes. At the time of harvest or slaughter, enzymes that control digestion and respiration proceed uncontrolled and cause tissue damage. Some of the post-harvest enzymatic reactions are desirable-for example, the ripening of tomatoes and the aging or tenderizing of beef. Heat, chemicals, and radiation can control enzyme action.

Heat and Cold: The higher the temperature, the faster the biochemical reactions. In fact, the rate of chemical reactions doubles with each 10-degree rise in temperature. On the other hand, subfreezing temperatures damage tissues. Cold temperatures may also cause discoloration, change the texture, break an emulsion, and denature protein. Chilling can injure the tissue of fruits.

Oxygen: Chemical oxidation reactions can destroy vitamins (especially A and C), alter food colours, cause off-flavours, and promote the growth of moulds.

1.5.3 Food-Borne Disease

Food infections are caused when a microorganism is present in the food and it causes infections in the human when the food is consumed. *Clostridium perfringen*, *Salmonella* sp., *Escherichia coli* and several others can cause infections. Food intoxication occurs when a food is consumed that contains chemical toxins which poison the humans. *Staphylococcus aureus* and *Clostridium botulinum* both produce toxins.

Microbes associated with disease: Disease-causing organisms that are associated with foods are very important from both a human health perspective and from economical perspective. The diseases that are caused by microbes associated with food are grouped into three categories: infections, intoxications, and toxico-infections.

Food-borne intoxications: Intoxications are the result of the ingestion of a toxin that is produced by a microbe living on the food product. The toxins that are produced by these organisms usually have a long half-life, even if the microorganism have died, the toxin remains. Intoxications also differ from infections in that the symptoms usually occur within hours after ingestion, instead of the days that are normally associated with food borne infections. Toxin producing strains of *Staphylococcus aureus* are responsible for staphylococcal food poisoning. It can be found in nasal passages, skin and throats of human. Most of these toxins are stable, even under heating conditions. The infective dose for the toxin is between 100-200 nanogrms.

Mycotoxins: Mycotoxins are toxins that are produced by molds that have the ability to grow on food products. Different species of *Aspergillus* and *Penicillium* can produce mycotoxins. Depending on the type of food and the conditions, the mold may be present or absent, even if the mycotoxins remains. Foods associated with mycotoxins include grains, such as corn, wheat, beans, rice and groundnut. If moisture is introduced, molds can grow and form mycotoxins. These toxins are then transferred into the food product that is made from the initial material.

1.6 RECENT TRENDS IN FOOD PROCESSING AND PRESERVATION

New food products and safe foods require new food processing methods and systems. In recent trends, firms exercising control over several stages of food production may increasingly dominate the food industry. This refers to the way products are acquired or traded in a market. Food industry firms form three basic types of vertical coordination.

Open production: A firm purchases a commodity from a producer at a market price determined at the time of purchase.

Contract production: A firm commits to purchase a commodity from a producer at a price formula establish in advance of the purchase. The contract farming comes in this group.

Vertical integration: A single firm controls the flow of a commodity across two or more stages of food production.

The food industry has traditionally operated in an open production system. However, more discriminating consumers, plus new technological developments that allow farm product differentiation, are contributing to a decrease in open production and vertical integration. Changing demographics and the increasing value of a person's time contributed to consumer preferences for a wide variety of safe, nutritious and convenient food products.

Providing food products with specific characteristics preferred by more discriminating consumers will likely involve increasingly more detailed raw commodity products, such as frying chicken of a specific weight and size, or a corn kernel with a specific protein content. This effort to carefully tailor raw commodities with processing in mind is already underway in food industries.

1.7 NEW PRODUCTS AND EQUIPMENT

The kind of food consumed is changing continuously and contributing to the competition and marketing. Over 10000 products are introduced each year in food processing sector. The initial focus of research was to reduce post-harvest losses through improved drying and storage technologies. Later research led to advances in processing techniques for food and feed. Latest research is being carried out to bring about improvement in safety and quality.

New industrial applications evolved, such as new forms of heat processing, low energy production, pasteurization, semi-finished production techniques (filtration, extraction, centrifugation), chilling and freezing. Now, computers are being used to develop sophisticated monitoring systems for instance scientists have developed computer sensors that continually measure plants 'vital signals' such as tissue temperature, and swelling and regulate the irrigation and atmospheric gas concentrations accordingly. Packaging technologies like vacuum packaging of milk have also improved.

Better grain storage techniques and post-harvest management allow developing countries with humid tropical climates to compete in the world grain markets with virtually insect free exports from temperate zones. Recent developments in biotechnology are fostering more concentrated seed production, vertical integration of production and processing and the need for segregated handling system to preserve the identity of distinct products.

New processes are continuously being tried in unit operations. New processes, which are coming up now, are Ohmic heating, irradiation, supercritical fluid extraction and high hydrostatic pressure technologies.

The success of freezing technology has opened a new field for food processors. Complete meals are being prepared now which are frozen until the consumer is ready to thaw and heat them. Many of these meals are sold in serving dishes. Other frozen foods, which are now coming up, are potpies, fish sticks, desserts and potatoes. Additives, food composition standards and labelling are also leading to the development of new products and machineries.

1.8 FOOD EVALUATION

Variety, season, geographical differences, harvesting, handling, processing, packaging, storage, display, home preparation, cooking, and serving influence nutrient content of foods. The food composition is determined by a variety of scientifically sound, standardized methods. The first system of approximating the value of food for nutritional purposes was developed at the Weende Experiment Station in Germany more than 100 years ago. This system separates a food into nutritive fractions. This system was known as proximate analysis. Various methods are developed to evaluate protein, carbohydrate, fat, vitamins and mineral, and fiber in the food. Some of the methods are standards developed by the Government organizations for quality analysis. Number of equipment and processes are also available for proximate analysis of food destructively or non-destructively. Newer methods of determining the composition of foods have replaced or supplemented the old proximate analysis and allowed determination of more specific nutrients in foods. These include spectrophotometry, liquid chromatography, and gas chromatography, which allow the determination of fatty acids, cholesterol, amino acids, specific minerals, and vitamins.

Food composition tables are used to evaluate the nutritional value of food supplies, to develop food distribution programs, to plan and evaluate food consumption surveys, to provide nutritional counselling, and to estimate the nutritional content of individual diets. The parameters that are evaluated for food evaluation are.

Description of food and measure
Moisture
Food energy (in Joules)
Protein, fat, different fatty acids (saturated, monounsaturated, polyunsaturated fatty acids and cholesterol), and carbohydrate (in grams)
Vitamins and Mineral (in milligrams and IU)

1.9 LET US SUM UP

Food is essentially required for human being for energy. Nutrition is the processes by which the foods people eat provide the nutrients they need to grow and stay healthy. There are six categories of nutrients: proteins, carbohydrates, lipids, vitamins, minerals and water. The chemistry of these nutrients influences the characteristics of the food.

Food deterioration includes changes in organoleptic quality, nutritive value, food safety, aesthetic appeal, colour, texture and flavour. To some extent, all food undergoes deterioration after harvest. Deterioration may be physical, chemical or biological. Some deterioration produces toxins that are not destroyed by heat. Some of toxins produced by microorganisms can cause infections in humans.

The kind of foods people eat change in response to many influences such as demographic shifts, supply of ingredients, availability and costs of energy, politics, scientific advances in nutrition, health and food safety. New processing methods and approaches are coming up in food science.

The digestive process includes ingestion, digestion, absorption and elimination. Nutrients in the diet are progressively broken into smaller components by mechanical, chemical, and enzymatic means. Small molecules resulting from digestion are absorbed to supply the body with energy, protein, vitamins and minerals.

Food composition tables are used to evaluate the nutritional value of food supplies, to develop food distribution programs, to plan and evaluate food consumption surveys, to provide nutrition counselling and to estimate the nutritional content of individual diets.

1.10 KEY WORDS

Food : Foods are materials, which in their naturally occurring, processed or cooked forms, are consumed by human beings for their nourishment, sustenance and enjoyment.

Food infection : Illness produced by the presence and growth of pathogenic microorganisms.

Lipids : A broad group of fat like substances with similar properties.

Minerals : Minerals are needed only in small amounts and have many different functions in the human body.

Nutrition	:	It is the processes by which the foods people eat provide the nutrients they need to grow and stay healthy.
Nutrient needs	:	It is the minimum requirement for a nutrient intake that will maintain normal functions and health.
Protein	:	Large molecules of long chains of amino acids.
Properties of foods	:	Properties of foods include physical, rheological, electrical, thermal and optical properties of foods.
Triglycerides	:	Neutral fat molecule made up of three fatty acids joined to one glycerol molecule through a special chemical linkage called ester.
Vitamins	:	Vitamins are chemical compounds in our food that are needed in very small amounts to regulate the chemical reactions in our bodies.

1.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include following points:
   - Geometric, rheological, thermal, electrical and mass transfer properties;
   - Significance of these properties.
2. Your answer should include following points:
   - Chemical composition and bonding.
   - Classifications.
3. Your answer should include following points:
   - Nutrients needed.
   - Significance, functions in body.
4. Your answer should include following points:
   - Digestive process.
   - Components of digestive system.

Check Your Progress Exercise 2

1. Your answer should include following points:
   - Physical, chemical and biological causes
   - Disease and other effects
   - Mycotoxins and intoxications
2. Your answer should include following points:
   - Proximate analysis
   - Food evaluation table

UNIT 2 FOOD PROCESSING INDUSTRIES

Structure

2.0 OBJECTIVES

After reading this unit, you should be able to:

- know scenario of food processing industries in India and world;
- explain trends of consumption of processed food;
- describe problems, prospects and status of food processing industries;
- learn about livestock and aquacultural processing industries; and
- explain national food processing policy.

2.1 INTRODUCTION

Food processing industries are major industries in developed countries. In developing countries, it is in growing stage. The food processing industires include cereals, pulses, oilseeds, bakery, horticultural crops, livestock and aquacultural produce etc. Now food is a global commodity and hence its processing industries will play important role in economy of any country. Type of food is now governed by consumers. The food processing in india is mainly done by unorganized sectors. So, there is a need to know the status of food procesing industries in india. The present unit covers the status of food processing industries in india, trends of food consumption, major processing industires of India and National Food Processing Policy.

2.2 FOOD PRODUCTION IN INDIA AND WORLD, PROCESSING AND VALUE ADDITION

The global food industry, with a value of US$ 2.2 trillion annually, is the single most important industry in the world economy. Food industry is expected to be worth $ 10 trillion by 2028 and most of this growth will come from developing world. The direct impact of the sub sector on growth and indirect stimulus to other type of economic activity carry important implications for employment, exports, food security and living standards. The development of food industries mainly depends upon the raw material coming from agriculture. The production of food grains of the world and percent share of India is given in Table 2.1.

Table 2.1: Production of major agricultural commodities and India' share in 2001

S.No.	Commodity	World production ('000 tons)	% Share of India
1.	Paddy	601128	21.9
2.	Maize	602814	1.9
3.	Wheat	585421	12.3
4.	Groundnut (in shell)	33802	17.7
5.	Sugarcane	1259906	23.3

On an average, agro-industries accounts for about 2% of GDP in developing countries but 9% in developed countries. The value of agro-processing is about three to four times that of agriculture in developed world, while it is typically a fraction of the value of agriculture in developing world. In developed countries, the share of total value added products in agro industries is 20-30%, whereas in developing world it is 30-45%.

The distribution of agro-processing industries within the developing world is relatively unequal. In 1997, 40% of agro-processing value added products in developing countries were concentrated in South and East Asia and Latin America. Among the developing countries, India ranked fourth with 9% value added products of the contribution from developing world. Trade in food products is increasing with a growth rate of 9.4% each year compared with an annual growth of 2.1% for agricultural commodities. Growth has been concentrated among developed countries. About 85% of European Union food exports are processed food while 60% of African export are primary commodities.

Now food is a global commodity. Food is traded and shipped around the world. The modern grocery store sells food from all over the world. These food might include cheese from Europe, beef from Australia, strawberries from Mexico, and apple from Argentina. The food processing industries are opening subsidiaries in other countries and fast food companies are opening outlets all over the world. Globalization and WTO will affect the world food processing industries to a great extent with the new global standards and food safety regulations.

2.3 PARTS OF THE FOOD INDUSTRY

The food industry is divided into four major segments:

i) Production
ii) Manufacturing/processing
iii) Distribution
iv) Marketing

Production: Production includes such activities as farming, ranching, orchard management, fishing and aquaculture. Technologies involved in production of the raw materials include the selection of plant and animal varieties, cultivation, growth, harvest, slaughter, and the storage and handling of the raw materials.

Manufacturing/processing: Manufacturing converts raw agricultural products to more refined or finished products. Manufacturing requires many unit operations and processes that are at the core of food sector.

Distribution: Distribution deals with those aspects conducive to product sales, including: product form, weight and bulk, transportation, storage requirements and storage stability.

Marketing: Marketing is the selling of foods in raw and processed form and involves wholesale, retail, institutions and restaurants

These four divisions are rather artificial as these actually overlap one another. Nevertheless, the food industry requires planning and synchronization in all its divisions to be successful. Another way of dividing the food industry is along major product lines:

- Cereals and bakery products
- Meats, fish and poultry
- Dairy products
- Fruits and vegetables
- Sugars and other sweets
- Fats and oils
- Non alcoholic beverages/alcoholic beverages

These divisions are typically where consumer consumption is measured and reported. Each segment can be divided into number of sub-segments. For example cereal processing may include wheat processing, pulse processing, bakery industries, weaning foods industries, fast food manufacturing etc.

Allied industries: Many companies do not sell food directly but they are deeply involved in the food industry. These are called allied industries. Allied industries produce non-food items that are necessary for marketing food. The packaging industry is a good example. Some specific examples include cans, food colour and flavour, paper products, and plastic products. Chemical manufacturers represent another group of allied industries. They supply the acidulants, preservatives, enzymes, stabilizers, and other chemicals used in foods. Monitoring and regulatory agencies such as the BIS, APEDA, FPO, Food & Drug Administration (FDA), lawyers, consumer action and information agencies, and other regulatory agencies are also part of allied industries.

2.4 TRENDS IN CONSUMPTION OF PROCESSED FOOD

Although expenditure on food has increased considerably over the years, the increase has not matched the gain in disposable income and hence percentage of income spent on food has declined. As income rises, the proportion spent for food declines.

Americans spent only about 8 percent of their personal consumption expenditures for food to be eaten at home. This compares with 10 percent for Canada and 11 percent for the United Kingdom. In less developed countries, such as India and the Philippines, at home food expenditures often account for more than 50 percent of a household's budget. In India, the percent total personal consumption expenditures spent on food consumed at home is 51.3%.

Consumption trends change over the years, and this influences what the food industry does. However, demand for individual foods is more responsive to prices as consumers substitute among alternative food commodities. Rising incomes increase expenditures on more expensive foods, as consumers demand more convenience and quality. Demographic factors, such as changes in household size and the age distribution of the population, can bring about changes in consumption.

Away-from-home meals and snacks now capture almost half (45 percent) of the U.S. food dollar. This is up from 34 percent in 1970. Fast food accounts for the largest and fastest rising share of sales in the food industry. Sales in fast-food industries now outpace the sales in full-service restaurants. People want quick and convenient meals. They do not want to spend to much time in preparing meals, travelling to pick up meals, or waiting for meals in a restaurant. Consumers want to combine mealtime with time engaged in other activities such as shopping, work, or travel. For example, McDonald's, Pizza hut, KFC, Burger King, Taco Bell, and others are now located in conversant outlets.

2.5 STATUS OF FOOD PROCESSING IN INDIA

India is the world's second largest producer of fruits & vegetables, but hardly 2% of the produce is processed. India is the land of spices producing all varieties worth over Rs. 3500 crores (US $ 900 million) amounting to 25-30% of world production, which is processed for value-addition and export. It grows 22 million tonnes of oilseeds covering most of the varieties. Other important plantation products include tea, coffee, cocoa and cashew.

India's livestock population is largest in the world with 50% of world's buffaloes and 20% of cattle, but only about 1% of total meat production is converted to value added products. India is the largest milk producer in the world but only about 15% of the total milk production is processed through the organized sector. Size of the semi-processed and ready to eat packaged food industry is over Rs. 4000 crores (US $ 1 billion) and is growing at over 20%.

India has become a surplus producer of food from being an importer of food grains. However, India does not figure significantly in the world trade of food and food products. Food processing industry in India has been stagnant for a long time, although consumers in India spend more than half their expendable income on food, beverages and tobacco totalling almost Rs. 4000 billion.

There are a large number of small and medium size processing units and only a few large process houses. There are more than 800 flour mills, almost 600 fish processing units with about 4500 cold storages, over 5000 fruit and vegetable processing units, 170 meat processing units, about 650 soft drink units, more than 400 sugar mills and 700 solvent extraction units. With bigger units run by multi national companies, the number may not change significantly but there might be a qualitative change in the character of the industry.

Processed food industry ranks 5^{th} in size in India accounting for about 5.5% of GDP, employing more than 1.5 million workers in the industry with a size of about US$ 30 billion. More than 75% of the industry is in unorganized sector in terms of turnover with value added foods account for US$ 17 billion. The size of semi-processed and ready-to-eat/packaged food industry is about US$ 1 billion.

Processed foods worth over US$ 4 billion were exported in 2002-03, of which rice is about 46% and marine products about 34%. Major exports besides rice and fish products, have been fruits and vegetable products, meat and poultry products both fresh and frozen, egg products and tea. There are good prospects of having grains and grain products as well as milk and milk products also among the major export items.

2.6 MAJOR FOOD PROCESSING SECTORS THEIR STATUS, PROBLEMS AND PROSPECTS

Food processing industry in India can be segmented as follows:

1. Cereal/ pulse milling
2. Fruit & vegetable processing
3. Milk & milk products
4. Beverages like coffee, tea & cocoa
5. Fish, poultry, eggs & products
6. Meat & meat products
7. Aerated waters/soft drinks
8. Beer/alcoholic beverages
9. Bread, biscuits & other bakery products
10. Edible oil/fats.
11. Confectioneries
12. Breakfast cereals, malt protein, weaning, extruded food products

2.6.1 Problems in Food Processing Industries

At present most of the industries are in unorganized sectors. So, numbers of problems are arising from different sections of the industries. Some of the basic problems encountered by Indian food industries at different levels are given below.

Farm level problems

- Poor yield of farm produce and therefore low returns
- Lack of material resources necessary for development
- Primitive methods of farming
- No control on quality of inputs and lack of finance to manage.
- Vagaries of weather
- Unavailability of reliable handling and transportation system
- Lack of storage facilities at farm

Distributors problems

- Lack of modern transportation facilities and high cost
- Inadequate cold storage faculties
- Irregular quality of farm produce

Processing industries problem

- Financing
- Higher import duties
- Higher cost of raw material and packaging
- Inadequate transport and cold storage facilities
- Infrequent availability of refrigerated containers
- Staggering advertising costs
- Limited domestic market

Consumer discontent

- Does not get value for money
- The price variation is a day to day affair
- Continued dependence on seasonal products
- Lack of variety of semi processed or prepared convenience food at affordable prices.

The reasons for slow growth of processed foods in India in past are many. Majority of the population has low-income levels and cannot afford processed foods. Indians traditionally prefer fresh foods that are cooked rather than use preserved foods. There is also no national character for food habits and these keep changing from region to region. However, the scenario is changing with some foods especially the fast foods acquiring the national character. Also some foods such as idli, dosa, some Punjabi foods like chhole, alu mutter etc., some Chinese foods and now the western foods like burgers and pizza are fast gaining national popularity.

There are some factors that impede growth in this industry. Transport (both road and railways) and communication are poor. This causes special problems for perishable products. There are no reliable cold chains, which are necessary for temperature sensitive foods like fruits & vegetables, ice creams etc. Modernization is unaffordable for small-scale manufacturer but the large companies do not find investment justifiable due to small size of market. Packaging costs are high. Even the retail business in small stores so large that an inventory needed to display various brands and that is lacking. Supermarkets are not yet popular although a few are making appearance.

2.6.2 Prospects

Indian government is now making an effort to promote better growth of this industry by giving it a priority sector status for lending by banks, most of the industry (except in alcoholic beverages and those products reserved for small scale), have been exempted from licensing, have relaxation in small scale reservation, foreign technology agreements, agro-based export oriented units, assistance in research and development etc. Government is also trying to improve infrastructure support such as cold chain facilities, transport, storage warehouses, etc. Governments are setting up Food Parks, 10-year tax holiday, and replacement of PFA Act with a new more rational act. The bill for Integrated Food Law is likely to be introduced in the Parliament.

Because of liberalization and other developmental measures being taken, future of the industry looks very bright. To some extent cold chain is being provided, which will help in retaining quality, freshness and reduce post-harvest losses. With the new hybrid varieties being added the production season is also being extended. These developments shall result in the greater availability of quality raw materials to the industry thus resulting in better capacity utilization and producing a wider range of products and of international quality. The quality is now the watchword for success. The multinationals now entering the food industry have an international marketing network and have their brand loyalties all over the world. This will enable the Indian products reaching all over the world in the form and packing required.

With the rise in the per capita income particularly of the middle classes a drastic change in the food habits has been noticed. This will lead to an increased domestic consumption of processed foodstuffs.

2.7 CEREAL PROCESSING

India produces about 200 million tonnes of different food grains every year. All major grains like paddy, wheat, maize, barley, and millets like jowar (great millet), bajra (pearl millet) & ragi (finger millet) are produced in the country.

The country is self sufficient in grain production and is the second largest wheat and rice producer in world, with a 20% share in total world production.

Primary milling of rice, wheat and pulses is the most important activity in food grains. There are over 91,000 rice hullers and 2,60,000 small flourmills engaged in primary milling. Further there are about 43,000 modernized rice mills/huller-cum sheller and the quantity of rice bran processed for bran-oil extraction stood at 3.4 million tonnes in 1999-2000.

Around 820 large flourmills in the country convert about 10.5 million tonnes of wheat into wheat products. Branded rice is becoming popular in the country and significant corporate presence is there in the domestic as well as export markets. Some quantity of wheat and wheat products is also exported.

The total market of bakery product, bread and biscuit is 1.5 million tonne and 1.1 million tonne respectively in year 1998. The cake market alone is estimated at 0.4 million tonne. The organized segment of the biscuit market is estimated to be 0.44 million tonnes whereas the unorganized sector accounts for the balance 0.66 million tonnes. Bread market is estimated to be growing at around 7% per annum in volume terms, whereas the biscuit market in the recent years has witnessed a little higher growth at around 8-10% per year.

Besides the industrial areas in leading metropolis, the bakery products and confectionery are carried on small-scale basis also at household level. Whereas, the confectionery industry has developed remarkably with the international brands mingling with the domestic market toffees, chocolates etc. produced at large scale in important industrial regions of the country. During the last 2 decades, small and unorganized players shared the growth in the industry. Currently, there are an estimated 2 million bakeries across the country engaged in production of bread, biscuits and other products. The estimated annual production of bakery products in India is in excess of 3 million tonnes, of which bread accounts for nearly 50% and biscuits 37% in volume terms in the organized sector. Sugar-boiled confectionery, consisting of hard-boiled candy, toffees and other sugar-based candies, is the largest confectionary segments and valued at around Rs 2,000 crore. The confectionery industry has a current capacity of 85,000 tons; the market is growing at the rate of 10-15% per annum.

2.8 PULSE PROCESSING

In India, around 75% of pulses produced is consumed after having been milled for removal of the husk and splitting or after some processing. Losses take place at various stages after harvest viz. during storage, loosening of husk, at the time of processing, etc. Among post harvest operations, storage causes the maximum loss of 7.5%, processing, threshing and transport causes 1%, 0.5% losses respectively, aggregating 9.5% total loss. Though the main cause of low per capita availability is considered to be poor productivity and production but reduction in post harvest losses can enhance the availability to a considerable extent. However, most of the commercial technologies available for this purpose are either obsolete or inadequate and result in heavy losses due to breakage and powdering of the grain. Successful efforts have been made to develop improved technologies to reduce milling losses and improve product quality. Similarly there is a need for development and utilization of improved technologies for the manufacture of products based on grain legumes.

Conversion of pulses to dhal is the third largest food processing industry in the country after rice and wheat milling industries. It is estimated that about 75% of the pulses produced in the country are converted to dhal. Milling of pulses has been practiced as a small-scale rural operation from time immemorial and more recently as large commercial operation. About 30% of the production of pulses is retained by the farmers and is processed in rural sector using traditional techniques. Presently the dhal available in the market comes almost entirely from the large-scale mills. There are about 10,000 dhal mills working in various parts of the country processing different pulses throughout the year.

A majority of the 5500 mills, reported in the country are big and semi-automatic/ automatic. They process more than 80% of the pulses produced in the country. However, there is a good scope for new entrants in this field is of particular significance as pulses are the main suppliers of proteins and nutritious food to the poor masses.

Depending upon the scope for processing pulses, dhal-milling plants can be setup in rural areas so that the waste material available from this industry could be beneficially used for cattle feed and other purposes.

Many pulse milling machines, technology and process have been developed by different research organizations of the country to overcome most of the anomalies of the traditional methods. Some of these methods have better milling efficiency, more yield in lesser time and at lesser processing costs compared to the traditional process.

2.9 OILSEED PROCESSING

The vegetable oil processing and extraction industry also plays a vital role in our edible oil economy. It comprises the orthodox bullock driven crushers and the modern expander/extruder units. In recent times the processing sector has passed through a transitional phase, attempting to cope with the rapidly changing processing methods the world over.

Over the years the demand for both edible and inedible oils in India has been on the rise. The gap between demand and supply has been largely bridged by using innovative technologies and unconventional oil sources from forest based oilseeds. In recent years per capita consumption of edible oil has also been rising. It was estimated that edible oil demand would be about 7.1 million tonnes or 26 million tonnes of oilseeds. Although India produces about 7 million tones of edible oils annually, a gap may still arise as the industry sources are expecting an increase in our annual per capita consumption of edible oil to 9 kg. The domestic demand for edible oils has been growing at about 6.7 percent per annum whereas production only at 4.5 percent per annum.

The processing by the solvent extraction industry declined to 10.4 million tonnes in 1996 compared to 11.2 million tonnes in the previous year. Exports of oil meal, oilseeds and minor oils have reached 4.55 million tones) valued at Rs. 3766 crores ($ 1067 million) during the year 1996-97 at against 4.54 million tonnes (valued at Rs. 2873 crore equivalent to $ 820 million) in 1995-96, i.e. a quantum jump of 35 per cent over the previous year.

India has about 2.5 lakhs ghanis and kolhus and around 50.000 oil mills of different capacities. While most of the former categories have low productivity, majority of the oil mills have only the capacity of 1 to 5 tonnes per day and about 150 are having that of 50 tonnes per day.

Vanaspati production has been growing at an annual rate of 1.6 per cent during 1990-91 to 1995-96. Yet of its 161 units, 49 have put down the shutter during 1996. The vanaspati producer's are pressing for decontrolling the use of mustard oil in vanaspati production. Now the Vegetable Oils Products (VOP) industry is permitted to use only certain specified varieties of mustard. High input cost is a major constraint faced by the manufacturers. The vanaspati industry's capacity utilization went down to 36 per cent in 1994-95 from a high of 66 per cent in 1987-88. The industry has also added substantial capacities is complete disregard to the market demand, 26.6 lakh tones in 1994-95 compared to 15 lakh tones in 1986-87.

For increasing domestic production potential for vegetable oil (edible & industrial) from non-conventional sources, and integrated approach is necessary for exploitation of non-traditional oilseeds. Soybean and oil palm are two promising oil bearing materials for achieving self-sufficiency for India.

……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………

2.10 HORTICULTURAL CROP PROCESSING

The commercial processing of fruit & vegetables is less than 2%. The main reason being that domestic consumption of processed items is quite meagre because of economic reasons and also as a matter of habit as consumers prefer fresh fruits & vegetables. The high cost of packaging pushes up the cost of the processed items and thereby makes them out of reach of the common man. Because of the varied agro-climatic conditions some fresh fruit & vegetable are available throughout the year.

Presently there are a little over 5198 units registered under the FPO distributed all over the country. Most of the units fall in the cottage and or small-scale sector. A few modern processing plants have, now come up and many more are in the pipeline. The installed capacity, which was 11.08 lakh tonnes, in 1993, increased to 21.00 lakh tonnes at the end of the year 1999. After the liberalization of the economic policies in the country, a few very modern plants produce mango pulp, tomato paste etc. in aseptic packing, freeze drying of many fruit & vegetables including mushroom is being taken up. It is expected that in the years to come, many modern state of the art plants shall come up.

The important items manufactured in the country are fruit pulps particularly of tomatoes & mangoes, ready to serve juices, canned fruits, jam, pickles, squashes, etc. Recently, items like frozen fruits, pulps, dehydrated & freeze-dried vegetables, canned mushrooms etc. are also being produced. In the coming years, new industries like carbonated fruit drinks, dehydrated and freeze dried fruits, fruit juice concentrates are expected to come up.

India in a small way has been in the export market for almost 30 years. Among the popular items in export are mango chutneys, pickles. Fruit juices, canned and dehydrated mushrooms, frozen & canned fruit & vegetables. In the year 1997-98 the exports of processed fruit and vegetables were in the order of 299 thousand tonnes valued at Rs. 761 crores (US $ 200 million).

Due to the WTO Agreement, all the exporting units will have to follow the Codex Alimentarius standards. This makes the compliance easier as one does not have to try to comply with several different legal requirements of different countries. There are many processors who export their products to several countries. Codex Alimentarius also has another requirement and that is Hazard Analysis and Critical Control Points (HACCP). This has been incorporated to ensure safety of food products. Although this is new to most Indian manufacturers, several processing units have already incorporated these requirements in their units.

The future looks quite promising for food processing industry. It is bound to grow at much more healthy rate as many plans are implemented. Government has a big role to play in its development and has already given its willingness to help the industry.

2.11 LIVESTOCK AND AQUACULTURAL PRODUCE PROCESSING

2.11.1 Fish Processing

With over 8000 km. of coastline, 3 million hectares of reservoirs and 1.4 million hectares of brackish water, India has vast potential for fishes from both inland and marine resources. Units mostly exist in the small-scale sector as proprietary or partnership firms or fishermen co-operatives. Over the last decade, the organized corporate sector has become increasingly involved in preservation, processing and export of coastal fish. But the wide variety of fish resources found in Indian inland waters, coastal areas and deep seas comprising India's Exclusive Economic Zone, still remain grossly under utilized

Processing of produce into canned and frozen forms is carried out almost entirely for the export market. In all, there are about 393 freezing units, 13 canning units, 160 ice-making units, 12 fishmeal units and also about 476 cold storage units. Processed fish products for export include: conventional block frozen products, individual quick frozen products (IQF), minced fish products like fish sausage, cakes, cutlets, pastes, surimi, texturised products and dry fish etc.

2.11.2 Meat Processing

India has a livestock population of 470 million that includes 205 million cattle and 90 million buffaloes. The country produces about 450 million broilers and 30 billion eggs annually. Animals, which are generally used for production of meat, are cattle, buffalos, sheep and goat, pigs and poultry. Mithun is also slaughtered for meat in North East and Sikkim. Rabbit meat is also used as a specialty in Kerala and some other states.

Consumption per head of both fresh and processed meat in India is very low at 1.5 kilograms. This compares with the world average of 35.5 kilograms. The production of meat and meat products has shown an impressive growth. The details of production of meat and meat products from 1994 to 1998 are as given Table 2.2.

Table 2.2: Production of meat and meat products (in thousand tonnes)

S. No	Meat product	1994	1995	1996	1997	1998
1.	Mutton and Goat Meat	637	647	669	670	675
2.	Pork Meat	366	420	420	420	420
3.	Poultry Meat	422	578	480	580	600
4.	Cattle Meat (Beef)	1290	1292	1202	1292	1295
5.	Buffalo Meat	1200	1204	1204	1205	1210

The total meat production in the country is 4 million tonnes, which includes beef, buffalo meat, mutton, goat meat, pork and poultry meat. However, only about 1% of the total meat is converted into value added products like sausages, ham, bacon, luncheon meat, kebabs, meatballs etc. The total meat export during 1999-2000 was Rs.845.00 crores consisting mostly of mutton and buffalo meat out of which 70% was contributed by export of buffalo meat.

The country has 3600 slaughterhouses, 9 modern abattoirs and 171 meat-processing units licensed under MPO. A few modern pork-processing plants are also coming up in the country. These are primary meat processing houses and are administered by local authorities. Most of them are outdated and use primitive technologies for the production of meat. There are very few modern facilities, although a few such units do exist for pork and bacon processing, for the integrated slaughter and processing of buffalo, sheep and goat meat and for the processing of poultry meat. In addition to this, a large proportion of meat production is slaughtered in houses or small-unlicensed establishments.

Poultry processing is still in its infancy. There are only seven modern integrated poultry processing plants. However, there are a good number of small poultry processing units engaged in production of poultry meat products. There are five egg-processing units engaged in exporting egg products.

The level of processing in the Indian market is very small and the potential for rapid growth is therefore substantial. With the advent of fast food outlets in all the metropolitan centers, the impact on meat processing industry is immense. As per capita incomes rises and urban families live in smaller units, the demand for processed meat products, which can be rapidly cooked, will rise.

2.12 NATIONAL FOOD PROCESSING POLICY

The Government has come out with a draft national food processing policy with a vision to motivate farmers and food processors and to provide interactive coupling between technology, economy, environment and society for steady development of food processing activities to build up a substantial base for production of value added agro food products for domestic and export markets with a strong emphasis on food safety and quality enabling the farmers especially to realize direct benefits of new technology and marketing network and to ensure adequate availability of quality food products for the consumers at affordable prices.

The policy will seek to create an appropriate environment for the entrepreneurs to set up food processing industries through rationalization of tax structure, harmonization & simplification of food laws, promotion campaign to create market for processed foods by providing financial assistance to Industry Associations, NGOs/cooperatives, private sector units, State Government organizations. It also includes infrastructural development programs like establishment of cold chain, low cost pre-cooling facilities near farms, cold stores and grading, sorting, packaging facilities, application of biotechnology, remote sensing technologies, energy saving technologies and technologies for environmental protection, building up a strong infrastructural base for production of value added products with special emphasis on food safety and quality matching international standards etc. The policy has many backward and forward linkages between farmers, market, processors and consumers.

2.13 LET US SUM UP

The food industry is divided into production manufacturing distribution and marketing. The industry is highly responsive to change and interrelated with others. Consumers drive the food industry and to some extent the food industry drives the consumer, making changes in food consumption, types and meals. Food is now a global commodity with changing tread scenario in the world.

The food processing industry in India is in its growing stage. It contributes 5.5% of GDP. Most of the foods processing industries are in unorganized sector. There are number of problems which are responsible for slow growth of food Industry. But the prospects of food industry are very good, as changes in the food habits have been observed in the recent past.

Cereal processing is the major food-processing sector in India. Numbers of bakery products are also produced in the India and the market is growing fast rate 7.5% of pulses produced in India is processed for preparation of dall. There are about 5500 processing mills in India. There are about 2.5 lakh *ghanis* in India. Vanaspati production sector is slow. The commercial processing of fruits and vegetables is only 2% in India. There are 5198 food processing units which are registered under food product order.

In fish processing the organized sectors are now coming up. There are about 393 freezing units in the country. Meat is one of the important export commodity in food processing export sector. Only 0.2% of total meat production is further processed at commercial scale. The poultry processing is in the starting phase.

The government has come out with a draft national food processing policy with a vision to motivate and provide interactive compiling between all stakeholders. The policy will seek to create an appropriate environment for the entrepreneurs to set up food processing industries through creating enabling environment, infrastructure development with backward and forward linkages.

2.14 KEY WORDS

National food processing policy : Draft of government on food processing policy of India.

Food processing industries	:	The industries engaged in commercial processing of foods.
Allied industries	:	The industries indirectly associated with food processing industries.
Cereal processing	:	The processing of cereals like wheat, paddy etc.
Primary processing	:	It includes cleaning/grading of raw material and dehusking.
Pulse processing	:	The processing of pulses to get the dall or any other product.
Oilseed processing	:	Processing of oilseeds to extract oil from oil-bearing seeds.
Horticultural crop Processing	:	Processing of fruits and vegetables to increase their shelf life and prepare other products.
HACCP	:	Hazard analysis and critical control points.
Fish processing	:	Processing of fish includes, freezing, canning, deboning etc.

Meat Processing: The processing of animal carcass for human consumption.

2.15 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include following points:

   - Classification based on units of industry
   - Classification on food products

2. Your answer should include following points:

   - Past and present status
   - Future prospects and scope

Check Your Progress Exercise 2

1. Your answer should include following points:

   - Problems of farmers, market, processor and consumers
   - Future scope, government policies

2. Your answer should include following points:

   - Cereal, pulses, oilseeds
   - Processing industries, potential

Check Your Progress Exercise 3

1. Your answer should include following points:

   - Meat, fish, poultry processing
   - Present status
   - Future scenario

2. Your answer should include following points:

   - Vision of policy
   - Linkages, creation of enabling environment, infrastructure

2.16 SOME USEFUL BOOKS

1. Economic Survey 2001-2002. Economic Division, Ministry of Finance, Government of India.

2. Fellows, P.J. (1998) Food Processing Technology, Principles and Practices. Woodhead Publishing Limited. Cambridge, England.

3. Parker, R. (2003) Introduction to Food Science. Thomson Learning Inc. New York.

4. Potter, N.N. and Hotchkiss, J.H. (1995) Food Science, 5th Edition. Chapman & Hall Publishing Inc, New York.

UNIT 3 FOOD LAWS AND ASSOCIATED BODIES

Structure

3.0 OBJECTIVES

After reading this unit, you should be able to:

- know types of standards;
- state prevention of food adulteration act (PFA), FPO & MPO, Bureau of Indian standards (BIS), AGMARK standards;
- learn international standards organization (ISO), AOAC, USDA and FDA
- explain codex Alimentarius, HACCP, GMP;
- know about different export promotion councils, APEDA, MPEDA;
- know the organisations - NABL, MFPI, FRAC; and
- organisation describe total quality management (TQM).

3.1 INTRODUCTION

Food processing involves number of unit operations and material handling. So, there are always chances that the food may be contaminated. The food material should also contain essential nutrients. So, standards are formed and number of agencies and organizations are involved at national and international level to make the standards implement and regulate them. This unit covers Indian and international standards and implementing agencies, export promotion agencies of India, NABL, etc. The quality assurance systems like HACCP, TQM and GMP are also covered in brief.

3.2 FOOD LAWS AND STANDARDS

Food is the basic need of all living organisms. Hence, its quality should be given top priority. Processing of the food and food products is usually done at mass scale. So, there are always the possibilities of food being adulterated. The contamination of food can affect a large number of populations at a time and hazards may occur. Secondly, the consumer must get the product for which he has paid. An article of food is called adulterated if the food contains any other substance which effects, or it so processed as to affect injuriously the nature, substance or quality, inferior or cheaper substance has been substituted, prepared and packed or kept under unsanitary condition whereby it has become contaminated or injurious to health, contains filthy, putrid rotten, decomposed or diseased animal or vegetable substance or is insect infested or is otherwise unfit for human consumption etc. The processors may add any prohibited preservative or permitted preservative in excess of the prescribed limits. So, it is essential to set the minimum quantities of desirable characteristics required and the maximum quantities of undesirable components that the food should contain. This also helps to set common standards for commodities and prevents confusion among consumers. Thus, the standards are formulated. There are several ways of arriving at the standards for product quality but four methods are commonly used;

1. **Legal standards:** Standards, which are established by government bodies.
2. **Company or voluntary standards:** Set by the various segments of food industry. Voluntary standards generally represent a consumer image and may become a trademark of product quality.
3. **Industry standards:** An organized group attempts to establish given limits of quality for any food product. Normally these become effective by pressure from marketing organizations or by specific commodity groups where legal standards are not involved.
4. **Consumer or grade standards:** The consumer standards represent the consumer requirements of a product and are generally based on experience of the industry with its consumer.

Out of these, the legal standards are the most important. In fact the government has empowered several agencies and promulgated a number of acts and orders to contract the menace. Agencies and institutions have also been created to lay down standards for the quality of foods. The manner in which the food is processed and packaged is also covered by a number of regulations. Many different types of standards apply to the evaluation, production, testing, and monitoring of dietary supplements. Regulations and product standards are used, as the "yardsticks" that define specific requirements manufacturers must follow to assure product safety and to provide accurate information to health professionals and consumers. These standards also encourage the safety and quality of products by manufacturer making sure that the product meets the standards.

3.3 INDIAN STANDARDS

The Government of India is fully aware of the possibilities of food being adulterated. It has therefore, several agencies, acts, standards and orders which have been formed to formulate standards, implement them, check the adulteration and protect the consumers. Some agencies and institutions were created to lay down standards for the quality of foods. The main agencies involved in this are described below.

3.3.1 Prevention of Food Adulteration Act (PFA)

One of the early acts to be promulgated in food laws and standards was the Prevention of Food Adulteration Act of 1954, which has been in force since June 1,1955, amended 1964 and again in 1976. The objective of this act was to ensure that food articles sold to the customers are pure and wholesome. It is also intended to prevent fraud or deception and encourages fair trade practices.

The Act prohibits the manufacture, sale and distribution of not only adulterated foods but also foods contaminated with toxicants and misbranded foods. A central committee for food standards has been constituted under the Act and has been charged with the function of advising the Central Government on matters relating to the Food standards.

The Food Health Authority is appointed at state level who is the Director of Public Health and Preventive Medicine. He is responsible for the good quality and standards of foods available to the consumers. Under FHA are the Local Health Authority (LHA). There is a Local Health Authority appointed in each city in every state.

3.3.2 Fruit Products Order (FPO)

The Government of India promulgated a Fruit Products order in 1946. In 1955, the order was revised. The Fruit Products Order (FPO) lays down statutory minimum standards in respect of the quality of various fruits and vegetable products and processing facilities. The FPO is enforced by the Department of Health. Presently there is a little over 5198 units registered under the Fruit Products Order of 1955 distributed all over the country. Most of the units fall in the cottage or small-scale sector. A few modern processing plants have, now come up and many more are in the pipeline. The installed capacity which was 11.08 lakh tonnes, in 1993 increased to 21.00 lakh tonnes at the end of the year 1999.

3.3.3 Meat Products Order (MPO)

It provides means to:

1. Detect and destroy meat of diseased animals.
2. Ensure that the preparation and handling of meat and meat products be conducted in a clean and sanitary manner.

3. Prevent the use of harmful substances in meat foods.

4. See that every cut piece of meat is inspected before sale to ensure its wholesomeness.

The order also lays down rules and conditions for the procedure to be adopted for the selection of disease-free animals, slaughterhouse practices.

3.3.4 Bureau of Indian Standards (BIS)

Bureau of Indian Standards (BIS) is the National Standards Organization established as a Society in 1947 as Indian Standards Institution and subsequently made a statutory body as BIS under Bureau of Indian Standards Act 1986. The Bureau comprises of members representing industry, consumer organizations, scientific and research institutions, professional/technical institutes, central ministries, State Government and Members of Parliament. The functions of Bureau are;

1. Standard Formulation.

2. Certification: Product, Quality Management System, Eco Mark, Environment Management System, Hallmarking of Gold Jewellery, Hazard Analysis and Critical Control Points.

3. Laboratory: Testing, Calibration and Management.

4. Standards Promotion.

5. Consumer Affairs.

6. Awareness and Training Programs.

There are 14 Technical departments engaged in formulation of Standards. So far 17000 Standards have been formulated in different technological areas depending upon the National priority. These standards are evolved through the consensus from sectors such as industry, Consumers, testing and laboratory experts and Government organization by co-opting them in the related technical committees, sub committee and panels. The standards are reviewed time-to-time and continuously updated to match the technological changes taking place. The BIS has formulated 1133 standards which pertains to food products.

3.3.5 AGMARK Standard

The AGMARK standard was set up by the Directorate of Marketing and Inspection of the Government of India by introducing an Agricultural Produce Act in 1937. The word 'AGMARK' seal ensures quality and purity. The quality of a product is determined with reference to the size, variety, weight, colour, moisture, fat content and other factors are taken into account. It covers the following commodities:

- Pulses
- Cereals, 1966, 2001
- Makhana
- Vegetable oils
- Fruits and vegetables
- Roasted Bengal gram
- Vermicelli, Macroni and Spaghetti

The grades incorporated are grades 1,2,3 and 4 or special, good, fair and ordinary. Any officer of the Central Government or a State Government, or any authority, authorized by the Central Government, may, if he has reason to believe that any provision of this Act or the rules made there under has been, or is being, contravened, enter any premises at any reasonable time and make necessary inspection of, and search for, the agricultural produce in relation which such contravention has been, or is being made. The officer can seize and penalize the firm for not meeting the standards. The Central Government can declare that the provisions of this Act shall apply to an article of agricultural produce not included in the schedule or to an article other than an article of agricultural produce and on the publication of such notification, such article shall be deemed to be included in the schedule.

3.4 INTERNATIONAL STANDARDS

Quality of food is major concern worldwide. So, each country has formulated its own standards and created agencies for strict quality control measures of the food products. Some of them are internationally accepted as standards. A brief description of some these standards are given in this section.

3.4.1 Association of Official Agricultural Chemists (AOAC)

AOAC is an independent association devoted to promoting methods validation and quality measurements in the analytical sciences. It does this by reviewing and validating approved standard methods of analysis. Promoting uniformity and reliability in statements of results, and developing and promoting criteria useful for laboratory accreditation and analysis certification.

AOAC official methods program is designed to provide methods of analysis for which performance characteristics have been determined and tested. The cornerstone of this program is the inter-laboratory collaborative study by which proposed methods are validated through independent testing in separate laboratories following the same method and analyzing the same samples. The methods can be used to determine compliance with government regulations, to maintain quality control and process requirements, to set and evaluate compliance with terms of procurement contracts, to conduct national and international trade and to support research.

The AOAC methods are recognized worldwide as an authoritative resource, because of thorough and rigorous testing characterization. They are written in U.S. Code of Federal Regulations, Product specifications, and product acceptance, relied on legal proceedings, and required as a basis of national and international trade. They are also adopted by other national and international standards organizations.

3.4.2 United States Department of Agriculture (USDA)

It is the main body of food standards in USA. Regulations and directives are developed by USDA to ensure compliance with all relevant federal laws of USA, executive orders, directives, and policies. It provides links to key Federal Regulations and public laws enacted for USDA food distribution commodity programs and food purchase programs. Regulations and policies of USDA govern food safety related programs, processed product directives, the import and export of meat, poultry, and egg products, and laboratory services. It manages the process of developing food and nutrition regulations and ensures that all the relevant food and nutrition agencies participate in this development process. These regulations provide official marketing standards for grains and oilseeds, and require that exported grains and oilseeds be officially weighed and inspected. The Department's laws also regulate the slaughter and manufacture of meat products. The regulations also protect and promote U.S. agricultural health, administer the Animal Welfare Act, carry out wildlife damage management activities, and ensure that America's agricultural exports are protected from unjustified trade restrictions.

3.4.3 Food and Drugs Administration (FDA)

The Food and Drug Administration of USA is one of the oldest and most respected consumer protection agencies. Its mission is to promote and protect the public health by helping safe and effective products reach the market in a timely way, to monitor products for continued safety after they are in use, and to help the public get the accurate, science-based information needed to improve health. FDA’s regulatory approaches are as varied as the products it regulates products such as new drugs and complex medical devices, other products such as x-ray machines and microwave ovens, cosmetics and dietary supplements that must be proven safe and effective before companies can put them in the market. FDA safeguards the USA food supply by making sure that all ingredients used in foods are safe, and that food is free of contaminants like disease-causing organisms, chemicals, or other harmful substances. The agency must approve new food additives before they can be used in foods. It also monitors the safety of dietary supplements and the content of infant formulas and medical foods. FDA regulates all medical devices, including simple items like thermometers to very complex technologies such as heart pacemakers and dialysis machines. However, only the most complex new medical devices are reviewed by the agency before marketing.

3.4.4 International Standards Organization (ISO)

ISO prepared a document called ISO 9000 series in 1987 (modified in 1994) as a guideline for all organizations on managing quality and standard. Its Indian equivalent is IS 14000 (1988). It is the principle and criteria for a management system, which will improve a company's performance. It is a media for ensuring orderly and systematic maintenance and upkeep of system. It covers quality, quality policy, quality management, quality system, quality control, quality assurance, quality improvement, product, service, process and customer. The ISO series is given below;

ISO 9000-1,2,3,4	:	Quality management and quality assurance
ISO9004-1:		Quality management and quality system elements subcontractor
ISO9004-2:		Guidelines for services
ISO9004-3:		Guidelines for processed materials
ISO9004-4:		Guidelines for quality improvement
ISO9004-5:		Guidelines for project management
ISO9004-6:		Guidelines for quality plans
ISO9004-7:		Guidelines for configuration management
ISO 10011-1,2,3	:	Guidelines for auditing quality system
ISO 10012-1,2	:	Quality assurance requirements for measuring equipment
ISO 10013:		Guidelines for developing quality manual
ISO 10014:		Guidelines for economic effect of quality
ISO 10015:		Continuing education and training guidelines

3.4.5 Codex Alimentarius

The term Codex Alimentarius is taken from Latin and means food code. The FAO/WHO Codex Alimentarius Commission was established to implement the joint FAO/WHO Food Standard Program. About 150 countries including India are member of the commission. The purpose of this program is to protect the health of consumers and to ensure fair practice in the food trade; to promote coordination of all food standards work undertaken by international governmental and non-governmental organizations; to determine priorities and initiate and guide the preparation of draft standards through and with the aid of appropriate organizations; to finalize standards and after acceptance by Governments, publish them in a Codex Alimentarius either regional or worldwide standards. It brings together all the interested parties -scientists, technical experts, governments, consumers and industry representatives to help develop standards for food manufacturing and trade. These standards, guidelines and recommendations are recognized worldwide for their vital role in protecting the consumer and facilitating international trade. As Codex Alimentarius represent a consensus of food and trade experts from around the world, these standards are more and more being used in international trade negotiations and also for setting of disputes by WTO.

The Codex contract Point in India is the Directorate General of Health Services (DGHS) in the Ministry of Health. Ministry of Food processing Industries is also closely associated with the activities of Codex Alimentarius.

3.4.6 Hazard Analysis and Critical Contort Point (HACCP)

Hazard Analysis and Critical Control Point (HACCP) is an important quality assurance system. This system ensures that the products are safe and have good quality. The system is extremely desirable in view of the changing scenario in the International trade. It is science based and systematic, identifies specific hazards and measures for their control to ensure the safety of food. HACCP is a tool to assess hazards and establish control systems that focus on prevention rather than relying mainly on end product testing. The system is capable of accommodating changes such as advances in equipment design, processing procedures or technological developments. It can be applied throughout the food chain from primary production to final consumption and its implementation should be guided by scientific evidence of risk to human health. The application of HACCP is compatible with the implementation of quality management systems, such as ISO 9000 series and is the system of choice in the management of food safety within such systems. The HACCP system consists of following seven principles;

1. Conduct a hazard analysis.
2. Determine the Critical Control Points (CCPs).
3. Establish critical limits.
4. Establish a system to monitor control of CCP.
5. Establish the corrective action to be taken when monitoring indicates that a particular CCP is not under control.
6. Establish procedures for verification to confirm the HACCP system is working effectively.
7. Establish documentation concerning all procedures and records appropriate to these principles and their application.

Prior to application of HACCP to any sector of food chain, the sector should be operating according to Codex General Principles of Food Hygiene, the appropriate Codex Codes of Practice, and appropriate food safety legislation. During hazard identification, evaluation and subsequent operations in designing and applying HACCP systems, consideration must be given to the impact of raw materials, ingredients, food manufacturing practices, role of manufacturing processes to control hazards, likely end use of the product, categories of consumers of concern and epidemiological evidence relative to food safety. The application of HACCP principles consists of following tasks;

1. Assemble HACCP team. The team must comprise of all experts required for the development of an effective HACCP plan for a specific food commodity.
2. All the information of the product such as composition, physical/ chemical structure treatments etc should be described.
3. The intended use should be identified. It should be based on uses of the product by the end user or customer.

4. The HACCP team should construct a flow diagram covering all the steps in the operation.

5. On-site confirmation of the flow diagram should be done and amendments in the flow diagram should be done if required.

6. All the hazards associated with each step should be listed, a hazard analysis should be conducted and controls measures should be considered for identified hazards.

In a large food factory the team should be multi-disciplinary that is, it should include a microbiologist, processing specialist, chemist, biochemist, engineer, packaging technologist, sales and training staff and personnel managers. For medium and small scale, the quality control and production managers and few supporting staff like sales and administrative managers should be enough.

3.4.7 Good Manufacturing Practices (GMP)

GMP provides quality assurances that off-the-shelf testing cannot. It provides continual measures of quality that can uncover problems and fluctuations as they occur before the product is shipped. The need for GMP takes on further importance because the issues involved in developing test methods for dietary supplements are many and complex. Until methods are further developed, standardized, and widely accepted, GMP serves as a primary vehicle for ensuring quality.

Good manufacturing practices (GMP) lie at the heart of quality. GMP comprise a variety of practices that ensure quality including things such as:

- Raw materials quality assurance
- Record-keeping of substances throughout the manufacturing process
- Standards for cleanliness and safety
- Qualifications of manufacturing personnel
- In-house testing
- Production and process controls
- Warehousing and distribution

Virtually every manufacturer adheres to an in-house GMP standard, which varies from producer to producer. In-house GMP, while often extremely effective, does not provide a means for outside verification of quality. In order to provide such verification, many are now embracing to industry-standard GMP that is usually subject to an independent outside audit for compliance.

3.5 EXPORT PROMOTION COUNCIL

The Export Promotion Council has been constituted to check the quality of a number of food materials meant for export. The council has powers to reject any food item, which does not measure up to the standards prescribed for the food. Federation of Indian Export Organizations (FIEO) is the apex body of all Export promotion councils/Commodity Boards/Export Development Authorities in India. There are 25 boards and export development authorities. The main work of these authorities is to promote the export, assure the quality of the product the international standards, formulate the standards for export etc. List of export councils related to food products are given below.

1. Agricultural and Processed Food Products Export Development Authority (APEDA)
2. Cashew Export Promotion Council of India
3. Coffee Board
4. Marine Products Export Development Authority (MPEDA)
5. Shellac Export Promotion Council
6. Spices Board
7. Tea Board
8. Tobacco Board
9. Wool and Woollen Export Promotion Council

3.6 APEDA AND MPEDA

3.6.1 Agricultural and Processed Food Products Export Development Authority (APEDA)

APEDA is an autonomous organization attached to the Ministry of Commerce of the Government of India. The main function of APEDA is to build links between Indian producers and the global markets. APEDA undertakes the briefing of potential sources on government policy and producers along with providing referral services and suggesting suitable partners for joint ventures besides arranging buyer-seller meets. It also provides recommendations to the Trade and Industry.

APEDA offers financial assistance under various schemes, which seek to promote and develop agro exports. Financial assistance under these schemes is available to exporters, growers, and trade associations, governmental agencies.

3.6.2 Marine Products Export Development Authority (MPEDA)

The Marine Products Export Development Authority (MPEDA) was constituted in 1972 under the Marine Products Export Development Authority Act 1972. The role envisaged for the MPEDA under the statute is comprehensive covering fisheries of all kinds, increasing exports, specifying standards, processing, marketing, extension and training in various aspects of the industry.

MPEDA functions under the Ministry of Commerce, Government of India and acts as a coordinating agency with different Central and State Government establishments engaged in fishery production and allied activities. The plan schemes of the Authority are implemented under four major heads:

1. Export production - Capture Fisheries
2. Export production - Culture Fisheries
3. Induction of New Technology and Modernization of Processing Facilities.
4. Market Promotion

It implements developmental measures vital to the industry like distribution of insulated fish boxes, putting up fish landing platforms, improvement of peeling sheds, modernization of industry such as upgrading of plate freezers, installation of IQF machinery, generator sets, ice making machineries, quality control laboratory etc.

3.7 FOOD HEALTH AUTHORITY

The Food Health Authority is appointed at state level that is the Director of Public Health and Preventive Medicine. It is responsible for the good quality and standards of foods available to the consumers. Under FHA is the Local Health Authority (LHA). There is a Local Health Authority appointed in each city in every state. The food Inspector is appointed by the Central or State Government by notification in official gazette. The main work of this authority is to take a random sample of any food article from any person selling such article, or who is in the course of delivering or preparing to deliver such article to a purchaser or consignee or a consignee after delivering of any such article to him. Then these samples are sent for analysis to the Public Analyst (PA) of local area.

3.8 NATIONAL ACCREDITATION BOARD FOR TESTING AND CALIBRATION LABORATORIES (NABL)

The concept of Laboratory Accreditation was developed to provide a means for third-party certification of the competence of laboratories to perform specific type(s) of testing and calibration. Laboratory Accreditation provides formal recognition of competent laboratories, thus providing a ready means for customers to find reliable testing and calibration services in order to meet their demands. It enhances customer confidence in accepting testing / calibration reports issued by accredited laboratories.

National Accreditation Board for Testing and Calibration Laboratories (NABL) is an autonomous body under the aegis of Department of Science & Technology, Government of India, as a registered Society. NABL has been established with the objective to provide Government, Industry Associations and Industry with a scheme for third-party assessment of the quality and technical competence of testing and calibration laboratories. Government has authorized NABL as the sole accreditation body for Testing and Calibration of laboratories.

NABL provides laboratory accreditation services to laboratories that are performing tests / calibrations in accordance with ISO/IEC 17025. These services are offered in a non-discriminatory manner and are accessible to all testing and calibration laboratories in India and abroad, regardless of their ownership, legal status, size and degree of independence.

NABL has established its Accreditation System in accordance with ISO/IEC Guide. In addition NABL has to also comply with the requirements of APLAC MR001, which requires the applicant and the accredited laboratories to take part in recognized Proficiency Testing Programs in accordance with ISO/IEC Guides. NABL has been conducting Proficiency Testing with the help of selected accredited laboratories as nodal laboratories in different fields.

NABL accreditation is a formal recognition of the technical competence of a testing or calibration laboratory for a specific task following ISO/IEC 17025 Standard. This is based on third party assessment.

NABL Accreditation is currently given in the following fields:

Testing laboratories	Calibration Laboratories	Clinical Laboratories
• Biological • Chemical • Electrical • Electronics • Fluid-Flow • Mechanical • Non-Destructive • Photometry • Radiological • Thermal	• Electro-Technical • Mechanical • Fluid Flow • Thermal & Optical • Radiological	• Clinical Biochemistry • Clinical Pathology • Haematology • Microbiology and Serology • Histopathology • Cytopathology • Cytogenetics • Immunology • Nuclear Medicine • Blood bank and transfusion services

3.9 FOOD RESEARCH AND ANALYSIS CENTER (FRAC)

The Food Research and Action Centre (FRAC) is a leading national organization working to improve public policies to eradicate hunger and under-nutrition in the United States. Founded in 1970 as a public interest law firm, FRAC is a non-profit and non-partisan research and public policy centre that serves as the hub of an anti-hunger network of thousands of individuals and agencies across the country.

- FRAC engages in a variety of activities at the national, state and local levels to form a comprehensive strategy for reducing hunger in this country.

3.10 MINISTRY OF FOOD PROCESSING INDUSTRIES (MFPI)

The Ministry of Food Processing Industries, set up in July 1988, is the main central agency of the Government of India responsible for developing a strong and vibrant food processing sector; with a view to create increased job opportunities in rural areas, enable the farmers to reap benefit from modern technology, create surplus for exports and stimulating demand for processed food. The subjects looked after by the Ministry are:

- Fruits and vegetable processing industry
- Food grain milling industry
- Dairy products
- Processing of poultry and eggs, meat and meat products
- Fish processing
- Bread, oilseeds, meals (edible), breakfast foods, biscuits, confectionery (including cocoa processing and chocolate), malt extract, protein isolate, high protein food, weaning food and extruded/other ready to eat food products
- Beer, including non-alcoholic beer
- Alcoholic drinks from non-molasses base
- Aerated waters / soft drinks and other processed foods
- Specialized packaging for food processing industries

The scope of the Ministry has been very much enlarged. It includes development of fruit &. Vegetable processing and promote food-grain milling including dairy products and processing of poultry, eggs & meat products. Processing of fish including canning & freezing and technical assistance to the industry also form a very important part of its activity. In addition planning & developing of industries relating to bread, oilseeds, breakfast food, biscuits, confectionery specialized packaging, including non-alcoholic beer, aerated drinks also fall within the scope of this Ministry.

3.11 TOTAL QUALITY MANAGEMENT

Total Quality Management is a process, which explores the formation of management and employees into a "team-concept" approach to production of quality products. It is a structured system for satisfying internal and external customers and suppliers by integrating the business environment, continuous improvement, and breakthroughs with development, improvement, and maintenance cycles while changing organizational culture.

One of the keys that are most important to the successful implementation of Total Quality Management is the idea that it is a structured system. It is basically a strategy derived from internal and external customer and supplier wants and needs that have been determined through daily management. The implementation of Total Quality Management requires the help of the following eight key elements.

1. Ethics
2. Integrity
3. Trust
4. Training
5. Teamwork
6. Leadership
7. Communication
8. Recognition

Total Quality Management is built on a foundation of ethics, integrity and trust. It fosters openness, fairness and sincerity and allows involvement by everyone.

3.12 PRODUCT CERTIFICATE AND LICENSING

Product certification and licensing in India is done by number of organization. BIS operate product certification under the rules and regulation of BIS Act 1986. A manufacturer is granted license to use the standard mark after assessment of his infrastructure facilities for manufacturing and quality control checks to produce goods in consistent with quality control. The conformity to standard is further ensured by regular surveillance at licensee's performance by surprise inspections and testing of samples from the factory and market. BIS offers certification schemes to food industries on

1. Food safety certification against IS 15000:1998

2. HACCP based quality system certification for two certification

    a) Audit certification of quality system against IS/ISO 9000, and
    b) Certification of HACCP against IS 15000:1998.

The BIS has brought 1435 items and over 7500 factories under its fold. Items affecting health and safety of consumer have been enforced through compulsory certification. In 1991 Government of India introduced "ECO" mark for environmentally friendly products.

The Directorate of Marketing and Inspection (DMI) issues "AGMARK" certificate to the notified food products. It enforces the Agriculture Produce Grading and Marketing Act 1937. Grading under this provision is voluntary. It involves sorting of commodities according to their quality followed by inspection to verify the correctness of grade assigned to them. It is also enforcing MPO.

Ministry of Civil Supplies, Consumer Affairs and Public Distribution is responsible for standardization of weight and measures. They regulate the quality of the vanaspati vegetable oils and fats through solvent extraction plants. The new act contains provision for regulation to pre-packed commodities, which are intended to establish fair-trading and price discipline for commodities sold to consumers in packed form with levelling.

For export materials, APEDA issues the certificate. . The authority feels that the products complying with the basic quality and safety requirements should carry a mark that remains sacrosanct across categories and communicates the adherence to quality assurance measures. With this in view, a system for grant of the Certification mark i.e. "Quality Produce of India" has been developed by APEDA for agricultural products being exported. The Certification Mark will be granted on the basis of compliance with hygiene standards, implementation of Quality Assurance System such as ISO 9000, Food Safety System such as HACCP, backward linkage, residue testing of pesticides and contaminants, laboratory facilities and nature of complaint etc. Initially, the proposal is to launch this scheme for few products like meat, rice, fruits and vegetables. This Certification Mark is owned by APEDA. Only such exporters whose produce/ products conform to the prescribed parameters are allowed/ licensed to use the trademark for exports.

3.13 LET US SUM UP

Consumers expect certain qualities from their food. To arrive the quality character tics, different types of standards are made. Food science determines and uses methods to measure food quality factors. Number of agencies and organizations are involved at national and international level to make the standards implement and regulate them.

PFA is implemented in 1955 to ensure that food articles sold to the consumers are pure and wholesome. FPO and MPO were also enforced to lay down statutory minimum standard for fruits, vegetables and meat. BIS is a body responsible for laying down policy guidelines for formulating standards.

International agencies like AOAC are involved in promoting methods validation and quality measurement of food products. USDA and FDA are the agencies for formulating and implementing standards. ISO is the organization on managing quality and standards codex Alimentarius was established to implement the food standard programme into member countries in post WTO era. HACCP and GMP are quality assurance systems.

Different export promotion councils are constituted in India to promote export like APEDA, MPEDA etc. NABL was developed to provide means for ratification of the competence of laboratories to perform specific type of works. MFPI is the main control agency in India for food processing.

3.14 KEY WORDS

AOAC : Abbreviation for Association of official Analytical chemists.

Certificate : A document providing evidence of status of qualification.

Critical control point : Any point in the process where loss of control may result in a heath risk.

Food safety : A judgment of acceptability of the risk involved in eating a food; of risk is relatively low, a food substance may be considered.

GMP : Good manufacturing practices guidelines that a company uses to evaluate the design and constriction of food processing plants and equipment.

HACCP : Hazard Analysis Critical Control Point; a preventive food safety system.

Standards : Set up and established by authority as a rule for the measure of quantity, weight, extent, value, or quality. Set by different agencies to specifically describe a food; to be labelled as such, a food must meet these specifications.

TQM : Total quality management.

NABL : National Accreditation Board for Testing and Calibration Laboratories.

FRAC : Food Research and Analysis Centre, an organization to improve public polices in USA.

3.15 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include following points:

   - Definition
   - Legal, company, industry, and consumer standards

2. Your answer should include following points:

   - BIS
   - Function of BIS
   - Formulation process

Check Your Progress Exercise 2

1. Your answer should include following points:

   - Associations information, functions
   - Status and regulations

2. Your answer should include following points:

   - Quality assurance system, need
   - Principles, tasks

Check Your Progress Exercise 3

1. Your answer should include following points:

   - Purposes, structure
   - Functions

2. Your answer should include following points:

   - Concept of accreditation
   - Need, functions of NABL

3. Your answer should include following points:

   - Need, importance
   - Key elements

UNIT 4 FOOD GRAINTS, PULSES AND OIL SEEDS

Structure

4.0 OBJECTIVES

After reading this unit, you should be able to:

- explain importance of cereals pulses and oil seeds in our day-to-day requirement and to national economy;
- state the important properties and primary processing methods to make them edible and their storage; and
- describe value added products and Utilization of by products of cereals, pulses and oilseeds.

4.1 INTRODUCTION

Food grains play a major role in the Indian economy as they meet our food and fiber requirements. Food grains are the basic need of day-to-day requirement of human life. With the increase in population and awareness, every human being need right quality of foodstuff at the right time. It is also our duty that the cost of the foodstuff to meet the basic need should be affordable to every one. Agricultural produce are seasonal, weather dependent thus their storage for whole year and some times more than a year is required. During the storage, the quality of the foodstuff should not deteriorate. Most of the agricultural produce (cereals, pulses and oil seeds) is not consumed as they are produced. These produce need to be processed. The processing should be economically viable and the loss of energy and nutrition should be the least. Therefore, knowledge of appropriate machines and process is must.

Food processing industries have enormous significance in the national development through linkage between two main pillars of economy namely industry and agriculture. Growth of food processing industry means raising agricultural yield and creating rural employment. It leads to rise in the economic standard of large number of people through out the country.

4.2 PRODUCTION AND IMPORTANCE

Agricultural production in India has travelled a long way in the post independent era from scarcity to surplus. After green revolution the country has become not only self-sufficient but also surplus in food grain production. Now the country is producing about 200 million tonnes of food grains (90 million tonnes of paddy, 75 million tonnes of wheat and other coarse grains) 15 million tonnes of pulses and 23 million tonnes of oil seeds. In spite of such huge production, our population have per capita availability is less than the dietary requirement given by Indian Council of Medical Research. Therefore, nation has to import edible oil from other countries.

Post harvest technology of food grains have also had a paradigm shift in the last 50 years. At the time of independence most of post harvest operations were carried out by small scale processing units. These units were operated by human or animal power. There recovery was less and losses were high. Now many modern processing units comprising primary to tertiary processing are working. These units not only process the material but also process the byproducts into value added products.

4.3 STRUCTURE AND COMPOSITION

Wheat is a single seeded fruit consisting germ and endosperm enclosed by epidermis and seed coat. Paddy, pulses and other crops consist an outer husk cover in addition to above parts. The husk consists of silica acts as a barrier to moisture migration, insect infestation and fungal damage.

The germ is the principal part of the seed. It is rich in fat and is heat sensitive. The endosperm is full of starch granules and works as reservoir of food for developing embryo.

The chemical composition of the seed is widely dependent upon the environment in which crop is produced, the variety, soil and fertilizer application. In general, cereals are rich in carbohydrate; pulses are in protein and oilseeds in fats and lipids. The proximate composition of important cereals, pulses and oilseeds are given in Table 4.1. In general outer layers (pericarp) contains cellulose, endosperm is rich in carbohydrate and small amount of proteins, germ contains the highest amount of fat, protein, enzyme and small amount of sugars.

Protein present in the cereals gets denatured above 50°C. Thus, their water absorbing and swelling capacity decreases. It affects the quality of dough. The starch is insoluble in cold water. Its quality is not affected even if the temperature is raised to 60°C. However, at temperature higher than 70°C geletinization of starch takes place. It leads to deterioration in the colour. Fats are heat resistant up to an extent. However, at higher temperature (above 70°C) partial decomposition starts and increases the acid numbers. Vitamins present in the germ are destroyed with the heat treatment.

4.4 POST HARVEST LOSSES

With the green revolution and support of farmers the country has increased its food grains production to four fold between 1950's and 1970's. Though the rate of increase in production has declined after 1980's but still it is more than our country's requirement. It is also estimated that about 8 to 12% of the produce is lost in various post harvest handling and storage practices. The loss amounts to be Rs. 20,000/- crores annually.

The traditional processing of dal and oilseeds results in poor recovery. In most of the pulse mills in India has the dal recovery of 65 to 70 % against maximum possible recovery of 81 to 84 %. Similarly oil remains in the residual oil cake which is about 10 to 15 % of total available oil in the oilseed.

The maximum loss of food grain occurs during storage. As you know, in India major portion of food grains (more than 75%) is stored in large number of small capacity rural godowns. These godowns have free access to insect-pest, rodents and also affect the quality of the grains by the change of environment. It is estimated that in some of the godowns the losses are as high as 30 % in humid region if grains are stored for 8-10 months.

4.5 PHYSICAL AND THERMAL PROPERTIES

The knowledge of properties of grains such as size, shape, surface area, different densities, colour, frictional properties, thermal properties, diffusivity, equilibrium moisture content etc. are important for designing the various post harvest handling, storage, separation and drying systems. Some of the properties are discussed hereunder in this unit.

- Physical properties
- Thermal properties

4.5.1 Physical Properties

Accurate measurement of size and shape of the individual grain are important engineering data. These data helps in designing of machines for the post harvest handling and processing. The size and shape of the grain helps in designing cleaner, grader and if grains are to be passed between two rollers for shelling, milling or crushing. The terminal velocity of the grain helps in designing pneumatic conveyor, winnower etc. The geometry of the grain provides the surface area, which helps in moisture migration (absorption or drying). In general three major axis are measured and denoted as dimension a, b and c of the grain. **The sphericity** is defined as the ratio of geometric mean of 3-major axis to the largest axis dimension. It represents degree of closeness of the grain with the sphere.

$$\text{Size of the grain} = (a \times b \times c)^{1/3}$$

$$\text{Sphericity of the grain} = (a\,b\,c\,)^{1/3} / a$$

Where, a: is the largest dimension of the grain.
b: is the medium dimension perpendicular to the largest dimension of the grain.
c: is the smallest dimension perpendicular to above two of the grain.

Some dimensions and sphericity of the grains is given in **Table 4.2**

Table 4.2: Major dimensions and sphericity of the grains

Grains	Longest dimension (a) (mm)	Medium dimension (b) (mm)	Smallest dimension (c) (mm)	Sphericity $\frac{(abc)^{1/3}}{a}$
Rice, IR-8	8.68	3.02	1.97	0.427
Wheat, PB593	6.43	3.55	3.09	0.652
Maize, Ganga 5	8.92	8.33	6.89	0.901

Soya bean	7.02	6.29	5.05	0.874

Source: Engineering Properties of Food Materials (1980) CIAE, Publication /80/15

The bulk density, specific gravity and porosity plays an important role for designing the storage structures, specific gravity separator, pneumatic conveyor and other handling equipments. The bulk density is defined as the weight of grains per unit volume. The specific gravity is defined as the ratio of true density (mass of the grains per unit solid volume) to the density of water. The true density of the grains is calculated by fluid displacement method using **pycnometer.** The density of the grains varies with the variety and moisture content. The porosity is calculated from the true and bulk density of the grains. The porosity is affected by degree of compaction. Some properties of the grains are given in Table 3.

Angle of repose and frictional properties of grains plays an important role in designing hoppers, discharge chutes, elevators, dryers, storage bins and other equipments for grain flow and handling. The frictional coefficient depends upon the shape of the grain, surface characteristics and moisture content of the grains. **The angle of repose** of the grains is the angle between the base and the slope of the cone formed, when grains are freely dropped on the horizontal plane. The frictional properties and angle of repose of some grains are given in Table 4.3.

Table 4.3: Some physical and mechanical properties of the grains

Grains	Moisture content (%, wb)	Bulk Density (Kg/m^3)	True Density (Kg/m^3)	Porosity	Angle of repose (Degree)	Friction coefficient on sheet metal
Wheat	8-14	790-700	1390-1400	40	26-28	0.40
Rice	9-11	610-580	1200-1240	54	27-30	0.48

Gram	8-9	815	1340	39	17	0.35

Source: Engg. properties of Food material (1980) CIAR Publication /80/15

4.5.2 Thermal Properties

Cereals, pulses and oilseeds are harvested at higher moisture content in order to reduce shattering losses and safety against untimely rains or weather. These grains are to be dried to safe moisture level for marketing, processing or storage. For that heating, drying and cooking may be involved. Therefore, thermal properties namely, conductivity, diffusivity etc are required to be known for designing the dryers, cookers etc. Thermal properties of some grains are given in Table 4.4.

Table 4.4: Thermal properties of grains

Grains	Moisture content (%, db)	Specific heat (KJ / Kg K)	Thermal conductivity (W / m K)	Thermal Diffusivity (10^{-7} m^2 /s)
Wheat	10-20	1.09	0.139	0.91
Rice	10-20	1.33	0.087	1.00
Corn	10-20	1.20	0.165	0.89

4.6 WATER ACTIVITY

Water activity is an important characteristic of food grains. It influences odour, flavour, texture, colour, enzymatic activity and microbial load on the food product. Therefore, for safe keeping the food grains its knowledge and relationship with the atmosphere is must.

Water activity is a ratio of partial vapour pressure in a food product over the equilibrium vapour pressure of the product at the same temperature. In general for safe storage of food grains water activity should be below 0.6. However, to avoid lipid oxidation (which leads to rancidity in fats) water activity should be below 0.3. The most congenial atmosphere for growing the bacteria is when water activity is above 0.8 and for yeast and molds above 0.7.

4.7 CLEANING AND GRADING

Cleaning is the first unit operations in any grain-processing unit. As the name explains, the purpose is to remove unwanted materials like chaff, stone, dust, and metallic pieces. In general, it is done with the set of sieves arranged one above other. The top sieve will have openings just equal to the size of the grains. The impurities bigger than the grain size are rolled above the screen and discarded. The grains and smaller impurities pass through the first sieve; fall on the second sieve, which have the openings smaller than the grain size. Here dust and smaller impurities pass through the sieve and collected separately. Clean grains roll over the screen and are collected. In general a fan is also attached with the cleaner. The fan blows/sucks the sufficient air to throw/carry away the finer impurities of the grains. Usually fan blows the air beneath the sieve. Thus, it helps in cleaning the screen to avoid choking of sieves. An oscillating screen cleaner with aspirator is shown in Figure 4.1.

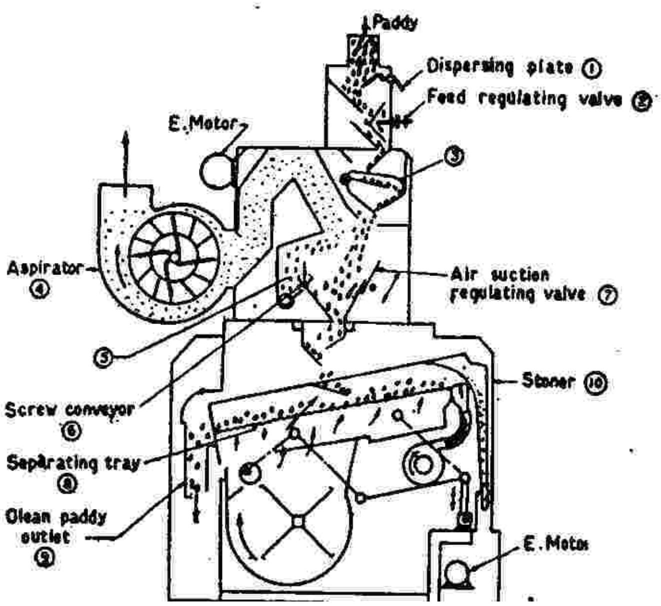

Figure 4.1: Oscillating screen cleaner with aspirator

In some cleaners, near the discharge end, a magnet is fitted. This magnet attracts the metallic impurities, which are removed manually at short intervals. Sieves may have round, oblong, rectangular or triangular openings depending on the requirement of the grains (Figure 4.2). In most of the cleaners, sieves are changeable to accommodate large variety of grains for cleaning. The oscillation speed of the sieve, feed rate and impurities composition decides the performance of the cleaner. In the modern cleaner, screen-cleaning brushes are fitted, which clean the screen to overcome problem of choking. Higher airflow of fan may carry away the grains and lower airflow may leave the impurities in the grain. So airflow based on terminal velocity of grains must be used.

Grading of grains is necessary as it aids to the value of the grains and helps in improving the performance and efficiency of processing machines. Grains, which are produced and harvested in the field, vary in their appearance, size, and location in the plant within the farm. If seeds sown are mixture of few varieties, the final produce may differ in the grain characteristics. The grading is defined as separation of the mixture in to separate sections based on their common quality characteristics. Grading is done based on size, wholesomeness of the grain, test weight, varietal purity, oil content, protein content, colour, hardness etc.

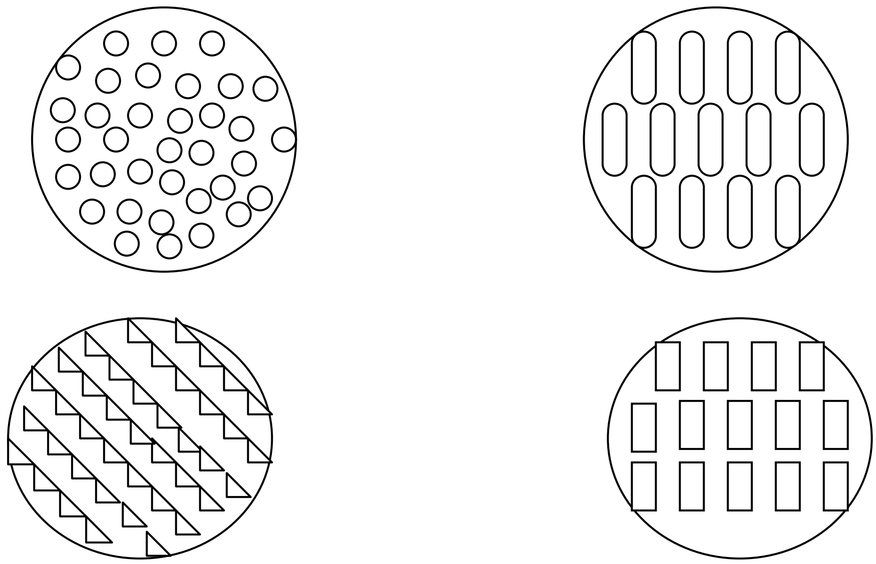

Figure 4.2: Different types of perforation on the sieve

4.8 PARBOILING CONDITIONING AND DRYING

Parboiling

Parboiling is a hydrothermal treatment given to grains specially paddy and wheat in order to make grain harder. In paddy, rice kernel become harder so that it could withstand the milling stresses and result in higher head yield. Parboiling is conducted in three steps namely soaking, steaming and drying. Soaking of paddy in the traditional method is done for 24 to 72 hours at the ambient temperature depending up on weather. In the modern method, soaking is done at 70^{o}C for 3½ hours. The void space between husk and kernel is filled with the water and moisture content of the grain is raised to 30% wet basis. After draining the excess water soaked paddy is steamed for 20-30 minutes. The moisture content of paddy is increased to 35% wet basis. Then paddy is dried to 14% moisture content. Traditional parboiling method has prolonged soaking, which imparts deep colour to the rice, off flavour, and some times in rainy season mold growth on the grains. In the modern parboiling method some of these defects are eliminated. In the process of soaking and steaming rice starch get gelatinized, protein get expanded and occupies the air space with in endosperm. It increases the cohesion and adhesion between starch granules and protein bodies. It also checks the cracks in rice kernel and it become stronger to withstand milling stresses.

During the process of parboiling vitamins of outer layer moves inside starchy endosperm and oil globules moves outside in the bran layer. Thus, after milling parboiled rice has more vitamins than raw rice and its bran has move oil content than raw rice bran. It is also found that due to heat treatment total water uptake, swelling index of parboiled rice is more than raw rice. Energy required in dehusking and loss of solids in the gruel is less in parboiled rice. The total rice turn out of parboiled rice is 70-73% which is 2-8% higher than raw rice and whole rice turn out is 60-65% which 20-30% more than raw rice.

Conditioning

Conditioning of grains specially pulses and oilseeds is done in order held or get better dal and oil recovery. Pulses are scratched, smeared with oil and water, dried in order to loosen the husk. Oilseeds are smeared with hot water prior to crushing to improve the oil recovery. Excess of wetting and drying of pulses affects their cooking quality as protein enclosed in the complex form, which changes its behaviour when hydrated and dehydrated.

Drying

Drying of grains is an important unit operation as it affects the ultimate quality of the grains. Grains {cereals 12-14%, pulses 10-12% and oil seeds 8-10%} moisture content is considered to be safe for storage.

Traditionally grains are dried in the drying yard with sun's energy. The grains are spread 5-10 cm thick layer and frequently turn to have uniform drying.

The limitations of the sun drying are:

- Weather dependent process
- Require more human energy for turning during drying
- Non-uniform drying
- Slow drying affects the quality of the product and increases the microbial load on the grains.

Thin layer drying through mechanical dryers with 10-15 cm thickness of the grain layer are the most common dryers used in the grain processing industry. Burning agricultural waste generates the heat, which is passed through heat exchanger. The hot air is blown and mixed with a falling bed of grains to get them dried. The main advantage of these dryers is the uniformity in drying and the drying time is reduced. These dryers are weather independent; require less space and energy.

In general drying air temperature depends on the type of grain, their moisture content and end use. For cereals, to be used for consumption, drying air temperature is to be limited to 70^{o}C, whereas for seed purpose it should be 45^{o}C. For oil seeds and pulses it should be 50-55^{o}C. Rapid drying develops fissures in the grain results in poor milling quality of paddy, affects, storability of wheat.

There are only few dal mills in the country where mechanical dryers are used. In general, sun drying is done for drying pulses in the process of dal milling (specially for pigeonpea the milling process takes 2-4 days longer depending on the weather.). Oil seeds are threshed/decorticated when fully dried. Conditioning is done to get maximum oil recovery. Generally dryers are not used in the oil industry.

4.9 GRAIN MILLING AND OIL SEED CRUSHING

Milling of cereals and pulses is a series of processing treatments prior to its conversion into edible form. These treatments vary from grain to grains. Flow chart for milling of paddy, pulses and oil seed given in Figures 4.3, 4.6 and 4.7.

4.9.1 Rice (Paddy) Milling

Paddy raw or parboiled is cleaned to remove all the impurities. Cleaned paddy fed in a sheller / dehusker. Traditional dehusker is an Engleberg rice huller. A huller is small mill operated by motor with a capacity 500-750 kg/h. The mill consists a cast iron roller, where shelling and polishing is done simultaneously. Therefore, bran, brokens are mixed with the husk, which is difficult to separate. As the moving part is cast iron roller, it results higher broken pieces during milling. Though, the machine is simple in operation, low in cost but results poor milling yield (total yield 62-64%, Head rice 40-50%).

The other low capacity paddy milling machines are centrifugal sheller and under runner disc sheller. A mini modern rice mill (Fig. 4.4) consists of feed hopper, rubber roll sheller, husk aspirator and a polisher in a single composit unit. The modern paddy sheller is rubber roll sheller. In it two rubber rolls are rotating in opposite directions at different speeds. Difference in surface speeds of rollers develops shearing action and results in removal of husk. Using rubber rollers only husking is done, in the machine. A blower sucks the husk and paddy-rice mixture is fed on a separator. In general, there are two types of paddy separator namely compartment type or deck type separators are used in the rice mills. Both the separators work on the principle of gravity separation. The heavier material rice remains in touch with the surface and moves along with the separator surface and carried against the gravity to upper side and discharged. Paddy being lighter moves with the gravity down and recycle to the sheller for shelling. Paddy rice mixture is recycled back to the separator. Only rice is fed in the polisher, where due to abrasion rice are polished and upper aleurone layers are removed. These layers are rich in oil content (14-26%). Rice bran is collected through cyclone separator and rice is fed in the grader. Whole rice are separated from the brokens parts through a grader. A typical flow diagram of modern rice mill is shown in Figure 4.5.

4.9.2 Wheat Milling

Traditionally wheat is milled in an attrition mill, where or (Break rolls) grains are fed in the center, moves radially out, between two emery/stone discs. Grains are compressed and sheared. The clearance between stones/is gradually reduced and whole grain flour is obtained. As the size from whole grains is reduced to fine in one go, there is significant rise in the temperature. It affects the quality of flour.

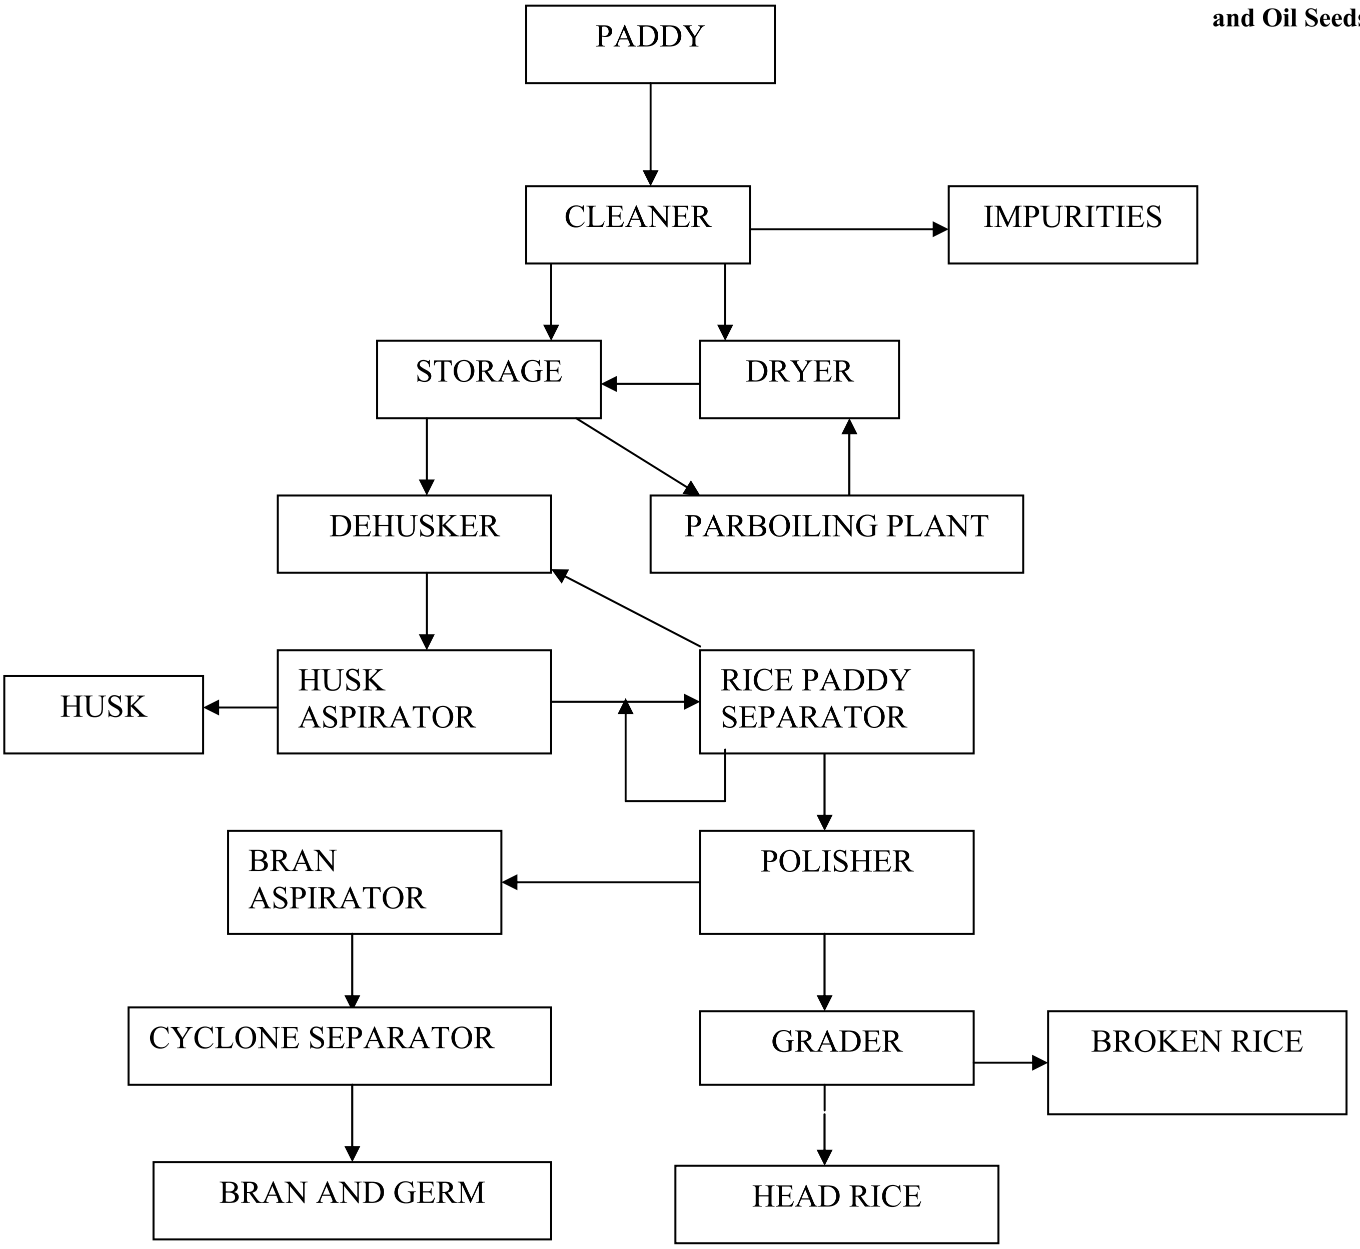

Figure 4.3: Process Flow Chart of Modern Rice Milling

Modern wheat mill consists of series of reduction rollers (about 15 to 18) where different fractions, Suji, maida etc are separated. Since size is reduced gradually, rise in temperature doesn't take place and quality of the constitutes is better.

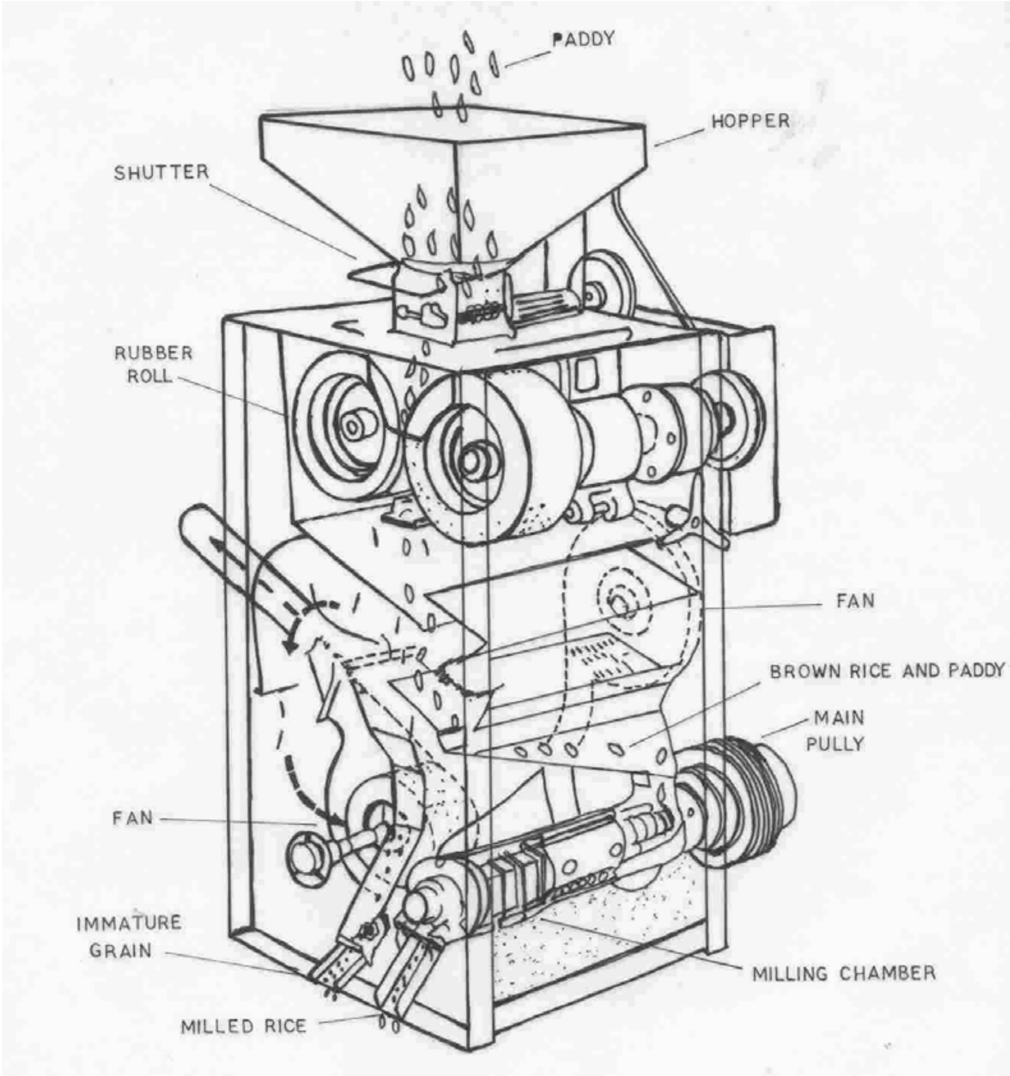

Figure 4.4: Mini modern rice (paddy) mill

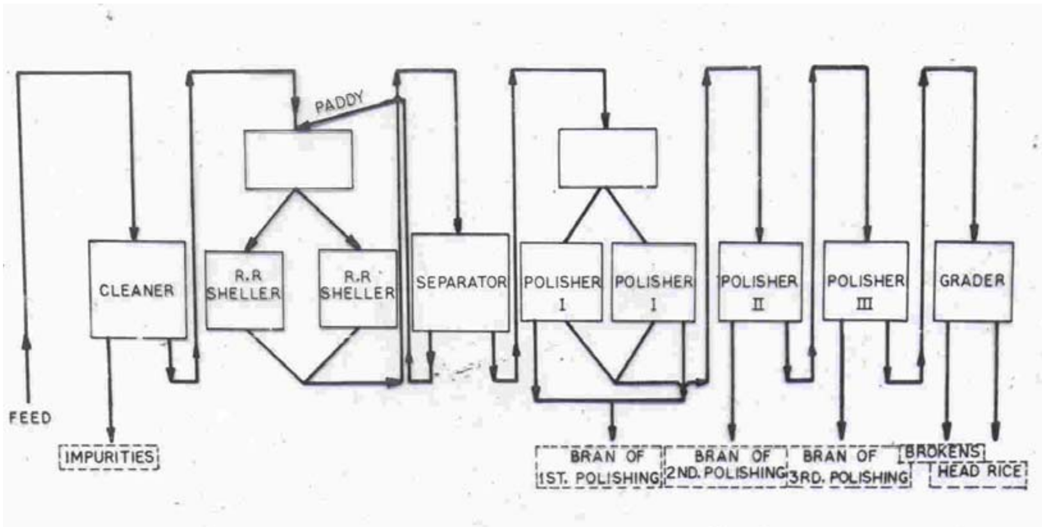

Figure 4.5: Typical Flow Diagram of Modern Rice (Paddy) Mill

4.9.3 Corn Milling

Corn can be milled by dry milling or wet milling. In dry milling moisture is raised to 24-25% and germ is separated by Beall degermer. Rest grain is dried and milled. In wet milling, corn is soaked in water (50°C) for 1-2 days. Germ is separated for oil extraction and rest is centrifuge to make starch, dextrin, sugar syrup etc. The water used for soaking is also drained and concentrated to 35-55% solids to be used for pharmaceuticals.

4.9.4 Pulse Milling

Pulses are rich source of protein. They are traditionally milled dry. Except pigeon pea, milling of pulses is easy as binding between husk and cotyledon is poor. For pigeon pea it is most difficult.

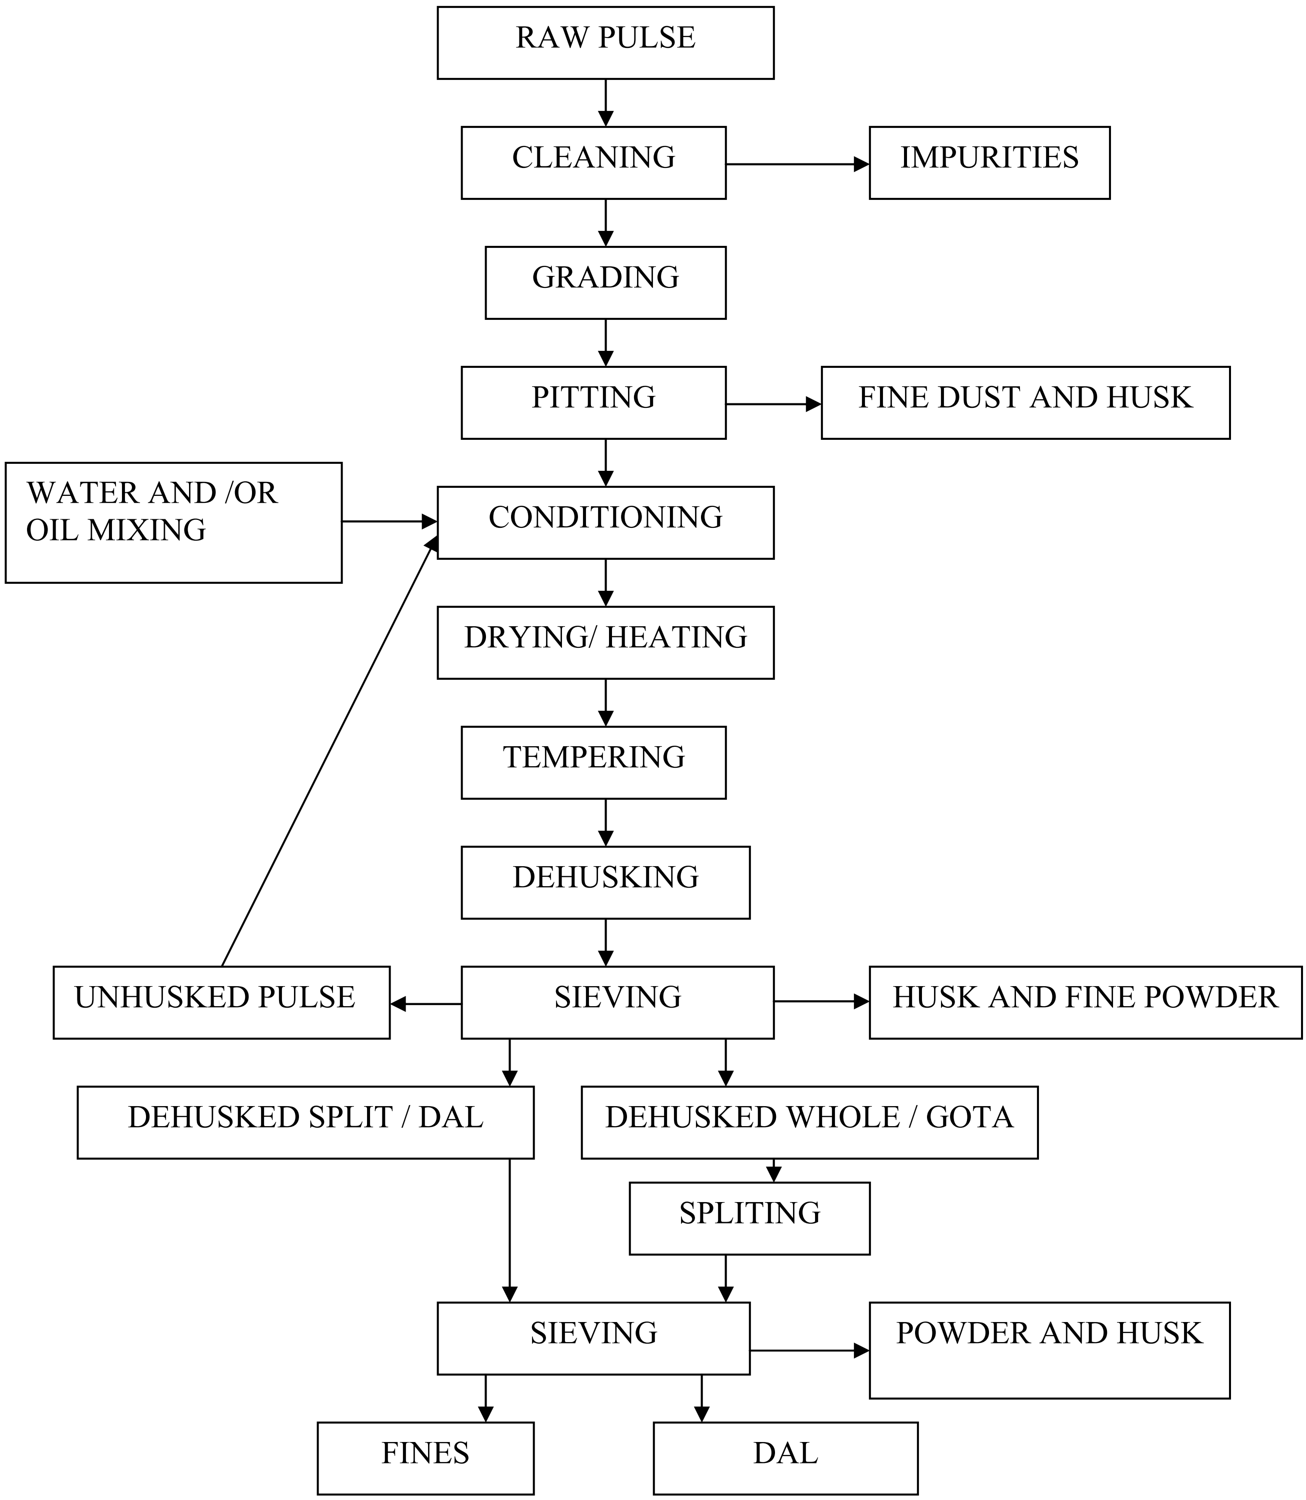

Figure 4.6: Process flow chart of improved pulse milling

Traditional milling of pigeon pea includes cleaning, scratching, treating with oil, and wetting, mixing with red earth, conditioning, scratching and splitting. In general, it yields 65-70% of dal recovery against potential of 81-84%. In modern pigeon pea milling, which includes cleaning, preconditioning, dehusking separating and splitting. It provides 72-78% dal recovery. The preconditioning includes addition of moisture, oil and drying in LSU dryer. In the modern method dal can be prepared in 1-2 days from pulses whereas in the traditional process it takes 5-10 days. A process flow chart of improved pulse milling as shown in Figure 4.6.

4.9.5 Oil Seed Crushing

Oil seeds like groundnut, castor etc are decorticated in manual or motorized decorticator. Clean seeds are crushed either in ghani operated by bullocks or mechanical power or in screw press oil expeller.

Ghanis are made of wooden taper barrel, where pestle is rotated in it. In general, 6-12 kg oil seeds are fed and hot water 1-5% is added in a batch, which takes 45 minutes to crush. A ghani recovers 60-75% of the total available oil in the oil seeds.

A screw press oil expeller is 6 to 12 bolt expeller having series of worms of different pitches. Due to pressure built up inside the horizontal casing, oil oozes out. The capacity of the expellers are to crush 60 to 120 kg oil seeds/ batch and recovers 80-85% of total available oil in two to three passes. Commercially 8 power ghanis with one mechanical oil expeller are in practice. Firstly, oil seed is crushed in ghanis and residual oil cake is passed through expeller. However, even after that 6-7% oil remains in the residual cake, which is extracted through solvent extraction process. Process flow chart of oil seed processing is given in Figure 4.7.

4.10 STORAGE OF GRAINS

Primary function of storage is to prevent food loss during the storage. The loss means any change in the availability, edibility, wholesomeness or quality of the food that prevents it from being consumed by people. Losses may be direct or indirect. A direct loss is disappearance of food by spillage, or consumption by insects, rodents, birds etc. An indirect loss is lowering of quality to the point where people refuse to eat it. All the types of losses could be conveniently categorized into two categories i.e. quantitative and qualitative.

Causes of deterioration of food grains are:

A) Environment
   i) Temperature
   ii) Ambient RH
   iii) Gaseous composition $\{O_2:CO_2:N_2\}$

B) External Micro-organisms
   iv) Insect
   v) Pest (birds, rodents)
   vi) Mites, fungi, bacteria, yeasts

C) Biochemical composition of the grain
   vii) Moisture content
   viii) Fat content

Changes occurring during storage on the grains are:

A) Wholesomeness/purity
   i) Excreta
   ii) Dockage-impurities
   iii) Damage grains

B) Quality of the grains
   iv) Weight loss
   v) Taste
   vi) Colour
   vii) Odour
   viii) Nutrition
   ix) Fat acidity
   x) Toxicity
   xi) Germination
   xii) Moisture content
   xiii) Post harvest quality: Milling and baking quality

Moisture is the most important factor, if taken care can limit development of bacteria, fungi, mites and insect attack which cause the spoilage of the grain during storage.

Some tips are:

1. Uniformly dried grains below 13% moisture content usually do not have growth of most of the microorganisms and mites.

2. Insect cannot attack the grains having moisture content below 10%.

3. In bulk storage, moisture content of the grain seldom remains uniform. Relative humidity of store, outside environment condition develops air currents. Thus within the bulk storage high and low moisture pockets develop. To check them, periodic inspection at these points is a must.

4. It is desired that relative humidity of the store should be 50-60%. Lower humidity results in over drying of the grains and develop fissures which affects milling, baking, cooking quality of the grains.

5. Higher humidity will increase the moisture content and grains are likely to be attacked by insects-pests and microorganisms.

6. Grains should be stored in dry and cool place. As the moisture content of the grains is directly proportional to the respiration of the grains.

7. The increase in respiration increases the temperature, growth of microorganisms and enzymatic activity of the bulk grain up to certain temperature.

8. Mites do not develop if the storage temperature is below 5°C, insects do not grow if the storage temperature is below 15°C and fungi do not develop if the storage temperature is below 0°C.

9. Most favourable temperature for insect growth is 25-30°C.

An ideal storage structure should:

- have adequate protection against insect-pest.
- maintain wholesomeness and purity
- be air tight during fumigation and allow air movement during ventilation
- be easy to inspect and clean.

In India, major portion of produce is stored in a large number of small capacity rural godowns. These godowns are neither air tight nor safe from insect-pest and rodent. It is estimated that the losses in such rural godowns is as high as 30 % in humid conditions if stored for 8-10 months. The grains with scientific storage are stored in the bulk either in bag storage or in silos. The bag storage has following advantages:

✓ Small lots of a number of crops or varieties can be stored in the same space

✓ Infested bags can be easily segregated and fumigated.

✓ Each bag can be handled independently

After the green revolution our food grain production has increased many fold. However, the warehouse capacity is limited. Therefore, for short period food grains are stored in CAPS (cover and plinth storage). The maximum safe storage period for CAPS is only 6 months under ideal conditions, but in practice grain is stored in CAPS even up to 2 to 3 years. It is mainly due to poor infrastructure facility for storing food grains in bulk or godowns.

The most modern and safe method of storage of single type food grains is silo. The advantages of storing in silos are:

❖ Greater storage capacity per unit volume of space,

❖ Loading and unloading is easier and cheaper as mechanical handling devices do it.

❖ No cost of purchasing gunny bags and dunnage

❖ No danger of rodents as they are metal or RCC bins/silo

❖ Insect infestation is considerably less and if required easy to fumigate.

- ❖ Minimal effect of outside environment on food grains and if required easy to turn with the help of mechanical handling devices.

4.11 VALUE ADDED PRODUCTS

There is a great scope for diversification and value addition to cereals, pulses and oil seeds. Consumer preferences especially in urban areas for processed, fast foods have gained significantly. Media and television have played a significant role for domestic market. Even developed and other countries are looking towards India as a big market for processed foods. Now–a-days time is the biggest constraint with the urban people. So ready to eat, fast to cook, extruded, puffed, baked snacks are convenient have great potential in the market. Some of the possible products are listed in Table 4.5.

Besides these blended products as functional foods have domestic and export market. Functional foods are modified foods that help to improve health (provide specific health benefit) and prevent diseases when ingested. Some examples are:

- **Energy bars:** Constitute simple sugar to complex, contain about 12 % fat; 8-20 % protein and can be fortified with vitamins and minerals. It is specially made for athletic group.
- **Weight loss bars:** Balance nutrition with control calories intake and fortified with vitamins and minerals.
- **Breakfast bars:** High carbohydrate, low protein and fortified with vitamins and minerals.
- **Nutrition bars:** High protein content (15-27 g per serving) for body builders and fortified with vitamins and minerals.

Containing essential vitamins and amino acids for heart patient, diabetic patient, obey people etc.

Table 4.5: Value added products from cereals, pulses and oilseeds

Grains	Existing products	Newer products
Paddy	Raw and parboiled rice; puffed and flaked rice and rice flour	Quick cooking rice; pasta products; rice based snacks and rice bran oil
Wheat	Flour; maida; suji; dalia; and noodles	Durum wheat; puffed product and extruded products
Corn	Flour; flakes; popcorn; starch; dextrose and dextrin	Corn oil and degermed corn flour corn chips
Pulses	Dal; Powder; roasted grains; animal feed (husk)	Mixed flour; blended products; fortified products; instant dal and dal analog
Millets	Flour and puffed	Blended products and baked products
Oil seeds	Oil and cake for feed and fertilizer	Edible deoiled cake as flour; protein isolate from soy flour and blended flour

4.12 BY-PRODUCT UTILIZATION

In the present day competition an industry has to use every source of earning from the product and by-products. Moreover, unutilized by-products are an effluent to the industry. As per the environmental regulation these effluents had to be safely disposed off so that they do not pollute the environment or surroundings.

In general grains, pulses and oil seed milling units have solid by products. Some of these by-products if properly processed and used can become more profitable than the main product. A list of some by-products of cereals, pulses and oil seed milling and their possible value added products or utilization is given in Table 4.6.

Table 4.6: By-products and their utilization in the vale added products

Grain	By-product	Utilization
Paddy	Husk	Fuel: Heating value 3000-3500kcal/kg. Insulating, packaging and building material. Husk ash mixed with hydrated lime produces cement like material. Husk as an abrasive. Producing activated carbon, sodium silicate for soap industry. Pure silicon can be produced from rice husk. Silicon carbide and silicon nitride can also be produced.
Rice	Rice bran	Rice bran oil as edible oil. Defatted bran as cattle feed. Defatted bran as fertilizer. Defatted bran contains vitamins like B complex, B_1, B_6, amino acids, phosphoric acid compounds etc. for medicinal and dietetics use. Defatted bran for bakery purposes. Crude rice bran oil is used in industries, for soap, cosmetics, plasticisers, emulsifiers, protective coating, synthetic fibre etc.
Rice	Broken rice	Pasta products, rice flour, production of starch, and alcohol.
Soya bean	Defatted soya cake	Defatted soya flour for soya nuggets, soya laddu, soya granules and blended flour, soy isolates & concentrates.

4.13 LET US SUM UP

Food grains play an important role in the national economy and a day-to-day requirement of human being. Post harvest handling, storage and processing of food grains is an important operation, which can create large amount of employment at all the sectors. Moreover, it has scope to reduce the post harvest losses, which amounts to be Rs. 20,000/- crore annually. Indigenously designed food processing machines based on the properties of the grains has another employment avenue. Traditional processing technologies and machines are consuming more energy, producing poor quality turnout and results in high losses. Therefore, improved machines and technologies can solve some of these problems. However, their capacity of processing is high. There is a need to develop proper storage techniques to reduce the loss of quality and quantity of the grains during storage. Food grains can be used to produce many value added convenience products to meet special requirements. Utilization of the by-products can make food-processing industry more viable.

4.14 KEY WORDS

Sphericity : It is the ratio of the geometric mean of 3-major axis with the largest axis dimension of the grain.

Angle of repose : It is the angle between the base and slope of the cone formed, when grains are freely dropped on the horizontal plane.

Cleaning : Removal of impurities from the grains.

Grading : Separation of the grains based on their value.

Parboiling : It is hydrothermal treatment given to cereals in order to improve their milling quality.

Silo : Modern bulk storage structure where single type of grains can be stored for longer duration.

Functional foods : Modified food that help to improve health and prevent diseases when ingested.

4.15 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Industry and agriculture are two pillars of Indian economy.

2. “Whole world is looking towards India as a big market” because of large population (more than 1 billion) and unorganized food processing sector.

3. The chemical composition of the grains depend upon the crop, variety, environment in which crop is grown, type of soil, water and fertilizer applications while raising the crop.

4. The solubility of starch increases with the increase in the temperature.

5. Post harvest losses in the pulses are mainly during milling. Theoretical expected dal yield is 81-84% but actual recovery is 68-72%.

Check Your Progress Exercise 2

1. The size of the grains helps in designing the cleaner, grader and some other processing machines.

2. Winnowing and pneumatic conveying are two machines, in which terminal velocity is used for designing.

3. **The angle of repose** of the grains is the angle between the base and the slope of the cone formed, when grains are freely dropped on the horizontal plane.

4. Pycnometer is used for measuring the true density.

5. Water activity influences odour, flavour, texture, colour, enzymatic activity and microbial load of the grain.

6. For safe storage of oil seed the water activity of the store should be below 0.3.

Check Your Progress Exercise 3

1. Cleaning is to be done in the beginning of the processing, where grading is done either in between or at the end to improve the economic value, performance of processing, or storage as the case may be.

2. In parboiling the grain become harder and can withstand the milling stress. Therefore, milling improves the yield. The process of parboiling involves partly fermentation so that the parboiled rice develops off flavour and dark colour.

3. Conditioning of pulses help in loosening the husk. So milling becomes easier. Conditioning of oil seed improves oil recovery.

4. Rapid drying develops fissures on the grain. Thus during milling it breaks and its storability is poor.

Check Your Progress Exercise 4

1. The causes of food grain deteriorations are:

   (A) Environment: Temperature, Ambient RH, Gaseous composition $\{O_2:CO_2:N_2\}$

   (B) External Micro-organisms: Insect, Pest (birds, rodents), Mites, fungi, bacteria, yeasts

   (C) Biochemical composition of the grain: Moisture content, Fat content

2. Characteristics of ideal storage structures are:

   - Adequate protection against insect-pest.
   - Maintain wholesomeness and purity.
   - Sufficient air tight during fumigation and air tight during ventilation.
   - Ease in inspection and cleaning.

3. The comparison of bag storage and silo storage system:

Bag storage	Silo storage
Small lots of a number of crops or varieties can be stored in the same space	Only one commodity can be stored. However, Greater storage capacity per unit volume of space is available
Infested bags can be easily segregated and fumigated	Insect infestation is considerably less and if required easy to fumigate. No danger of rodents as they are metal or RCC bins/silo
Each bag can be handled independently	Loading and unloading is easier and cheaper as mechanical handling devices do it.

4. Ideal storage temperature below is 15° C, Relative humidity 50-60% and moisture content of the grain between 10-13% for safe keeping of the grains.

UNIT 5 FRUITS AND VEGETABLES

Structure

5.0 OBJECTIVES

After reading this unit, you should be able to:

- know production, composition, properties and factors responsible for determination of quality of fruits and vegetables and their control;
- describe post harvest handling, processing and storage of fruits and vegetables and by-product utilization of fruits and vegetables; and

- explain techno-economic feasibility of some small-scale fruits and vegetable base processing industry.

5.1 INTRODUCTION

Fruits and vegetables have an important place in our day-to-day life. Being rich in minerals and vitamins they are called protective foods. India's economy is based on the agriculture. India is one of the largest producers of fruits and vegetables in the World play a very significant role in the national economy.

India's geographical location and topography provides an excellent opportunity to produce every thing in our country. However, round the year availability of fruits and vegetables provides passive response towards commercial processing of fruits and vegetables. The people also have poor acceptability of processed foods. This often led to glut, more post harvest losses besides less contribution of processed foods in the national economy.

5.2 PRODUCTION AND IMPORTANCE

Fruits and Vegetables play an important role in agriculture, human health and national economy. In India, a decade back production of fruits and vegetables was just 50% of food grains production but it has been raised to 66% and anticipated that by 2010 it will be 80%. India is the second largest producer of fruits and vegetables in the world. India produces about 100,000 corers of rupees worth fruits and vegetables every year. However, a considerable amount of this produce in lost due to negligence and improper post harvest handling, which amounts to be 25 to 30%. Besides, this huge financial loss the wastage also affect the per capita availability of fruits and vegetables. It results in quality of health and life of majority of the people of the country.

You know, India with round the year sunshine, variate soil type, climate and topography produces variety of fruits and vegetable. Our nation is the largest producer (Table 5.1) of mango, banana, papaya, sapota, cashewnut, coconut, cauliflower, okra, capsicum, pea etc.

Though, our country is one of the highest producer of the fruits and vegetables but productivity is significantly lower in most of the fruits and vegetables as per the international bench mark (Table 1). The lower yields are mainly due to poor quality of planting material including varieties, unplanned farm management practices like fertilizer, water management and small from holding. However, some farmer have obtained better yield with competitive quality of international standard.

Table 5.1: Area, production, productivity of some fruits and vegetables

Fruits or vegetables	International benchmark (t / ha)	Area ('000 ha)	Production ('000 t)	Productivity (t / ha)	Percent world contribution (%)
Banana	35.5	491	16813	34.3	29 (I)
Mango	30.0	1487	10504	7.1	44 (I)
Papaya	-	60.5	1666.2	27.5	30 (I)
Citrus	24.5	527	4651	8.8	3
Guava	-	151	1711	11.3	- (IV)
Pineapple	60.0	76	1025	13.6	8 (III)
Sapota	-	64	800	12.4	- (I)
Coconut	-	1778	8429	4.7	18 (I)
Cashewnut	-	686	520	0.76	44 (I)
Cauliflower	-	248	4718	19.0	34 (I)
Pea	-	273	2712	9.9	38 (I)

Onion	-	493	4899	9.9	11 (II)

Source: NHB Data Book 2002

In spite of huge production, India shares only 2.3% of the world trade of fruits and vegetables. It also process only 2.5% of the total produce in a organized sector whereas Thailand 30%, Brazil 70%, Philippines 78% and Malaysia 80%. One of the reason is the varieties have poor recovery of process product for i.e. Indian tomatoes have 4 ^{o}b of total solids whereas varieties in European countries have 6 ^{o}b. Thus, to produce same quantity of tomato end product 50% more tomatoes are required in our country.

Fruits and vegetables processing industry ranks 5th in its size and employees 19% of work force which is about 1.6 million people. It accounts for 14% total industrial output against 5.5% industrial investment and contribute 18% to the GDP. Annual turnover of fruit and vegetable industry is Rs. 1800 billion and out of which Rs. 1400 billion are from unorganized sector.

5.3 TYPE OF FRUITS AND VEGETABLES

The fruit is derived from the Latin word "fructose" which means to enjoy, produce. The fruit is a product of fertilization and is a ripened ovary. Fruits are classified into pome (apple and pear); stone (mango, peach, plum, cherry), berry (strawberry, tomato); nut (walnut, cashewnut); hesperidium (citrus); synconium (fig), sorosis (mulberry); coenocarp (jack fruit) and syncarp (custard apple).

The vegetables develop from variety of plant parts (cabbage pea, potato). On the basis of plant parts used as vegetables they are grouped as fruits (gourds, brinjal, capsicum); stem (asparagus, amaranths), leaves (cabbage, lettuce, spinach) flowers (broccoli, cauliflower) and underground portion (radish, carrot, potato, onion, garlic).

For processing or storage purpose fruits are also classified as climacteric and non-climacteric fruits. The climacteric fruits are those, which develop total senescence sometime after the harvest during storage. For e.g. apple, banana, ber, fig, guava, mango, pear, peach, papaya, sapota, tomato. Whereas non-climacteric fruits ripen on the plants. for i.e. citrus, grape, litchi, pineapple, pomegranate, strawberry etc. The climacteric fruits have high rate of respiration and production of carbon dioxide and ethylene than the non-climacteric fruits during the process of ripening. It leads to change in colour, flvaour, texture and some chemical changes.

5.4 COMPOSITION AND FOOD VALUE

You know that fruits and vegetables are considered as protective foods as they are major source of nutritients such as vitamins and minerals. The quantity and quality of these nutrients vary with the variety, pre-harvest practices and maturity. These nutrients imparts their colour, flavour, and texture. Colour of the fruits is basically due to sugar derivatives of anthocynidins. Flavour in the fruits depends on the proportion of sugars and acids. Besides that there are some volatiles flavouring compounds. The texture of the fruits is governed by polysaccharides. Fruits are also containing phenolics compounds. They impart astringency, bitterness and aroma, which provide resistance to pathogens and stress.

Food value namely major constituent, vitamins and minerals of some important fruits and vegetables have been given in Table 5.2 A, B and C at their maturity stage.

5.5 PHYSIOLOGY OF FRUITS AND VEGETABLES

Physiological maturity is the state of harvest of fruits and vegetables, which provides some flexibility of time for marketing the produce, so that produce attain desirable eating quality when it reaches the consumer. The produce harvested prior to attainment of physiological maturity exhibit lack of flavour and loose moisture rapidly. If harvested late may be overripe and have very short post harvest life.

Objective and subjective methods for assessing the maturity of fruits and vegetables have been standardized. They are classified as :

- Physical methods
- Chemical methods
- Biochemical methods

Table 5.2a: Food values of fruits and vegetables

Name of produce	Major constituents (percent)					
	Moisture	Protein	Fat	Mineral matter	Fiber	Carbohydrate
Fruits						
Apple	85.9	0.9	0.1	0.3	-	13.4
Aonla	81.2	0.5	0.1	0.7	3.4	14.1
Banana	61.4	1.3	0.2	0.7	-	36.4
Guava	76.1	1.5	0.2	0.8	6.9	14.5
Lime	84.6	1.5	1.0	0.7	1.3	10.9

5.5.1 Physical Methods

In the physical method, the maturity of the fruit is judged by visual observations or by simple methods. They are size, shape, colour, weight, specific gravity, firmness, juice content, total soluble solids (TSS), and produce holding strength by the pedicle of the plant.

Usually size and weight of individual fruit depends on several factors so they can be considered only when such factors are known. For ex. Cultivar, planting material, nutritive available, soil type and climatic condition effect the size and weight of individual fruit. Some fruits develop colour, angularity and their specific gravity changes with the maturity. In general fruit and vegetable when they attain maturity do not develop enough force required to detach them from plant. Table 5.3 provides some indices of maturity of fruits and vegetables.

Colour charts are used for determing the maturity of some fruits, which changes the colour on maturity like stone fruits, tomatoes and banana. Colour charts or photographs can be provided to the worker engaged in harvesting to make the process effective.

Firmness is measured as degree of softness of the fruit and measured by the penetrometer. After choosing an appropriate plunger, hold the fruit against firm surface. Press the plunger with the uniform speed till it punctures the fruit peel.

In some fruits like grapes, citrus, mango, muskmelon etc sugar is the main soluble solids in the fruit juices. Thus, total soluble solids (TSS) measured by the hand refractrometer can considered as index for degree of maturity of these fruits. In juicy fruits like citrus, juice content can be an index of maturity.

5.5.2 Chemical Methods

The fruit maturity is judged by the chemical analysis of the constituents. They are titrable acidity, TSS/acid ratio, sugar/acid ratio, starch content, tannin content etc. In many fruits acidity decreases with the maturity. It can be determine by titrating fruit juice with 0.1 normal sodium hydroxide and phenolphthalein as an indicator.

Some fruits acidity alone cannot be taken as index of fruit maturity. However, a ratio of TSS to acid provides better judgment. We have already read that TSS can be measured by hand refractrometer.

Sugar either free or as derivative play an important role in imparting taste, flavour and texture to the fruits. It is considered as reliable index of maturity of fruits. As the fruit ripens, its starch is partly converted into sugar. Thus, measurement of starch by colorimetric method or by iodine reaction method can also provide an index of maturity.

Table 5.3: Maturity indices for fruits and vegetables

Fruits/Vegetable	Maturity Indices/Characteristics
Mango	Specific gravity 1.01-1.02, fullness of checks and roundness of shoulders
Banana	Angularity to round shape change of colour in some cultivars

Citrus	TSS:acid =12
Grapes	TSS: acid=20
Apple	TSS 12; Firmness 7kg
Peaches/Pears	Colour change from green to yellow, TSS=12
Plums/ber	Skin colour change
Custard apple	Turning of skin as creamy white between segments
Pomegranate	TSS = 16
Brinjal	Glossy skin and seeds are not hardened
Cabbage	Solid
Carrot	Size
Brocoli/cauliflower	Compact flower
Cucumber/Gourd	Tender, before hardening of seed coat
Lady finger	Non-fibrous, tips of pods pliable
Onion	40-50% tops fall
Peas	Shining green, filled
Capsicum	Green and shining
Chilli (hot)	Dark red colour
Potato	Foliage get dried
Tomato	For processing : Red For medium distance market : turning stage (pink) For distant market : breaker stage (green ripe)

Source: Research compilation from different papers and reports of PHTS (Post Harvest Technology Subject)

5.5.3 Biochemical Methods

Evolution rates of carbon dioxide and ethylene are considered as the most reliable methods to judge the maturity index of the fruits. In the climacteric fruits, carbon dioxide evolution increased during ripening stage. Ethylene is considered as ripening hormone and is also a good indicator for judging maturity, suitability of storage and other end uses. However, for non-climacteric fruits their suitability has not been established.

5.6 CULTURAL PRACTICES

Soil type and climate do affect the quality of the end produce. But these are not in the hands of the growers. The cultural practices like soil-water management, canopy management, fruit thinning, doze and time of mineral application chemical sprays, pest management, affect the quality and quantity of horticultural produce not only at the time of harvest but also during storage. It is difficult to analyze the effect of each one of them individually. Affect of cultural practices on citrus fruit is shown in Table 5.4.

Table 5.4: Cultural practices affecting the quality of citrus fruit

- : indicates negative effect; decreases, delays, thin, soft, rough and poor flavour

5.7 PRE-HARVEST TREATMENTS

It is well known that mineral content greatly affect the fruit quality at harvest and changes after harvest. Post harvest shelf-life is mainly dependent upon level of calcium in the fruit. Usually application of higher level of nitrogen, phosphorous and magnesium and lower level of potash and boron leads to calcium deficiency in fruits and reduces the post harvest shelf-life. Pre-harvest treatments of calcium delays ripening and senescence and improves the quality of produce. Low calcium content in tissues lead to physiological disorders such as : (i) bitter pit in apples ; (ii) cork spot in pears; (iii) end rot in tomatoes ; (iv) tip burn in lettuce and (v) hollow heart in potatoes.

Application of zinc and boron improves the mobility of calcium in the leaves and to the fruit. It increases firmness, soluble solids, organic acids, and ascorbic acid and reduces disorders. Chemicals used to extend the shelf life of fruits and vegetables are listed in Table 5.5.

Table 5.5: Chemicals and their schedule of pre-harvest application to enhance

Post Harvest Shelf-life of Horticultural Produce

Fruit/ Vegetable	Chemical & concentration	Time of application (Days before harvest)	Response
1. Apple	Boric acid (0.1-0.2%) silver-nitrate, 75 ppm	60 and 45 45	Improve calcium mobility Enhance shelflife
2. Mango	Calcium nitrate (1%) Or Calcium chloride (0.6%) Bavistin 0.1%		Enhances shelf-life Controls anthracnose and Stem end rot
3. Mango	Thiaphenate methyl 0.05% Gibberllic acid 10-15 ppm Phosphonomethylcin 5%	10	Post harvest losses Delayed ripening High TSS
4. Guava	Calcium 0.6%	20 and 10	Delayed ripening
5. Ber	Calcium compound 1.79/litre Ethereal, 750 ppm	10	Delayed fruit ripening Hasten maturity
6. Grape	Calcium nitrate 0.75%	10	Reduces weight loss & decay
7. Onion	Meleic hydrazide 2000-3000 ppm	15	Reduces sprouting during storage and reduces losses

5.8 SAFE HARVESTING

Harvesting is an important unit operation in horticultural crop production. Though, it appears simple but it does require certain skills. Harvesting period is usually short. Improper harvesting may result in poor quality produce and also damage the plant. Therefore, the harvesting is further subdivided in following sections:

- Identification
- Clipping / Cutting / Picking
- Collection
- Do's and don'ts of Quality Harvest

5.8.1 Identification

Identification of properly mature fruits based on the parameters studied earlier i.e. size, shape, colour, acidity, TSS, firmness etc is the first most important task of the person engaged in harvesting.

5.8.2 Clipping / Cutting / Picking

Identified fruit which is separated from the plant is called clipping/cutting/picking. Improper harvest not only damages the produce but also causes injury to the plant. Manual method of harvesting includes holding the fruit, twisting it and pulling it. It damages the fruit as thumb impression and due to the pressure some times it injures the fruit near the pedicle and also plant stem. On such fruits mould growth is observed after 48-72 h. So they are not suitable for long distance transport.

Clippers and knives provide smooth cut with the desired length of pedicle. Long pedicle is likely to damage neighbouring fruits during transport. It is preferred to have as small a pedicle as possible. Some times fruits are not accessible. Pricking poles attached with collecting bags can be used without climbing on the tree. Tripod ladders could also be used, which are stable and person can reach the fruits.

5.8.3 Collection

In general harvested fruits are dumped on the ground. Where these fruits come in contact with soil. Impact by which it is dropped on the ground and microbes present in the soil contaminates the fruits. Therefore, harvested fruits are to be collected in cloth bags, put on shoulder. These bags are to be carefully unloaded in the plastic crates kept under shade. Plastic crates may be expensive in the beginning but they are reusable. They help in reducing post harvest damage during transport and provide sufficient ventilation to remove field heat. They can also be stacked easily.

5.8.4 Do's and Don'ts of Quality Harvest

i) Harvest as per the market need and proper maturity stage of produce.

ii) Use proper tool to harvest, bag-to collect and crate during handling.

iii) Containers used should be clean, smooth, free from rough edges.

iv) Avoid hand touching of the fruits.

v) Train pickers for harvesting, handling the produce.

vi) Keep produce free from soil contamination.

vii) Keep produce in shade.

viii) Harvest early morning or late evening as these are low temperature at that time.

ix) Field sorting and packing is to be promoted.

x) Cure the roots and tubers before storing.

5.9 POST HARVEST TREATMENTS

On-farm post harvest treatments are basically into two:

1. Removal of field heat by cooling
2. Disinfections of the produce

5.9.1 Pre-cooling

Cooling of fresh produce means removal of the field heat. You remember that in article 2.8.4 it was mentioned "harvesting/picking should be done in the early morning or late evening during low temperature". It is well proven that if the fresh produce temperature is lowered by 10^{o}C in first hour, its shelf life is doubled. You know fruits and vegetables are living. They respire if the temperature is more, their respiration rate increases. Thus, during handling it releases more heat and deteriorates the quality of the produce. The fresh produce can be cooled by:

- Natural cooling
- Forced air cooling
- Hydro cooling

Natural Cooling

The natural cooling is the simplest method in which harvested produce is to be kept in shade on a pucca floor or polyethylene sheet. It is the slowest method of cooling and sometimes time taken to remove the field heat is so high that spoilage of produce starts during cooling itself. Some people misunderstood this and kept the freshly harvested produce in cold room. It may cause harm to the produce as warm fresh produce releases water which when condenses and spoils the produce. Thus, such places should be equipped with good ventilation to remove the field heat.

Forced Air Cooling

Cold air is blown above the freshly harvested produce. It is many times faster than the natural cooling. It suits most of the fruits, which cannot be dipped inside the water for hydrocooling for i.e. strawberry, grapes etc. The main advantage of forced air cooling is that it not only carried heat librated but also carries the moisture evaporated from the fruits. The only disadvantage is if excess air is blown. Then loss of weight of fruit is high.

Hydro Cooling

It is the most effective method in which freshly harvested produced are dipped in cold water or cold water is sprayed over them. The advantage of this method is that it is fastest method of cooling and washing the produce. However, it requires more energy because surface water of the fruit is to be removed before packaging is done by forced aeration. The temperature of water should not cause cold injury or the shower pressure shouldn't damage the produce.

5.9.2 Disinfections of Produce

Fruit and Vegetables are exposed to nature, which is a vast ocean of microbial load. As long as they are on the plants, there resistance power is more. Once detached, the produce needs to be disinfected. The produce can be disinfected by treating with the hot water or chemicals (fungicides).

Hot Water Treatment

Most of the microorganisms and heat sensitive. Thus by dipping the produce for 1 to 5 minutes (depending on type of produce) in hot water (50-55^{o}C) checks the microbial load. In some of the produce time-temperature combination for disinfection is carried out this is given in Table 5.6. After the hot water treatment produce is kept in a cool room and gentle air is to be blown. It removes surface moisture and cools the produce.

The heat treatment temperature and time depends on the type of fruit/vegetables, and their microbial load. Care should be taken that it should not affect the quality of fruit.

Chemical and Fungicidal Treatments

Dipping in aqueous solution of some chemicals reduces the physiological loss in weight and microbial load and enhances the shelf-life of the fruit and provides uniform ripening. Some chemical treatments are given in Table 5.7.

Table 5.6: Hot water treatment to horticultural produce

Fruits/ Vegetables	Temperature (°C)	Time controls (sec/min)
Mango	52 °C 5 min	Controls anthracnose
Mango	46°C 65 min	Anthracnose and fruits fly
Citrus	50 °C 2 min	Enhances post harvest shelf-life
Capsicum	55 °C 12 ± 2 sec	Checks respiration, PLW and shriveling during storage. Enhances Post harvest shelf-life and capacity to with stand thermal stress.

Source: Research compilation from different papers and reports of PHT (Post Harvest Technology Subject)

Table 5.7: Post harvest applications of chemicals / fungicide

Fruit	Chemical / fungicide and doze	Treatment	Effect
Mango CV. Banganapally	Wax, 6%	1 min	Reduces PLW
Mango	Ethylene 10-100 ppm Ethepon/ Etheral 500 ppm	21-25°C for 12-48 h hot water	Uniform ripening and colour development
Mango	Calcium chloride solution less than 4%	Dipping	Delayed ripening
Banana	Waxol –12 Potassium permanganate	Dipping	Delayed ripening
Banana	Sulphur 0.1%	Pasting	Control crown fungi
Grape	Sulphur oxide fumes or 0.5% water spray	Fumigation	Reduces respiration, enhances shelf-life and control growth and spread of rot
Citrus	Waxing bavistin or GA_3-200 ppm or Cytokine 20 ppm	Dipping/spraying	Control spoilage, enhances shelf-life
Guava	GA 200 ppm	Sealed PLDE bags	Enhances shelf-life
Peaches	Potassium permanganate 1000 ppm	Paper soaked lined CFB	Enhances shelf-life
Apples	Calcium chloride 2-3%	Dipping	Helps in ripening
Cabbage	Alum 15% or lime powder at butt end	Treating	Controls Bacterial soft rot

5.10 POST HARVEST MANAGEMENT

In our country the most (above 97%) of the horticultural produce is consumed as fresh. The post harvest handling involves movement of the horti produce from field to the dining table. This may be in bulk or retail. The better quality, produce fetches better returns. Therefore, the quality of produce is to be maintained by keeping a close eye on the movement of the produce. The steps involves are:

- Sorting
- Cleaning

- Trimming/chopping
- Waxing
- Grading
- Packaging
- Labelling
- Storage
- Transportation

5.10.1 Sorting

It is an important unit operation, which is advised to be carryout at the field itself. Removal of damaged, diseased, immature or over mature produce are to be rejected in the field. By removing them, the cost incurred in their transportation and handling can be saved. Moreover, these produce have higher respiration rate, so heat evolved by them is higher and very likely spoil the adjoining produce.

5.10.2 Cleaning

Fruits and Vegetables are exposed to the outer atmosphere. Thus, soil, dust and other impurities are adhered to their peel. Cleaning may be dry or wet (washing) is required to remove the adhered impurities from the produce. It helps in improving the appearance and also cools the produce. Some fruits, whose peel is very soft do not require washing with water like strawberry, kiwifruit, avocados etc. For them gentle air is blown to clean them. Fruits whose natural wax is removed during washing is also not washed with the water.

Spray washing or dipping in a tank with gentle brushing is done to remove adhered impurities. The choice of brushing mainly depends upon type of commodity and contamination.

Hygienic and sanitary conditions are to be maintained to check the spreading of disease and microbial load of washing water. Water may be treated with chlorine (100-150 ppm) to control spores.

5.10.3 Trimming

Some crops contain non-edible parts/excess leaves with the produce. These unwanted portion not only creat an unnecessary bulk but also lead to microbial infection and water loss. Thus such produce are to be trimmed/detopped before storage and handling.

5.10.4 Waxing

Food grade waxing of green vegetable like cucumber, tomatoes and fruits like citrus, apples, peaches is a common practice. It helps in reduction in loss of water during handling and marketing and enhances the shelf-life. Wax coating is done by mist applicator on a moving belt. After wax coating the produce their surface has to be dried before further handling.

5.10.5 Grading

Grading of the produce based on size or colour often fetches premium price in the market. Uniformly graded material provide better appearance and they are easy to pack. Experienced person generally does the grading in India manually.

However, for round produce, size base grades and for some specific fruits weight base mechanical graders are available in different capacity.

5.10.6 Packaging

The main purpose of packaging is to protect the produce during handling, transportation and storage from deterioration due physical, chemical or biological factors. Horticultural produce are highly perishables. After grading, the produce have the uniform maturity and requirement for safely against mechanical injury, and physiological activities like respiration. The package should have the following features:

- ✓ It should have sufficient mechanical strength which can withstand dead load during transportation (including impact and vibrations).
- ✓ It should be well aerated to remove respiration heat and humidity.
- ✓ It should be attractive and economical.

In general horticultural produce are handled through wooden cartons, corrugated fiberboard boxes and plastic crates. To avoid damage produce by touching each other liners/fillers are used of corrugated fiberboard or newspapers or grasses. Polyethylene lines are used to increase the humidity and decrease the water loss from the fruits.

5.10.7 Labelling

Fruits and Vegetables are delicate. Labelling of packages helps the people handling them during loading/unloading, stacking during storage or transportation. The label should contain information regarding maximum stack height, storage temperature and relative humidity conditions, date of packing and best before use. It should also have name of the commodity, its net weight and address of the producer.

5.10.8 Storage

In general fruits and vegetables are stored at low temperature and high humidity. It helps in reduction in respiratory rate and enhances the shelf-life. Appropriate storage conditions for storage of different horticultural produce is given in Table 5.8.

For temporary/transit storage for 1-day produce can be kept in the evaporating cool chamber where humidity is 90-95% and temperature is 10-15 ^{o}C lower than the atmospheric temperature.

Horticultural produce can be stored in modified atmosphere package (MAP) or controlled atmosphere (CA). In this storage, the oxygen concentration is reduced (in general below 5%) and carbon dioxide concentration is increased (3 to 7%). It helps in enhancing the shelf life and maintaining the quality for longer period.

Table 5.8: Storage conditions for fruits and vegetables

Produce	Temperature (°C)	Relative Humidity (%)	Storage life
Fruits			
Apples	1-2	90-95	12 months
Grapes	1-2	90-95	1 month
Citrus	3-8	80-90	3 month
Peaches	1-5	80-90	2 weeks
Pears	1-5	90-95	4-6 weeks
Strawberry	2-5	95 +	1 week
Banana	12-15	80-85	2 week
Mango	10-15	85-90	3 week
Vegetables			
Cabbage	0-2	95-98	3-6 months
Cauliflower	0-2	90-95	4-6 weeks
Cucumber	10-13	95	2 weeks
Brinjal	10-12	90-95	1 week
Onion / garlic	0 to 5 or 25-28	65-70	6 months
Ginger	10-13	65	6 months
Okra	7-10	90-95	10 days
Pea (Green)	0	95 +	2 weeks
Potatoes	4-8	90-95	10 months
Tomatoes	12-15	90-95	1-2 weeks

Source: Food Preservations by modified atmosphere, By Calderon amnd Golan, CRC Press

5.10.9 Transportation

The refrigerated vans are the best method for transporting the produce from one place to another. However, it is not common practice in our country. Therefore, open vans with system of air movement to remove the respiratory heat should be practiced. In the van stacks should be arranged uniformly with thick cushioning pads (straw) to absorb the shocks.

5.11 PROCESSING OF FRUITS AND VEGETABLES

Fresh fruits and vegetables contain 70% or above water on wet basis. Large amount of water and respiration trigger the chain reactions of microbial activity. The purpose of processing is to develop value added products which are stable. The stability can be obtained by:

- Reducing the chemical potential of water by
  - application of heat
    - → Pasteurization
    - → Canning
    - → Dehydration (Drying & reducing a_w)
    - → Concentration
  - addition of solute
    - → Jams, jellies, marmalades
    - → Salting
- Fermentation
  - → Pickling
  - → Beverages (Fermented & non fermented)

5.11.1 Reducing the Chemical Potential of Water

Water present in the fresh produce can be removed by dehydration or addition of solutes which can strongly bind the water and not allow it to take part in deteriorating reactions.

a) Dehydration

It is the simplest and the oldest method to remove the free water from the produce and make it shelf stable. The quality of dehydrated materials depends upon the method of drying, temperature and rate of drying. Natural sun drying is the oldest practice but it provides uneven drying, sometimes gets contaminates from the atmosphere. Therefore, indirect sun drying (solar dryer), or the dryers operated with electricity, diesel or gas can be used to develop good dehydrated product.

Prior to drying, the product is to be blanched and exposed to sulphur fumes which helps in drying and maintaining the colour and flavour of the dried product Table 9 provides the temperature required for drying different produce. Excess temperature may cause loss of nutrients and or caramalization of sugar. Dried product can be stored for few months without refrigeration.

Table 9: Drying air temperature and time required for drying for different produce

Produce	Drying air temperature (°C)	Time required for drying (h)
Apple	50-55	6-8
Banana	50-55	6-8
Grapes	50-55	24-48
Mango (unripe)	50-55	24-36
Garlic	55-60	6-8
Onion (slices)	50-55	8-12
Pea	55-60	12-18
Green chilli (cut)	55-60	4-5
Spinach	55-60	4-5
Cauliflower	55-60	8
Potato chips	50-55	4.

b) Solute Addition

It is well known that by adding sugar or salt, fruits and vegetables can be preserved longer. These chemicals bind the water present in the food and thereby prevent the water to take part in deteriorating reactions. Jams, Jelly, fruit bar, preserves are sugar-preserved products whereas pickles are salt preserved.

The products can be made of intermediate moisture content (18-35%) by partially drying them in air. Such products retain more nutrients, colour, flavour and require less energy in product development.

5.11.2 Fermentation

It is an aerobic/partial anaerobic oxidation process. During the process desirable microorganisms are produced. Some of the useful products from fermentations are acids and alcohols.

The list of some products prepared from fruits and vegetables are given in Table 10.

Table 10: List of some products prepared from fruits and vegetables

Produce	Existing Products	Newer Products
Green Mango	Pickle, chutney, dried slices powder	Drink, juice, concentrate
Ripe Mango	Canned slices, pulp, juices nectar, jam, bar	Frozen slices, concentrate wine, vinegar
Banana (unripe)	Chips	Defatted chips and powder
Banana ripe	Pulp, figs	Powder, bar
Grapes	Raisins, juice, wine	Concentrate
Guava	Jelly, juice, nectar	Bar, powder
Apple	Juice, jam	Juice concentrate, bar dehydrated slices
Oranges	Juice	Juice concentrate, segments
Papaya (raw)	Tuttifruity	Papain
Papaya (ripe)	-	Pulp, slices
Aonla	Preserve, pickles, juices power	Salted and sweet segments
Pea	Dehydrated, brive solution canned	-
Carrot	Juice, pickle, canned	Dehydrated
Onion	Dehydrated slices powder	-
Tomato	Puree, sauce, drink	Powder
Chilli	Dehydrated, powder, pickle	Paste

5.12 BY PRODUCT UTILIZATION

Fruits and Vegetable processing industry is called as sunrise industry in the country. During the processing more than 50% of the material goes as waste. Thus, waste disposal and its utilization is a challenge.

The fruit industry waste contains mainly cellulose, starches, pectins, vitamins, minerals and other micronutrients. These waste can be used for oil, animal feed, fuel, manure and some value added products like pectins, tartaric acid, citric acid etc. Table 11 gives the different waste material and their possible value added products.

Table 11: By-products of horticultural produces and their possible uses

Produce	Waste	Possible uses
Mango	Peel, stone, kernel trimmings	Starch, fat, vineagar kernel flour, animal feed, manure, besides medicinal use to cure diarrhoea, piles etc.
Guava	Seed, core, pomace	Ethanol, oil from seeds, pectine, animal feed
Grapes	Stem, pomace, peel, seeds	Seed oil, cream of tartar, tannin, wine fertilizer
Citrus	Peel, seed, pomace	Molasses, peel oil, cosmetics, soap, textile, pectine, wines, citric acid

Check Your Progress Exercise 4

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Why sorting at farm level is preferred?

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

2. How sanitary conditions are maintained during washing?

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

3. How waxing of fruits and vegetables enhances shelf life?

4. List the properties of ideal fruit package.

5. "Moisture is torture to fruits". Explain?

6. Why blanching is done prior to drying?

5.13 TECHNO-ECONOMIC FEASIBILITY

Some product base techno-economic feasibility has been given. The plant capacity can be enhanced or some other products can be taken up with the same machines.

5.13.1 High Moisture Products like Fruit Jam, Jelly, Preserve, Canned Slices etc.

Plant capacity	100 kg/day
Land	20 × 25 m
Constructed area	12 × 15 m
Cost of machines	Rs. 5,00,000/-
Rolling capital	Rs. 75,000/-
Quality control klaboratory	Rs. 1,00,000/-
Essential utilities	Food grade water Liquid waste water disposal system Electric power
Other utilities	Assured quality raw material Approachable Telephone
Rate of return	25% +
Break even point	45%

5.13.2 Intermediate Moisture Products like Raisin, Figs, Fruit Bar etc.

Plant capacity	100 kg/h
Land	20 × 25 m
Constructed area	10 × 15 m
Cost of machines	Rs. 6,00,000/-
Rolling capital	Rs. 1,20,000/-
Quality control laboratory	Rs. 1,00,000/-
Essential utilities	Food grader water Electric supply Liquid waste disposal system
Other utilities	Telephone Quality raw material Approachable
Rate of return	17% +
Break even point	About 60%

5.13.3 Dehydration Plant

Plant capacity	1000 kg/day
Land	20 × 25 m
Constructed area	15 × 15 m
Cost of machines	Rs. 10,00,000/-
Rolling capital	Rs. 2,00,000/-
Quality control laboratory	Rs. 1,00,000/-
Essential utilities	Food grade water Electric supply Solid and liquid effluent disposal system
Other utilities	Telephone Quality raw material Approachable
Rate of return	21%
Break even point	62 % (about)

5.13.4 Tomato Processing (Juice, Sauce, Ketchup, Puree)

Plant capacity	1000 kg /day
Land	20 × 25 m
Constructed area	12 × 15 m
Cost of machines	Rs. 6,00,000/-
Rolling capital	Rs. 1,00,000/-
Quality control laboratory	Rs. 1,00,000/-
Essential utilities	Food grade water Quality raw material Effluent disposal system
Other utilities	Electric power, approachable , telephone
Rate of return	23 %
Break even point	65%

5.13.5 Fruit Juice, Concentrates and Beverages

Plant capacity	500 kg/day
Land	20 × 25 m
Constructed area	15 × 15 m
Cost of machines	Rs. 10,00,000/-
Rolling capital	Rs. 125,000/-
Quality control laboratory	Rs. 75,000/-
Essential utilities	Food grade water Effluent disposal systems Electric power
Other utilities	Approachable Assured quality raw material Telephone
Rate of return	35%
Break even point	50%

5.14 LET US SUM UP

Fruits and Vegetables are of immense significance to man. Their nutrition, taste helps in good health in a human being. In the present scenario where horticultural production has increased many folds in last few decades but due to poor post harvest management losses has also increased. It is estimated that losses in fruits and vegetables amounts to be Rs. 67,000 crores annually. The main places where losses or damage initiate in the horticultural produce are on the plant itself, harvesting time, handling and storage. These losses can be minimized by pre and post harvest treatments and post harvest management. Surplus produce can be diverted for the processing, which will also create employment.

5.15 KEY WORDS

Climacteric Fruits : Those fruits that develop total senescence sometime after the harvest during storage. Fruits having higher respiration rate, produces of carbon dioxide and ethylene more than the non-climacteric fruits.

Pentrometer : Instrument to measure firmness of produce

Refractometer : Instrument to measure total soluble solids in the produce

Sorting : Removal of damaged, diseased, immature or over mature produce.

Blanching : Heat treatment given to the produce prior to the drying to inactivate enzymes, stabilize product and facilitate easy drying.

Sulphiting	:	Soaking (30 minutes) in the solution of potassium meta bisulphite prior to drying to maintain the colour.

5.16 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Any three fruits: Banana, Mango, Papaya, Sapota
   Any three vegetables: Cauliflower, Pea, Okra

2. Reasons for huge post harvest losses are:

   i) Poor infrastructure facility at the production site.
   ii) Poor post harvest handling and transport facility.
   iii) Less awareness about safe harvesting, sorting and grading at farm level.

3. Reasons for poor farm yield compare to International benchmark are:

   i) Poor planting material
   ii) Unplanned farm management practices.

Check Your Progress Exercise 2

1. Fruits and vegetables are major source of nutrition (minerals and Vitamins) so they are called protective foods.

2. Penetrometer

3. Refractometer

Check Your Progress Exercise 3

1. In Apple – bitter pit
   In potato – hollow heart
   Due to low calcium content – in tissue

2. Steps of safe harvesting are:

   i) Use proper tool to harvest, bag-to collect and crate during handling
   ii) Containers used should be clean, smooth, free from rough edges
   iii) Avoid hand touching of the fruits
   iv) Keep produce free from soil contamination
   v) Keep harvested produce in shade

3. Fruits and vegetables respire and release the heat. The rate of respiration is high at higher temperature. It reduces the shelf life of the produce. So they are cooled.

Check Your Progress Exercise 4

1. Sorting at farm level helps in reducing the cost incurred in the transporting and handling of unwanted produce. Moreover, damaged and immature produce respire more and release more heat. Thus, it may spoil other adjoining produce.

2. Sanitary conditions can be maintained by treating with water containing 100 –150 ppm chlorine.

3. Waxing of perishables reduces the rate of respiration and checks water loss thus, it enhances the shelf life of the produce.

4. Ideal fruit package should have

   i) Sufficient mechanical strength to withstand dead load during transportation. (Including impact and vibrations)

   ii) Good aeration to remove respiration heat and humidity.

   iii) Be attractive and economical.

5. Moisture in the fruits triggers the chain reactions of microbial activities, so moisture is a torture.

6. Blanching helps in drying by evacuating the air from pore spaces, and stabilize the product from microbial load.

5.17 SOME USEFUL BOOKS

1. Chakraverty, A., Mujumdar, A.S., Raghavan, G.S.V. and Ramaswamy, H.S. (2003) Hand Book of Postharvest Technology of Cereals, Fruits, Vegetables, Tea and Spices. Marce; Dekker Inc., New York.

2. Anonymous (1990) Home Scale Processing and Preservation of Fruits and Vegetables. CFTRI Publications, Mysore.

UNIT 6 DAIRY, POULTRY, MEAT AND FISHERIES

Structure

6.0 OBJECTIVES

After reading this unit, you should be able to:

- state the present production status and importance of livestock products including fisheries in national economy;
- enumerate important value added products from milk;
- indicate steps for clean milk production;
- give the basic features of poultry management and preservation of eggs and meat;
- indicate important preservation and processing techniques for meat;
- differentiate between the culture and marine fisheries; and
- outline the principles of preservation and processing of fish.

6.1 INTRODUCTION

Animal husbandry, dairying and fishery activities along with agriculture have been an integral part of human life since the beginning of civilization. Man has been domesticating animals either for food or for cultivation and transport. These domestic farm animals or livestock such as, dairy cows/ buffaloes, goat, sheep, beef cattle, horses, pigs, chicken and turkeys play an important role in the socio- economic life of India. Livestock products play a pivotal role in improving the livelihood of a large number of people by providing food products and by-products for human utility. Besides providing high quality foods such as milk, eggs, meat, fish etc; the livestock sector provides employment to millions of rural farmers and people engaged in secondary and tertiary business related to it. The unit gives a profile of important livestock products in reference to food processing industries.

6.2 PRODUCTION AND ECONOMIC IMPORTANCE

6.2.1 Production

India has vast resource of livestock and poultry. India ranks first in respect of cattle and buffalo, second in goat, third in sheep and seventh in poultry population in the world. The country has 57% of the world's buffalo population. Table 6.1 gives the livestock population details and a profile of livestock products, i.e. milk, eggs, meat and fish is given in Table 6.2, 6.3 and 6.4.

Table 6.1: Livestock population

(million nos.)

Sl. No.	Species	Livestock census		Growth rate (%) 1997 over 1992 annual (comp.)	
		1992	1997		
1.	Cattle	204.58	198.99	-2.79	-0.56
2.	Buffalo	84.21	89.91	6.77	1.32
3.	Sheep	50.78	57.29	12.82	2.44
4.	Goat	115.28	122.71	6.45	1.26
5.	Pigs	12.79	13.29	3.91	0.77
6.	Others	3.22	3.28	1.86	0.37
Total Livestock*		470.86	485.36	3.08	0.61
7.	Poultry	307.07	347.11	13.04	2.48

2003-04 (P)	3.0	3.4	6.4	412 (P)	5739

Source: Economic Survey (2004-05)

Requirement: The per capita animal protein availability is about 10 grams as against minimum requirement of 20grams (from milk 10g, meat 4g, fish 4g, egg 2g). The estimated demand for the present population would be milk 104 million tonnes, meat 7.7 million tonnes, fish 7.7 million tonnes and eggs 4.6 million tonnes (104 million number). A significant gap exists between the requirements and production.

Milk Production: India continues to be the largest producer of milk in the World. The milk output during 2003-04 was anticipated to be 88.1 million tonnes and is expected to reach the level of 91.00 million tonnes during 2004-05. The per capita availability of milk is also expected to increase to 232 g per day during 2004-05 from 207 g per day in 1997-98.

Egg Production: Poultry development in the country has shown steady progress over the years. The current production of eggs is estimated to about 41.00 billion (in numbers) during 2004-05. Currently India ranks fifth in egg production in the World.

Fish Production: There has been significant growth in fish production in the country in the recent years. India is now the third largest producer of fish in the world, and second largest producer of fresh water fish in the world. During the year 2002-03, the total fish production was 62.00 lakh tonnes comprising 30.00 lakh tonnes of marine fish and 32.00 lakh tonnes of inland fish. The fish seed production during the year 2002-03 was 16,333 million fry. Fish is a source of cheap animal protein and current per capita consumption of fish in India is around 9 kg per annum as compared to 11 kg recommended by World Health Organization (WHO).

Meat and Meat Products: Though the country has a good livestock population yet most animals are not bred/ reared in industrialized or scientifically controlled methods for meat production, which is reflected by a generally low annual slaughter rate across all species except pig. Most of the production of meat and meat products continues to be in unorganised sector. The share of bovine meat in the total meat production is about 60% as against small ruminants (sheep and goats – 15%), pigs (10%) and poultry (12%). There are about 3,600 licensed slaughter houses operating in the country, most of them being run and maintained by local municipal bodies. Overall, the scenario is: abattoir management is poor, technologies employed are out of date and hygiene and sanitary conditions are not perfect. As per FAO data the per capita / year meat consumption is 5.2 kg.

6.2.2 Economic Importance

Employment Generation: Animal Husbandry sector provides large self-employment opportunities. According to National Sample Survey Organization's latest survey (1999-2000), the estimate of employment in animal husbandry sector was 11 million in principle status and 8 million in subsidiary status, which is 5% of the total working population. Women constitute 71% of the labour force in livestock farming. Poultry provides employment to about 1.5 million people. The fisheries sector provides employment to over 11 million people. About 0.5 million women are employed in pre and post harvest operations in marine sector.

Value of Output: According to estimates of the Central Statistics Organization (CSO), the value of output from livestock and fisheries sectors together was about Rs. 1,86,094 crores at current prices during 2002-03 (Rs.156, 080 crores for livestock sector and Rs. 30,014 crores for fisheries). The livestock and fisheries sectors contributed 6.5 percent of total GDP(5.4 percent from livestock and 1.1. percent from fisheries) in 2003-03.

Export Earnings: Total export earnings from livestock, poultry and related products were Rs. 4734 crores in 2003-04. Out of the total exports, leather sector accounted for Rs. 2568 crores in value terms.

Export Potential of Marine Products: There has been steady growth in the export of fish products. During 2001-02, the country exported 4.58 lakh tonnes of marine products, which resulted in export earning of Rs. 5815.00 crores. Efforts are being made to boost the export potential through diversification of products for export. The country has now also started export of frozen squid, cuttle fish and variety of other finfishes. During 2002-03, the country has exported 5.21 lakh tonnes of marine products valued at Rs.6793.05 crores.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.

6.3 DAIRY

We know that the milk is the lacteal secretion of the mammary glands of animals. Milk provides both energy and the building material necessary for growth. It also contains antibodies which protect the young animals against infection. In short, milk is a complete food in itself and nature has designed it as a food for the young ones during the first period of life. Let us know more about milk.

6.3.1 General Characteristics of Milk

The principal constituents of milk are water, fat, proteins, lactose (a type of sugar) and minerals (salts). Figure 6.1 shows the important constituents of milk in brief.

The milk of different species, although containing- the same constituents in general, varied in composition and properties in minor ways. Table 5 gives the composition of milk of a few mammals. Milk constituents are divided mainly into three groups namely, water, fat and solid-not-fat (SNF). Milk contains on an average 87 per cent water, 3.9 per cent fat, 4.9 per cent lactose, 3.5 per cent protein and 0.7 per cent minerals, vitamin and other constituents. Milk of ruminants like cow, buffalo and goat is ideally suited for human consumption and meet the basic dietary requirements of human beings.

Table 6.5: Average composition of milk from various species

Species	Constituents %					
	Fat	Proteins	Lactose	Ash	Total Solids	Water
Cow	4.0	3.4	4.6	0.74	13.64	86.36
Buffalo	7.3	3.8	4.9	0.78	16.78	83.22
Goat	4.0	3.7	4.5	0.85	13.05	85.95
Sheep	6.2	5.2	4.7	0.90	17.00	83.00
Camel	3.0	3.9	5.4	0.74	13.04	86.96
Human	3.5	2.0	6.8	0.30	12.60	87.40

Please incorporate the concept and role of co-operatives in milk production following account may help:

In India 'White Revolution' was brought due to operation Flood, largest dairy project for increased milk production in world. The key role in its success was played by "Co-operatives" a concept introduced by Dr. V. Kurien, father of white revolution small co-operatives at village level that involved the participation of farmers (milk produces) and collection centre (processors) was mutually helpful. Today almost all states have 'Milk Co-operatives' with AMUL (Anand Milk Producers Union Ltd.) becoming a global brand.

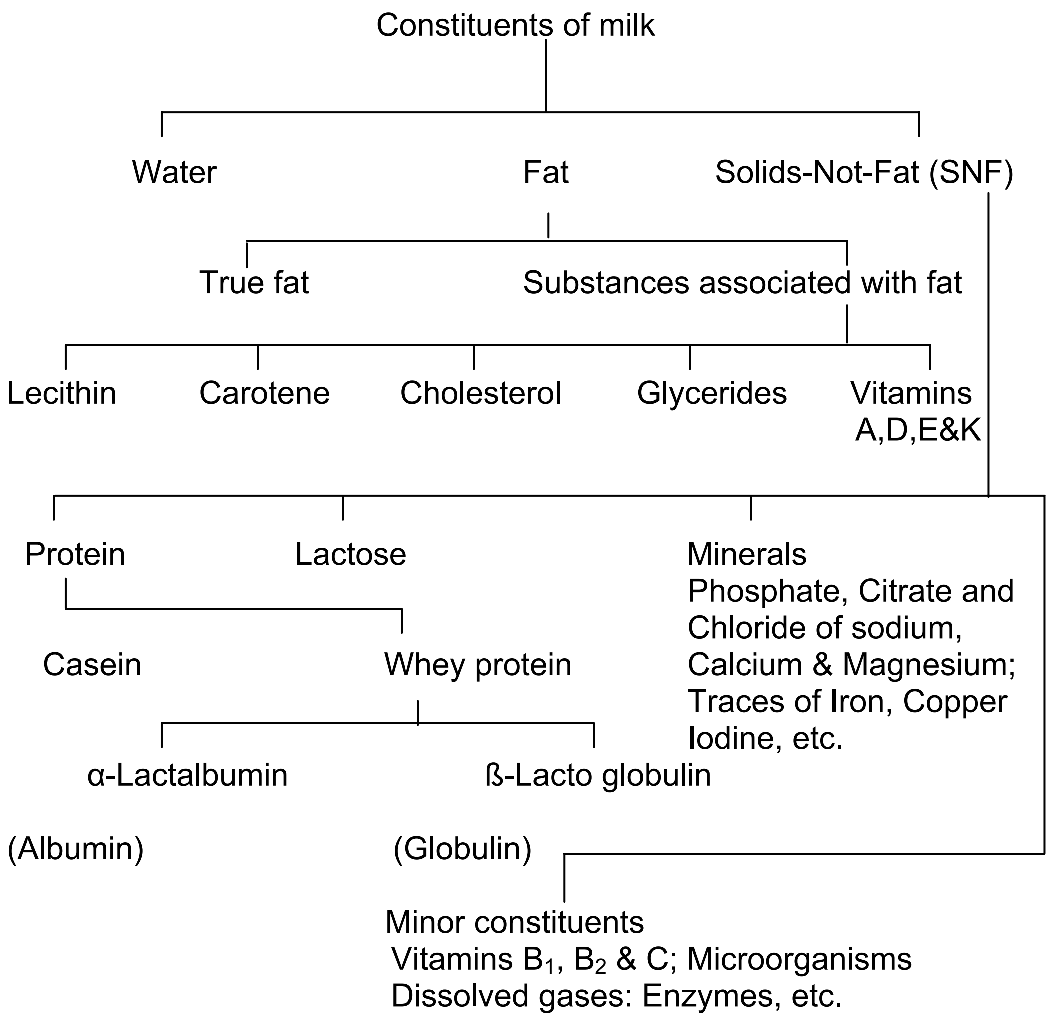

Figure 6.1: Milk constituents

6.3.2 Nutritional Importance of Milk

We know that the milk is recognized as almost an ideal food. It has high nutritive value. It supplies body- building proteins, bone- forming minerals and health giving vitamins. Lactose and milk fat furnish energy. Besides supplying certain essential amino acids and fatty acids, it contains the nutrients in an easily digestible and assimiliable form. All these properties make milk an important food for pregnant mothers, growing children, adolescents, adults, invalids, convalescents and patients alike. The nutritional importance of milk is significant with reference to our country as large population is vegetarian and for them milk & milk products are the only source of animal proteins. Besides, human milk has immunoglobuling, lactoferried, lysozyme and bifidus factor. These Bioprotective attributes make it a perfect food for infants. It's been clinically established that breast fading is best for infants.

6.3.3 Clean Milk Production

Milk is virtually sterile in the udder of a healthy animal. Milk once secreted becomes the target for contamination during milking, milk handling, transport and storage. The degree of infection and the composition of the bacterial population depends on the cleanliness of the animal's environment and the cleanliness of the new surface with which the milk comes into contact, e.g., the pail or milking machine, the strainer, the tanker or the tank and agitator. The bacteria can also get into the milk via the milker, the animal, the litter and the ambient air. Initially high bacterial counts and rapid growth of microorganisms will badly affect the keeping quality of the raw milk and the quality of products manufactured from such milk. Milk contaminated with pathogenic bacteria may be harmful to human health. Therefore, all possible measures should be taken to limit the contamination of milk and to prevent further bacterial growth. The quality aspects are gaining importance and emphasis is on the Clean Milk Production (CMP). The important steps for clean milk production are:

i) Clean and healthy animals: The cow's body especially the udder, should be washed and brushed before milking. Diseased animals should be kept separately.

ii) Clean Housing: Sheds, mangers, paddocks, water trough, floor should be clean and there should be good drainage.

iii) Fly proof milking parlour.

iv) Disease-free environment: milker with clean habits (nails well trimmed).

v) Clean Utensils, Milking pails.

vi) Clean water.

vii) Clean milking: Before milking, clean the udder with a cloth dipped in antiseptic solution such as potassium permagnate; wetting of hands with milk should be avoided.

6.3.4 Basic Milk Processing

Milk after being received at dairy plant is subjected to various unit operations. A few basic processing operations to which the milk is subjected are given here.

Reception and storage of milk : Each milk processing plant or chilling centre where milk is received in raw or chilled condition, requires a separate area for milk reception, commonly known as Raw Milk Reception Dock (RMRD). Milk is received at the dock either in cans directly from the producers / collection points or in insulated tankers from the chilling centres. The steps involved in the process are given in Figure 6.2.

Steps involved in Milk Reception at the Dock (RMRD)

In cans	**In tankers**
1. Unloading	1. Weighing
2. Grading	2. Grading
3. Weighing	3. Sampling
4. Sampling	4. Unloading
5. Dumping	5. Cleaning of tankers
6. Cleaning of cans	

Figure 6.2

The milk is chilled as early as possible in order to check the growth of organism present and maintain the keeping quality of milk. The chilled milk is stored in storage tanks or silos (large storage vertical tanks).

Milk separation: The process of separating out cream from milk is known as separation. It is based on the principle of difference in specific gravity between the fat (0.90-0.93) and the serums or solid-not-fat (1.027-1.036). This can be done either by gravity or by applying the centrifugal force. The dairy plants use 'Centrifugal Cream Separators' in which centrifugal force is applied to enhance rate of skimming, i.e. separating force is multiplied many times than that of gravity and the separation takes place more completely and instantaneously.

Pasteurization: Pasteurization is a process applied to a product with an object of minimizing possible health hazards arising from pathogenic micro-organisms associated with milk by heat treatment, which is consistent with minimal chemical, physical and organoleptic changes in the product. The term pasteurization as applied to market milk today refers to process of heating every particle of milk to at least 63° C (145° F) for 30 minutes or 72° C (161° F) for 15 seconds (or the temp-time combination which is equally efficient) in an approved and properly operated equipment. After pasteurization milk is immediately cooled to 5° C (41° F) or below. LTLT (Low temperature long time) is suitable for small quantities ranging from 200-1000 litre requiring low initial cost of production. HTST (High temperature short time) treatment is ideal for large scale handling of 5000 litres per hour (LPH) or higher. The complete process of preheating, heating, holding, pre-cooling and chilling is completed in a plate type heat exchanger mounted on a compact frame with inter connected sections to make the process continuous. Phosphatase test is carried out to determine whether milk has been properly pasteurized or not.

6.3.5 Milk Products

We know that milk is a rich source of nutrients and is an essential part of diet. Milk is a unique biological fluid which can be dehydrated, concentrated, coagulated, fermented and fractionated into a vast range of milk products. The popularity and consumption of milk products is constantly increasing in our country. Nearly, 50% of the total milk production is converted into various milk products. The focus is being given to value addition and international quality assurance to the indigenous dairy products as tremendous potential has remained untapped. A profile of few popular indigenous and western products is given here.

Butter: A fat rich dairy product obtained from churning milk, cream or curd and working the grains thus obtained into a compact mass. The butter making process involves a number of stages. Churning is the key step and it involves giving violent medium agitation which breaks the emulsion of fat in serums and induces the clumping of fat globules. It is a perishable product, and therefore, it should not be stored longer than necessary. For short period butter can be stored at 4° C but if longer storage is involved it must be stored at –21 to –29° C.

Concentrated and Dried Products: Drying the milk is an efficient method of preservation. In addition, drying also greatly reduces the volume of milk, which is an advantage for long distance transportation and extended storage. Alternatively, only part of the water can be removed from the milk and water activity is further decreased artificially increasing the amount of dissolved solids. This is done by dissolving sugar in a milk concentrate. Accordingly, on the industrial scale milk is preserved by drying or evaporation. The representation composition of these products is summarized in Table 6.6.

Table 6.6: Composition of preserved milk products

Product	Fat%	Milk solid not fat %	Sucrose (%)	Water (%)
Milk powder				
Skim	1	95.5	–	3.5
Whole	26.5	71.0	–	2.5
Evaporated Milk				
Unsweetened	8	18	–	74
Sweetened	8	20	45	27

Cheese: It is defined as a product made from the curd obtained from milk by coagulating the casein with the help of rennet or a similar enzyme in the presence of lactic acid produced by adding starter culture and from which part of the moisture (whey) has been removed by cutting, cooking and pressing. The concentrated solids thus obtained are shaped in a mould and then ripened by holding it at suitable temperature (8-10° C) and humidity. There are many varieties of cheese in the world today that are differentiated by thousands of name. Moisture content of cheese serves to distinguish various categories such as hard, semi-hard, and soft. Cheddar cheese, processed cheese, mozzarella and cottage cheese are quite popular in our country.

Frozen Dairy Products: Ice-cream is a popular frozen dairy product made by rapid freezing of pasteurized mix with agitation to incorporate air and ensure uniformity of consistency. As per PFA definition, the product should contain not less than 10% milk fat, 3.5% milk protein and 36% total solids. It may contain permitted stabilizer and emulsifier not more than 0.5%.

Khoa: *Khoa* or *Mawa* is an important traditional milk product of India. It is prepared by partial desiccation of cow or buffalo or mixed whole milk in an open fire. It is used as the base in several milk sweets viz. *burfi, kalakand, peda, milk cake, gulab jamun,* etc. As per PFA rules, the khoa is the product obtained from cow or buffalo (or goat or sheep) milk or a combination thereof, by rapid drying. The milk fat content shall not be less than 20% of the finished product. In our country, khoa of three varieties, viz. *Pindi, Dhap* and *Danedar* is produced. *Pindi* type of khoa has lowest moisture content. Product obtained from buffalo milk is considered superior being whiter in colour and having soft smooth body and granular texture.

Chhana: It is a popular indigenous milk product obtained by acid coagulation of hot milk followed by draining of whey. According to PFA, the product shall contain not more than 70% moisture and not less than 50% fat on dry matter basis. *Chhana* is used as a base and filler for preparation of a large number of sweets such as *rasogolla, sandesh, ras-malai*, etc. Cow milk *chhana* with moist surface, light yellow colour, soft body, smooth texture and mild acidic flavour is more suitable for Bengali sweets preparation than buffalo milk *chhana*.

Ghee: Ghee is the most important traditional Indian milk product being extensively used for dietary and religious purposes. Cow ghee is golden yellow in colour whereas buffalo ghee is greenish in colour. Ghee is characterized by its pleasant, cooked and rich flavour. The preferred texture is of large uniform size grains uniformly distributed throughout the lot. Ghee produced at different places and different conditions vary in quality. It is refined by heating in large pans at 70-80°C, the product being allowed to settle for 2 to 5 hours after removing the scum formed at the top.

Dairy By-Products: A byproduct may be defined as a product of commercial value produced during the manufacture of a main product. Skim milk, whey and butter milk are the industry's principal byproducts, residues from the manufacture of cream, cheese and butter, respectively.

6.4 POULTRY

Poultry keeping in our country is as old as our civilization. Red jungle fowl found in India and its neighbouring countries is considered to be progenitor of all domestic breeds of fowl. Now, we include ducks, geese, turkeys, pheasants, pigeons, peafowl, guinea fowl and chickens in the list of species under the general term poultry. Chicken, the most popular domesticated poultry, account for more then 90% of the total poultry population of the country. The poultry provides us eggs and chicken.. Rural backyard poultry contributes about 30% of the egg production. The Govt. of India has taken a new initiative of development of rural backyard poultry with a more holistic and self-reliant approach. Let us know more about eggs and poultry.

6.4.1 Poultry Production

The current poultry population in the country is above 435 million and accounts for 4% of the world poultry. The common breeds are shown in table 6.7.

Table 6.7: Common poultry breeds

S. No.	Breed	
1.	American Breeds	Plymouth Rock, Rhode Island Red, New Hampshire
2.	Asiatic Breeds	Brahma Cochin Langshan
3.	Mediterranean Breeds	Leghorn Minorca
4.	English Breeds	Cornish Australorp
5.	Indigenous Breed	Aseel Busra Chittagong, Kadaknath

The important economic traits in reference to rearing of poultry at small scale for egg purpose are - egg production, egg weight, egg quality, body size and confirmation, growth, feed efficiency and fertility and hatchability. Production economics of a commercial layer (for egg purpose) is entirely different than that of a commercial broiler (chicken purpose). The main attributes of a commercial layer are high egg production, low body size, less feed consumption, optimum egg size, good egg quality and high mobility and of a commercial broiler are high juvenile body weight especially at the marketing age, better feed efficiency and low brooder house mortality.

Hatching of Eggs: Hatching is production of baby chicks from fertile eggs. In early days eggs were hatched by placing them under broody hens and desi hens were ideal for this purpose. At present, incubators are used to hatch eggs. They provide similar environment as that of broody hens but more efficiently. Incubators can hatch several thousands egg at a time. The physical factors necessary for successful incubation are temperature, humidity, gaseous environment and turning of eggs. The incubation temperature usually varies from 37.2 – 37.8º C (99.5º F to 100.5º F). In fowls, the hatching period is 21 days. For obtaining better hatch and healthy chicks, the incubators and hatchers should be neat, clean and free from microbial load and should function properly.

6.4.2 Poultry Management

It refers to the husbandry practices to maximize the efficiency of production by satisfying the basic needs of the birds. It involves the management of chicks, layers and broilers.

a) *Chick Management:* It is also known as brooding management. The chicks are transferred to a brooder house immediately after hatching and reared there for 6 to 8 weeks of age. Brooder house should be draft-free, rain-proof and protected against predators. Suitable litter material like saw dust and paddy husk should be spread to a depth of 5 cm. depending upon their availability and cost. Right temperature in a brooder house is very essential. Too high or too low a temperature slows down growth and causes mortality. During the first week the temperature should be 95º F (35º C) which may be reduced by 5º F per week during each successive week till 70º F (21º C). The behaviour of chicks provides good indication of whether they are getting desired amount of heat. Infrared lamps are also good for brooding. Plenty of clean and fresh water should be provided.

b) *Grower Management:* The objective of the growing phase is to produce a pullet (young hen) which will come to lay around 20 weeks of age with an average body weight of 1.2 to 1.4 kg. Grower management especially remains the same as that of chick management except for the additional floor, water and feeder space. The floor, water and feeder space required for a grower are 950-2350 cm^2, 1.5 to 2.5 cm. and 7.5-12.5 linear centimeter, respectively. Water is essential and its requirement depends upon temperature, humidity, age, dietary constituents, activity and air movement. Deworming is essential and is done bi-monthly to keep the birds free from parasitic diseases. De beaking is recommended between 12 and 16 weeks. Feed restriction is essential to reduce the feed cost and productivity.

c) *Layer Management:* The flock should be transferred from grower to layer house at 18 to 20 weeks of age. Floor space of 2300-2800 cm^2, feeder space of 10 cm. and water space of 2.5 cm. per bird are recommended for egg type chicken in floor house. One laying nest for every 4 pullets is necessary. A platform in front of the nest entrances helps the birds to have access to the nest. From 21 weeks, the lighting should be increased gradually till it reaches 16-17 hours per day and maintained at that level thereafter. Correct lighting boosts up egg production by 5 to 10 percent.

d) *Male Management:* Breeder mate management remains essentially the same as that of layer management except that male breeder's diet should be fortified with extra calcium, manganese and vitamin E to ensure proper fertility.

e) *Housing:* The objective of providing housing to poultry is to protect from sun, rain and predators. Poultry houses should be well ventilated, reasonably cool during summer and warm in winter. In our country, open-sided poultry houses are popular. The poultry house should not be expensive. The floor should be moisture proof, free from cracks, easily cleaned, rat-proof and durable.

f) *Feeding of Poultry:* Feeding constitutes an important concern in poultry management since major expenditure (60-70%) in poultry raising is feed cost. More than 40 nutrients are required. The birds should be given balanced ration, i.e. supply different nutrients – i.e. fat, carbohydrates, proteins, minerals, vitamins and water in right proportion. Conventional poultry ration include many cereals like maize, rice, wheat, barley and a few by-products such as wheat barn or rice polish, animal and vegetable protein sources like fish-meal, meat-meal, soyabean-oil-meal, groundnut cake, etc. The ration is fortified with adequate quantity of minerals and vitamins either in chemically pure form or through ingredients known to be rich in these nutrients. Efforts are being made to use agro-industrial products to replace more costly ingredients.

6.4.3 Composition and Nutritive Value of Egg

The main parts of an egg are shell (8-11%), albumen (56.61%) and yolk (27-32%). Egg contains about 2 parts white to 1 part yolk by weight. The whole mixed egg contains about 65% water, 12% protein and 11% fat. The composition of the white and the yolk differ considerably. The yolk is rich in fat, fat soluble vitamins A,D,E, and K and in phospholipids including the emulsifier lecithin (Table 6.8)

Table 6.8: Chemical composition of the hen's egg

Fraction	**%**	**% of Constituents**			
		Water	**Protein**	**Fat**	**Ash**
Whole Egg	100	65.5	11.8	11.0	11.7
White	58	88.0	11.0	0.2	0.8
Yolk	31	48.0	17.5	32.5	2.0
Fraction	**%**	**Calcium carbonate**	**Magnesium carbonate**	**Calcium phosphate**	**Organic matter**
Shell	11	94.0	1.0	1.0	4.0

Nutritionally, eggs are a good source of fat, protein, vitamins and minerals, especially iron. It is often used as a standard for measuring the quality of other food proteins. Its high nutrient content, low calorific value and easy digestibility make it a valuable protective food in human diet.

Quality Factors

The important quality attributes of eggs are: egg size, cleanliness and soundness of shell, albumen and yolk quality, nutritive value, wholesomeness, functional properties, etc. Egg size can be adversely affected by inadequate level of protein and essential fatty acids in layer's (hen's) diet and high environmental temperature.

The quality of egg starts deteriorating soon after it is laid unless proper care is taken to maintain it following better methods of assembly, cleaning, grading, packaging, storage, transport and distribution. Fresh eggs have a high yolk rather than a flat yolk and a larger amount of thick white relative to running thin white. This causes a stale egg to spread out over a larger area than a fresh egg. Fresh eggs taste better, are nutritious superior, are easier to separate into whites and yolks for manufacturing purposes, and perform better in whipping and baking applications. Storage is best at a temperature slightly above the freezing point of the egg. For short period of storage, fresh eggs could be stored at 12.5º C to 15.5º C (55-60º F) and 70-80% RH. For long term storage, the room temperature should be at – 10º C (14 $\pm$ 1º F) and RH 80-90% as this relative humidity will sufficiently retard evaporation without danger of mould growth.

6.4.4 Preservation of Shell Eggs

Preservation of shell eggs are based on simple principle of retarding the microbial growth and sealing pores of the shell to minimize the evaporation of moisture and escape of gases. The common methods include i) thermal processing, ii) immersion in liquid, iii) oil-coating, iv) cold storage, and v) pickling.

In flash heat treatment, the eggs are immersed for 2 to 3 seconds in water at 71º C. The treatment destroys bacteria present on the surface of shell and seals the shell internally by coagulating a thin film of albumen immediately below the shell membrane. Oil treatment preserves the egg by forming a thin film on the surface of shell and thereby sealing the pores. This treatment should be given preferably within a few hours of lay to retain better internal quality. The eggs should be washed before coating. The oil used must be colourless, odourless, less viscous and free from fluorescent materials. Eggs can be dipped in oil or sprayed with it. Vegetable oils such as groundnut oil mixed with 0.0125% BHT is a good sealing agent, but the mineral oils of food grade are preferable as they are less susceptible to oxidative changes during storage. Under village conditions, immersion in lime water and water glass is also useful. In lime sealing, the eggs are immersed in clear lime solution (prepared by using quick lime, water, table salt) and then taken out. Eggs are dried at room temperature and transferred to filter flats.

Dehydration and freezing are the commonly used methods for the preservation of liquid whole egg, albumen and yolk separately, depending upon their use in bakery products, confectionaries and other food or non-food products.

6.4.5 Processing of Poultry Meat

Poultry meat has high nutritive value. It is easily digestible and its protein content is in general higher and fat content lesser than in most of the red meats. Chicken meat contains all the essential amino acids and quantitatively compares closely with milk and egg proteins. It has less carbohydrate, but is a good source of Vitamin B, iron and phosphorus.

The scientific and hygienic processing of poultry is must for processing the quality of meat. Figure 6.3 gives the flow sheet for preparation of ready-to-cook chicken. These are packed immediately either in polyethylene bags of medium density (200 gauges) or vacuum packaged in heat shrinkable film bags.

6.5 MEAT

We know that the word “meat” in its broadest sense means the flesh of animals, especially of mammals or birds rather than fish. However, the term in reference to food processing includes all those parts of the animals that are used as a food by man, and covers glands and organs such as tongue, liver, heart, kidney, brain and so on besides the skeletal tissue or flesh. In our country, sheep, goat, pig and poultry are reared primarily for meat production. Though meat has a very high biological value, its production and processing has always been the subject of social considerations. The per capita animal protein availability is about 10g as against the World average for 25g. Considering the targeted minimum requirement of 20g per capita per day for animal protein, 4g will come from meat remaining 16g from other livestock products. The estimated demand of meat for the present population would be 7.7 million tonnes as against the present production of 5.7 million tonnes. The meat is not an essential item of diet for a large population of the country. The annual meat production of the country is about 4-6 million tonnes and we are placed at number eight position in the world. .

We export both frozen and fresh chilled meat to more than 54 countries in the world. There is, however, very little processing of meat (1%) for ready to eat meat products. About 40 million people are engaged in meat sector, namely, trade of live animals, hides, bones, caesings, horns and hooves, etc. This sector when organized on scientific lines will generate more employment in rearing of animals on scientific lines and processing of slaughter house byproducts for allied industries. The country is poised to achieve the Pink Revolution through buffalo rearing for meat production. A brief profile of meat production and meat products in reference to food technology is given below.

6.5.1 Structure and Composition of Meat

Meat is predominantly composed of muscle tissue along with various types of connective tissue. A cut of meat consists of lean tissue, which, aside from water, is chiefly protein, with some fatty tissue and bone. Muscle is composed of bundles of hair like muscle fibers. These protein muscle fibers are held together by proteniaecous connective tissue which merges to form a tendon which in turn connects the muscle to bone. The connective tissue contains two proteins called collagen and elastin. Collagen on heating in the presence of moisture dissolves and yields gelatin. Elastin is tougher and is a constituent of the ligaments. In well fed animals, fat penetrates between the muscle fiber bundles and this is fat marbling. There are relationships between muscle structure and meat technology. Thinner muscles fibers are tenderer than thicker muscle fibers, and thinner muscle fibers are more common in young animals. Marbled fat within the muscles makes for more tenderness.

Composition of Muscle Tissue: Muscle tissue contains approximately 75% water and 25% solids, of which 19% are proteins. Lipids constitute about 2.5% to 5% of muscle. It contains Cu, Zn, Na, Hg, K, Mg and low amount of Ca. Most of the calcium in the body of an animal is found in the bones, so the edible portion of meat is low in this mineral. Liver is an especially rich source of iron and a concentrated source of Vitamin A. Meats are excellent source of niacin and riboflavin and are good source of thiamine.

6.5.2 Nutritive Value

Meat is a very nutritious food. It is almost fully digestible. The nutritive value of meat is attributed to its abundant high quality proteins, essential fatty acids, some important minerals and B complex group of vitamins (thiamine, riboflavin, niacin, pantothenic acid, B_6, folic acid, biotin and B_{12}). Calories supplied by meat vary with the contents of fat. Organs such as tongue, brain, thymus (sweet breads), heart, liver and kidney are called variety meats. They are also excellent source of nutrients. Variety meat (organ meat) especially liver and kidney contain appreciable amounts of vitamins A, B, C, D, E and K.

6.5.3 Production of Wholesome Meat

The essential stage requiring applications of effective measures for production of quality meat are:

i) Animals should be given sufficient rest before slaughter.

ii) Ample drinking water should be available to them and about 1 hour before slaughter, they should be given very little to eat but should not be starved.

iii) The weak and diseased animals should not be slaughtered. Only those animals which produce carcasses of quality and nourishment should be slaughtered.

iv) Slaughtering and bleeding of the animals should be done without causing excitement.

v) The carcass unfit for human consumption should be destroyed.

vi) Ensure environmental sanitation during transportation of meat and it is safe to the public.

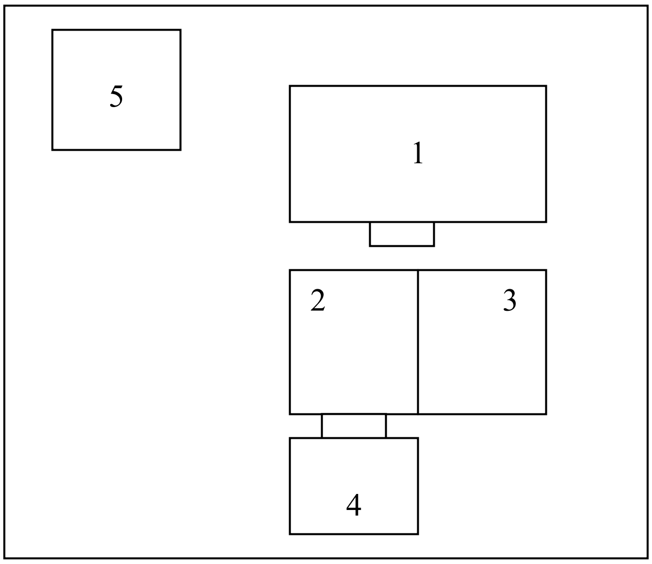
vii) Ensure personal hygiene of all those engaged in slaughtering, dressing and handling of meat.

viii) Process equipment should be kept thoroughly clean and disinfected before use.

ix) Meat and meat products should be stored in fly-proof containers. These must be refrigerated during summer.

Slaughter Houses or Abattoir: Slaughter houses or abattoir means any premises that is approved and registered by the controlling authority in which animals are slaughtered and dressed for human consumption. Abattoir may be small, medium or large based on the number of animals slaughtered. Based on the level of technology adopted the operations are manual, semi-mechanized or fully automatic. The slaughter houses play an important role in the processing of animals for production of safe and wholesome meat and in the effective recovery of by-products.

The important sections of the modern abattoir are (a) Lairage for resting the animals prior to slaughter; (b) slaughter hall; (c) By-product room; (d) Meat cutting room (optional); and (e) Rendering room (optional) or simple system of treating offals or condemned carcass. The building should be furnished with fly- proof system, sufficient lighting, ventilation and water supply (Fig.4). Let us appreciate that application of modern scientific methods for processing of meat in abattoirs would provide safety, value addition, convenience and consumer satisfaction. The Govt. of India has initiated a number of programmes for improvement and modernization of slaughter production.



1. Lairage
2. Slaughter room
3. By-product room
4. Holding room
5. Effluent room

Figure 6.4: Slaughter house

Towards this end, we as trained technicians, should ensure for humane methods of slaughter and production of meat under hygienic conditions. Slaughtering of animals in unconscious state will facilitate prevention of cruelty. The essential processing steps in abattoir are: i) resting animals in lairage prior to slaughter; ii) ante-mortem inspection; iii) stunning (depends on religious customs); iv) slaughter and bleeding on the cradles; v) skinning, dressing and evisceration on the overhead rail; vi) post – mortem inspection; vii) washing; and viii) holding the carcass in chill room (optional); ix) cutting and packing (optional).

6.5.4 Preservation Techniques

Meat is a highly perishable commodity due to nearly neutral pH (low acid food), high moisture contents and rich nutrients. Various methods to extend the shelf-life of meat are: i) chilling / refrigeration; ii) freezing; iii) curing; iv) smoking; v) thermal / processing; vi) canning; vii) dehydration; and viii) irradiation.

Refrigeration/chilling: This is the most widely used method of preservations for short terms storage of meat. Storage of fresh meat is done at a refrigeration temperature of 2 to 5^0 C. Fresh meat can be maintained in good conditions for a period of 5-7 days at a refrigerated temperature of 4 ± 1^0 C. The cooling slows down the microbial growth and enzymatic as well as chemical reactions. Processed meat products are also stored under refrigeration till these are fully consumed.

Freezing: It is for the long terms preservation of meat. It stops the microbial growths and retards the action of enzymes. Large quantities of meat and meat products are stored, distributed and marketed in frozen form. A product can be considered frozen when its centre has a temperature of -12^0 C or less. The speed of freezing is a very important factor as frozen meat quality depends mainly on the size of the ice crystals formed. The quality of meat and meat products can be preserved for months together during frozen storage at -10^0 C. However, a storage temperature of -18^0 C is recommended because at this level almost all water in meat is frozen and minor fluctuations can be taken care of.

Curing: Preservation of meat by heavy salting is an age old practice. Sodium chloride and sodium nitrite are commonly used. Now a days curing of meat products is mainly for specific flavour and colour development and preservative effects of curing ingredients is an added advantage.

Smoking: Smoking helps in preservation of meat. It contains a large number of wood degradation products such as aldehydes, ketones, organic acids, phenols, etc. which exert bacteriostatic effect besides imparting characteristic smoky flavour.

Thermal processing: Thermal processing as a preservative method is employed to kill the spoilage microorganisms as against the refrigeration methods that slows or stop microbial growth. Pasteurization and sterilization are common heat processing operations that are generally used.

Pasteurization refers to moderate heating in the temperature range of 58^0 C to 75^0 C. The process extends the shelf life but the product needs to be stored under refrigeration. Sterilization refers to severe heating above 100^0 C whereby all spoilage microorganisms in meat are killed. It renders the product commercial sterile. Such meat products have a recommended shelf life of two years in cans and one year in retort pouches at ambient temperature in tropics.

Canning: It is a process of preservation achieved by thermal sterilization of a product held in hermetically sealed containers. The product have a shelf life of at least 2 years at ambient temperature. The steps involved are (i) Preparation of meat and gravy, (ii) Precooking of meat, (iii) Filling in cans, (iv) Exhausting, (v) Seaming, (vi) Retort or thermal processing, (vii) Cooling and (viii) Storage.

Dehydration: Removal of water from meat lowers the water activity considerably to prevent the growth of spoilage organisms. Freeze drying of meat is a satisfactory process of dehydration preservations due to better reconstitutions properties, nutritive quality and acceptability. Freeze dried products are packaged under vacuum and have very good storage stability. The process has been largely used for preparations of the dehydrated meat soup mixes.

Irradiation: Food irradiation is referred as cold sterilization as microbial destruction of foods take place without significantly raising the temperature of food. A doze of 50-100 k rad (radurisation) can enhance the shelf – life of fresh meat cuts and poultry products by 19 days whereas a doze of 4-5 M rad (radurisation) can sterilize pork, poultry and fish.

6.5.5 Meat Products

Meat cutting: Meat cutting refers to the skill of separation of carcass into wholesale primal cuts in order to facilitate requirements of meat trade, cater to the consumer preference and convenient handling by the butchers. The basic requirements in cutting are:

i) The carcass has to be essentially chilled for proper meat cutting and trimming job.

ii) Meat cutting room should be maintained at a temperature of 15-20^0 C and relative humidity of 80%. This environment is wholesome for meat and convenient to workers.

iii) All the meat cutting equipment and machinery should be made up of stainless steal and be sufficiently sharp.

iv) Cutting methods varies from country to country. Bureau of Indian Standards (BIS), specify the division of carcass into right and left sides. In our country, people go for six cuts only – neck, shoulder, rack, foreshank and breast, loin and leg.

Tenderizing meat is another important operation which is done by using mechanical methods, enzymes and salt. It affects palatability of meat.

Type of products: Meat products include a variety of products such as sausages, cured and smoked meat products (ham, bacon), canned meat (canned beef, luncheon meat, canned hams) and cooked meat products (patties, kababs, meat balls, nuggets). The purpose of meat processing to products are primarily preservations by inhibiting or preventing spoilage, improving the palatability and providing variety for trade. Meat processing to products facilitates utilization of certain cuts from the carcass which are having poor utility otherwise. The processing also help in development of convenience products for consumers. Economics of meat processing rests with the ability to utilize fats and other carcass trimmings and low value carcass cuts and by products to produce acceptable products.

Nature and role of ingredients: Meat quality plays an important role. Additives such as water or ice, salt, phosphate, nitrate, nitrite, sugar and anti-oxidants are added to improve product quality characteristics during processing. Ice chills meat during chopping or mixing operations and prevents mechanical over-heating, helps in dissolving salts, gives fluidity and facilitates proper filling. Salt reduces microbial growth, solubilizes muscle protein and imparts taste. Phosphates increase water holding capacity, fat binding, emulsion stability and ensure decreased cooking losses. They have a synergistic effect in improving the quality of meat products in combination with 1 to 2 % salt, and are used at 0.5 % level. Sugar at the level of 0.5% is added to provide flavour, mask the salt flavour and act as a preservative. Spices and condiments such as onion, ginger, black pepper, cloves, etc. are also used to improve flavour and taste of the meat products.

Processing methods: Processing refers to any treatment including salting which brings about a substantial chemical and physical changes in the natural state of meat. The preservatives processes such as curing, smoking, cooking, canning, freezing, dehydration, are also used in meat product preparations. Processing imparts considerably shelf stability to meat. The common processing techniques in reference to meat product preparations include: (i) comminution, (ii) emulsification, (iii) meat extension, (iv) pre-blending, (v) hot processing and (vi) cooking.

Meat products: Meat products are classified into the following groups

i) Cured and smoked meats
ii) Sausages
iii) Intermediate moisture and shelf stable meat products
iv) Restructured meat products
v) Canned meats
vi) Other meat products

Ethnic meat products: The range of popular products include, meat curries with gravy, fry or *pulav* (with rice) kababs (*sheek kababs, shami kababs, boti kababs), tandoor products* (tandoor chicken), grilled products and pickles.

By-products: Animal by-products are available from live animals, slaughtered animals and dead animals. The returns from the by-products are also important as meat forms only one–third of live weight of the animal while by-products from two–third. Utilization is important not only to ensure cost-effective utilization process but also for proper disposal to prevent environmental pollution and adverse effect on the main enterprise. Edible by-products from slaughtered animals include blood, variety meat, organ meats (tongue, heart and liver), casing and bones. Non–edible by-products include blood (blood meal), bones (bone-meal, ossein), horns and hooves, gastro-intestinal contents (feed, fertilizers), glands (hormones) and bile (bile salts). Dead animals are also a significant source of useful by-products when collected and processed. Hides and skins, horns and hooves, bones and bone – products, meat-meal and technical fat are the useful products from dead animals.

Among the animal by-products leather and leather products, bone and bone products, and woollen carpets are the major items of export. Other by-products those are exported include animal casings, edible offals, bile paste, gallstones and bristles. Animal glands and organs, viz. ovary, testis, pituitary, adrenal, pineal, parathyroid, thyroid, thymus, spleen, bile, lungs, liver, stomach, brain, spinal column, and seminal vesicles are utilized for medicinal and pharmaceutical purposes.

6.6 FISHERIES

Fish is a valuable food due to presence of high quality proteins, i.e. presence of essential amino acids and fat (high proportion of poly unsaturated fatty acids - PUFA); rich source of B group of vitamins namely thiamine, riboflavin, niacin and pantothenic acid and important minerals such as iodine, phosphorus, active iron and sodium. The composition of flesh of fishes is (a) water 80%, (b) protein 15-25%, (c) mineral matter 1-2% and (d) other constituents 1%. The consumption of fish and fish products is continuously increasing. The nature has bestowed on India a wide variety of fishes. The aquatic endowment is supporting more than 2200 fishes, out of which nearly 1440 species are marine species, 143 species are brackish species, 544 warm water species and 37 are cold water forms. Let us know more about fish production, preservation and processing.

6.6.1 Growth rate

The country has witnessed a quantum jump in the fish production. The country occupies third position in the world and second position in the inland fish production. The fish production is the fastest growing sector in the agriculture. As compared to agriculture and animal husbandry, the fish production rate per unit area is much higher in terms of productivity as well as income. The growth rate of 2.5 percent and 8.0 percent has been proposed for marine and inland fisheries, respectively during the tenth plan. By the end of tenth plan, this will enable a total fish production of about 8.2 million tonnes with 3.3 million tonnes coming from marine sector and rest from inland sector.

Fish is a highly perishable food and therefore due importance be given for marketing, processing, preservation and keeping quality of fresh fish. Lowering, the temperature of fish from 10° C to 0° C, delays the growth phase of micro-organisms that are present and cuts the spoilage by a factor of 5 to 16. Therefore, the fresh fish should be refrigerated (near 0° C) immediately.

6.6.2 Culture Fisheries

The fish culture in ponds and paddy is an age old practice. A series of activities such as controlled breeding in captivity, production of quality seeds in sufficient quantities, rearing of spawn to fry stage, fry to fingerling stage and ultimately raising the table size are christened under the scientific fish farming. The induced breeding in captivity is widely used to get adequate quantity of quality seeds of major cultivated fishes. The process of releasing egg by female and milt by male is called spawning. The mature fishes are induced to breed by giving the pituitary injection. The hormone pellets are implanted into muscle during initial period of gender development for inducing maturation and spawning. Fishes having developed gonads are called brood stock. Hatchery management is an essential component under scientific fish farming. It involves supply of quality water, brood stock development, spawning operation, incubation of eggs, rearing of larvae from egg to post larval stage, nutrition and artificial feeding and health monitoring. The quality of water is very vital component for the survival and growth of larvae and post larvae. It is also important to maintain favourable temperature, water level, flow of water and adequate level of oxygen during larval rearing.

Construction of Fish Farm

The ponds are constructed to have high survival rate. The ponds are classified into nursery pond, rearing pond and stocking pond. The nursery ponds are used to nurse the spawn upto fry stage and are small and shallow. The rearing ponds are used to rear fry up to fingersling stage. The stocking ponds are used to grow the fish to marketable size. Generally, rectangular shape ponds are constructed with a depth of 0.5 to 0.10 m for nursery ponds, 0.6 to 1.5 m for rearing ponds and 1.0 to 2.5 m for stocking and brooder pond. An assured supply of good quality water free from pollution and turbidity is to be ensured. The pH of water should in range of 6.5 – 7.5 and for correcting the pH liming is done. The optimum concentration of dissolved oxygen (above 5 ppm) is maintained by adequate aeration by means of aerator, paddle wheel aerators, surface agitators and air blowers. The practice of using composite fish culture has revolutionized the aqua food sector in the country. The feed management and health management also play an important role in productivity.

Aquaculture has mainly contributed to the high growth of inland fisheries (6.6% per annum) as compared to marine fisheries (2.2% per annum) during the nineties. Indian major carps/ Labeo rohita (rohu), Catla catla (catla) and Cirrhinus mrigola (mrigalo) contribute about 78% of the total aquaculture production. The productivity has also gone up from about 600 kg/ha year in seventies to about 2000 kg/ha year.

6.6.3 Marine Capture Fisheries

We know that the country has a long coastline of 8118 km and an equally large area under estuaries, backwaters, and lagoons good for developing capture as well as culture fisheries. After declaration of the Exclusive Economic Zone (EEZ) in 1997, the area available to India is about 2.02 millions sq. cm. The harvestable potential of marine resources in EFZ has been estimated at about 3.921 million tonnes. The marine fishing fleet comprises about 0.281 million traditional craft (including about 44578 motorized traditional craft), 53684 mechanized chained craft and about 170 large fishing vessels of 21 m overall length (OAL) and more. The major fishing activities are concentrated in the areas within 0 to 70-80 m depth zone. Fish production has increased over the years with the motorization of traditional craft and introduction of mechanized boats in the traditional sector as well as diversification of fishing effort beyond 50 m depth.

As spoilage of fish starts from the time it is caught, the proper storage, preservation and prompt disposal or transport services are essential. The wastage is acute during monsoon when upto 30% of the catch is lost. Therefore, strengthening of post-harvest infrastructure such as storage facilities, ice plants, cold chains, roads and transportation etc., as well as effective marketing system in identified areas are the key requirements for the development of this sector.

6.6.4 Post Harvest Care

As we know fish is a highly perishable and decomposes quickly. The problem is acute in our country as heat and moisture promotes deterioration. Bacteria of water and air attack the flesh slowly at first and more rapidly later. Chemical changes cause breakdown of protein and other nitrogenous matter leading to the production of substances like hydrogen sulphate and indol. The characteristics odour of stale or spoiled fish is due to trimethyl amine which is formed by reduction of tri-methyl oxide. Fishes are preserved by various methods such as drying, salting, pickling, smoking, canning, chilling and freezing. Before preservation, fishes are washed with clean water to remove saline, blood stains, mud and sand. Larger fishes are gutted (i.e. on the internal organs or vice-versa are removed) and the body county is washed.

To remove natural moisture from the fish tissues, fishes are cured by means of heat, sun dry air and salt all along the coast. Drying of small marine fishes such as ribbon fish, silver bellies and Bombay duck in sun or shade is a very ancient method of fish preservation. In this method fishes are spread on the open sandy beach, mats, bamboo platform or hung on ropes/rods. Mechanical drier are also used for this purpose and this method yields high quality products which retains the nutritive value and flavour. Salting is a form of pickling in which common salt is used to prevent bacterial growth and methods of dry salting and wet salting are employed. In the dry salting method, fishes are rubbed with salt powder and than packed in the plastic/cemented tanks. In between two layers dry salt is applied and after stipulated period these fishes are removed, washed in the salt water and then dried. In wet salting method, gutted and cleaned fishes are placed in the container containing concentrated salt solution and stirred properly. Wet salted fishes are sold in the market without drying. In smoking, wood smoke is utilized as a preservative. In this method, cleaned and gutted fishes are soaked in the salt or brine for a short period and then suspended on rod in the smoke house. In chilling, fishes are packed in ice and then saw dust or rice husk is sprinkled over it to prevent the melting of the ice. Freezing is the most modern method of preservation. Fish intended for long storage are frozen in large deep freezers. Individual quick freezing method is gaining popularity. Frozen fishes retain their nutritive values for a longer time.

Value added products: A number of value added products are available in the market, viz. battered and breaded products like fish fillets, fish cutlets, fish cakes, fish burgers, fish balls, fish sausages, fish noodles, fish rolls, fish patties, stuffed squids, etc. The switch over from block freezing to individually quick frozen (IQF) products has changed the profile of value added products.

IQF provides, lobster, imitation products like kamabaka, crab legs, imitation shump are becoming popular. The value added products like (i) prawn and fish pickle, (ii) fish and prawn papad, (iii) fish jhuri bhagra, (iv) fish noodles and (v) fish pulp can be prepared dry woven fishers also. The techno-economic advantages of the products are (i) wide acceptability (ii) greater shelf life, (iii) more palatability, and (v) stringent quality control. There is a good potential for export of preferred products.

By-products and other uses: Fishes are also source of numerous byproducts such as (i) Fish oil, (ii) Fish-meal, (iii) Fish flour, (iv) Fish proteins, (v) Fish glue and singlass. Two important fish oils are (i) Liver oil and (ii) body oil. Liver oil is popularly known as cod-liver oil. There are numerous by-products besides oil, which are economically useful. The most important are fish-meal, fish-flour, fish-protein, fish-ghee and fish-skin.

6.7 LET US SUM UP

The country has a considerable livestock population. Processing and production of value added products hold an important place in the national economy. We are the largest milk producers in the world. The quality of milk plays an important role in processing of milk and milk products. The important value added products from milk are butter, concentrated and dried milk products, ghee, cheese, frozen dairy products, *khoa, chhana* and a range of by products such as skim milk, whey, etc. The poultry provides us eggs and chicken. The major expenditure in poultry raising is feed cost. The methods used for preservation of shell eggs are based on retarding of microbial growth and sealing pores to minimize the evaporation of moisture and escape of gases. The meat production in our country is largely a byproduct system of livestock production utilizing spent animals at the end of their production life. Meat is a highly perishable commodity and methods to extend the shelf life are (i) chilling/refrigeration; (ii) freezing (iii) curing (iv) smoking (v) thermal processing (vi) canning (vii) dehydration and (viii) irradiation. The common indigenous popular products are meat curries with gravy, fry or *pulav* (with rice), *kababs* (*sheek kababs*, *shami kababs, boti kababs*), *tandoor* products (*tandoo*r chicken), grilled products and pickles. Fish is a source of cheap animal protein. It is highly perishable and various methods adopted for preservation are drying, salting, smoking, canning, chilling and freezing. Cod-liver oil one of the important by-products.

6.8 KEY WORDS

Preservation : Aims to inhibit microbial spoilage and arrest physio-chemical changes which bring about deterioration in quality.

Lactose : A type of natural disaccharide consisting of glucose glactose present in milk.

Brooding : Rearing of chicks upto 6 to 8 weeks of age.

Milk : It is the lacteal secretion of the mammary lands of animals.

Milk separation : The separation of milk into cream and skim milk.

Pasteurization : A process of heating every particle of milk or milk product to specified temperature and holding at that temperature for specified period followed by immediate cooling and storage at low temperature.

Hatching : Production of baby chicks from fertile egg.

Abattoir : Premises that is approved and registered by the controlling authority in which animals are slaughtered and dressed for human consumption

Comminution : It refers to subdivision or reduction of raw meat into meat pieces or particles.

Processing : Treatment or unit operations which bring about a substantial chemical and physical change in the natural state of milk/meat/fish/egg.

Post-mortem : It is the systematic exposure and scientific examination of the tissue and organ of a dead body to determine the cause of death, the nature of lesions and illness.

Aquaculture : The term relates to the culture of fish in fresh water, backlash water and sea water.

Spawning : The process of releasing eggs by female and wilt by male is called spawning.

6.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. The milk output during 2002-03 was 86.2 million tonnes and the per capita availability of milk during the period was 230 g per day.

2. Cattle population: 198.99 million and buffalo: 89.91million.

3. The livestock and fisheries sectors contributed 6.5 percent of total GDP (5.4 percent from livestock and 1.1. percent from fisheries) in 2003-03.The value of output livestock and fisheries sectors together was about Rs. 1,86,094 crores at current prices during 2002-03 (Rs.156, 080 crores for livestock sector and Rs. 30,014 crores for fisheries). Total export earnings from livestock, poultry and related products were Rs. 4734 crores in 2003-04.The sector provides large self-employment opportunities.

Check Your Progress Exercise 2

1. Milk contains on an average 87 per cent water, 3.9 per cent fat, 4.9 per cent lactose, 3.5 per cent protein and 0.7 per cent minerals, vitamin and other constituents.

2. The important steps involved in clean milk production are:

   - Clean and healthy animals.
   - The cow's body especially the udder, should be washed and brushed before milking. Diseased animals should be kept separately.
   - Clean Housing: Sheds, mangers, paddocks, water trough, floor should be clean and there should be good drainage.
   - Fly proof milking parlour.
   - Disease-free environment: milker with clean habits (nails well trimmed).
   - Clean Utensils, Milking pails.
   - Clean water.
   - Clean milking: Before milking, clean the udder with a cloth dipped in antiseptic solution such as potassium permagnate; wetting of hands with milk should be avoided.

3. The term pasteurization as applied to market milk today refers to process of heating every particle of milk to at least 63° C (145° F) for 30 minutes or 72°C (161° F) for 15 seconds (or the temp-time combination which is equally efficient) in an approved and properly operated equipment

Check Your Progress Exercise 3

1. Brooding is management of the chicks.

2. The composition is given in Table 6.9:

Table 6.9: Chemical composition of the white and yolk

Fraction	%	% of Constituents			
		Water	Protein	Fat	Ash
White	58	88.0	11.0	0.2	0.8
Yolk	31	48.0	17.5	32.5	2.0

3. The common methods of preservation of shell eggs include (i) thermal processing, (ii) immersion in liquid, (iii) oil-coating, (iv) cold storage, and (v) pickling.

Check Your Progress Exercise 4

1. The essential stage requiring applications of effective measures for production of quality meat are:

   a) Animals should be given sufficient rest before slaughter.

   b) Ample drinking water should be available to them and about 1 hour before slaughter, they should be given very little to eat but should not be starved.

   c) The weak and diseased animals should not be slaughtered. Only those animals which produce carcasses of quality and nourishment should be slaughtered.

   d) Slaughtering and bleeding of the animals should be done without causing excitement.

   e) The carcass unfit for human consumption be destroyed.

   f) Ensure environmental sanitation during transportation of meat and it is safe to the public.

   g) Ensure personal hygiene of all those engaged in slaughtering, dressing and handling of meat.

   h) Process equipment should be kept thoroughly clean and disinfected before use.

   i) Meat and meat products should be stored in fly-proof containers. These must be refrigerated during summer.

2. Various methods to extend the shelf-life of meat are: (i) chilling/ refrigeration; (ii) freezing; iii) curing; (iv) smoking; (v) thermal/processing (vi) canning; (vii) dehydration, and (viii) irradiation.

3. The value added products prepared from meat products are sausages, cured and smoked meat products (ham, bacon), canned meat (canned beef, luncheon meat, canned hams) and cooked meat products (patties, kababs, meat balls, nuggets)

Check Your Progress Exercise 5

1. The process of releasing egg by female and milt by male is called spawning.

UNIT 7 COMMERCIAL CROPS, SPICES, MEDICINAL AND AROMATIC PLANTS

Structure

7.0 OBJECTIVES

After reading this unit, you should be able to:

- state the importance of commercial crops, spices, medicinal and aromatic plants in the national economy;
- know about post harvest processing of these crops into value added products; and
- describe the by products and other uses of these crops.

7.1 INTRODUCTION

Commercial crops, spices and medicinal and aromatic plants are high value crops. These crops require special attention during production and also during post harvest processing, handling and storage. Some of these crops play a significant role in the national economy, export or in employing large number of people. Therefore, the study of these crops is to be separated from the other crops like cereals, pulses and oil seeds or horticultural crops.

The Unit 4 has been divided in three sections namely; commercial crops, spices and medicinal and aromatic plants. Under section 4.2 mainly two main commercial crops namely sugarcane and cotton are discussed. In the section

4.3, six major spices namely chilli, cardamom, pepper, tamarind, turmeric and ginger are discussed. Lastly medicinal and aromatic plants are discussed.

7.2 COMMERCIAL CROPS (SUGARCANE AND COTTON)

7.2.1 Importance

Crops, which are important from commerce points of view, are called commercial crops. Mainly two crops are considered as major commercial crops in India namely sugarcane and cotton.

Sugarcane is widely grown in almost every state of the country and two union territories. Sugar industry is the second largest processing industry in the country. There are more than 400 sugar industries in the country who receive raw material from 35 million sugarcane growers in the country. India is the largest sugarcane producer of the world and at one time (1975-76) it had exported over 1 million tonnes of sugar and earned Rs. 468.5 crores.

Wealth of Sugarcane: From energy transformation points, sugarcane is the most efficient crop. It receives the solar energy and converts it in to energy producing substances like sugar, cellulose and non-cellulose products. Thus its processing is valuable contribution to food and industry. Sugarcane produces sucrose which is a direct source of food and wide range of by products as shown in Figure 7.1. These products are useful for human and animal consumption and also provide huge renewable energy.

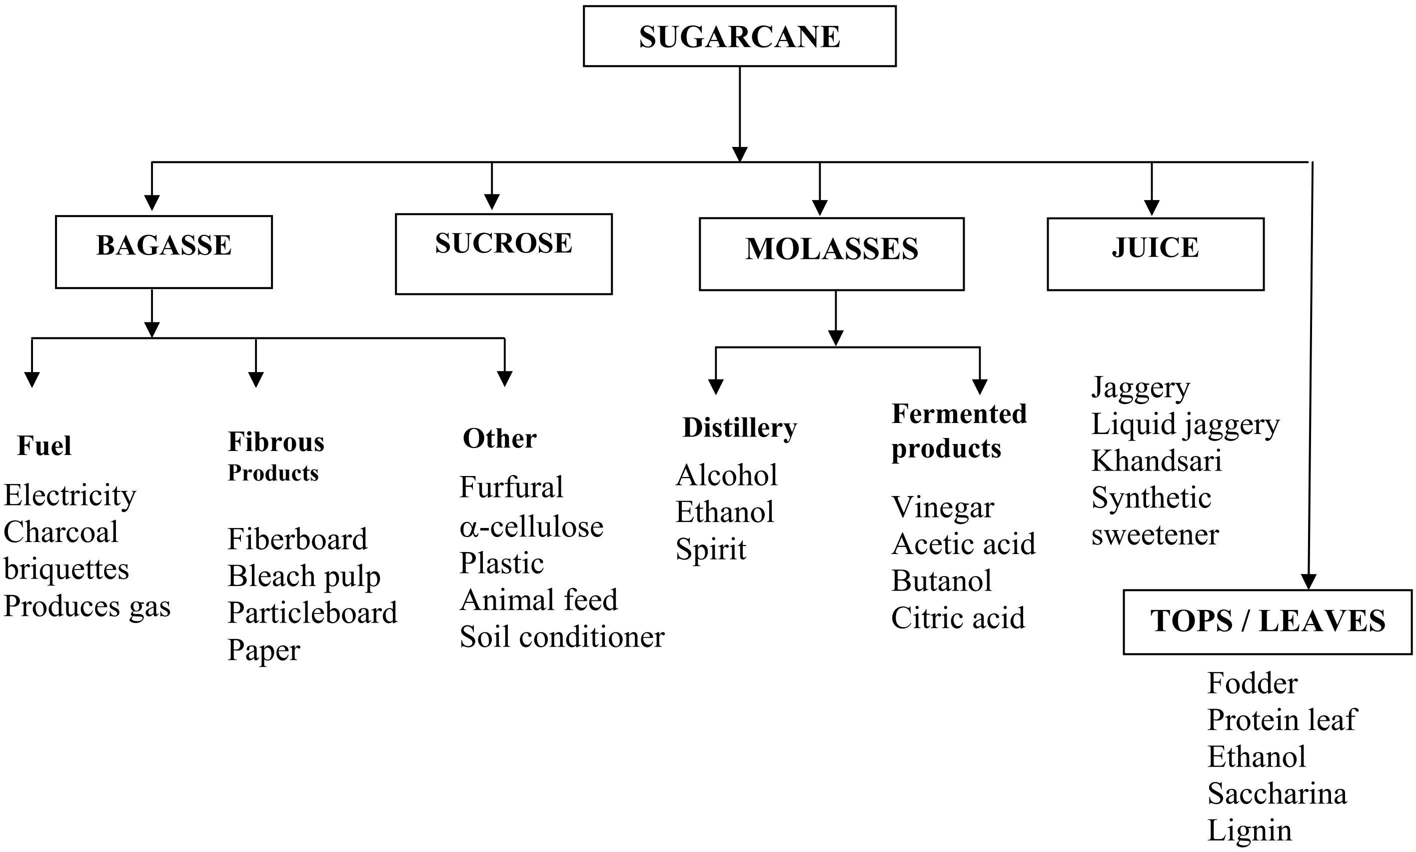

Figure 7.1: Products and by products of sugarcane

Cotton is the most important commercial crop playing a key role in economic, political and social fabric of the world. In India it is the biggest organized sector which provides employment to several million people. It is the largest industry in terms of annual value of output and labour employment. Besides this large number of power loom and handloom have employed around 2.5 million people.

Cotton is not only known for production of lint, which is the basic raw material of textile industry but also to produce cottonseed, which is rich in oil.

7.2.2 Processing of Sugarcane

In a typical sugar factory 100 tones of cane produces: Sugars (10 t), molasses (4 t), filter mud (3 t), Bagasses (30 t) and cane tops and leaves 30 t. Besides these it also can produce electricity of 1500 kW.

Juice Extraction

Sugar cane is crushed in sugarcane crusher (IS:1973-1973) in general where first dry crushing is done and about 73% of total available juice is recovered. Then wet crushing is done to recover remaining juice. IS-6983-1973 is the specification of rollers and axles for sugar cane crusher. Extracted juice is acidic (pH 5.2-5.5) in nature. It is neutralized to pH 6.4 by the addition of lime solution. In general in 100 kg juice, 1 kg lime (80-90% purity) is mixed with 4 litre of water and 60-75 ml of milk of lime is sufficient to bring desired neutralization.

Juice boiling: To avoid sugar inversion, the boiling should be done within 8-12 h of juice extraction. A traditional furnace, where *bagasse* is used as fuel should have high heat utilization efficiency and Juice clarification.

Jaggery

Jaggerry and *Khandsari* are ancient *sweetners* and still popular among masses for its high food value and medicinal properties. In India about 40% of sugarcane produced is used for making *jaggery* in the organized and unorganized sector. The *jaggery* is considered to be diuretic, refreshing tonic and cooling. Table 7.1 provides the comparison of composition of sugar, *Jaggerry* and *Khandsari.*

Table 7.1: Proximate composition of sugarcane sweeteners (100g)

Sweetener	Sucrose (g)	Reducing sugar (g)	Protein (g)	Fat (g)	Moisture (g)	Ca (mg)	P (mg)	Fe (mg)	Energy (Kcal)
Sugar	99.5	-	-	-	0.4	-	-	-	398
Jaggery solid	60-85	5-15	0.4	0.1	3-10	8	4	11.4	383
Khandsari	96	-	-	-	0.5	100	-	-	398
Bura	90-95	1-3	-	0.5	1.5	100	-	-	395
Misri	99.5	-	-	-	0.2	-	-	-	402

Source: Annual report of ISARI< Lucknow 1999-2000

The traditional process of *jaggery* preparation is shown in Figure 4.2. Sugarcane is crushed in sugarcane crusher. About 48 % of sugarcane mass as juice goes to clarifier. The clarified juice is boiled. To neutralize the juice lime is added and concentrated juice is put in the moulds (1, 5, 10 and15 kg). After cooling moulds are stored. Bagasse, which is a byproduct, is used as source of fuel in the *jaggery* preparations.

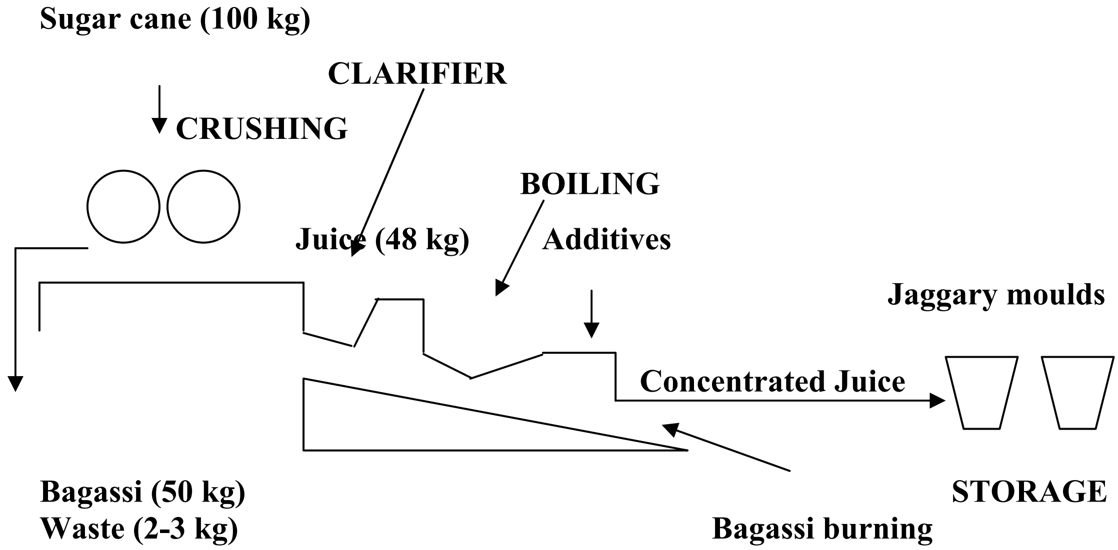

Figure 7.2: Traditional process for *jaggery* preparation

7.2.3 Byproducts of Sugarcane

Sugarcane plant has four major byproducts namely bagasse, molasses, sucrose, tops and leaves.

Bagasse

Bagasses, is the fibrous residue of cane stalk after crushing and extraction of juice. It consists water, fibers and small quantity of soluble solids. Its composition includes fiber 46-52%, moisture 43-52% sugar 3% and minor constituents 0.55%. Where as the dry bagasses composition is: Cellulose (45%), Pentosans (28%), Lignin (20%), Ash (2%) and sugar (5%).

Bagasse can also be used as –

i) **Pulp**: Bagasse can be converted in to pulp. This pulp can be used to make paper for wrapping, printing, writing, toilet, tissue, corrugated medium, linerboard etc. Fluff pulp can be used to make sanitary napkins and absorbent disposable products.

ii) **Paper Industry:** Process of paper manufacturing includes **digestion, washing, screening, bleaching, dewatering and thickening.** Bagasses are digested in close units at pre-specified pressure, temperature and time with chemicals. Later washing is done to remove the effect of chemicals.

iii) Fuel (briquettes, charcoal, produces gas)

iv) Fodder for animals

v) Production of mushroom

vi) Soil conditioner

Molasses Based Products

Molasses yield is 2.2 to 3.7% of the total cane crushed. It is graded based on total sugar content and yield of ethyl alcohol produced from it. Alcohol producing industry consume about 80-90% of the molasses produced in the country. The other important product is ethanol. The ethanol produced is used for

Ethanol

Dehydration	**Oxidation Dehydrogenation**	**Modification**
Polystyrene	Ethyl butyl acetates	Chloroform
Polyethylene	Acetic anhydride	Butadiene
Poly ethers	Charcoal	Diethyl then
	Butaaraldehyde	Ethylamines
	Acetamide	Ethyl chloride

Sucrose

Sucrose is a regenerable potential raw material obtained from sugarcane. Though it is not as sweet as saccharin, suralose, aspartame etc, but it has wide commercial applications. There are some added derivatives which have market potential such as:

- Ethers and anhydro derivatives
- Esters of fatty acids as surfactant and emulsifiers
- Sulfuric acid or sulphate esters.
- Polymers and resins, acrylics, etc

The other uses of sugarcane tops press mule and waste is in animal feed, fertilizer cane wax etc.

7.2.4 Processing of Cotton

Ginning

It is an important unit operation in the handling cotton as a raw material from field to the factory for processing. It is the process of separation of lint from seed cotton. It is done either by roller gin or with saw gins.

Quality Evaluation of Cotton

The quality of cotton is judges by the quality of yarn which be spun from it. The spinning performance in expressed as **"Highest Standard Count" (HSC)** which cotton can spin. For i.e. 40 counts means one pound of a particular yarn contain 40 lakhs of 840 yards each. Based on the end-use of the yarn, certain strength standard have been prescribed. The maximum HSC for cotton is the finest count of yarn, which can be spun to satisfy the yarn strength standards. Thus important parameters are fineness, maturity and strength.

Fiber length – Longer lnited cotton provides better spinning performance than shorter linted ones.

Short staple	19 mm or below
Medium staple	20 .0 – 21.5 mm
Superior medium staple	22.0 – 24.0 mm
Long staple	24.5 – 26.0 mm
Superior long staple	27.0 mm and above

7.3 SPICES

7.3.1 Importance

The Indian spices are perhaps older than the recorded history. India is well known to the world as **Home of spices**. Spices contribute an important group of agriculture commodity as they are considered as indispensable in the culinary art for flavouring of foods. These crops will also show our heritage and national wealth in utilization of them for several medicinal uses. Some are also used as pharmaceuticals, perfumery, cosmetics etc. Besides this, spices play an important role in the national economy.

Chilli is the dried ripe fruit of genus "capsicum" which is also called as red pepper and it is considered as an important commercial crop used as a condiment, culinary supplement as a vegetable. In India, chilli is cultivated in about 10 lakh hectares with an annual production of 10 lakh tonnes, which is about one fourth of the world's chilli production. The annual Indian export of chilli in recent times is around 13000 tonnes valued about Rs. 500 million. Together with whole chilli, the value-added products like chilli powder, curry powder, chilli oleoresins etc. add a major share to our export earnings.

Among the various spices cultivated in India, cardamom is called "**Queen of spices**". It is native of India; enjoys a unique position in the International spice market. At present, India is the second largest consumer of small cardamom in the world after Saudi Arabia. The cardamom growing tracts in the country are facing severe ecological degradation due to diminishing forest cover, leaving the region open to devastation by floods and droughts. As cardamom requires tropical forest conditions for better growth, both the area and production of cardamom in the country are declining.

Pepper (*Piper nigrum*) popularly known as the **King of spices**. It is the dried fruit of perennial climbing vine, mostly found in hot and moist parts of Southern India. Kerala alone contributes 96% of the total production in India. Apart from Kerala, pepper is also cultivated in the hill districts of Karnataka and Tamil Nadu. Mostly pepper is cultivated as intercrop with other plantation crops.

Pepper is widely used as a condiment, preferred for its characteristic aroma, pungency and biting taste. It is used to garnish culinary preparations, ketchups, sauces pickles and in pharmaceutics. Indian pepper, commonly known as "Malabar pepper" is considered to the best in the world for its excellent aroma flavour and pungency. India is the largest producer, consumer and exporter of black pepper. India contributes about 35 to 40 percent to the total world production and thus occupies the unique position in the international trade of pepper. The annual production of pepper in India is in the range of 60,000-85,000 tonnes.

Tamarind (*Tamarindus indica* Linn) is one of the important economic trees of India. Tamarind is a much-loved tree throughout the semi-arid regions for its deep, cool shade and for its valuable fruit. It is an ideal plant for optimum use of wastelands. It is a regular bearer and provides assured returns to the farmers even under extreme soil and climatic conditions.

Turmeric adds typical flavour and colour in curries and makes them the best. Turmeric is also used as dye in textile industries, it is also used for medicinal purposes and cosmetics. India exports only 5-8 % of its turmeric produce and ranks 6th in spice export and earns over Rs. 100 million annually.

India is the largest producer and exporter of pepper, chilli, ginger and turmeric. It also exports substantial amount of cardamom and black pepper. India alone contributes 50% of the world ginger requirement. Ginger is used principally as an ingredient in various spices blends, food processing and beverage industry.

7.3.2 Proximate Composition of Spices

Spices are an important group of agriculture commodity as they are considered indispensable in the culinary art for flavouring of foods. These crops also show our heritage and national wealth. Some are also used as pharmaceuticals, perfumes, cosmetics etc. Proximate composition of spices is given in Table 7.2.

7.3.3 Harvesting and Drying of Chilli

The crop becomes ready for harvesting in about 105-120 days after planting. The picking of ripe fruits continues for about 2 months. Chilli is picked in about 6-10 pickings with an interval of 7 or 8 days. Some traditional varieties require only 5-6 pickings; while the hybrids may require up to 12 pickings. Harvesting is done after 1 or 2 days of irrigation and picked fruits are kept in shade to avoid sunscald.

Chilli is harvested at moisture content of around 60-70% (w.b.) and need to be dried for further preservation and storage. In the absence of efficient mechanical drying systems, currently all the chilli produced in the country is sun dried.

Table 7.2: Nutritional constituents of spices per 100 g

7.3.4 Processing and Uses of Cardamom

As the flowering continues over a long period, cardamom capsules ripen successively over an extended period. Thus, it requires several pickings. In most of the areas, the peak harvesting is continued at an interval of 15 days and completed in 8 to 10 rounds

Harvesting should be taken up only at a time when seeds inside the capsules have become black in colour. It is the index of maturity stages of the fruit. At this stage the pericarp (the seed cover or skin of the capsule) will still be green. When light picking is done, great care is to be exercised to harvest only the green and mature capsules. This process will naturally give a lower green crop per picking. When the hard picking is done, semi-mature crop is also removed. While this process could reduce curing percentage, it could increase the picking average and ensure green coloured capsules.

Bleaching is an important pre-treatment given to either dried cardamom or freshly harvested capsules as starting material. The bleached cardamom is creamy white or golden yellow in colour. The advantages of bleached cardamom are white appearance and their resistance to weevil infestation due to sulphur dioxide content. Different methods to achieve bleached cardamom and are given in Table 7.3.

Table 7.3: Treatments for bleaching of cardamom

Treatment	Concentration of content bleaching agent	Contact time (min)	Remarks
Steeping in H_2O_2 containing 0.5% sodium silicate	6% H_2O_2	15	For dry cardamom
Bleaching with H_2O_2 and SO_2 fumigation	0.3%	60	Dry cardamom
Steeping in acidified powder solution	20 g/l	75	Fresh cardamom
Subsequent steeping in H_2O_2 containing 0.5% sodium silicate	1% H_2O_2	30	Fresh cardamom

Cardamom capsules should be dried within 24 to 36 hours of harvest to avoid deterioration. Drying is one of the important unit operations as it determines the colour of the end product, which is the attractive and most important quality character. The retention of green colour is very important in cardamom drying as green coloured cardamom fetches premium price in the export market.

Cleaning of cardamom by removing the discoloured ones, split capsules and other impurities is done by manual method. The grading of dried capsules as per AGMARK specifications is generally carried out using round sieves. Mostly 7 mm round holes sieves are used for grading.

Mainly cardamom has three products namely decorticated seed or seed powder, essential oil and oleoresin. The decorticated seed or its powder has poor storability, as volatiles are lost during the storage. Thus it is stored in pods. Cardamom oil is produced by steam distillation of crushed fruits. Cardamom is used as flavouring material as whole, decorticated seed and ground powder. It has medicinal value for scanty urination, diarrhoea, dysentery, and exhaustion due to over work, depression.

7.3.5 Post Harvest Technology of Pepper and its Products

The stage of harvest is very important for the production of black pepper. Well-matured but unripe berries are harvested. Pepper becomes ready for harvest in about 6-8 months after flowering, during November-December and harvest continues up to March-April. The spikes are picked when they are blackish green and most pungent.

Harvesting is done manually, by climbing on the ladders. The well-matured spikes, of dark green colour are picked by the person standing on the ladder and dropped. The person standing on the floor will collect the spikes in the bags. A pair of women will be able to pick about 90 to 100 kg of spikes and paid @ Rs. 1 per kg of berry picked.

The harvested green spikes are some times heaped for a day, before threshing for easy separation of the berries. In few estates, mechanical threshes are used for separating and cleaning the berries. However, the threshing efficiency of these machines is only about 90 percent. The freshly harvested berries contain moisture of above 70% (w.b.). The berries as soon as they are harvested are separated from spikes and spread out on mats for drying. In about 2 days, the moisture content decreases to 20-25%. Due to enzymatic oxidation of colourless compounds present in the skin, the colour of pepper fruits turn black and masks the green colour after drying. The subsequent operations involve further drying of safe moisture level below 11% (w.b.)

Since drying with periodic turning is commonly adopted, since it is feasible when the quantity is small and monsoon does not interfere. But for large scale drying, artificial drying is preferred. The moisture in partially sun-dried pepper is brought down from 25 to 11 % in two stages in a counter current hot air flow system. After one pass in dryer, the pepper is stored for 24-48 hours, after which it is dried again to safe moisture level.

The dried pepper is cleaned for removal of extraneous matter such as dirt, girt, stones, stalks leaves, etc. Magnetic separator is used to remove metallic contamination such as iron fillings and stray nails. Vibration conveyors with inclined decks in combination of air classification are used for efficient destoning of spices. The composition of the dried black pepper is given in the Table 7.4.

Table 7.4: Composition of the dried black peppe

Composition	Value in per cent
Moisture Content	8.7 – 14.1
Total Nitrogen	1.55- 2.60
Nitrogen in non volatile ether extract	2.7 – 4.22
Volatile ether extract	0.3 – 4.2
Non-volatile ether extract	3.9 – 11.5
Alcohol extract	4.4 – 12.0
Starch (acid hydrolysis)	28 – 49
Crude fibre	8.7 –18
Crude piperine	2.8- 9.0
Ash	3.6 –5.7

The ungarbled black pepper contains pinheads, immature pepper and large berries. Broken pepper and light pepper grades are separated pneumatically; pin heads which come along with garbled pepper are separated by sieving. As the export market potential for pepper is more, the market value can be increased by the removal of unwanted foreign materials.

Grading is done by a combination of size sieving and weight classification by air blast. The major grade is the average sized black pepper known as Malabar Garbled (MG), which constitutes 95% of India's export. Tellichery Garbled (TG) is another bold grade of black pepper. The recovery of black pepper from fresh berries is 33-36%. According to Agmark grading, grades have been formulated as given in Table 7.5.

Table 7.5: AGMARK specification of pepper

Pepper grade	Diameter (mm)
Tellichery Garbled Black pepper Special Extra Bold (TGSEB)	>4.75
Tellichery Garbled Extra Bold (TGEB)	4.25
Tellichery Garbled (TG)	4.0-4.25
Malabar Garbled Black Pepper (MG)	3.75
Malabar Ungarbled Black Pepper (MUG)	<3.75

Pungent principle

The alkaloid piperine (melting point 130^{o}C) is considered to be the major constituent responsible for pungency. It is not present in the leaves and stem. It is also not soluble in the water, readily soluble in alcohol and on hydrolysis splits into piperdine and piperic acids. Major adulteration in the black pepper is done with the papaya seeds. The best method to identify them is cut the seed in to two pieces. Papaya is a dicot, so it will show a line. Black pepper berries are monocot, have a hollow cavity in the center.

Processing of White Pepper

White pepper is the white inner corn obtained after removing the outer skin or pericarp of the pepper berries. It is preferred over black pepper in light-coloured preparations such as sauces, cream soups etc., whereas dark coloured particles are undesirable. White pepper imparts pungency and a modified flavour to food. White pepper is liked for its mellow flavour, mild pungency, low fiber, high starch content and above all the white colour itself is liked. Varieties like Balankotta and Panniyur-1, are ideal for making white pepper owing to their large sized berries. The composition of white pepper is given in Table 7.6.

Table 7.6: Composition of white pepper

Constituent	Water	Protein	Fat	Carbohydrate	Fiber	Ash
Content, (%)	11.4	10.4	2.1	68.6	4.3	1.6

Packaging

Black pepper berries are hygroscopic, so have to stored in cool, dry atmosphere away from sunlight. For retail packaging in 200 gauges HDPE pouches are used. Ground powder is packed in laminated heat sealed aluminium foil.

7.3.6 Products and By-Products of Tamarind and their Uses

Tamarind is a forest tree. It is rarely grown as orchards. However, it is planted as social forestry. Every part of the tamarind is useful for human being as culinary or medicinal purposes.

Root: The root of tamarind is bitter and used in controlling the dysentery. It is cleaned, boiled and consumed or the powder is taken with water.

Stem bark: The stem bark is an astringent and a tonic. The bark is also used medicinally for loss of sensation in paralysis. The ash of the bark with salt is used as a remedy for colic and indigestion. A gargle of bark ash with water is used in sore throat to heal aphthous sores. The ash is given in urinary discharges and gonorrhea. The dry bark of the tree is peeled off for medicinal purposes. Usually it is done after the flowering season. The bark contains about seven percent tannin and is used in tanning industry.

Timber: The wood is hard, close-grained, yellowish white with red streak. The heartwood is small, near the center of the old trees and is dark purplish brown. It is a most valued timber for making tool-handles, agricultural implements, wheels, mallets, planks, furniture, rice-pounders, and oil and sugar crushers. It is also priced much higher as a fuel as it has high calorific value (4980) and chiefly used for making gun-powder, charcoal, and in brick kilns where great heat is required for brick-making.

Leaves: The tamarind leaves contain tartaric and malic acids. The latter is being found in excess and increasing with the age of the leaves. The leaves also contain certain enzymes. The leaves are astringent and the tender leaves are cooling and anti-bilious. A poultice of leaves is used as for inflammatory swellings and in rheumatism to relieve pain. Decoction of leaves is used for gargle, and juice is used in dysentery bilious fevers and in urinary troubles. The leaves yield a reddish yellow dye, which is used locally in colouring woollen and silk fabrics. The leaves and flowers are also used as auxiliaries in dyeing.

Flowers: The flowers of tamarind are also cooling and antibilious. Poultice of flowers is used in inflammatory affections of the conjunctiva. The juice extracted from flowers is used in cases of internal bleeding of piles.

Fruits: The fruits contain 55% pulp, 33.9% seeds and 11.1% shell and fiber. In India, the production of pulp is estimated at about 3,00,000 tons per year. Dry pulp of fruits yield about 16% of free tartaric acid and its salts along with Citric, Malic acids. Two kinds of pulp are known, the red coloured and the brown coloured. The former is having the superior quality. The pulp is non-proteinaceous and the pulp of tender fruits contains far less nitrogen than the ripe fruits. The pulp consists of crude protein 3.1%, carbohydrate 67.4%, fiber 5.6%, and minerals 2.9%. Chemical analysis of pulp give tartaric acid with potassium bi-tartarate 10-12%, moisture 20-30%, reducing sugars 25-30%, other solubles 3-4%, and the rest insoluble cellulose. Its vitamin contents are as follows: riboflavin 0.07mg, niacin 0.7mg and vitamin 'C' (3mg/100 g) and carotene (60 μ per 100 g). Of the reducing sugars present, about 70% is glucose and 30% fructose.

The pulp is edible and largely used for culinary purposes. The pulp contains tartaric acid, which is used as acidulent for soft drinks and fruit jellies. It is refrigerant, carminative and antibilious. It is also useful in preventing and curing scurvy and in sobering the intoxicating effects of alcohol and *Ganja (Cannabis sativa* Linn.). The pulp with wood-ash is extensively used for cleansing and brightening brass and copper vessels.

During storage, the reddish-brown colour of the pulp becomes darker and in about a year it is almost black. This is mostly due to the onset of Maillard reaction, since, free amino acids and reducing sugars are present in the pulp. The pulp also becomes soft and sticky as pectolytic degradation takes place and moisture is absorbed, especially in humid climates. The pulp could be preserved well for 6-8 months without any treatment, if packed in airtight containers and stored in cool and dry place.

Seeds: The seeds are used as famine food and for cattle in several districts in Tamil Nadu, Andhra Pradesh, Madhya Pradesh and elsewhere. The hard kernel is dried, roasted and powdered into flour and used for making cakes and chappatties, either alone or with flour of other edible kinds. The tamarind kernel powder can be fortified up to 15% in the preparation of bread and biscuit.

Industrial Uses

Tamarind Kernel Powder (T.K.P): Tamarind kernel powder is about 50% of the weight of the seeds. Commercial samples of T.K.P has the composition of : polysaccharides 48.7%, albuminoids 18.9%, fatty matters 7.5% moisture 8.8% ash 1.6%, soluble matters 3.2% and insoluble matters 11.3%. The commercial TKP finds extensive use as a sizing material in the textile industry. The sizing properties of TKP are due to the presence of a polysaccharide (called jellose) which is present to the extent of 6 percent.

7.3.7 Processing of Turmeric and its Uses

After harvesting the turmeric fingers are separated from mother rhizomes. Mother rhizomes are usually kept as seed material. Curing of green turmeric is done by boiling in the water with 20 g of sodium bi sulphite and 20 g of hydro chloric acid per 45.3 kg of tubers. It provides a yellow tint. The cured tubers are sun dried for 10-15 days till they become hard, brittle and produce metallic sound on breaking. Thereafter they are cleaned and then polished in a metallic drum rotated manually or by power. Generally dried cured turmeric is 20% of freshly harvested green rhizomes. It is also recommended that to develop attractive colour, half polished 100 kg turmeric rhizomes are mixed with the alum (0.040 kg), turmeric powder (2 kg), castor seed (0.14 kg), Sodium bisulphite (30 g) and concentrated hydrochloric acid (30 ml). After thoroughly mixing it is again dried in the sun.

Common products of turmeric are its powder, volatile oil and oleoresin. It is mainly used as food flavourant and colourant, cosmetics and as dye. It is used as medicine for stomachic, carminative, tonic, blood purifier, vermicide and antiseptic. Its powder is also used in tooth powder for relieving dental problem. It is also used as a face pack as it helps in clearing pimples and unwanted hairs.

7.3.8 Post Harvest Technology of Ginger

Freshly harvested ginger is cleaned with water to remove adhered soil, and then dried in the sun for 7-10 days. During drying, regular turning is required for uniform drying. After drying rhizomes are rubbed with the gunny bag to remove the remnants of the skin which results in smooth finish of the final product. In some places raw rhizomes are soaked in water and thick milk of lime (1kg slaked lime per 120 kg water). Some times the dried rhizomes are exposed to the sulphur dioxide fumes (3.2 kg of sulphur per tonne of rhizomes for 12 hours). It helps in bleaching the colour and results in white polished rhizomes.

The polished rhizomes are graded as per IS specification IS: 1908-1968. In general, indian ginger is graded in three grades namely (1) 3 fingerd rhizomes; (2) 2 fingered rhizomes and (3) pieces.

For the good quality of ginger its appearance, volatile oil content, fibre content, pungency, aroma and flavour are evaluated and compared with the standards.

In the rural India, ginger is heaped covered with the soil and ginger leaves in a shade. The heap may be plastered with the mud or cow dung. It can be stored well between 21-30^{o}C with 60-90 % relative humidity for two months. Scientifically ginger is stored in cold store at 2-5^{o}C with 90 % relative humidity for 4 months.

There various ginger products available in the market namely ginger oil, oleoresin, dehydrated ginger, bleached ginger, preserve, drinks, candy, pickle and wine. Besides this as a medicine it is considered as a stimulant and a carminative. It is also given in dyspepsia and flatulent colic.

7.4 MEDICINAL AND AROMATIC PLANTS

7.4.1 Uses of Medicinal and Aromatic Plants

Medicinal plants are the local heritage with global importance. Indian herbs are principal form of medicine and presently popular throughout the developed world. Basically herbs work in combination with the body's own defense system. The human body is much better suited to treatment with herbal remedies than with the isolated chemical medicines. The chemical medicines after expiry may cause harm to the body whereas the natural products that have lost their active qualities are not harmful to the system. The digestive systems and physiology of human evolved utilizing capacity of plant based foods and medicines. Many plants provide food as well medicines for i.e.

i) Lemon improves resistance to infections.
ii) Papaya is used for expelling worms in stomach.
iii) Onion relives bronchial infections.

iv) Oats support convalescence.
v) Burdock herbals are helping in removing toxins from the body.
vi) Comfrey encourages blood clotting and help in healing the wounds fast.

It also plays an important role in the rural areas, particularly in remote places with fewer medicinal facilities.

It is estimated that about 70000 plant species are used for medicinal purposes. In Ayurveda about 2000 plant species are considered to have medicinal values, while, Chinese list over 5700 as traditional medicines. The Indian traditional medicine the Charak Samhita (1000 BC) records the use of over 340 drugs of vegetables origin.

Medicinal plants have curative properties due to the presence of various complex chemical substances of different composition, which are found as secondary plant metabolites in one or more parts of these plants. The plant metabolites are grouped as alkaloids, glycosides, cortico steroids, essential oils etc. Table 7.7 indicates name of some herbs useful to cure some diseases.

Table 7.7: Medicinal use of herbs

System/Disease	Plant/Herbs	Uses
Skin		
(a) Antiseptic	Tea tree (Melaleuca attemifolia)	Disinfect the skin
(b) Emollients	Marigold (Calendula officinalis)	Deduce itchiness, edness and soreness
(c) Healing	Comfrey (Symphytum offcinale)	Blood cotting, fast healing of wounds
Respiratory system		
(a) Antiseptic	Garlic (Allium sativum)	Helps the lungs resist infection
(b) Spas molytics	Visnaga (Ammi visnaga)	Relax bronchial muscles.
Urinary system		
(a) Antispectic	Buchu (Barosma betulina)	Disinfect the urinary tubules
(b) Astringents	Horsetail (Equisetum arvense)	Tightness & protect the urinary tubules
Musculo-skeletalsystem		
(a) Analgesics	Yellow Jasmine (Gelsemium sempervirens)	Relieve joints and nerve pain
(b) Antiinflammatories	White willow (Salixalba)	Reduce swelling and pain in joints
(c) Antispasmodics	Cinchona (cinchona spp.)	Relax tense and cramped muscles.
Nervous system		
(a) Relaxants	Lemon balm (Melissa officinalis)	Relax nervous system

(b) Sedatives	Mistletoe (Viscum album)	Reduce nervous activity
(c) Stimulants	Kolanut (Colaacuminata)	Increase nervous activity
(d) Tonics	Oats (Avena Sativa)	Improve nerve function and tone
Circulation and heart		
(a) Cardiotonics	Ddanshen (Salvia mittiorrhiza)	Improve the regularity and strength of the heart contractions
(b) Circulatory stimulants	Cayenne (Capsicum frutescens)	Improve circulations of the blood to the extremities.
(c) Diaphoretics	Juhua (Chrysanthemum × morifolium)	Promote sweating & lower blood pressure
(d) Spasmolytics	Cramp bark (Viburmum opulus)	Relax the muscelers & helps to lower blood pressure
Digestive organs		
(a) Antiseptics	Ginger (Zingiber officinalis)	Protect against infections
(b) Astringents	Bistort (Polygenum bistorta)	Tighten the inner line of intestines and provide protecting coating over them.
(c) Bitters	Wormwood (Artemisia absinthum)	Stimulate secretion of digestive juices
(d) Laxatives	Senna (assia senna)	Stimulate bowel movements
(e) Stomachs	Cardamom (Eletterio cardamomum)	Protect and support

Aromatic plants have been of great interest to mankind from the beginning of civilization. Aromatic plants and their products, particularly the essential oil, are now becoming one of the most important export items from many developing countries. The upswing trends basically is due to raising the standard of living of the people and technological advancement in the production and processing of these essential oils.

Essential oils are complex mixtures of odours and steam-volatile compounds which are deposited by plants in the sub-cuticular space of glandular hairs, in cell organelles (oil bodies of Hepaticae), in idioblasts, in excretory cavities and canals or exceptionally in heartwoods.

The main aromatic plants are mint (mentha oil), cymbopogons. turpentine, sandal wood, vetiver, eucalyptus and ocimum. The other aromatic plants are celery, jasmine, rose, dill, geranium, hops, cinamomum, cedar wood, cyperus etc.

7.4.2 Processing of Medicinal and Aromatic Plants

The unit operations involving processing of plants based medicinal or aromatic constituents are:

1. **Comminution:** It is the process of size reduction. So that the surface area of the produce increases and solvent can easily interact with the produce. Most of the natural produce is to be dried. Drying can be done in sun or shade or in the protected area depending upon the type of the constituents. It is preferred that drying should be slow at low temperature. The dried material is to be crushed or broken into small parts before extraction/ distillation. During crushing/grinding temperature of the produce should not be increased. Some of the volatiles get evaporated even at 45^{o}C. The homogeneity of the ground particle shows the efficacy of the extraction of active ingredient

2. **Extraction of active ingredient:** Extraction is the process of separation of the active constituents from the plant material using a solvent. Firstly plant produce is pre-treated with the solvent outside the extractor. It facilitates the breaking of the cell walls to release the extractable component. The rate at which the solvent reacts with the solute depends upon solute solvent ratio, pH, particle size and temperature. Alcohol is the widely used solvent. It has the ability to extract many soluble constituents. Most of the alkaloids are soluble in acids.

For extraction of essential oil, steam distillation process in widely used. In this the steam is produced and passed through the bed of plant material. The steam carries the volatiles, which generally boils at a temperature lower than steam. It condenses and most of essential oils are insoluble in water. They are separated in the aqueous phase, forming two layers, then they can be easily separated. The factors, which influence the quality and quantity of extraction, are; size of load, steam pressure, density of packing of planting material in the bed, duration of distillation and rate of steam injection.

The aroma constituents are heat sensitive. So the technique must be carried out with pure and low boiling solvents such as pentane or hexane. Extraction with super critical solvents generally carbon-di-oxide is the most effective but capital intensive.

7.5 LET US SUM UP

The knowledge of commercial crops, spices and medicinal and aromatic plants is necessary. It provides ample employment opportunity. India is known for its knowledge in their cultivation and quality processing since ages. Indians were deployed to other countries to teach cultivation of sugarcane. The merchants traded Indian spices many centuries ago. The ancient herbal medicines suits human bodies as they do not have any side effect.

The production, processing of each of the crop is different. The process technology depends up on the active constituent which is to be extracted. Its purity decides the price.

7.6 KEY WORDS

Molasses	:	A by-product of sugarcane industry and base material for distillery and fermented products.
H.S.C.	:	Highest Standard Count (HSC) is a unit to express and evaluate quality of the cotton.
Pungent principal	:	The main constituent responsible for pungency. For i.e. pepper it is alkaloid piperine.
T.KP.	:	Tamarind Kernel Powder (TKP) is the powder of dried tamarind kernel seeds. It is used as material in textile industry.
Essential oils	:	It is a complex mixture of odours and steam-volatile compounds, which are deposited by plants in the sub-cuticular space of glandular hairs, in cell organelles or in canals of woods.

Comminution : It is the process of size reduction of any substances so that surface area is increased.

Steam distillation : It is the process of boiling the substances with water, so that water soluble volatiles oils are carried away by the steam. Then steam is to be condensed so that oils being lighter can be easily separated.

7.7 ANSWER TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Sugarcane plant harnesses solar energy and converts it into sugar, cellulosic and non-cellulosic energy producing substances. So it is called as energy efficient crop.
2. It provides huge employment, produces lint as well as oil seed.
3. About 100 kg sugar
4. To avoid inversion of sugar.
5. It is diuretic, refreshing and cooling.
6. Digestion, washing, screening, bleaching, dewatering and thickening are the unit operations in paper manufacturing.

UNIT 8 NUTRITIONAL ASPECTS

Structure

8.0 OBJECTIVES

After reading this unit, you should be able to:

- explain food, nutrition, nutrients, optimum nutrition, under nutrition, assessment of nutritional status;
- describe the role of different foods in our body;
- describe balanced diets; and
- state the importance of nutritional labelling.

8.1 INTRODUCTION

We need food for growth, development and to lead a healthy life. Since all foods are not of same nutritional quality, man's ability to meet his nutritional requirement depends upon the type and quantity of foodstuffs included in diet. It is not only the purchasing power of food but also the knowledge and awareness about nutritional needs at different stages of life, which is of paramount importance for maintaining nutritional health. We should consider the nutritive aspects of food from two broad points of view: first, what nutrients do foods contain and their requirement; and second, what are the relative stabilities of these nutrients and how are they affected by processing and handling. A brief description of general principles underlying the nutritional aspects is presented in the following sub-section.

8.2 SCOPE AND IMPORTANCE

We require more than 45 different nutrients throughout our life. Food materials ingested by our body are digested, absorbed and metabolized. A number of foodstuffs have to be selected to get all nutrients. Our health depends on the type and quantity of foodstuffs we choose in our diet. For sustaining healthy and vigorous life, diet should be planned according to the principles of nutrition.

Good nutrition is the fundamental basic requirement for health, functional efficiency and productivity. Good nutritional status is achieved not through drugs, tablets and pills but through a well and balanced diet. There is no known nutritional deficiency disorder that cannot be prevented by proper diet. Only the need is to provide adequate information to the common man as to how his nutritional needs can be fully met through judicious use of foods available at his own doorstep. The affluent sections need to be informed of the deleterious effects of dietary excesses and errors and how these can be avoided.

8.3 NEED FOR ENERGY

We need energy for work and different body functions. Whatever our age and sex, we need energy for three important functions of our body.

a) Basal metabolism
b) Physical activities
c) Dietary thermogenesis

a) Basal metabolism

The energy metabolism of a subject at complete physical and mental rest and having normal body temperature and in post absorptive state (i.e. 12 hours after the intake of last meal/ food) is known as basal metabolism.

b) Physical activity

Any movement of the body, or even a small part of it, expends energy. Greater the movement, higher the energy requirement. The actual amount of energy requirements of a person are determined by body weight, age, type and intensity of activity, and duration of activity.

Table 8.1: Effect of Body weight and type of physical activity on energy requirement (Kcal/day) of a moderately active person

Body weight (kg)	Men			Women		
	Light activity	Moderate activity	Very active	Light activity	Moderate activity	Very active
50	2100	2300	2700	1800	2000	2330
55	2310	2530	2970	2000	2200	2600
60	2520	2760	3240	2160	2400	2830
65	2700	3000	3500	2340	2600	3055
70	2940	3220	3780	2520	2800	3290

c) Dietary thermogenesis

Thermogenesis can be induced by diet, which is called as dietary thermogenesis, specific dynamic action or thermic effect of food. It is the amount of energy utilized by the body to digest, absorb, transport and store the nutrients. It is between 5-10% of the total energy intake. For example, it was found that in a fasting dog requiring 400 kcal, feeding of 100 g carbohydrates produces 425 Kcal, 44.4 g of fat produces 416 Kcal and 100 g of proteins produces 520 Kcal of heat. The extra heat produced is obtained by oxidation of tissue constituents and the animal will be in negative energy balance. This stimulating effect of carbohydrates, fats and proteins on energy metabolism is called specific dynamic action. The SDA of proteins is highest (about 30 %) while that of carbohydrates and fats is only 6% and 4% respectively.

8.4 BASAL ENERGY METABOLISM

Biochemical reactions (when body is at rest) are necessary to provide energy for maintenance of normal body temperature, breathing, heartbeat, muscle tone and other essential activities of cells and tissues. The basal metabolic rate is an expression of the amount of calories expended hourly in relation to the surface area of the body (calories/ meter^2/ hour).

Basal metabolic rate (BMR) is influenced by following factors:

Body surface area: A person who is tall and has greater proportion of lean tissues normally requires more basal energy than a shorter person of same weight.

Age: Age affects BMR because it changes the lean body mass especially the amount of muscle. BMR is highest during first 2 years of life due to rapid growth and declines about 2 % per decade after 21 years of age.

Gender: In general BMR of women is lower (about 6-10 %) than men due to higher body fat and other factors.

Pregnancy produces a BMR 15-25 per cent above the normal. Lactation also increases BMR.

Sleep: BMR during sleep is about 5-10 per cent less than in waking sate.

Environmental temperature: BMR increases when environmental temperature is low. At high temperature, BMR may decrease to lower heat production by the body.

Recent exercise: Following a period of exercise BMR remains elevated for some time.

Health factors: An elevation of body temperature above 98.6^0 F increases BMR by 7 per cent for each degree. Prolonged undernutrition, hypothyroidism, depression etc. tend to decrease BMR. Hyperthyroidism, anger, fear and other strong emotions increase BMR.

8.5 ENERGY VALUE OF FOODS

The energy yielding food factors are carbohydrates, proteins and fats. Vitamins and minerals do not provide energy, although they take part in liberating energy. Within the body, nutrients providing energy are oxidized in the cells with the help of catalysts. The process is one of continuous utilization of oxygen and production of CO_2, water and heat:

$$\text{Carbohydrates and fats} \xrightarrow{O_2} CO_2 + \text{water} + \text{heat}$$

$$\text{Proteins} \xrightarrow{\text{Oxidation}} CO_2 + \text{water} + \text{urea}$$

The energy value of foods depends on the quantity of carbohydrates, fats and proteins present in them. This can be determined by oxidizing a known weight of food in an instrument called bomb calorimeter and measuring the heat produced. The energy value of foods can be expressed in terms of kilocalories (Kcal) or mega joules (MJ).

One kilo calorie = 4.186 kilo joules
1000 kilo calorie = 4.186 × 10^3 kilo joules or 4.186 mega joules
1 Mega joule = 1000 kilo joules
1 Mega joule = 239 Kcal
1 Kilo calorie = 4.186 kilo joules

Addition of ghee or oil or butter to a food during preparation will increase the calorie content of that food. The average calorific value of pure carbohydrates, fats and proteins determined using the bomb calorimeter are:

1 g carbohydrates	4.1 Calorie
1 g fats	9.45 Calorie
1 g proteins	5.65 Calorie

The physiological energy value of carbohydrates, fats and proteins are 4,9,4 after making allowances for losses in digestion and metabolism.

8.6 NUTRITIVE VALUE OF FOODS

Foods can be broadly classified into (i) cereals and millets (ii) legumes and pulses (iii) oilseeds and nuts (iv) vegetables (v) fruits (vi) fats and oil (vii) egg, meat, fish and other animal foods (viii) milk and milk products (ix) starchy and sugary foods and (x) spices and condiments.

Cereal and millets

Cereals are the main source of energy in our diet. They contribute 70-80% of daily energy intake of majority of Indians. They also contribute significant quantities of proteins, calcium, and vitamin B complexes. Cereal proteins are deficient in an essential amino acid lysine. However, if supplemented with pulses rich in lysine, biological value of cereal products increases.

Cereals contain invisible fat that can meet more than 50 percent of our essential fatty acid requirement. Cereals are also fair source of calcium and iron. Ragi is rich in minerals especially calcium. Millets including ragi are rich in minerals and fibre. Millets are also rich in phytate and tannin, which bind minerals and hence interfere with their bioavailability. Cereals do not contain either vitamin C or vitamin A except that yellow maize and some varieties of sorghum contain small amounts of β-carotene.

Legumes and pulses

Pulses are rich source of protein but do not contain vitamin C. They are a good source of B vitamins also. Germinated legumes are good source of vitamin C. Fermentation also improves the nutritive value particularly thiamin and niacin are enhanced. Legumes and pulses are also deficient in vitamin A, D, and B_{12}.

Khesari dhal, consumed in some parts of the country may cause lathyrism if the consumption is more than 300 gm/day for 6 months.

Table 8.2: Nutrients content of some commonly used cereals, legumes & nuts (values/ 100 g)

Particulars	Calories (Kcal)	Protein (g)	Fat (g)	Fibre (g)	Calcium (mg)	Iron (mg)	Carotene (µg)
Bajra or pearl millet	360	11.6	5.0	1.2	0.05g	8.8	132
Barley	335	11.5	1.3	3.9	0.03g	3.7	10

Rice (raw, milled)	345	6.8	0.5	0.2	10	0.7	-
Rice, puffed	325	7.5	0.1	0.3	23	6.6	-
Whole wheat flour	341	12.1	1.7	1.9	48	4.9	-
Wheat bread, white	245	7.8	0.7	0.2	11	1.1	-
Bengal gram, whole	360	17.1	5.3	3.9	202	4.6	189
Bengal gram dhal	372	20.8	5.6	1.2	56	5.3	129
Black gram dhal	347	24.0	1.4	0.9	154	3.8	38
Rajmah	346	22.9	1.3	4.8	260	5.1	-
Red gram dhal	335	22.3	1.7	1.5	73	2.7	32
Almond	655	20.8	58.9	1.7	230	5.09	0
Coconut dry	662	6.8	62.3	6.6	400	7.8	0
Gingelly seeds	563	18.3	43.3	2.9	1450	9.3	60
Groundnut	567	25.3	40.1	3.1	90	2.5	37

Source: Nutritive value of Indian Foods, 1991.

Nuts and oilseeds

Nuts and oilseeds (except coconut) are rich in proteins containing about 18-40 per cent. Soybean is the richest source in proteins (containing about 40 per cent). They do not contain much carbohydrates but are rich in B-vitamins. Groundnuts are particularly rich in thiamin and niacin. Sesame seeds are rich in calcium.

Fats and oils

Fats and oils provide energy; vitamin A, E, D and K. Vegetable oils contain vitamin E and essential fatty acids (viz. linoleic and linolenic acids) except coconut and palm oils. Vegetable oils do not contain vitamin A and D except red-palm oil, which is exceptionally rich in carotene, a precursor of vitamin A.

Table 8.3: Nutritive values of fats (per 100 g)

Particulars	Moisture (%)	Fat (%)	Energy (Kcal)	Vitamin A (I.U.)	Vitamin E (mg)
Butter	14	86	774	700	2.4
Ghee	-	100	900	600	2.0
Vegetable oils and fats	-	100	900	-	8-140
Red palm oil	-	100	900	4000-10,000	10-15
Margarine#	14	86	774	700	10-50
Vanaspathi#	-	100	900	700	10-30

Processed fat

Vegetables

Vegetables are termed as 'protective foods' due to their high vitamins and mineral content. These generally have high water content, low protein and energy and varying amount of dietary fibre. Vegetables can be broadly grouped into green leafy vegetables, roots and tubers, and other vegetables. Green leafy vegetables are good source of calcium, iron, carotene, dietary fibre, vitamin C and vitamin B-complexes except vitamin B_{12}.

Table 8.4: Nutritional compositions of green leafy vegetables

Constituents	Range of values (per 100 g)
Moisture (g)	79-92
Energy (Kcal)	32-96
Carbohydrates (g)	4-14
Proteins (g)	109-607
Fat (g)	0.1-1.7
Calcium (mg)	30-500
Iron (mg)	0.8-16.0
Carotene (μg)	1200-7500
Vitamin C (mg)	48-200
Thiamin (mg)	0.05-0.16
Riboflavin (mg)	0.11-0.34
Nicotinic acid (mg)	0.4-1.8
Folic acid (mg)	10-30
Total dietary fibre (g)	2-6

Roots and tubers are rich in carbohydrates mainly starch and provide energy. In general, these are poor in proteins, vitamin and minerals but carrot and yellow flesh variety of sweet potato, and yellow yam are good sources of carotene. Potato is a fair good source of protein and vitamin C. Tapioca and yam are rich in calcium. Other vegetables (brinjal, okra, beans, all gourds, pumpkin, etc) not only provide variety to the diet but also provide vitamin C, some minerals, and fibre and thus add bulk to the diet.

Fruits

Fruits are priced for their vitamin and minerals content. Amla (600 mg/ 100g), guava (212 mg/ 100g) are rich source of vitamin C. Some fruits like banana and mango provide high calorie because of high sugar content. Eating fruits raw and fresh makes the vitamins and minerals present in them easily available to the body. Dried fruits like raisins, dates and apricots are good source of iron and calcium. Fruits also contain dietary fibre.

Foods from animal origin

Milk is almost a complete and ideal food. Milk and milk products like paneer, curd, khoa, etc. are good source of proteins, calcium, riboflavin and vitamin B_{12} but very poor in iron and vitamin C content. Milk does not contain vitamin E.

Eggs contain all nutrients except vitamin C and dietary fibre. Eggs contain proteins of very high biological value. Egg white contains about 12% proteins and some of B-vitamins but is devoid of fat and vitamin A. Egg yolk contains about 15% proteins, 3% fat, rich in vitamin A, iron, B-vitamins and vitamin D.

Flesh foods like meat, poultry and fish are rich in good quality proteins (18-22%) and vitamin B-complexes. Meat does not contain vitamin A, C and D. Fatty fish contain some vitamins A and D. Liver is rich in vitamin A and richest source of vitamin B_{12}.

Table 8.5: Nutritive value of some commonly used foods of animal origin (values/ 100 g)

Particulars	Calories (Kcal)	Protein (g)	Fat (g)	Calcium (mg)	Iron (mg)	Carotene (μg)
Milk (cow's)	67	3.2	4.1	120	0.2	174
Curd (cow milk)	60	3.1	4.0	149	0.2	102
Egg (hen)	173	13.3	13.3	60	2.1	600
Mutton (muscle)	194	18.5	13.3	150	2.5	0
Pork (muscle)	114	18.7	4.4	30	2.2	0

Other foods

Foods like sugar, jaggery, glucose, honey, custard powder, sago etc. mainly contain carbohydrates and provide energy.

Condiments and spices are accessory foods used for flavouring purposes to enhance the palatability of products. These are used in small amounts and their contribution to nutrient intake is very limited.

8.7 FOOD PYRAMID

The food pyramid is an outline to show the groups of foods that make a balanced diet. It is a general guideline that lets you choose a variety of foods from different food groups to get the various nutrients in right proportions. Its pyramid shape helps to explain which foods should be eaten more or less. The foods that make up the base of the pyramid i.e. widest part should provide the bulk of our diet. As you go up the pyramid, the amounts of different foods get smaller. Each of these food groups provide some, but not all, of the nutrients we need. Foods in one group can't replace those in another. No one-food group is more important than another - for good health, we need them all. The USDA has made some recommendation and provides a set of guidelines for healthy eating, represented in Figure 8.1.

Figure 8.1: Food pyramid

New guidelines emphasise more as weight control, whole grains, plant oils, vegetables & fruits and less on consumption of red meat, butter and refined foods such as white rice, white bread, pasta, etc.

8.8 DIGESTIVE PROCESS

Food do not get absorbed into the body as such except only a few substances namely water, simple sugars and some of mineral salts and vitamins. The principal component of food namely carbohydrates, fats and proteins undergo digestion.

8.8.1 Digestion of Carbohydrates

Digestion of cooked starch by salivary amylase begins in the mouth. This continues in the stomach for 10-15 minutes, till the food get mixed with gastric juice and action of amylase ceases due to high acidity.

A greater part of starch and glycogen present in food is digested by pancreatic amylase in small intestine.

- Starch and glycogen $\xrightarrow{\text{Pancreatic amylase}}$ Maltose + Isomaltose
- Sucrose $\xrightarrow{\text{Sucrase}}$ Glucose + Fructose
- Maltose $\xrightarrow{\text{Maltase}}$ 2 molecules of glucose
- Lactose $\xrightarrow{\text{Lactase}}$ Glucose + Galactose
- Isomaltose $\xrightarrow{\text{Isomaltase}}$ 2 molecules of glucose

The resulting monosaccharides viz. glucose, fructose, galactose are absorbed in small intestine. Cellulose, hemicellulose, pectin etc. are not digested and excreted as such.

8.8.2 Digestion of Proteins

Hydrolysis of proteins is accomplished by proteases secreted in gastric juice, pancreatic juice and in the small intestine.

Gastric digestion: The proteolytic enzyme present in gastric juice is pepsin. Since food remains in stomach for short time, pepsin hydrolyses dietary proteins mainly into a mixture of polypeptides.

Dietary protein $\xrightarrow{\text{Pepsin}}$ Polypeptides

Digestion in small intestine: The main digestion of polypeptides produced in stomach takes place in small intestines. The proteases involved in digestion are trypsin, chymotrypsin and carboxypeptidase secreted in pancreatic juice and amino peptidases present in intestinal mucosa.

- Protein and Polypeptides $\xrightarrow{\text{Trypsin and Chymotrypsin}}$ Peptide + amino acids
- Peptides $\xrightarrow{\text{Carboxy peptidase}}$ Amino acids
- Peptides $\xrightarrow{\text{Amino peptidases}}$ Amino acids
- Dipeptides $\xrightarrow{\text{Dipeptidase}}$ Amino acids
- Tripeptides $\xrightarrow{\text{Tripeptidases}}$ Amino acids

The resulting amino acids are absorbed in small intestine.

8.8.3 Digestion of Fat

Almost all fats present in our meal are triglycerides. Only a small fraction of dietary fat consists of cholesterol esters and phospholipids. Fats are primarily hydrolyzed in the small intestine. In stomach gastric lipase brings about some hydrolysis of finely divided fats only such as egg yolk and cream. Brief description of digestion and absorption of fat is given below.

Reaction in intestinal lumen	**Reaction within intestinal wall**	**Mode of entry into circulation**
Fat (Triglyceride) — 3-10% absorbed as micelle →	Triglycerides and diglycerides may be hydrolysed by intestinal lipase into monoglycerides & fatty acids	Lymphatic vessels (lacteals)
↓ Lipase		
Diglycerides + fatty acids — 3-10% absorbed as micelle →		
↓ Lipase		
Monoglycerides + fatty acids — 60-68% absorbed as micelle →	Resynthesis of neutral fat, Phospholipids and cholesterol esters and formation of chylomicrons	
↓ Lipase		
Glycerol+ fatty acids — 20% absorbed as micelle		
Phospholipids		
↓ Phospholipase		
Glycerol + fatty acids + phosphoric acid + organic base — (choline etc.) Absorption →		
Cholesterol esters		Portal blood
↓ Cholesterol esterase		
Cholesterol + fatty acids — Absorption →		
Short chain fatty acids (C_4-C_{10}) — Absorption →	Short chain fatty acids (C_4-C_{10}) →	Short chain fatty acids (C_4-C_{10})
→ Glycerol — Absorption →	Glycerol →	Glycerol

8.9 DIETARY ALLOWANCES, STANDARDS AND BALANCED DIETS FOR DIFFERENT AGE GROUPS: CHILDREN, ADULTS, PREGNANT AND LACTATING WOMEN, OLD PEOPLE

8.9.1 Dietary Allowances and Standards

Dietary allowances are measures of nutritional need in terms of specific amount of nutrients that a person should receive every day to achieve full growth and development potential. The Nutrition Advisory Committee of Indian Council of Medical Research (1989) recommended the dietary allowances of different nutrients, which are presented in Table 1.11. Reference man is between 20-39 years of age, weighs 60 kg, free from diseases and physically fit for active work. Reference woman is between 20-39 years, weighs 50 kg and healthy.

8.9.2 Balanced Diets for Different Age Groups

A balanced diet is one which includes a variety of foods in such quantities and proportion that the need for nutrients is adequately met to promote and maintain the health. Food requirement will differ according to age, sex, physical activity, and physiological state viz. pregnancy, lactation etc.

Balanced diets for different age groups, sex, moderate activity and physiological state are given in Table 8.6 to 8.10. These diets are formulated using food exchange system suggested by Gopalan et al. (1991) and recommended dietary allowances of nutrients for Indians (I.C.M.R, 1989).

The food stuffs given in these tables should be considered as raw food items that represent a food group, for example, cereals may include wheat, bread, rice, puffed rice, maize etc. depending upon the dietary habits of individual/ family.

Mother's milk is the best food for newborns and infants up to 6 months of age. Afterwards, supplementary foods along with milk, is necessary. Strained fruit juices and soups, mashed banana, papaya, sago porridge, rice porridge, soft boiled egg yolk, mashed and well cooked khitcheri etc. may form the supplementary foods for the infants.

8.10 TECHNIQUES FOR ASSESSMENT OF HUMAN NUTRITION

The nutritional status of an individual is influenced by food intake both in terms of quantity and quality and also by physical health of the person. The main objective of nutritional assessment is to obtain precise information on prevalence and geographical distribution of nutritional problems of a given community and identifying the individuals or groups of people 'at risk' or in a greatest need of nutritional assistance.

The assessment of nutritional status involves various techniques viz. clinical examination, anthropometry, biochemical evaluation, assessment of dietary intake, vital and health statistics, ecological studies.

Clinical Assessment of Nutritional Status

There are a number of physical signs, some specific and many non-specific known to be associated with states of malnutrition. Clinical signs, which are useful in assessment of nutritional status are: moon face, angular stomatitis, xerosis of conjuctiva, Bitot's spots, magenta tongue, etc. However, malnutrition cannot be quantified on the basis of clinical signs and many deficiencies are unaccompanied by physical signs.

Anthropometric Measurements

Anthropometric measurements such as height, weight, skin fold thickness and arm circumference are valuable indicators of human nutrition. In young children, additional measurements such as head and chest circumference are good indicators.

Laboratory and Biochemical assessment

Haemoglobin estimation is, most common laboratory test carried out to assess the prevalence of anaemia. Stools are examined for intestinal parasites. Urine is examined to assess the presence of albumin and sugar, etc.

Biochemical tests are applied to measure nutrient concentration in body fluids (e.g. serum iron, serum albumin, etc.) or detection of abnormal amounts of metabolites in urine (e.g. urinary creatinine, etc.) or measurement of enzymes in which the vitamin is a known co-factor (as in riboflavin deficiency) to assess malnutrition in its preclinical stages.

Radiological and Biophysical Assessment

Radiological examination may help in diagnosis of rickets, osteomalacia, infantile scurvy, beriberi, fluorosis, and protein-calorie malnutrition.

A large number of tests have been devised to assess dark adaptations of the eye, nerve accommodation, physical performance, muscle co-ordination etc., in different deficiency states to assess the degree of alteration in physiological function.

Assessment of Dietary Intake

Assessment of food consumption involves dietary surveys, which may be household inquiries, or individual food consumption surveys. A diet survey may be carried out by one of the methods viz. weighment of raw foods, weighment of cooked foods, oral questionnaire method to get information about dietary intake patterns; specific food consumed and estimated nutrient intakes.

Vital Statistics

An analysis of vital statistics – mortality (infant mortality rate, rate of low birth weight babies etc.) and morbidity data (hospital data or data from community health and morbidity surveys) particularly protein energy malnutrition, anaemia, xeropthalmia and other vitamin deficiencies, endemic goiter, diarrhoea, measles and parasitic infestations can be of value in providing additional information contributing to nutritional status of the community.

Ecological Studies

Malnutrition is the end result of many interacting ecological factors. A study of ecological factors comprises of food balance sheet, socio-economic factors (family size, occupation, income, education, customs, cultural influences etc.), health and educational services (primary health care services, feeding and immunization programme), and conditional influences (e.g., parasitic, bacterial and viral infections etc.).

8.11 NUTRITIONAL LABELLING

Labelling for nutrition information has been mandatory for (i) any food to which a nutrient has been added – enrichment, fortification, or restoration and (ii) any food for which a claim is made for nutritional properties either on the label or in advertising. All food for special dietary use require labelling. At present most nutrition labelling is voluntary, but many manufacturers have adopted it for their products.

Reasons for nutrition labelling:

- The main reason for nutrition labelling is to make the consumer aware about the nutritional properties of the product.
- Labelling also leads food processors to be constantly aware of the nutritive values of foods that they produce.
- Labelling will help persons who require modified diets to select those foods appropriate for their needs.

Regulations for nutrition labelling established by the Food and Drug Administration (FDA) are presented in Figure 8.2.

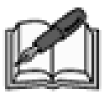
8.12 LET US SUM UP



Food is essential for our health and vitality. It is the food that provides us nourishment to perform various voluntary and involuntary functions of our body and prevents from deficiency diseases. Purchasing power of food and nutritional knowledge and awareness about nutritional need are the most important factors that affect the dietary consumption and nutritional health of a person and of any community.

It is the food pyramid which is a good guide in choosing a variety of foods from different food groups to get the required nutrients. Nutritional labelling also makes us aware about nutritional properties of purchased products.

8.13 KEY WORDS

Absorption : Transfer of nutrients across cell membranes; following digestion, nutrients are transferred from the intestinal lumen across the mucosa and into the blood and lymph circulation.

Digestion : Hydrolysis of foods in the digestive tract to simpler substances so that they can be used by the body.

Health : State of complete physical, mental and social well being and not just absence of disease.

Kilo Calorie : Kilo Calorie is the quantity of heat required to raise the temperature of 1 kg of water through 1^0C.

Metabolism : Physical and chemical changes occurring within the organism; includes synthesis of biological materials and breakdown of substances to yield energy.

Enzyme : An organic compound which can be protein or RNA produced by living tissue to accelerate certain specific metabolic reactions, viz. hydrolases, oxidases, peptidases and others.

Cholesterol : The commonest member of sterol group; synthesize by body and is essential for its functions.

8.14 ANSWER TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answer should include the following points:

1. We need nourishment to perform various voluntary and involuntary body functions.

   The nutrients; carbohydrates, proteins, fats, vitamins and mineral are required by body to provide energy, development of body tissue, bones, teeth etc. See Sub-sec. 8.1, 8.2 and 8.5.

2. Basal metabolism

   Physical activities

   Dietary thermogenesis. See Sub-sec. 8.

3. Some of the energy is required at rest.

   Basal metabolic rate is the amount of calories required in the state of complete rest.

   Basal metabolic rate is influenced by body surface area, gender, age, health factors, sleep etc. See Sub-sec. 8.4

Check Your Progress Exercise 2

Your answer should include the following points:

1. Broadly foods can be classified in to ten different groups.
   Fruits and vegetables are termed as protective foods.
   Fruits and vegetables provide vitamins and minerals. See sub-sec. 8.6.

2. Food pyramid shows the food groups.
   Food pyramid helps in selecting balanced amount of foods. See sub-sec. 8.7

3. Hydrolysis of food is essential for absorption of different nutrients. Amylase, proteases, lipase etc. are enzymes essential for digestion of food. See sub-sec. 8.10.

Check Your Progress Exercise 3

Your answer should include the following points:

1. Dietary allowances are measures of nutrients that we need to take daily.

   An amount of 100 g of each of fruits, green leafy vegetables and other fruits can fulfil our daily requirements. See sub-sec. 8.9.2. and Tables 8.1 to 8.5.

2. Clinical examination, anthropometry, biochemical evaluation, assessment of dietary intake, vital and health statistics, ecological studies are techniques for nutritional assessment.

   Important anthropometric measures are height, weight, skin fold thickness, arm circumference, head and chest circumference. See sub-sec. 8.10.

3) Nutritional labelling is helpful in selecting nutritious products from variety of available products.

   FDA has established regulations for nutrition labelling. See sub-sec. 8.11

UNIT 9 FOOD FOR GROWTH AND REPAIR

Structure

9.0 OBJECTIVES

After reading this unit, you should be able to:

- describe the effect of processing and storage on food quality and how to prevent them;
- state safe limit of preservatives; and
- discuss the health foods.

9.1 INTRODUCTION

Each food, although contains a wide range of nutrients but serves as a major source of one or two main nutrients. Since each food has a different nutritional profile, a judicious use of different foods is desired to maintain good health. The health of an individual is influenced by the utilization of nutrients, called nutritional status. The application of knowledge of nutrition in selecting food, its combination, preparation, storage, physiological need, nutritional knowledge; all affects the overall nutrition of a person and the community.

Food occupies the first position in the hierarchical needs of man but ignorance of basic food facts is still widespread. Consequently, various forms of nutritional disorders results, that can be prevented by proper dietary counselling. There is no known nutritional deficiency disorder that cannot be prevented by appropriate dietary habits. Only the need is to lay adequate emphasis to this fact and to provide adequate nutritional information to all of us. Food-based approach is the only sustainable way to improve the nutritional status of all.

It is not only the foods but also the quality of foods which is of prime importance for us. Foods if not processed properly, may loose their nutritive properties. Even if stored under improper storage condition or handled carelessly, they may get contaminated with microorganisms. Hence, for proper storage of fresh produce to retain their freshness, nutritive value and acceptability, proper handling, transport and storage of fresh or processed products is of great importance.

9.2 IMPORTANCE OF FOOD FOR GROWTH AND SUSTENANCE

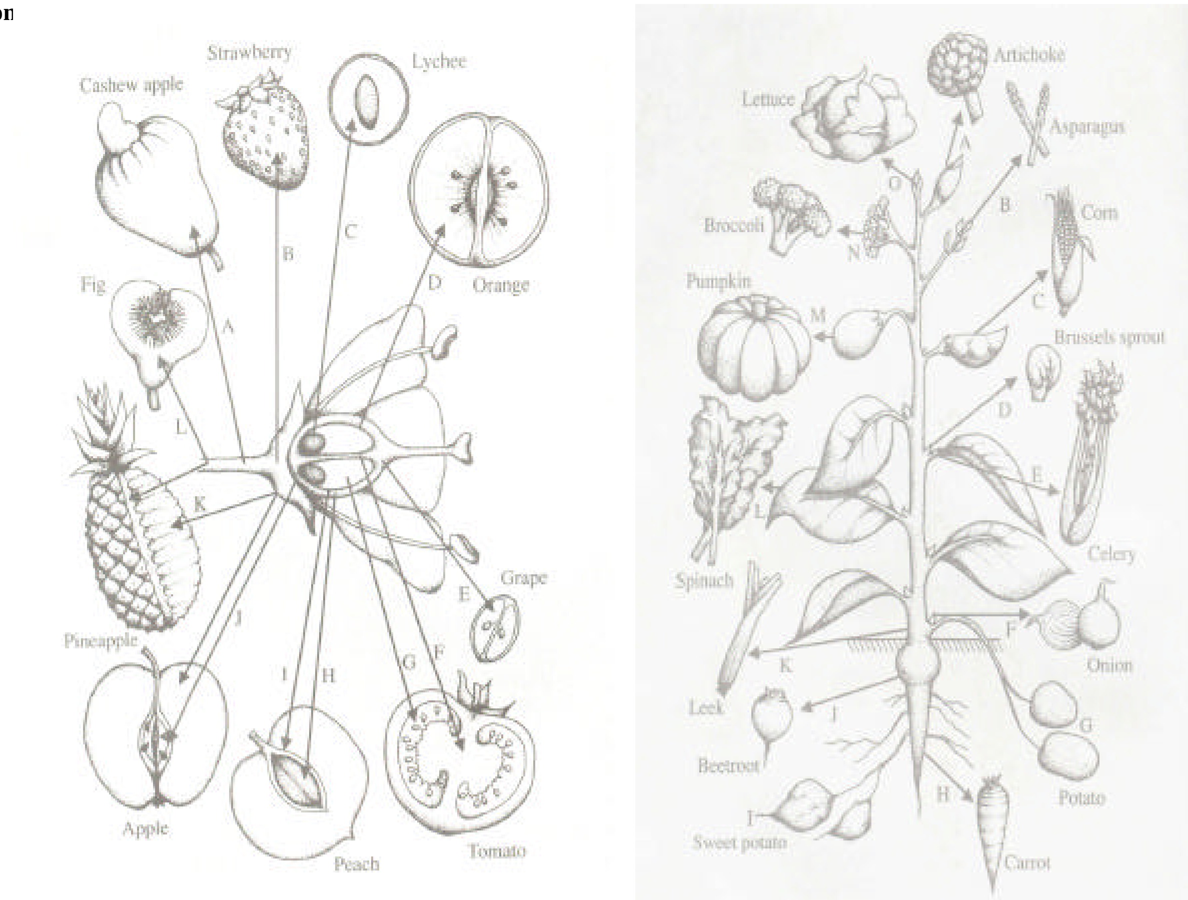
Food provides nourishment to our body. Food is absorbed by the body and used as an energy source. It is also used for growth and regulation. Further it also gives protection against diseases. In short, food is the raw material from which our bodies are made. Right kinds of food in right proportions can ensure good health, which may be evident in our appearance, efficiency and overall well being.

The foods which we use daily include rice, wheat, pulses, vegetables, fruits, milk, eggs, meat, fish, sugar, oils, etc. These foods are made up of a number of chemical substances called nutrients. According to their chemical structure, these nutrients can be classified as carbohydrates, proteins, fats, vitamins, and minerals. Water and fibre are also essential component of foods. Carbohydrates comprise sugars, starches, fibre, and related materials and mainly provide energy to our body. Proteins are nitrogenous compounds and form major component of tissue in our body. Fats provide energy and fatty acids to our body. Vitamins and minerals are required for metabolism and play a protective role in our body. In short, nutrients are essential for each and every voluntary or involuntary activity of the body and must be supplied by the diet.

9.3 FOOD STRUCTURE, TEXTURE, FLAVOUR, COLOUR, KEEPING QUALITY

9.3.1 Food Structure

Fruits and vegetables are important parts of our diet, they play a protective role as they supply the essential components to our body. Fruits and vegetables are living organisms and diverse in structure, in composition and in general physiology.



(a) **(b)**

Fig.9.1: a) Derivation of some fruits from plant tissue. The letters indicate the tissues that comprise a significant portion of the fruit illustrated as follows: A) pedical, cashew apple; B) receptacle, strawberry; C) aril, lychee; D) endodermal intralocular tissue, orange; E) pericarp, grape; F) septum, tomato; G) placental intralocular tissue, tomato; H) mesocarp, peach; I) endocarp, peach; J) carpels, apple; K) accessory tissue, apple and pineapple; L) peduncle, pineapple and fig. b) Derivation of some vegetables from plant tissue. The letters indicate the principal origins of representative vegetables as follows: A) flower bud, artichoke; B) stem sprout, asparagus; C) seeds, corn; D) axillary bud, brussels sprout; E) petiole, celery; F) bulb (underground bud, onion; G) stem tuber, potato; H) swollen root tuber, sweet potato; J) swollen hypocotyls, beetroot; K) swollen leaf base, leek; L) leaf blade, spinach; M) fruit, pumpkin; N) swollen inflorescence, broccoli; O) main bud, lettuce.

In general, however, the ovule develops into seeds and the ovary into fruit. Normally three layers are differentiated in the ovary wall or pericarp, these being the outer exocarp or skin, the mesocarp, which may be fleshy, and the inner endocarp. The structural features of fruits and vegetables on the basis of their derivation are shown in Fig 2.1a & 2.1b.

9.3.2 Food Texture

Food texture is a combination of sensations derived from the lips, tongue, walls of the mouth, teeth, and even the ears and touch by hand. The texture of fruits and vegetables depends on the turgor of the living cells as well as on the occurrence of supporting tissues and the cohesiveness of the cells.

9.3.3 Food Flavour

Flavour is the subtle and complex perception that combines taste, smell, heat and cold, and texture. The substances mainly responsible for the flavours of foods are volatile compounds. These may be aliphatic esters, aldehydes or ketones which are present in fruit and other natural foods in very low concentration. Orange, lemon and grapefruit peels contain a number of flavanone glycosides. Terpenoids are major components of citrus oils and contribute to the flavour of citrus fruits. Certain volatile sulphur containing compounds possess powerful and distinctive odours which contribute to both the pleasant and unpleasant aroma of many foods e.g. onion, garlic, cauliflower, broccoli etc.

9.3.4 Food Colour

The characteristic colour of raw food is due to the pigments naturally present in it. The natural colours (pigments) in vegetables and fruits can be classified on the basis of chemical structure as carotenoids (yellow -orange), chlorophylls (green), flavonoids and anthocyanins (red, blue, and purple) and anthoxanthins (cream yellow). Animal foods contain myoglobin and hemoglobin.

Chlorophylls are present in plants and vegetables especially leafy vegetables such as cabbage and lettuce etc.

Carotenoids are present in many vegetables and fruits such as carrot, pumpkin, mango, orange etc. Some of the carotenoids have vitamin A activity.

Anthocyanins - These occur in many fruits and vegetables e.g. coloured grapes, red cabbage, cherries, strawberries, plums, apple and in many flowers.

Flavonoids - Flavones and anthoxanthins are responsible for the yellow-white or creamy white colour of potato and cauliflower. Flavonoids are usually more stable to heat and oxidation than the anthocyanins.

Anthoxanthins – present in some fruits and vegetables.

Poly-Phenols - These are colourless or yellow substances which turn brown when fruits and vegetables containing them, e.g. brinjal, bottle gourd, apple, are cut and exposed to air. *Xanthones* are a group of red and yellow pigments. One well-known member is mangiferin, which occur as a glucoside in mangoes.

Betalains – betalains are a group of red and yellow pigments found in red beet and to some extent in cactus fruits, pokeberries and a number of flowers

9.3.5 Keeping Quality

The quality of fresh fruit and vegetables is related to their appearance, colour, uniformity, taste, flavour, texture, aroma, nutritive value, chemical composition, defective marks on the skin, chemical residue, additives and any other parameter the consumer chooses to be acceptable on the basis of their experience and education. Harvesting of fruits and vegetables disturbs the normal life process. As the fruits and vegetables continue to respire after harvesting, they start losing their vitality, turgidity, colour, appearance and food value and thus overall quality of food during storage at room temperature. Maturity level at the time of harvesting, harvesting practices of fruits and vegetables, handling practices, moisture content of foods, storage temperature, humidity and other storage conditions (light, oxygen, etc.) affects the keeping quality of the food. Keeping quality or storage stability (to preserve the overall quality during storage) is measured under storage and handling conditions that are set up to stimulate or somewhat exceed the conditions the product is expected to encounter in normal distribution and use.

9.4 DEGRADATION OF NUTRIENTS, COLOUR PIGMENTS AND MICROORGANISMS DURING THERMAL PROCESSING AND STORAGE

9.4.1 Effect of Thermal Processing on Nutrients, Colour Pigments and Microorganisms

Almost all foods except fruits and some of the vegetables (used for salads) are subject to some type of heat processing to make them palatable and digestible. Thermal processing has both beneficial and adverse affects i.e. loss of nutrients. The loss of nutrients depends upon the processing temperature, duration of heat treatment and type of nutrients.

Blanching is a process in which dipping of fruits and vegetables in boiling water or exposing to steam for a few minutes stops all enzymatic and biological activities prior to processing. Losses of nutrients due to blanching occur directly from leaching of water soluble vitamins into water used for processing. In blanched vegetables such as asparagus, green beans, peas, spinach, the retention of ascorbic acid (67-95%), niacin (83-94%), riboflavin (88-90%) and thiamine (85-92%) is variable.

Pasteurization destroys pathogenic microorganisms associated with food and increases the shelf life by decreasing the microbial population and inactivates some enzymes. Pasteurization affects the vitamin content to a greater extent than other nutrients, e.g. vitamin C and riboflavin are most sensitive whereas vitamin E and K are slightly affected. Thiamine undergoes 3-20% destruction and riboflavin reduces to about 5%. Niacin content increases by about 10%, probably because of the liberation of protein bound nicotinic acid. Ascorbic acid being most sensitive undergoes oxidation. About 8% loss of vitamin C takes place during pasteurization.

Canning

Heating of canned fruits, juices, soups, vegetables, meat, and meat products etc. to destroy food spoilage microorganisms and enzymes result in some undesirable changes in the nutritive value of food. During canning, denaturation of proteins may occur. Heat, metallic tins and light accelerate oxidative rancidity of fats/ oils. The rate of oxidation of fat is doubled for each degree increase in the temperature. Sugars and starches are degraded by prolonged heating at high temperature. Browning reactions takes place in sugars on heating. Canning of vegetables causes losses in nutrients such as vitamin C (33-90%), thiamine (16-83%), riboflavin (25-67%), niacin (0-75%), folic acid (35-84%) and vitamin A (0-84%).

Ionizing Radiations

Effects of irradiation on the nutritional quality of foods vary with doses. Higher doses result in more destruction of nutrients than lower doses. Irradiations produce molecular changes in starch, converting it into sugars. Lipids are very sensitive to radiations. Auto-oxidation of lipids increases peroxide value i.e. the number of peroxides increases leading to off-flavours. Losses of amino acids also occur. During irradiation most of thiamine is found to be lost whereas riboflavin is heat stable and retained upto 91%. Niacin and folic acid are extremely radio-resistant and are fully retained. Vitamin K is sensitive to radiation and is destroyed in significant quantity during irradiation.

Colour Pigments

Vegetables and fruits contribute a variety of colours to the diet. The plant pigments chlorophyll (green leafy vegetables), carotenoids (yellow-orange carrots), flavonoids (white potatoes) and anthocyanins (red beetroot) are present singly or in combination in plant foods. These may be affected by the method of food processing. The soluble pigment such as anthocyanins may leach in the cooking water and changes may occur due to the effect of heat and pH (Table 9.1).

Table 9.1: Effect of heating on colour pigments of plant foods

S. No.	Food source	Name of pigments	Colour	Soluble in	Effect of prolonged heating	In presence of	
						Acid	Alkali
1.	Rice Potato	Flavones Flavanols	White or yellowish red	Water	May darken	White	Yellow
2.	Beetroot	Anthocyanin	Red	Water	Little	Bright red	Reddish purple
3.	Leafy vegetables	Chlorophyll	Green	Fat	Olive green	Olive green	Intense green
4.	Carrot Mango Tomato	Carotene Xanthophyll Lycopene	Yellow - orange	Fat	May darken	No change	No change

9.4.2 Effect of Storage on Nutrients, Colour and Microorganisms

The quality of food deteriorates during storage due to action of microorganisms on them if not stored properly. Deterioration is usually noticed by the presence of rancid odour of fats (caused by oxidation of fats), fermented odour of fruit or fruit juices due to yeast growth, or appearance of mould growth on bread, roti, etc. Hence, proper storage of food and food products is very important to avoid the quantitative and qualitative losses.

Fresh fruits and vegetables continue to respire after they are harvested. Harvesting disturbs the normal life processes, and vegetables start losing their vitality, turgidity and food value. The harvested vegetables continue to respire during transport and storage. This involves the use of oxygen, the metabolism of cell food materials and the release of carbon dioxide, water and energy. Most of the energy is released in the form of heat.

Most of the fruits such as mango, banana, citrus, guava, grapes, papaya, etc. are prone to injuries which become avenues for fungi especially moulds which deteriorate the fruits. The fruit packaging material is infested with organisms, which also act as source of infection. Due to unhygienic practices, fruits are subjected to various diseases causing huge losses. The most common type of spoilage in fruits and vegetables are bacterial soft rot, gray mould rot, blue mould rot, black mould rot, pink mould rot, etc. Fungal spoilage of vegetables often results in water soaked mushy areas, while fungal rots of fleshy fruits like apple and peaches mostly show brown or cream coloured areas in which moulds grow in the tissue below the skin. Whereas bacterial soft rot is commonly spread among the vegetables which are not very acid and among the fruits which are not highly acid.

Sometimes normal changes occur in raw fruit juices at room temperature such as alcoholic fermentation (conversion of sugars to acid, alcohol and gases) by yeasts, which further cause an oxidation of alcohol and fruit acids yeasts and moulds growing on the surface when it is exposed to air. Mostly at temperatures above 32.2^{0}C to 35^{0}C lactobacilli would be likely to grow and form lactic acid and some volatile acids.

Vitamin C and thiamine may be lost if canned foods are stored at ambient temperature. At room temperature, there is discolouration of pigments present in vegetables such as anthocyanins, flavanols and flavones very rapidly because of the activity of enzymes. Roots and tubers can be stored in cool ventilated place to avoid sprouting. Storage temperature should be maintained between 3 and 10^{0}C. Green leafy vegetables after harvest start losing resulting in loss of moisture. These vegetables can be stored at low temperature in clean and dry plastic bags to prevent loss of moisture.

The most common deteriorative changes taking place in milk at room temperature are souring, decomposition of protein, rancidity or bitter taste, off flavour, colour changes etc.

Deteriorative changes in meat can take place in aerobic conditions, anaerobic conditions and also by bacteria, yeasts or moulds. The changes, which take place under anaerobic conditions, are changes in colour, oxidation of unsaturated fats, undesirable flavour, off odour, of taste, etc.

Fish gets spoiled easily because of the rapid autolysis by the fish enzymes. The fat in pork and poultry are more easily oxidized than others.

Eggs are more spoiled by bacteria than moulds. If not properly stored there is a loss of CO_2 gas through the egg shell, loss of moisture and increased air space, loss of moisture from white to yellow, loss of normal firmness of egg white, etc.

Foods when properly stored retain their freshness longer; have better nutritive value and acceptability. Therefore, for better storage and long shelf life, all food and food products should be stored in a proper place according to their requirement.

9.5 PERMITTED COLOURS

Food Colours

The acceptance of food depends to a large extent upon its attractive colour. The characteristic colour of raw food is due to the pigments naturally present in it. Sometimes, artificial colour is added during the preparation and processing of foods to make them more attractive.

List of Permissible Harmless Food Colours

i) Natural colouring matter that may be used:

According to Fruit Product Order, India (1955), the natural colouring matters, whether isolated from a natural source or synthesized, are permitted to be added to any food product. Some of these are carmine, carotene and carotenoids, chlorophyll, caramel, annatto, ratanjot, and saffron.

ii) Coal tar dyes which may be used:

No coal tar dyes or a mixture thereof except the following shall be used in fruit products:

Colour	Common name	Colour index (1956)	Chemical class
i. Red	Ponceau 4R Carmosine Fast Red E Amaranth Erythrosine	16255 14720 16045 16185 45430	Azo Azo Azo Azo Xanthene
ii. Yellow	Tartrazine Sunset Yellow FCF	19140 15985	Pyrazolone Azo
iii. Blue	Indigo Carmine Brilliant Blue FOF	73015 42090	Indigoid Triphenyl-methane
iv. Green	Green S Fast Green FOF	44090 42033	Triphenyl-methane Triphenyl-Methane

Dyes when used in fruit products shall be pure and free from all harmful impurities. The maximum limit of any permitted coal tar colours or mixture of permitted coal tar colours which may be added to any fruit products, shall not exceed 0.20 g per kg of the final products for consumption.

As per the 'Code of US Federal Regulations (1979); and Prevention of Food Adulteration Act (India), Acid Magenta II, Blue VRS, Brilliant Black, Red FB, Red 6B colours have been prohibited for use in the food products.

9.6 HEALTH FOOD, GREEN/ ORGANIC FOOD, TRADITIONAL FOODS, DESIGNER FOODS

9.6.1 Health Food

Health foods are those, which are nutritious, prevent diseases and maintain health. Health foods are also known as 'designer foods'. Such foods must possess characteristics like modified composition, limit the presence of certain potentially harmful components and possibility of including certain desirable ingredients either naturally or by addition. These include vegetable foods, whole grain cereals, food processed without chemical additives, foods grown on organic compost, 'magic' foods (honey, molasses, yoghurt, etc.), and so on.

9.6.2 Organic Foods

Organic foods refer to the foods (either plant or animal foods) that are grown organically. These are grown on soils enriched with compost and manure and without the use of chemical fertilizers, insecticides or pesticides. Organic foods are the need of the hour because these foods offer protection of future generations, prevent soil degradation and erosion, protect water and aquatic life, save energy, protect farmers and farm women, help small farmers, support a true and sustainable economy, promote biodiversity, produce better, tasty, pure and nutritious foods.

9.6.3 Traditional Foods

Traditional foods are different types of food preparations with varying shelf life. These foods had been invented to overcome the monotony in the diet of the people, modified and repetitively processed by human communities. Their composition and preparation were based on the Pak Sastra i.e. Science of cooking. Traditional food processing began when man ceased to be a food hunter. To start with, it was confined to primary processing of food grains. Gradually, primary processing spread to other foods, gathering variety, variegation and velocity. In regions of primitive agriculture, food manufacture and management, man is still engaged in simple food processing practices, passed down through generations of tradition.

Indian traditional foods based on cereals, legumes and fats or oil - both sweets and savories, are innumerable in number, with characteristic features reflecting the diverse socio-cultural environments in different parts of the country. In our country; a nation steeped in culture and tradition dating beyond 5000 BC, these heritage foods for which preparative guidelines passed on from generation to generation are still made by skilled mothers and grandmothers, though many of these products have attained commercial importance during last 20 – 30 years.

Amongst various traditional foods, cereals and pulses based products still occupy an important place in the diets of our people. Historically, legumes are the natural protein supplements to cereals in the Indian diets. ‘Khichari’ one of the traditional products prepared from rice and pulse to prove a good quality diet, was in practice long before nutritionists and food scientists understood the nutritional importance of mixing grains.

The important traditional foods which are still popular among Indian population can be broadly categorized as: processed grain products, dehydrated foods, pickles/chutneys/sauce/relishes, ground spice/spice mixture, fried food products, confections and sweet dishes, and dairy products. Some popular traditional foods prepared and served at homes, restaurants and public eating places (bus stops, railway stations) with subtle differences in blends and flavours but essentially Indian are listed in Table 2.2.

Table 2.2: Some characteristic traditional foods of India

Major raw material	Products
Cereals/legumes	Papads, Wadian, Vermicelli, Soji, fried snacks.
Milk	Malai, Khoa, Chhana, Paneer, Curd, Butter milk.
Milk and sugar/jaggery	Peda, Burfi, Rasagolla, Jamun, Sandesh, Kheer, Halwa
Gram flour, sugar/jaggery	Mysore Pak, jilebi, Laddu and Chikki
Fruits and vegetables	Pickles chutneys, Murabbas, Patha, candied fruits, Aamchur, Fruit leather, dried fruits, dehydrated vegetables and pickled vegetables.
Spices and condiment	Spice powder, Sambar and Rasam powders and Garam masala
Miscellaneous	Neera, toddy, arrack, feni, vinegar, jaggery, khandasari, Sugar, and honey.

9.6.4 Designer Foods

Designer foods are foods that naturally contain or are enriched with certain specific concentration and proportion of nutrients/ substances that are important to health and prevent certain diseases such as phytochemicals (prevent cancer). The term was first coined in 1989 by Dr. Herbert Pierson, The National Cancer Institute (U.S.). The designer foods are also called as medical foods, fortified foods, nutritional foods, neutraceutical foods, functional foods, indulgence foods, slow foods, premium foods, therapeutic foods and healthier foods. Such foods are most commonly conceived as health foods that have therapeutic or prophylactic characteristics. The term "designer food" is subjected to change based on nutritional labelling regulations, new developments, consumer perceptions and expectations. Therefore it can be said that designer food is an evolving concept meant for reducing or delaying the risk of diseases.

9.7 PACKAGING FOR SAFETY AND QUALITY

Packaging of fruits and vegetables is undertaken primarily to assemble the produce in convenient units for marketing and distribution. The package must be capable of (i) protecting the produce from the hazards of transport, (ii) preventing microbial and insect damage and (iii) minimizing physiological and biochemical changes.

The important consideration in selecting the packaging material are (i) the product itself, (ii) the system of production, (iii) the systems of storage, (iv) the systems of handling, (v) the system of transport, (vi) the systems of merchandising, (vii) the consumer attitude, (viii) requirement of recycling/ reuse/ disposal, etc.

The traditional types of food packaging are boxes, cartons, metal cans, glass bottles and jars whereas the new innovations in packaging are aseptic packaging, PET containers, microwaveable containers, controlled/ modified atmosphere packaging etc.

a) Packaging for fresh fruit and vegetables

Fresh produce contains 80-90 per cent of moisture or even more and equilibrate humidity as high as 98%. Under normal atmospheric conditions, they will dry rapidly (transpiration). This causes wilting and shriveling due to shrinkage of cells. The existing postharvest loss of fruits and vegetables could be considerably reduced by adopting improved packaging, handling and efficient system of transport. The fresh fruits and vegetables during postharvest phase continue all vital processes. The respiratory heat liberated by fruits and vegetables must be taken out from the pack in order to extend their storage life. For this purpose film thickness, ventilation in the packs plays a very important role.

Modified Atmosphere packaging (MAP)

Plastics play a great role in creation of modified atmospheric (MA) condition around the commodities when the fresh fruits and vegetables are packed in plastic film bags. MA condition was reported to reduce bitter pit reduction and better retention of vitamin C in apples. The acute problem of ripening of Suvernarekha mangoes during transit was solved by adopting the MAP technology. However, proper temperature management and postharvest handling practices are required for storing these mangoes for longer duration (30-40 days). Similarly by adopting MAP technology, Mallika and Amrapali varieties of mango fruit could be kept up to 25 days at low temperature. The technology was also successfully applied to enhance the storage life with better quality attributes in many other fruits and vegetables viz. guava, cauliflower etc.

Prepackaging is generally defined as packaging the produce in consumer size units either at producing center/ farm before transit or at terminal markets. Prepackaging protects the produce against the damage and excessive moisture loss, reduce transportation cost by eliminating unwanted and inedible portion of fruits and vegetables, reduces the shopping time of the consumer as the produce is graded before packaging.

b) Packaging for processed products

The packaging materials used for various food products are metal cans, glass bottles/ jars, rigid/ flexible plastic packaging materials etc. Products like fruit jams, jellies, pickles are packed in wide mouthed glass jars. Products like fruit, squashes, syrups, RTS beverages, carbonated beverages etc. are packed in glass bottles.

Packaging for dried or dehydrated products

Dehydrated vegetables absorb moisture; they require a moisture resistant pack. Smaller sized packs of dehydrated vegetables are packed in heat sealable laminates consisting of PE, aluminium foil and paper. Powdered dehydrated products like fruits juice powders, soups, and custard powders require protection against ingress of moisture, oxygen and loss of volatile flavours and colour. They are usually packed in heat sealable laminates containing a layer of Aluminium foil. Cabinet dried, sulphured or sulphited mango pieces could be stored for 6 months in 400 gauge PE pouches for making Amchur.

Packaging for accelerated freeze dried (AFD) foods

The light, porous and brittle nature of AFD foods renders them susceptible to mechanical damage that affects the reconstitution characteristics. So, AFD foods must be protected against physical breakdown, moisture and oxygen absorption. *Aluminium foil laminates* are the best suited. Glue and cartons with foil laminates secured to the walls by spot gluing are suitable for over-all protection of AFD foods.

Bulk packaging of base products like fruits pulp and other intermediate products in plastics laminated pouches is practiced widely amongst manufacturers and processors. A variety of the finished products of fruits and vegetables viz. tomato products, fruit syrups, carbonated drinks and dehydrated fruits and vegetables are packed in plastic containers/ pouches.

Aseptic packaging

Aseptic packaging refers to a technique in which the product and the containers are sterilized separately and packed in a completely aseptic environment till it comes out of the system. Aseptically packaged juices and puree can be distributed in parts where refrigeration is not common. In aseptically processed 'bag-in-box' packed guava and papaya puree, no loss of vitamin C and flavour was observed but loss in colour took place.

Vacuum packaging

Vacuum packaging is used when the foodstuffs is susceptible to deterioration in the presence of oxygen. The air from the container is removed after filling the container and before sealing. This packaging increases the shelf life and quality of the packed material.

9.8 LET US SUM UP

Food is essential to provide nourishment to our body to perform various functions. The appearance, colour, flavour, texture, and all other food qualities affect acceptance of the fresh and processed products. As respiration continues after harvesting, fruits and vegetables lose their vitality, turgidity, colour, appearance and food value, and thus overall quality at room temperature. Improper handling and transport increase the qualitative and quantitative losses. Heating brings several changes in the soluble colour pigment of fruits and vegetables. In order to maintain the wholesomeness of the fresh and processed products, these should be handled properly, transport carefully, stored under appropriate conditions and processed following the standard practices.

The packaging of produce and products is important to protect the produce from the hazards of transport, prevent microbial and insect damages, minimize physiological and biochemical changes and for longer shelf life.

9.9 KEY WORDS

Blanching : dipping of fruits or vegetables in boiling water or exposing these to steam for a few minutes to kill enzymatic and biological activity prior to processing.

Canning : process of sealing of foodstuffs hermetically (air tight) in containers and sterilizing them by heat for long storage.

Degradation : loss of quality.

Denaturation : structural change in proteins due to effect of heat, light, change in pH etc.

Deterioration : includes adverse changes in organoleptic quality, nutritional value, food safety, asthetic appeal, colour, texture and flavour.

Growth : increase in the physical size.

Oxidation : change in a molecule, which involves gain of oxygen, removal of hydrogen or loss of electron.

Quality of fruits and Vegetables : often referring to particular flavour characteristics, appearance, size or levels of a particular type of damage.

Turgor : pressure of cell contents on the partially elastic wall of a cell, tending to produce rigidity. One of the best known forces affecting cell volume is osmosis.

9.10 ANSWER TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answer should include the following points:

1. Any eatable items provide nutrients is food.

   Food contain different nutrients namely carbohydrates, proteins, fats, vitamins, and minerals to perform various functions. See sub-sec. 9.1 and 9.2.

2. Volatile compounds are responsible for food flavour.

   Flavour compounds present in different fruits and vegetables. See sub-sec. 9.3.3

3. Different colour pigments with examples. See sub-sec.9.3.4.

Check Your Progress Exercise 2

Your answer should include the following points:

1. Blanching causes loss of water soluble vitamins due to leaching.

   Pasteurization (<100^0 C) destroys some of vitamin C and Riboflavin.

   High temp. during canning destroys water soluble vitamins significantly.

   Effect of canning on protein and fat. See Sub-sec. 9.4.1.

2. Effect of heating on colour pigments of plant foods. See Sub-sec. 9.4.1.

3. Respiration continues after harvesting.

   Metabolic heat of fruits and vegetables, improper handling and storage conditions causes deterioration in quality. See sub-sec.9.4.2.

4. Room temperature is favourable for growth of microorganisms.

   Enzymatic activities in fresh produce are high at room temperature. See Sub-sec.9.4.2.

Check Your Progress Exercise 3

Your answer should include the following points:

1. List of permitted colours.
   Limit of colours in fruit product. See sub-sec. 9.5.

2. Definition and characteristic of health foods. See sub-sec. 9.7.1 & 9.7.4.

UNIT 10 LOSS OF FOOD VALUE IN FRESH PRODUCE AND PROCESSED PRODUCTS

Structure

10.0 OBJECTIVES

After reading this unit, you should be able to:

- describe the protection and preservation techniques;
- explain biochemical changes after harvesting and slaughter; and
- discuss the handling, transport and safe storage of fruits and vegetables.

10.1 INTRODUCTION

Fruits and vegetables are highly perishable commodities. These are affected by a number of factors leading to post harvest spoilage and hence, post harvest losses are the major source of food loss. Besides, packaging, transportation, and marketing of these perishables also contribute to post harvest losses. These are passed through a long channel before their use, which may lead to a number of undesirable physico-chemical changes in their composition. The losses may take place further, if the produce is not processed following the scientific methodology. In order to reduce the losses and maintain the quality to a maximum extent, effective post harvest management of fruits and vegetables during handling, transportation, marketing, and storage of fresh and processed products is of great importance.

10.2 ASSESSMENT OF LOSS

Fruits and vegetables respire even after harvesting and undergo biochemical changes. Their condition and marketable life are affected by temperature, humidity, composition of the atmosphere which surrounds them, level of damage that has been inflicted on them before, during and after harvest, and the type and degree of infection with microorganisms, insects etc. Fruits and vegetables will deteriorate during storage through loss of moisture, loss of nutrients, physical loss through pest and disease attack, loss in quality from physiological disorders, fibre development, greening (potatoes), shoot growth, seed germination etc.

Various loss assessment methods have been used in practice for perishable commodities. In a study of apples arriving at a central market in Mexico over a period of one year, various measurements were made using European Community (EC) Standards (Table 10.1).

Table 10.1: Quality standards and losses of apples at wholesale market level in Mexico

Quality rating	Reasons for being unmarketable	Percentage
Extra		0.2
1		11.0
2		29.6
3		25.7
Below 3		15.5
Unmarketable		18.0
	Physiological (dehydration, over-maturity, physiological disorders)	9.0
	Fungal diseases (Penicillium, Gloeosporium, Phytophthora)	10.0
	Insect infestation	2.1
	Bitterpit	1.4
	Freezing injury	0.2
	Mechanical damage	6.8

Source: Noon R.A. (1979). Report on an assignment as Plant Pathologist to CONAFRUTA, Mexico City, March 1977-September 1979. Tropical products Institute Report R923, 34 pp.

The factors in the life cycle of fresh fruits and vegetables, which can influence their post-harvest losses, are crop production factors (temperature, nutritional status, light, day length, chemical treatments, infections or infestations etc.), maturity level at harvesting, method of (manual or mechanical) harvesting, removing crops from the field, treatments (pesticides, heat, sprout suppressants, curing), storage and transport conditions, packaging, type of transport, type of store, temperature (pre-cooling, store temperature), humidity, and atmospheric gases.

Losses occur at different times during the production and post harvest cycle of crops, and have a variety of causes. If it is clear that the losses are due to infections caused by microorganisms the control measures will depend on the type of microorganism, the time of infection, the reason for the success of infection and permissible control measures. It follows that effective and sustainable control of post harvest losses should be an integrated approach taking into account health, economics and practicality of the situation. It is important to know the time in marketing chain when losses occur. Losses are usually higher when the crop enters the marketing chain (particularly during wholesale marketing) than in crops consumed by the producer.

10.3 FACTORS CAUSING SPOILAGE: PHYSICAL, PHYSIOLOGICAL, THERMAL, MICROBIAL, CHEMICAL, INSECTS, PESTS, DISEASES

Factors causing spoilage often do not operate in isolation. At one time, many forms of deterioration may take place, depending on the type of food and the environmental conditions that its exposed to.

Physical Factors

Storage conditions like temperature, oxygen, light, duration of storage etc are the important factors that influence the type of microbial growth and spoilage.

The rate of a chemical reaction doubles itself for every 10^0 C rise in temperature. Excessive heat brings about protein denaturation and destruction of vitamins. Several fruits and vegetables deteriorate even at refrigeration temperature (4^0 C) resulting in disclouration, changes in texture etc. Freezing may also cause deterioration of liquid foods e.g. separation of fat particles from a food emulsion.

Atmospheric oxygen brings about undesirable changes in foods such as discolouration, flavour changes and loss of vitamin A and C. Light destroys riboflavin, vitamin A and C and also many food colours. All the other food deterioration factors are time-dependent. The longer the storage time, greater the deterioration of food.

Physiological Factors

Rate at which the stored product respires is a major factor in determining the pace of physiological ageing. Deterioration in fruits and vegetables occurs mainly through the process of physiological ageing and water loss.

The characteristics of a food influence the type of microorganisms that can grow in it and thus determine the changes in its appearance, flavour and other qualities. Proteins are degraded by proteolytic organisms. Fats are digested by relatively few microorganisms, mainly moulds. Fats become rancid due to hydrolytic decomposition to mal-odourous fatty acids. Carbohydrates are affected by carbohydrates fermenting microorganisms; particularly yeasts and moulds.

Moisture is required both for chemical reactions and microbial growth. Foods with a high percentage of moisture deteriorate fast. Variation in surface moisture due to change in relative humidity can lead to lumping and caking, surface defects, crystallization and stickiness in foods. Condensation of even small amounts of moisture can result in multiplication of bacteria.

Acidity- Due to low pH, most of fruits are mainly spoiled by yeasts and moulds. Nonacid foods (vegetables, meat, fish, milk) are particularly subject to bacterial spoilage, but also support growth of moulds under favourable conditions.

Thermal Factors

Inappropriate temperature during food processing and storage are one of the main causes of food deterioration. At high processing temperature proteins get denatured and browning takes place (Maillard reaction). Water soluble vitamins particularly vitamin C, thiamine and riboflavin are heat sensitive and destroyed at high temperatures. Oxidative rancidity is accelerated by heat, metallic tins and light. The rate of oxidation of fat is doubled for each degree increase in temperature. Sugars and starches are degraded by prolonged heating at high temperature.

Microbial Factors

Bacteria, yeasts and moulds often cause food spoilage after harvesting, during handling, processing and storage. They attack all the food components – sugar, starche, cellulose, fat and protein. Depending on the food and the microorganisms, the action on food could be to produce acids, making the food sour, or produce alcohol. Some microorganisms produce gases, making the food foamy; still others produce unwanted pigments or toxins.

Chemical Factors

Pesticides can leave residues on plant produce much more than safe limits and make them unfit for consumption. Poisonous chemicals may enter foods from utensils, e.g., from cadmium plated ware or cheap enamelled ware containing antimony. Lead and arsenic residues from fruit sprays may be on fruit surface, but usually in harmless amounts, especially after washing. Indiscriminate use of all plastic packaging material like polyvinyl and polyethylene material can be a health hazard, e.g., it may lead to the reaction of acid and oil of pickles with plastic packaging as observed in some cases.

Insects, Pests, Diseases

Insects, worms, bugs and fruit flies may damage foodstuffs such as grains, fruits and vegetables and render them unfit for consumption. Apart from losses due to food eaten, insects cause greater damage due to bruises and cuts they make in foods exposing them to microbial attack resulting in total decay. Pests such as rodents introduce high degree of filth in form of excreta, bodily secretions and spoilage microorganisms. For example, rats can transfer the bacteria S*almonella* to the food, may cause salmonellosis.

Several types of pathogenic fungi are able to initiate an infection on the surface of floral parts and on, developing fruits. Many fungi that cause considerable wastage of produce are unable to penetrate intact skin of the produce, but readily invade broken skin. In addition, the cut stem is a frequent point of entry for microorganisms, and stem-end rots are important forms of post harvest wastage of many fruits and vegetables.

Table 10.2: Major post harvest diseases of some fresh fruits and vegetables

Crop	Disease	Pathogens
Apple, pear	Lenticel rot Blue mold rot	*Phlyctaena vagabunda* *Penicillium expansum*
Banana	Crown rot Anthracnose	*Colletotrichum musae Arx, Fusarium roseum, Verticillium theobromae, Ceratocystis paradoxa* *Colletotrichum musae*
Citrus fruits	Stem end rot Green mould rot Blue mould rot Sour rot	*Phomopsis citri Faw, Diplodia natalensis, Alternaria citri* *Penicillium digitatum Sacc.* *Penicillium italicum Wehmer* *Geotrichum candidum*
Papaya, mango	Anthracnose	*Colletotrichum gloeosporiodes*
Pineapple	Black rot	*Ceratocystis paradoxa,*
Potato, leafy vegetable	Bacterial soft rot Dry rot	*Erwinia carotovora* *Fusarium species*
Leafy vegetables, carrot	Watery soft rot	*Sclerotinia sclerotiorum*

10.4 POST-HARVEST/ SLAUGHTER – BIOCHEMICAL CHANGES

10.4.1 Post-Harvest Biochemical Changes

The perishable foods like fruits and vegetables continue to undergo chemical changes even after harvest. The changes of fruits after harvest are numerous. Some of the very important changes include changes in (i) rate of respiration, (ii) water content, (iii) carbohydrates and (iv) organic acids and pH.

i) A major metabolic process which takes place in harvested produce or in any living plant is respiration. Respiration rate per unit weight is highest for the immature fruits or vegetables and then steadily declines with the age.

ii) When fruit and vegetables are picked from the plants, water no longer flows into the foods although the loss continues. In dry atmosphere and at high temperatures, water loss is rapid. For e.g., apples rapidly cooled after delivery to the storage area have a much smaller water loss than those cooled slowly. During the ripening period of bananas, the water content in the pulp increases and in the peel decreases. Water loss in bananas (and probably in other fruits) is checked by waxy layer of the skin.

iii) Many changes occur in the carbohydrate fraction of fruits during ripening. This alters both taste and texture of the produce. The green fruits usually contain an abundance of starch, but are short on the soluble sugars that give ripe fruit its sweetness. On ripening, however, starches decrease and sugars increase in concentration.

One of the most obvious changes in fruit is the alteration in texture. The breakdown of polymeric carbohydrates, especially pectic substances and hemicelluloses, weakens cell walls and the cohesive forces binding cells together. In the initial stages, the texture becomes more palatable, but eventually the plant structures disintegrate. Protopectin is the insoluble parent form of pectic substances. During ripening and maturation, protopectin is gradually broken down to soluble pectin. The rate of degradation of pectic substances is directly correlated with the rate of softening of fruit. For e.g. pears are picked in the hard stage and held at low temperatures until required for ripening. On return to room temperature they rapidly ripen and soften due to increase in soluble pectin. Fruits like banana, peaches, plums and tomatoes also show loss of protopectin and rise in soluble pectins on ripening.

10.4.2 Post-Slaughter Biochemical Changes

There are a series of biochemical changes occurring after slaughter. When an animal dies, the skeletal muscles stiffen in rigor mortis and remain in this condition for a period after which they soften and become flexible again. The onset of rigor is quickened by high temperatures and delayed by low temperature. Rigor mortis is important in meat products since muscles cooked while still in rigor are much tougher than if it is allowed to soften before cooking. The stiffness, that develops when muscles pass into rigor, is the result of changes in the proteins. Living muscle fibres contain protein in a soft, pliable gel. During rigor this gel stiffens, but when rigor passes, the muscle again becomes soft and pliable. After the passing of rigor mortis, meat becomes progressively more tender, juicier, and more flavourful. The speed with which this ripening or aging occurs, depends on the time and temperature of keeping the carcass. Changes occur quite rapidly at room temperature but more slowly at refrigerator temperatures.

10.5 HANDLING AND TRANSPORT

Fruits and vegetables continue to respire even after harvesting. We cannot improve the quality of the harvested commodities but it can be retained till consumption if the rate of metabolic activities is reduced by adopting the appropriate post harvest handling operations (Fig. 10.1).

Pre-cooling

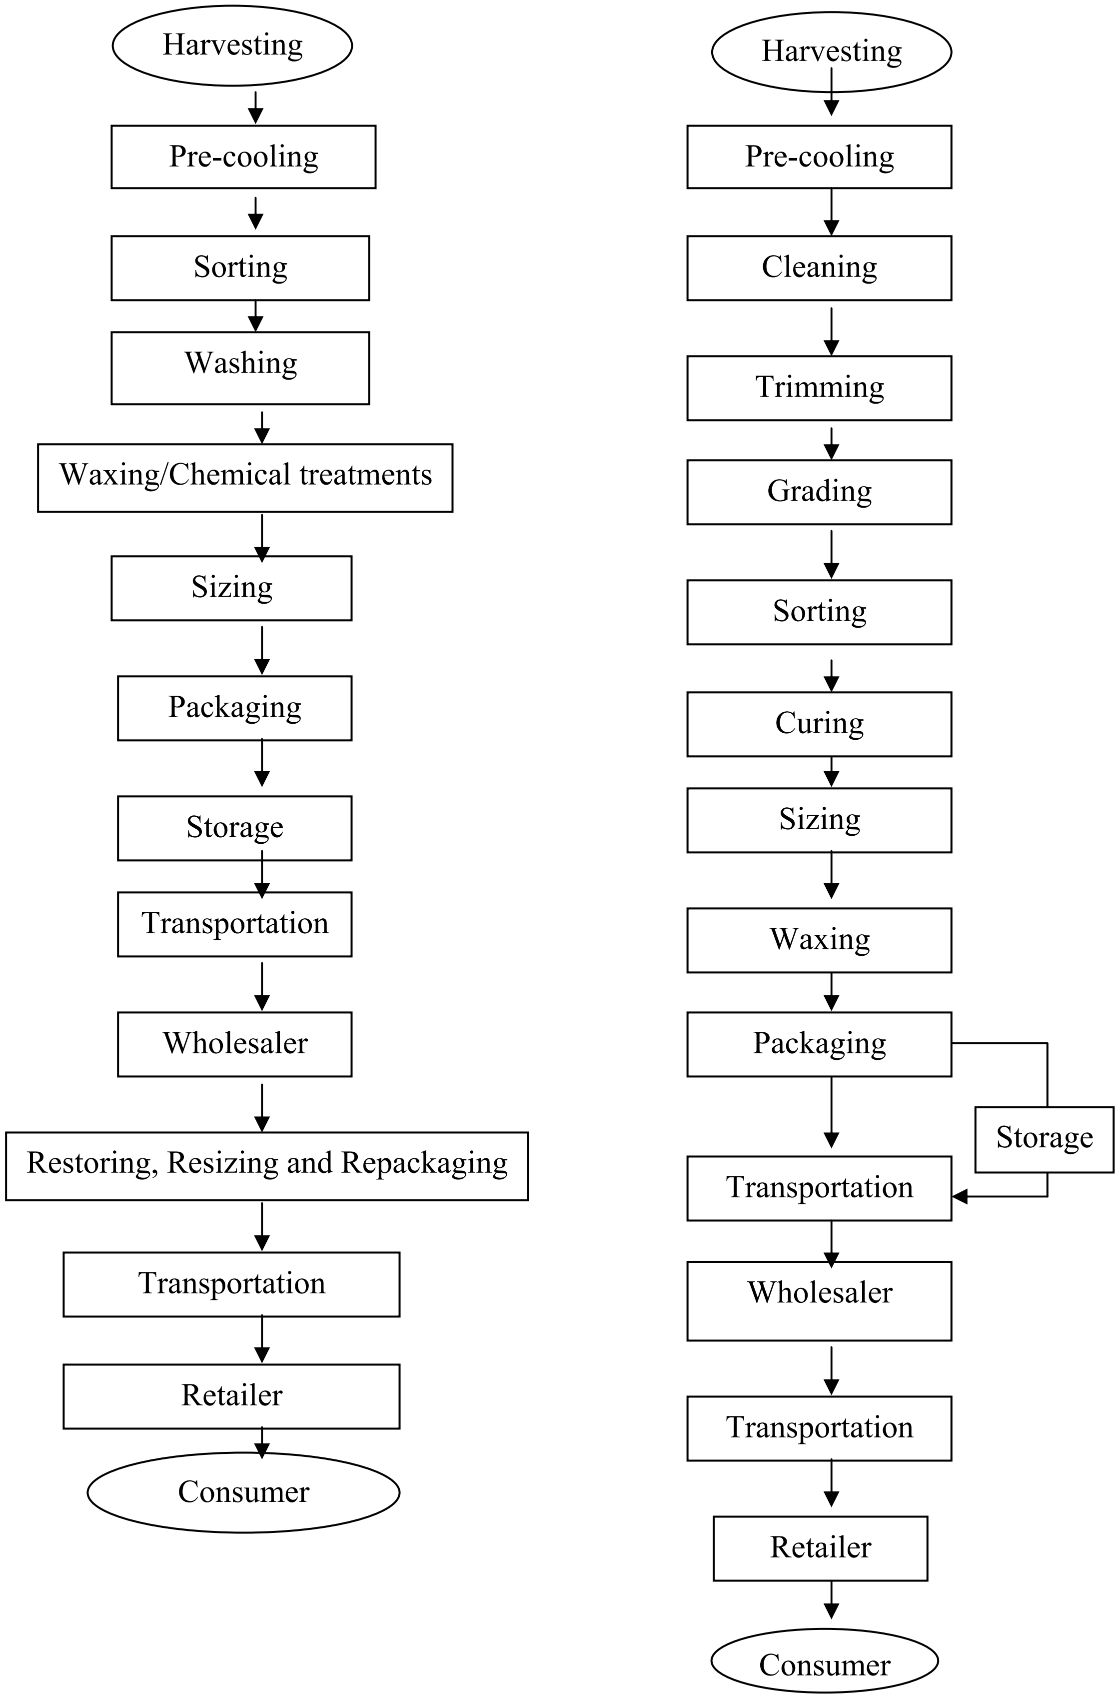
Pre-cooling (prompt cooling after harvest) is important for most of fruits and vegetables because they may deteriorate as much in 1 hour at 32^0C as they do in 1 day at 10^0C or in 1 week at 0^0C. In addition to removal of field heat from commodities, pre-cooling also reduces bruise damage from vibration during transit. Cooling requirement for a crop vary with the air temperature during harvesting, stage of maturity, and nature of crop. Different methods of cooling are given commodity-wise in Table 10.3.

Table 10.3: Commodity-wise cooling methods

Cooling method	Commodity
Room cooling	All fruits and vegetables.
Forced air cooling (pressure cooling)	Fruits and fruit type vegetables, tubers and cauliflower.
Hydro cooling	Stem, leafy vegetable, some fruits and fruit type vegetables.
Package icing	Roots, stem, some flower type vegetables, green onions and brussel sprouts.
Vaccum cooling	Some stem, leaf and flower type vegetables.
Transit cooling Mechanical refrigeration Top icing and channel icing	 All fruits and vegetables Some roots, stems, leafy vegetables

Washing, Cleaning and Trimming

Before fresh fruits and vegetables are marketed various amounts of cleaning are necessary which typically involves the removal of soil, dust, adhering debris, insects and spray residues. Chlorine in fresh water is often used as disinfectant to wash the commodity. Some fungicides like Diphenylamine (0.1-0.25%) or ethoxyquin (0.2-0.5%) may be used as post-harvest dip to control an important disorder of apple known as superficial scald. Many vegetables need trimming, cutting and removal of unsightly leaves or other vegetables parts.



(a) (b)

Figure 10.1: Post-harvest handling operations of a) fruits, and b) vegetables

Sorting, Grading and Sizing

Sorting is done by hand to remove the fruits, which are unsuitable to market or store due to damage by insects, diseases or mechanical injuries. The remainder crop products are separated into two or more grades on the basis of the surface colour, shape or visible defects. For example, in an apple packing house in India 3 grades viz. extra fancy, fancy and standard may be packed for marketing. After sorting and grading, sizing is done either by hand or machine. Sizing on the basis of fruit shape and size are most effective for spherical (oranges, tomato, certain apple cultivars) and elongated (delicious apples, European pears or of non-uniform shaped commodities, respectively. Grading-packing line machines with facilities of washing, waxing and drying in addition to sizing are now days available in the market.

Curing

Curing is an effective operation to reduce the water loss during storage from hardy vegetables viz. onion, garlic, and other root vegetables. The curing methods employed for root crops are entirely different than that from the bulbous crops (onion and garlic). The curing of root and tuber crops develops periderm over cut, broken or skinned surfaces for wound restoration. It helps in the healing of harvest injuries, reduces loss of water and prevents the infection by decay and attack by pathogens. Onion and garlic are cured to dry the necks and outer scales. For the curing of onion and garlic, the bulbs are left in the field after harvesting under shade for a few days until the green tops; outer skin and roots are fully dried.

Waxing

Waxing generally reduces the respiration and transpiration rates, but other chemicals such as fungicides, growth regulators, preservative can also be incorporated specially for reducing microbial spoilage, sprout inhibition etc. However, it should be remembered that waxing does not improve the quality of any inferior horticulture product but it can be a beneficial adjunct to good handling. Some of the commonly used waxes are paraffin wax, carnauba wax, bees wax, wood resins, shellac, etc.

The majority of quality contributing factors as affected by wax application includes reduction in the physiological loss in weight (PLW), delay in respiration rate, reduction in post-harvest spoilage and maintenance of improved quality of commodity intended for storage to increase the shelf life. The principal disadvantage of wax coating is the development of off flavour if not applied properly. Adverse flavour changes have been attributed to O_2 and CO_2 exchange, thus resulting in anaerobic respiration and elevated ethanol and acetaldehyde contents.

Packaging

Proper or scientific packaging of fresh fruits and vegetables reduces the wastage of commodities by protecting them from mechanical damage, pilferage, dirt, moisture loss and other undesirable physiological changes and pathological deterioration during the course of storage, transportation and subsequent marketing. For providing uniform quality to packed produce, the commodity should be carefully supervised and sorted prior to packaging. Packaging cannot improve the quality but it certainly helps in maintaining it as it protects the produce against the hazards of transportation.

Transportation

Mechanical damage to packages occurs particularly during handling and transportation. Rail, road, sea and air transport may all be used to move produce to its destination. Air-transport relies on short journey time to maintain produce quality. The packaging requirement during surface transport are generally greater than by air owing to longer time taken for the journey, higher humidity and usually greater stack heights. The use of pallets and mechanical aids can reduce handling damage to the package considerably. It is very important that the package maintains its integrity throughout the journey.

10.6 COLD STORAGE

Fresh produce changes in quality and quantity between harvest and consumption. These losses have been observed to the tune of 20-50 per cent particularly in developing country depending upon the commodity. Fresh produce like fruits and vegetables and ornamentals are living tissues, which are subjected to continuous change after harvest due to inadequate handling, packaging, transport and storage. Deterioration in fruits and vegetables occur mainly through the process of physiological ageing and water loss. The rate at which the stored product respires is a major factor in determining the pace of physiological ageing.

The deterioration in the agricultural produce of high value (milk, meat, fish, fruits, and vegetables) depends largely on storage temperature. One way to minimize deterioration reduce losses consists of lowering their storage temperature to an appropriate level. The storage of foods for extended periods at lowered temperatures is called as cold storage.

Refrigeration or Chilling

Chilling temperatures are obtained by means of ice or mechanical refrigeration. Fruits, vegetables and their products and other high value foods can be stored for a few days to many weeks when kept at chilling temperature. It is necessary to refrigerate fruits and vegetables as soon as they are harvested, fish as soon as they are caught and meat as soon as slaughter has taken place under good hygienic conditions, eggs recently laid, etc. to maintain the quality of the foods. It is important to cool the produce before refrigeration, maintain RH conditions for the food, and carry out renewal of air.

Freezing

Freezing method is most harmless method of storage of food for longer duration. At temperature below the freezing point of water (-18^0 to -40^0 C) growth of microorganisms and enzyme activity are reduced to a minimum. Most perishable foods can be preserved for several months if the temperature is brought down quickly (quick freezing) and the food is kept at these temperatures. Quick frozen foods maintain their quality and freshness when they are thawed because only very small ice crystals are formed when foods are frozen in this manner.

Table 10.4: Practical storage life of some frozen products

Product	Practical storage Life (in months)		
	-18^0C	-25^0C	-30^0C
Fruits			
Peaches, apricots or cherries (sweet or sour) in sugar	12	18	24

10.7 PROTECTION AND PRESERVATION TECHNIQUES

Foods are perishable and hence cannot be stored at ordinary temperatures for any length of time. So there comes the need of protection and preservation. It becomes necessary to take the preventive measures to increase the shelf life, or to treat these commodities with some life enhancer or processing them to various products. In the preservation of food, the following methods are involved:

I. Prevention or delay of microbial decomposition

   a) by keeping out microorganisms (asepsis- packaging prevents entry of microorganisms in food, e.g. canned peas);

   b) by removal of microorganisms, e.g. filtration;

   c) by hindering the growth and activity of microorganisms, e.g., by low temperature, drying, anaerobic conditions, chemicals or antibiotics; and

II. By killing the microorganisms, e.g., by heat or irradiation.

III. Prevention or delay of self-decomposition of food

   a) by destruction or inactivation of enzymes, e.g., by blanching or boiling;

   b) by prevention or delay of chemical reactions, e.g., prevention of oxidation by means of an antioxidant.

IV. Prevention of damage by insects, animals, mechanical causes, etc.

Various methods generally used for preservation of foods are as under:

I. Preservation by High Temperature: Two common methods of preservation by high temperatures are preservation are usually: pasteurization and sterilization.

a) Pasteurization

Pasteurization destroys pathogenic microorganisms and extends shelf life of the product by decreasing the microbial population and inactivation of enzymes, for example, pasteurized milk and other dairy products, beer, fruit juices and aerated drinks. Dried fruits like raisins, apricots and dates can also be pasteurized in the package.

b) Sterilization

Sterilization means the destruction of all viable microorganisms. The time and temperature necessary for sterilization vary with the type of food. Vegetables like green peas, beans, okra etc being non acidic contains more starch than sugar, require higher temperature to kill the spore forming organisms. Continuous heating or 30 to 90 minutes at 116^0 C is essential for their sterilization. Temperature above 100^0 C can only be obtained by using steam pressure sterilizers such as autoclaves.

Aseptic Canning

Aseptic Canning is a technique in which food is sterilized outside the can and then aseptically placed in previously sterilized cans, which are subsequently sealed in an aseptic environment, e.g., fluid and semi fluid products. The temperature employed may be as high as 149^0 C and sterilization takes place in 1 or 2 seconds.

Hot Pack or Hot Fill

Hot pack refers to the filling of previously pasteurized or sterilized food while still hot, into clean but not necessarily sterile containers under clean but not necessarily aseptic conditions, e.g. filling of hot jams in jars. Heat of the product and some holding time before cooling render the container sterile.

II. Preservation by Low Temperature

Microbial growth and enzymatic recitations are retarded in foods stored at low temperatures. Low temperatures can be obtained by (a) refrigeration or chilling (0-5^0C) suitable for storage of potatoes, apples and other perishables, and (b) freezing (-18 to -40^0 C) suitable for storage of most of the perishables.

III. Preservation by Chemicals

Certain chemicals when added in small quantities can hinder undesirable chemical reaction in food by interfering with cell membrane and enzymatic activity of microorganisms or their genetic mechanisms and acting as antioxidants. Benzoic acid, potassium metabisulphite, sorbic acid, calcium propionate are some of the chemicals used as preservative.

The development of off flavours (rancidity) in edible oils is prevented by the use of butylated hydroxy anisole (BHA), butylated hydroxy toluene (BHT) or lecithin, which act as antioxidants.

IV. Preservation by drying

When the moisture content of food is brought down below a certain level, microorganisms are unable to grow. Moisture can be removed by heat application as in sun drying or by mechanical drying (dehydration), e.g. dried green peas, cauliflower and raw mango, and fruit juice powder, etc.

V. Preservation by filtration

In this method, the juices are clarified by settling or by using ordinary filters and then passed through special filters, which are capable for retaining yeasts and bacteria. Various types of germ proof filters are used for this purpose.

VI. Preservation by Carbonation

Carbonation adds to the life of a beverage and contributes in some measures to its tang. Another advantage of carbonation is the removal of air thus creating an anaerobic condition, which reduces the oxidation of ascorbic acid and prevents browning.

VII. Preservation by Salt or Sugar

Salt at a concentration of 15 to 25 per cent is sufficient to preserve most products by: (i) causing high osmotic pressure resulting in the plasmolysis of microbial cells, (ii) dehydrating food as well as microorganisms by drawing out and tying up the moisture (iii) ionizing to yield the chloride ion which is harmful to microorganisms, (iv) reducing the solubility of oxygen in water, sensitizing the cells against carbon dioxide, and interfering with the action of proteolytic enzymes. Sugar absorbs most of the available water resulting very little water for microbial growth hence their multiplication is inhibited and even those already present die out gradually. Thus sugar acts as preservative by osmosis as in case of jam, jelly, candy, marmalade, etc.

VIII. Preservation by Fermentation

Decomposition of carbohydrates by microorganisms or enzymes is called 'fermentation'. By this method, foods are preserved by the alcohol or organic acid formed by microbial action. The keeping quality of the alcoholic beverages (wine, beers), vinegar and fermented pickles depends upon the presence of alcohol, acetic acid and lactic acid, respectively. About 2 per cent acetic acid prevents spoilage in many products.

IX. Preservation by Acids

Acidic conditions inhibit the growth of many microorganisms hence organic acids are added to or allowed to form in foods to preserve them. Acetic acid in pickles, citric acid in squashes, jam and jellies, lactic acid are commonly used for preservation.

X. Preservation by oil and spices

A layer of oil on the surface of any food produces anaerobic conditions, which prevents the growth of moulds and yeasts. Thus pickles in which enough oil is added to form a layer at the top can be preserved for long periods. Spices like turmeric, pepper, and asafoetida have very little bacteriostatic effect but their primary function is to impart their characteristic flavour to food.

XI. Preservation by Antibiotics

Certain metabolic products of microorganisms have been found to have germicidal effect and are termed as antibiotics. Nisin, an antibiotic used in canning of mushrooms, tomatoes and milk products. Subtilin is used for the preservation of asparagus, corn, and peas. *Pimaricin* can be used for treating fruits and fruit juices. At present these three antibiotics are permitted only in such foods. Residual antibiotics are expected to be destroyed during cooking as these foods are expected to cook prior to consumption.

XII. Preservation by irradiation

The ionizing radiations (gamma rays or electro beams) can be used for sterilization of foods in hermetically sealed packs, reducing the spoilage flora on perishable foods, elimination of pathogens in foods, control of infestation in stored cereals, prevention of sprouting of potatoes, onion etc. The irradiation of food can be considered to a method of 'cold sterilization', i.e. food is free of microorganisms without high temperature treatment. This method has not yet gained general acceptance due to the unacceptable flavour of some irradiated food and fear of hazard.

10.8 EVAPORATIVE COOLING AND STORAGE

Temperature and moisture content are two most important parameters, which control the rate of decay of food commodities during storage. The higher the temperature the more is the rate of respiration and other biochemical processes, and the food is more likely to develop abnormalities with resultant loss of quality and nutritive value. The vital activities of the tissues such as transpiration, respiration and ripening etc. continue even after harvest. The high moisture content of the horticultural commodities accelerates these reactions making them highly perishable. Very low humidity in the storage space causes undesirable moisture loss from the commodity leading to desiccation and shrivelling. Thus, the principal aim of storage in fresh form is to control wilting and shrinkage alongwith the above undesirable physiological and biochemical changes and infections. This can be achieved by maintaining lower temperature and high humidity conditions through evaporative cooling.

Evaporative cooling is the adiabatic saturation of moist air. It is a thermodynamic process, where a part or all of the sensible heat of moist air is converted to latent heat, thereby, producing a reduction in temperature. Evaporation of water produces a considerable cooling effect and the effect increases with increase in the amount of evaporation. Theoretically, the lowest temperature that can be achieved by the evaporation of water is the wet bulb temperature of the moist air. Evaporative cooling has been extensively utilized for creating a modified atmosphere in an enclosure for crop growing, livestock housing or storage of horticultural produce. Evaporative cooling has also been recommended for removal of field heat from produce on the farm and for short duration storage after it is removed from the cold stores before distribution.

Evaporative cool chambers maintain 10-15^0 C lower temperature compared to field temperature, depending on the season and also maintain around 90 per cent relative humidity. The fruits and vegetables can be stored in plastic crates in the chamber. The shelf life of some fruit and vegetables in the cool chambers have been observed to increase from 3 to 90 days as compared to storage at room temperature.

10.9 LET US SUM UP

Fruits and vegetables are highly perishable commodities. Fresh produce changes in quality and quantity between harvest and consumption. These changes depend upon a number of factors. The quantitative losses have been observed to the tune of 20-50 per cent mainly because of inappropriate handling, packaging, transport and storage of the fresh produce. Deteriorative changes in fruits and vegetables occur mainly due to the action of microorganisms, storage conditions like temperature, oxygen, light, duration of storage, characteristics of the food, insects, pest, diseases etc.

Post harvest handling is one of the major factors that affect the overall quality and losses during transport and marketing. Spoilage in fruits and vegetables depends largely on storage temperature. Deteriorative changes and quantitative losses can be reduced significantly by lowering the storage temperature to an appropriate level. The storage of foods for extended periods at lowered temperatures is called as cold storage.

Most of the fruits and vegetables cannot be stored for too long. So there arises the need of protection and preservation. Fruits and vegetables can be preserved by high temperatures (as in case of pasteurization, sterilization, canning), low temperature (refrigeration or freezing), preservatives, removal of moisture, use of salt, sugar, acids, oils, antibiotics, and irradiation.

10.10 KEY WORDS

Canning : the process of preserving food by sterilization at >100^0 C and cooking in a sealed metal can, which destroys bacteria and protects from contamination.

Carbonation : is the process of dissolving sufficient carbon dioxide in water or beverage so that the product when served gives off the gas as fine bubbles and has a characteristic taste, e.g. carbonated fruit beverages.

Maillard reaction : the reaction between lysine (an amino acid in protein) and sugars is known as Maillard reaction. This deteriorative change takes place on heating or prolonged storage.

Pasteurization : when food is heated in containers or by other method to a temperature below 100^0 C for a definite period of time, the process is known as pasteurization.

Respiration : oxidative breakdown of complex materials, present in cells, such as carbon dioxide and water, with the production of energy and other molecules that can be used by the cell for synthetic reactions.

Spoilage : is a condition produced by excessive growth of microorganisms leading gradually to decay or decomposition or by other physical and chemical causes.

10.11 ANSWER TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answer should include the following points:

1. Undesirable changes in foods.

   Food spoiled due to action of microorganisms, insects, pests, enzymes and other factors. See sub-sec. 10.3.

2. Physical factor, physiological factors, thermal factors, microbial factors, chemical factors, insects, pests, diseases. See Sub-sec 10.3.

3. Rodents contaminate the food with their urine and droppings.

   Rats can contaminate the food with microorganisms. See Sub-sec 10.3.

Check Your Progress Exercise 2

Your answer should include the following points:

1. Respiration.

   Changes in water content.

   Organic acids and starch content decreases. Sugar content increases.

   See sub-sec 10.4.1.

2. Reduces field heat.

   Reduces the rate of deterioration. See sub-sec 10.4.

3. Pre-cooling, washing, cleaning, trimming, sorting, grading, curing, sizing, waxing, packaging. See sub-sec 10.4.

Check Your Progress Exercise 3

Your answer should include the following points:

1. Prevention or delay of microbial decomposition

   By killing the microorganisms.

   Prevention or delay of self-decomposition of food. See sub-sec. 10.7.

2. High temperature enhances decay.

   Low temperature reduces losses and enhances shelf life. See sub-sec. 10.7 and 10.8.

UNIT 11 ANTI-NUTRITIONAL FACTORS, FOOD CONTAMINANTS AND TOXIC ELEMENTS

Structure

11.0 OBJECTIVES

After reading this unit, you should be able to:

- describe food contamination, factors contributing contamination and methods of prevention;
- list the anti-nutritional factors in food;
- discuss food born illness; and
- state deficiency diseases.

11.1 INTRODUCTION

Foods are exceedingly complex mixtures of chemicals substances. Apart from containing nutritionally important constituents, some foods also contain substances, which are harmful. The presence of nonnutritive constituents in foods represents potential health risks of different characters and magnitudes to persons consuming them. If such food is ingested, it can cause food poisoning and infection. Food poisoning could be caused by ingestion of foods containing certain chemicals, toxic plants or animals, toxins produced by bacteria and ingestion of animal parasites. Pathogenic microorganisms may enter foods through poor handling and grow in it. When such contaminated food is ingested, it could cause food infections. Hence, food safety should be a major concern of processor for the public health.

11.2 ANTI-NUTRITIONAL FACTORS

11.2.1 Anti-Nutritional Factors in Plant Foods

Plants are capable of synthesizing a multitude of chemical that cause toxic reaction when consumed. Pulses contain a number of toxic factors, such as protease inhibitors, lathyrogens and favism agents, cyanogens, haemagglutinins and saponins. Some of these toxins are also present in other foods, e.g., protease inhibitors in cereals and potatoes. Solanine, ordinarily the green parts of the potato are removed with the peel, is a toxicant in potatoes. Goitrogens (cause thyroid enlargement) are present in cabbage and related species, rapeseed and mustard. Some varieties of mushroom (e.g. Amanita) are poisonous. Oxalic acid present in spinach, beet etc may cause oxalic poisoning. Soybean contains trypsin inhibitor that affects protein metabolism. Cassava and Lima beans contain linmarin, a toxic glycoside. Lathyrism is a neurological disease caused by the ingestion of *Lathyrus sativus* (khesari dhal) for a period of 6 months or more. Favism agents in fava beans, gossypol in cottonseed are also potent toxic substances.

The active flavoring principles present in some spices may have toxic effects if consumed habitually over long periods or in excessive amounts. Active principles in some of the foods are allyl isothiocyanate in mustard, capsaicin in chillies, myristicin in nutmeg and mace, etc.

11.2.2 Toxicants in Animal Foods

The ingestion of shellfish (clams, mussels) results in paralytic shellfish poisoning. Saxitoxin, an extremely toxic metabolite, is p roduced from the plankton. The toxin resists ordinary cooking procedures. Sea food poisoning, for examples, ciguatera poisoning, moray eel poisoning, scombroid poisoning, puffer fish poisoning, cephalopod poisoning, is mostly prevalent in the areas where marine organisms constitute about 10 per cent of the diet.

11.3 CONTAMINATION OF FOOD BY MICROORGANISM, PATHOGENS

A large number of careless practices cause contamination of food with potentially pathogenic microorganisms. The more common ones are unhygienic practices of food handling, personnel handling food suffer from communicable diseases, cross contamination of food, contaminated water and containers, soil adhering to foods, insects, droppings of rodents.

Contamination by Bacteria

Certain bacteria release poisons known as toxins. Some toxins produced by *Clostridium botulinum* are often cause death of persons consuming food contaminated with this organism. The bacteria such as Staphylococcus aureus and Bacillus cereus produce toxins in food during multiplication or sporulation. Although cooking may destroy these bacteria but the toxin is unaffected and can still cause the problems if food is eaten. Endotoxin are generally produced by bacteria such as *Salmonella* in the intestines of persons consuming food contaminated with such organisms.

Contamination by Moulds

Almost any food can be invaded by mould growth. Moulds cause various degree of visible deterioration and decomposition of foods. Moulds may produce abnormal flavours and odours due to fermentative, lipolytic, and proteolytic changes caused by enzymatic reactions with carbohydrates, fats, and proteins, respectively in foods.

Contamination by Yeasts

Food that is highly contaminated with yeasts will frequently have a fruity odour. Yeasts can grow in a product with low sugar concentration. Most of them do not develop in solutions containing more than 66% sugar or 0.5% acetic acid. Boiling destroys the yeasts cells and spores completely. Foods liable to be spoiled by yeasts are fruit juices, syrups, molasses, honey, jams and jellies.

Contamination by Viruses

Viruses are transmitted to food by workers who are carriers. An infected food handler can excrete the organism through the faeces and respiratory tract infection. The inability of host cells to perform their normal function causes illness due to viral infection.

....

....

....

11.4 FOOD INTOXICANTS

The undesirable constituents that affect the safety of foods include toxicants naturally occurring in foods, toxins resulting from microbial growth, environmental contaminants such as processing and accidental contaminants and chemical contaminants.

Naturally occurring toxicants in plant and animal foods

Foods contain thousands of compounds that are potentially toxic. For example protease inhibitors, lathyrogens, favism agents, cyanogens, haemagglutinins and saponins in pulses, solanine in potatoes, goitrogens in cabbage, rapeseed, etc., trypsin inhibitor in soybean, beta oxalyl amino alanine in khesari dhal, linmarin in cassava and lima beans, Favism agents in fava beans, gossypol in cottonseed are potent toxic substances. Some spices contain active principals (e.g., allyl isothiocyanate in mustard, etc.) may have toxic effects. Paralytic shellfish poisoning from oysters, calms, mussels, and scallops has caused many fatal illness. Saxitoxin, an extremely toxic metabolite, is produced from the plankton.

Microbial Toxins

Microorganisms promote desirable changes in foods under controlled conditions. However, they also cause harmful effect and are involved in most cases of food poisoning.

Bacterial food intoxication: Staphylococcal poisoning occurs abruptly after ingestion of food containing the enterotoxin, produced by staphylococci present in semisolid foods. Foods such as corn, peas, meat, fish are likely to be contaminated with the spore of Clostridium botulinum. They act on nervous system and are potent poisons and cause a disease known as botulism. The food infected with Bacillus cereus, if consumed is also harmful.

Some species of fungi such as Aspergillus flavus, Aspaergillus parasiticus (produced aflatoxins) Claviceps purpurea, Fusarium species produce toxins in foods infected with them and make the foods unfit for consumption.

Environmental Contaminants

These include residues that become part of food as a result of processing, handling and distribution of food. For examples, ethylene oxide used as fumigants to sterile some food reacts with inorganic chlorides to form ethylene chlorohydrin, which is toxic. During smoking of meat and fish for preservation and flavouring, these foods get contaminated with polycyclic aromatic hydrocarbons (e.g. benzopyrine), many of which are carcinogenic.

Metals, find their way into foods through air, water, soil, industrial pollution and many other routes, when present beyond the permissible limit, are toxic. Mercury, cadmium, lead, tin, etc. are the toxic metals present in foods.

Other contaminants from food processing such as lubricants, boiling water additives, packaging material, inside coating of the packaging materials, etc. may contaminate the food and their products and make them unfit for consumption.

11.5 MYCOTOXINS

Mycotoxins are toxic metabolites produced by various moulds when they grow on agricultural products before or after harvest, and during transportation or storage. Some moulds such as Aspergillus species and Penicillium species can invade grains after harvest and produce mycotoxins, while others such as Fusarium species, infect grains and produce mycotoxins before harvest. Mycotoxins remain in the food long after the mould producing them has died and can therefore, be present in foods that are not visibly mouldy. Further many mycotoxins, but not all, are stable and survive the usual conditions of cooking or processing.

Mycotoxins are undesirable because of their adverse effect on both human and animal health. Many mycotoxins have been found to occur naturally in a large number of commodities, but only few of these are widely accepted as causing significant food safety risks. Food grains, especially rye, bajra, sorghum and wheat have a tendency to get infected with the ergot fungus, Claviceps purpurea. Consumption of ergot infected grains leads to ergotism. Mycotoxins produced by certain moulds, Aspergillus flavus and Aspergillus parasiticus are known as aflatoxins. These fungi develop in many foods particularly in maize, sorghum, groundnut, etc. under improper storage conditions and produce aflatoxins of which B_1 and G_1 are the most potent hepatotoxins, in addition to being carcinogenic.

Moisture content of foods above 16 per cent and temperatures ranging from 11 to 37^0 C favour toxin formation. Fungal contamination can be prevented by proper storage after drying the grains to 10 per cent moisture level.

11.6 FOOD POISONING AND FOOD INFECTIONS

11.6.1 Food Poisoning

Food poisoning is an acute gastro-enteritis or any other disorder caused by ingestion of food contaminated with either living bacteria or their toxins or inorganic chemicals and poisonous plant and animal foods.

i) Food poisoning by microorganisms

Botulism is a severe form of food poisoning caused by ingestion of inadequately cooked canned food (beans, peas, etc.) contaminated with bacteria; Clostridium botulinum. The symptoms of botulism occur 18 to 36 hours after ingestion of contaminated food and begin in gastrointestinal tract. The principal hazard is the effect on the nervous system. Death may occur as a result of respiratory paralysis and cardiac failure.

Staphylococcal food poisoning is the most common form of food poisoning which occurs after ingestion of food contaminated with Staphylococcus aureus. Staphylococcus contamination of food may either be from human or animal sources. Some strains of *Staphylococcus aureus* can produce an enterotoxin. Staphylococcal food poisoning can be characterized by salivation, nausea, vomiting, abdominal cramps and diarrhoea. Pasteurization kills all the Staphylococci that may be present in foods but toxins may not be destroyed by pasteurization or ordinary boiling.

Salmonella food poisoning caused by the ingestion of foods particularly commercially prepared animal foods, contaminated with S. typhimurium, S. cholera-suis and S. enteritis besides many others. Salmonellosis may be characterized by enteric fever, gastro-enteritis.

Clostridium perfringens food poisoning: C. perfringens has been found in faeces, soil, water and air. The majority of this type of poisoning has been associated with ingestion of fresh or frozen meat, meat preparations and poultry. The common symptoms of this poisoning are diarrhoea, abdominal cramps and fever, occurring 8 to 24 hours after consumption of the food. The bacteria are destroyed by ordinary cooking temperature but spores survive at this temperature and need thorough cooking.

Cereus food poisoning caused by Bacillus cereus and their toxin, found in raw, dried and processed foods. The spores can survive at cooking temperature and multiply rapidly when food is held at room temperatures. The poisoning is characterized by gastro-intestinal tract symptoms.

Some of the species of fungi such as *Aspergillus flavus*, *Aspergillus parasiticus*, *Claviceps purpurea*, *Fusarium* species produced toxins in foods and make those foods unfit for human consumption.

ii) Contaminants arising from processing, accidental contaminants and chemicals

These include residues that become part of food as a result of processing, handling and distribution of food, e.g., fumigants. Ethylene oxide is a commonly used fumigant. Ethylene oxide reacts with inorganic chlorides to form ethylene chlorohydrin, which is toxic. Solvents like trichloroethylene, used for extraction of oil from oilseeds reacts with the substances and produce a toxic product.

During smoking of meat and fish for preservation and flavouring, these foods get contaminated with polycyclic aromatic hydrocarbons (e.g. benzopyrine), many of which are carcinogenic.

Metals find their way into foods through air, water, soil, industrial pollution and many other routes. Metals (mercury, lead, tin, aluminum, etc.) beyond the permissible limits are toxic.

Poisoning by chemicals is not very common. Poisonous chemicals like arsenic, cadmium, antimony can enter foods through improperly coated utensils. Insecticide and pesticides (malathion etc.) residues can also cause food poisoning if contaminated food is consumed without washing.

iii) Poisonous plants and animals

Certain varieties of mushrooms are very poisonous and could be fatal if consumed. Snakeroot poisoning could result from drinking milk from cows that have fed on this weed. Seafood such as mussels and clams sometimes contain a poisonous alkaloid. Death camas contains a poisonous alkaloid that decrease blood pressure if consumed. Bush tea contains toxic factors, which are known to cause occlusive disease of the liver, often leading cirrhosis. Pulses contain a number of toxic substances such as protease inhibitors, lathyrogens and favism agents, cyanogens, haemagglutinins and saponins. Saponins goitrogens, oxalic acid present in some foods can cause poisoning if consumed in large quantities. Gossypol is a toxicant found in cottonseed. Sea foods poisoning, toxicants present in certain spices and flavours. Toxic substances found in certain food fats cause food poisoning when consumed in large amounts.

11.6.2 Food Infections

Pathogenic microorganisms and parasites may enter foods through poor handling and grow in it. Food containing a large number of pathogens if ingested can cause food infections. Food borne infections are especially prevalent in communities with inadequate facilities for storing foods and insanitary water supplies and lavatories. The principal types of infectious organisms that may cause diseases are: bacteria, moulds and viruses.

Bacterial food infections result from the ingestion of large amount of viable bacteria, which multiply inside the host and cause infections. Some of the common infectious diseases caused by bacteria are:

- Cholera is one of the most acute and violent infections, characterized by fever, severe diarrhoea, abdominal cramps, vomiting, intense thirst followed by collapse. Cholera spreads from infected person and faecal-contaminated food and water.

- *Bacillus cereus* infection characterized by severe vomiting 1 hour after ingestion or diarrhoea later.

- Escherichia coli food infection is spread by contaminated food and water. It is characterized by gastroenteritis and most common infection in infants.

- Salmonellosis is characterized by diarrhoea, abdominal cramps and vomiting, which usually lasts for 2 to 3 days. Salmonella bacteria grow rapidly in cooked eggs, meat, custards and salads, which have been left at room temperature for several hours.

Some other bacterial infections, which are caused by ingestion of contaminated food, are tuberculosis and typhoid.

Many diarrhoeal diseases, viral hepatitis, gastroenteritis, etc. are transmitted primarily by faecal-oral route. Faecal oral transmission may be water born, food born, or direct transmission, which implies an array of other faecal-oral routs such as via fingers, or fomites, or dirt.

Parasitic Infestation of Foods

Many protozoa, helminthes (worms) gain admission to the body by means of food and cause injury to the intestinal lining and sometimes other tissues. Amoebiasis is a common infection of gastrointestinal tract, caused by potentially pathogenic strain of Entamoeba histolytica. The helminthes that frequently invade the intestinal tract include nematodes (round worms), cestodes (tapeworms), and trematodes (liver, intestinal, and lungs flukes). Tricinosis, one of the most serious infestation results from ingestion of raw or partially cooked pork infected with Trichinella spiralis, a very minute roundworm. Trichinella is destroyed by cooking pork, until no trace of pink remains. Foods act as a carrier for the parasites but none of these organisms grow in the food as such. Usually such contamination occurs due to poor handling of food and preparation.

11.7 FOOD BORN DISEASES

Food borne disease is caused by agents that enter the body through the ingestion of food. Food borne diseases may be classified as:

A) Food Borne Intoxications

i) Due to naturally occurring toxins in some foods, e.g., lathyrism, endemic ascites, etc.

ii) Due to toxins produced by certain bacteria, e.g., botulism, staphylococcal food poisoning.

iii) Due to toxins produced by some fungi e.g., aflatoxins, ergot, fusarium toxins, etc.

iv) Food borne chemical poisoning

- Heavy metals, e.g., mercury (in fish), cadmium (in certain shellfish), and lead (in canned food)
- Oils, petroleum derivatives and solvents
- Migrant chemicals from packaging materials
- Pesticide residues (DDT, BHC)

B) Food borne infections

i) *Bacterial infections:* typhoid, cholera, salmonellosis, shigellosis, etc.

ii) *Viral infection:* viral hepatitis, gastroenteritis

iii) *Parasitic infestations:* ascariasis, amoebiasis, trichinosis, etc.

(Details about food borne diseases was covered under food toxins, food poisoning and food infections)

11.8 METHODS OF PREVENTING FOOD CONTAMINATION

Contamination can be reduced through effective housekeeping and sanitation, protection of food during storage, proper disposal of garbage and litter, and protection against contact with toxic substances.

The Environment

Only cleaned hands should touch food during handling and processing. A processed product should be kept covered to prevent the entry of dust or other things. If the nature of food does not permit this kind of protection; it should be placed in an enclosed, dust free cabinet at appropriate temperature. Equipment and utensils for food processing, packaging, preparation, and service should be cleaned and sanitized between uses.

Storage

Storage facilities should provide adequate space with appropriate control and protection against dust, insects, rodents, and other extraneous matter. Organized storage layouts can reduce contamination and facilitate cleaning. In addition storage area floors shelves and/ or racks should be cleaned regularly. Waste materials should not be accumulated in the food storage area.

Litter and Garbage

Waste and refused materials (used packaging materials, containers and waste products) should be placed in appropriate containers for disposal. These receptacles should be seamless, with close fitting lids. Plastic liners are inexpensive and provide added protection. All receptacles should be washed and disinfected regularly. Containers kept in food processing and food preparation areas should not be used for garbage or litter, other than that produced in those areas.

Toxic Substances

Poisons and toxic chemicals should not be stored near food products. In fact, only chemicals (well labelled) required for cleaning should be stored in the same premises. Only cleaning compounds, supplies, utensils, and equipment approved by regulatory or other agencies should be used in food handling, processing, and preparation.

11.9 DEFICIENCY: PROTEIN, VITAMIN AND MINERAL – CONSEQUENCES AND CORRECTIVE MEASURES

As a consequence of dietary deficiency, several nutritional problems are encountered namely (i) PEM (ii) vitamin A deficiency, (iii) iron deficiency anaemia, (iv) iodine deficiency, (v) vitamin B-complex deficiencies.

Protein Deficiency

Protein energy malnutrition (PEM) is the name given to various degree of nutritional disorders caused by inadequate quantities of protein and energy in the diet of young children. This leads to various degree of growth retardation. When growth retardation is severe, functional deficiencies, like resistance to infection, poor intellectual development and body may have wasted away. Kwashiorkor and marasmus are two clinical forms of PEM at opposite poles of a single continuum. Kwashiorkor (growth failure, oedema, diarrhoea, fatty liver, dermatitis and other symptoms) occurs when there is a lack of protein in the diet but calories or energy in the form of carbohydrates is available in sufficient quantity. However, when both protein and energy are insufficient, over prolonged periods, a condition known as marasmus (growth failure, wasting of muscles, and dry and atropic skin and other symptoms) occurs in children. Both kwashiorkor and marasmus can be complicated with other infections due to intestinal parasites and bacteria.

The dietary management along with medical treatment for infection, if any is necessary for rapid recovery of the child with PEM. The diet should be rich in easily digestible proteins (4-5 g/ kg normal body weight of the child) of high nutritive quality (from milk and milk product, legumes, sprouts etc.), calories (140 Kcal/ kg body weight) and all dietary essentials (vitamin A and iron supplementation).

Vitamin Deficiencies

Vitamin A deficiency is a major nutritional problem in young children leading to blindness. Night blindness (inability to see in dim light), Conjuctival xerosis (conjuctiva becomes dry and non-wettable, appears muddy and wrinkled), Bitot's spot (triangular, pearly-white or yellowish, foamy spots on the bulbar conjuctiva on either side of the cornea), corneal xesosis (cornea appears dull, dry, non wettable and eventually opaque) and keratomalacia (cornea may become soft and burst open) are important deficiency states due to vitamin A deficiency. The person with vitamin A deficiency should be given well balanced diet including green leafy vegetables and yellow and orange fruits in sufficient quantities with the vitamin A supplementation.

Vitamin D deficiency causes Rickets in children (characterized by enlarged joint, bowed legs, knocked knees, bulging forehead, pot belly, delayed eruption of temporary teeth, muscular hypotonia etc.) and Osteomalacia in adults, in which bones soften, become distorted, and fracture easily. The subjects (children or adults) should be given a well balanced diet containing plenty of milk, ragi, and green leafy vegetables along with calcium and vitamin D supplementation.

Vitamin C deficiency produces the disease scurvy characterized by swollen and inflamed gums, loss of weight, anaemia, poor wound healing, pain in joint and muscles. Severe form of scurvy is fatal. In addition to well balanced diets with sufficient amount of locally available fruits and germinated legumes, vitamin C supplementation is important.

Vitamin B-complex deficiencies commonly encountered are riboflavin deficiency leading to angular stomatitis, glossitis and cheilosis; thiamine deficiency leading beri-beri and niacin deficiency (Pellagra). Thiamine deficiency is prevalent in areas where polished rice is the staple food. Inclusion of under milled, or parboiled rice, whole wheat and wheat products, nuts, legumes could help to remove thiamine deficiency. Use of milk and milk products, eggs, green leafy vegetables could prevent riboflavin deficiency. Groundnuts are rich in niacin. Use of combination of cereals, pulses and inclusion of groundnuts would help in preventing vitamin B-complex deficiency.

Mineral Deficiencies

Nutritional aneamia and iodine deficiency are the major public health problems due to mineral deficiencies. Aneamia affects all segments of population in general and children, women and pregnant women in particular. Anaemia may be due to deficiency of iron, or folic acid or vitamin B_{12}. The incidence of anaemia can be reduced by inclusion of leafy vegetables, pulses, whole grains and vitamin C rich seasonal fruits in diet. Since change in dietary habits is a slow process, some interim public health measures have been taken to reduce the incidence of anaemia. These include distribution of tablets containing iron and folic acid at primary health centers. In order to combat and prevent iron deficiency anaemia, fortification of a universally consumed dietary item with iron can be one of the most effective methods.

The Iodine deficiency in man leads to a number of disorders, which include goiter, mental retardation, cretinism, myxoedema, and neuropsychic retardation. The simplest way of eradicating iodine deficiency is by consumption of iodized salt.

11.10 METHODS OF NUTRIENT RETENTION DURING PROCESSING AND STORAGE

Using food preparation methods maximizing nutrient retention is most important to maintain the quality of foods. The processing methods generally used in food preparation; also affect the nutritive quality of various foodstuffs.

i) Nutrients retention during milling

Milling of cereals like paddy to get rice causes considerable loss of vitamins, minerals and proteins. Parboiling of paddy can significantly reduce the nutritional losses during milling of paddy. During parboiling of paddy, B-vitamins present in the bran gets fixed to the grain and hence not removed during milling. Washing of rice before cooking in limited amounts of water also reduce the loss of thiamine due to leaching.

Nutritional loss also occurs during dehulling of pulses. The dehulling losses, in terms of broken and powder fractions can be reduced by following suitable pre-milling treatment (heat treatment or oil treatment etc.) and conditioning of legume seeds before dehulling.

ii) Prevent nutrients from leaching

Water leaches out some vitamins and minerals from the foods. Presoaking of food grains has negligible effect on nutrients such as proteins and fats but digestibility of starch improves. If soaking water discarded, reduction in some nutrients such as minerals and B-complex vitamins will occur. Rice should not be washed for longer time to avoid the loss of thiamine and niacin. The nutrients are also lost if water in which vegetables are cooked, discarded. Vegetables and fruits should be washed before cutting to avoid the leaching of nutrients in washing water.

iii) Avoid excessive heat treatment

Excessive heat destroys heat sensitive vitamins and decreases the protein quality. Preparing food in smallest amount of water at optimum temperature for the shortest time does least nutritional damage. Reheating of food products will add to the loss of nutrients. If required microwave heating for a few seconds may serve the purpose.

iv) Save foods from exposure to oxygen and light

Oxygen in the air and light decreases the amount of vitamins A, B_{12}, C, D, and E, folic acid, and thiamine in foods. Light also decrease the vitamin B_6 and riboflavin. Unsaturated fatty acids are unstable in the presence of air. Packaging of food material is an important measure to protect the foods from losses due to exposure to air and light.

v) Avoid wide changes in pH

pH is important because vitamin A and K and folic acid are unstable in an acidic environment, whereas, vitamin C, D, and K, pantothenic acid, riboflavin, and thiamine are unstable in an alkaline medium.

vi) Minimize trimming and peeling

Trimming and peeling should be kept to a minimum. The skin of fruits has valuable amounts of fibre and vitamin C. The outer leaves of vegetables are good sources of some vitamins and minerals.

vii) Careful handling of perishable foods

Removal of diseased, damaged and scratched fruits and vegetables during grading and post harvest treatment are highly useful in reducing the losses.

viii) Avoid the use of sodium bicarbonate to cooking water

Addition of sodium bicarbonate to hasten the cooking of dhal or to retain the colour of vegetables causes heavy loss of thiamin and vitamin C, hence should be avoided.

ix) Moisture content of food

For best storage and to prevent nutritional losses in food grains and oilseeds, these should be thoroughly cleaned, graded and dried to bring down the moisture content below 10 per cent.

x) Packaging

Packaging of foods particularly fruit and vegetables minimize physiological and biochemical changes. Packaging in modified atmospheric (MA) condition reduce the losses of vital nutrients during storage.

xi) Storage at low temperature

The loss of moisture is reduced by storing the vegetables in an atmosphere of high relative humidity at low temperature. Canned foods retain higher levels of vitamin C and thiamine if stored at low temperature. Roots and tubers can be stored at a temperature between 3 to 10^0C to keep sprouting minimum. Ageing of leafy and other vegetables, and fruits can be retarded by low temperature storage.

11.11 FOOD ANALYSIS, RESIDUE ANALYSIS

11.11.1 Food Analysis

Food analysis enables us to know the composition of fresh food and food products. A complete analysis of fruits and vegetable products includes determination of water content, protein, fat, nitrogen-free extract, fibre and ash. Each group is not made up exclusively of allied chemical substances, but rather of substances that happen to have one or more properties in common. The methods employed for the determination of these six constituents involves precipitation, colour comparison, or centrifuging or titration.

The water is determined by drying at $\leq 120^0$ C (depending on the commodity) in ovens for a certain period; the protein by calculation from the total nitrogen; total nitrogen by digestion (of sample), distillation and titration using some chemicals; the fat by ether extraction; the fibre by removal of all acid and alkali soluble constituents, and weighing the residue; the ash by incineration.

11.11.2 Residue Analysis

Residue analysis is concerned with the safety of food for human consumption. Whether applied to analysis of any kind of residue, all residue analysis has its ultimate aim; the capacity to identify food as safe or unsafe for human consumption. Residues analyses on food are undertaken for a very wide range of purposes. In the development of agrochemicals and veterinary drugs, for example, detailed studies on persistence of drugs in crops and/ or animal tissues post-treatment are required. In addition, studies on the metabolism of these chemicals require extensive residue analysis. For chemicals used in farming or occurring as contaminants from the environment and/ or industrial processes, residue analysis is undertaken as part of the monitoring programmes of regulatory agencies to ensure that residues, where they occur in foods, are at levels with respect to the established maximum residue limits (MRLs). In the case of prohibited substances, residue testing is designed to monitor compliance with the regulations. Generalized format for residue analysis is shown in Figure 11.1.

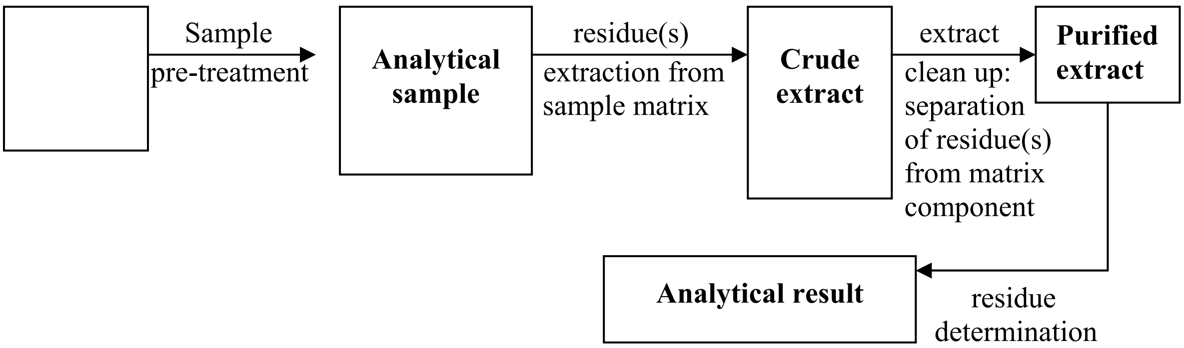

Figure 11.1: Generalized format for residue analysis

Within the spectrum of residue analysis methods, including screening, quantitative and confirmatory methods, there are methods ranging from single-step to multi-step methods. Example of the former are the four plate test for inhibitory substances in meat, for which all pre-determination steps are combined into a single step of cutting disc of frozen meat from the sample, placing them on prepared agar plates and incubating overnight, and a sol particle immunoassay (SPIA) test for sulphamethazine in urine, for which all pre-treatment steps are eliminated and the sample is applied directly to the test device. At other extreme are complicated methods with multiple steps such as methods for confirming the presence of residues of anabolic agents in tissues or bile. These methods involved weighing and homogenizing of sample, pH adjustment of the homogenate, overnight incubation with glucuronidase/ sulphatase to hydrolyse conjugates, extraction of residues directly with solvent or on a diatomaceous earth column, liquid/ liquid partitioning steps and multiple column chromatography or solid phase extraction (SPE) steps to remove co-eluting interferences, multiple evaporation of solvents, derivatisation of the residues and clean-up of the derivatised extracts, prior to determination by gas chromatography-mass spectrometry. In between these extremes lie the majority of residue methods but, in general, the extent of quantification and confirmation and the nature of the sample (solid or liquid) determine whether simple or more complex methods are used.

Table 11.1: Categories of chemical that can arise as residue in food

Category	Examples
a) *Natural*	
Normal components in food	Phytoestrogens, glycoalkaloids, erucic acid
Natural contaminants in food	Mycotoxins, phycotoxins (aquatic biotoxins)
b) *Synthetic*	
– Agricultural chemicals	– Pesticides, fertilizers
– Veterinary drugs	– Antibiotics, anthelmintics, growth promoters
– Food additives	– Preservatives, antioxidants
– Chemicals from packaging	– Vinyl monomers, oligomers
– Food processing chemicals	– Nitrosamines, polycyclic aromatic hydrocarbons (PAHs)
– Environmental contaminants	– Dioxins, polychlorinated biphenyls (PCBs)

11.12 LET US SUM UP

Some foods contain toxic constituents, if consumed in sufficient quantities may prove to be hazardous. The hazardous substances include toxicants naturally occurring in foods, toxins produced by microorganisms, and environmental contaminants. The microorganisms most common to food are bacteria and fungi; get their entry in food as a result of unhygienic practices during food handling, processing and storage. Bacterial contamination is the most significant as it may result in food poisoning. Botulism is the most fatal and Staphylococcal food poisoning is the most common form of food poisoning due to bacterial contamination of food. Contamination can be reduced by safe food handling practices, processing under sanitary conditions, protecting food during storage, proper disposal of waste materials, and protection against contact with toxic substances. These practices will not only reduce the contamination from toxicants but also the nutritional losses and thus prevent food losses and nutritional deficiencies amongst population.

11.13 KEY WORDS

Aneamia	:	is a condition characterized by reduction in red blood cells, packed cell volume or circulating haemoglobin, resulting in pallor appearance and shortness of breath especially on exertion.
Contamination	:	entry of undesirable organisms in some material or object.
Endotoxins	:	toxins produced inside the cell wall and can only permeate the food or the body when the organism is killed.
Exotoxins	:	toxic substances produced by bacteria which diffuse out of the cells and stimulate the production of antibodies.
Malnutrition	:	is a condition result from an inadequate (under nutrition) or excessive intake of one or more nutrients (over nutrition) or some defect in metabolism, which prevents the body from using the nutrients properly, e.g., PEM, Vitamin A deficiency, obesity.
Pathogens	:	disease causing microorganisms.
Toxicity	:	is the capacity of a substance when tested by itself to harm living organisms.

11.14 ANSWER TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answer should include the following points:

1. Foods contain some anti-nutritional factors.

   Excess consumption over a long period can cause health problems, e.g. lathyrism. See sub-sec. 11.2.

2. Protease inhibitor and solanine in potatoes, goitrogens, oxalic acid. See sub-sec. 11.2

3. Some bacteria produced toxins inside the cell wall.

   Unhygienic practices, cross contamination of food, contaminated water and containers, soil adhering to foods, insects, droppings of rodents, etc. See Sub-sec. 11.3.

Check Your Progress Exercise 2

Your answer should include the following points:

1. Ingestion of contaminated food may result in food poisoning.

   Botulism, Staphylococcal food poisoning, Salmonellosis, Clostridium perfringens food poisoning, Cereus food poisoning, lathyrism. See sub-sec. 11.6 and 11.7.

2. Food may be contaminated by pathogenic organisms.

   Diseases caused by agents that enter the body through ingestion of contaminated food.

   Typhoid, cholera, salmonellosis, hepatitis, amoebiasis, etc. See sub-sec.11.6 and 11.7.

3. Moulds grow on agricultural products and produced toxic metabolites.

   Bacteria- Aspergillus flavus and Aspergillus parasiticus produce aflatoxins. See sub-sec. 11.5.

4. Residues in foods from fumigants, presence of metals beyond the permissible limits, chemical residues See sub-sec. 11.6.1.

Check Your Progress Exercise 3

Your answer should include the following points:

1. Undernutrition, over nutrition.

   PEM. See sub-sec. 11.10.

2. Parboiling, optimum heat treatment, save from exposure to oxygen and light, avoid wide changes in pH, careful handling of perishable foods, minimum trimming and peeling, storage at Low temperature. See sub-sec. 11.11.

11.15 SOME USEFUL BOOKS

1. Marriott Norman G. (1999) Principles of Food Sanitation (4th Edition), Aspen Publishers, Inc., Gaithersburg, Maryland.

2. Park, K. (1994) Textbook of Preventive and Social Medicine (14th Edition), Banarasi Das Bhanot Publishers, Jabalpur.

3. Ranganna, S. (1991) Handbook of Analysis and Quality Control for Fruit and Vegetable Products (2nd Edition), Tata McGraw-Hill Publishing Company Limited, New Delhi.

UNIT 12 QUALITY CHARACTERISTICS

Structure

12.0 OBJECTIVES

After reading this unit, you should be able to understand quality attributes:

- physical factors;
- appearance factors;
- textural factors;
- kinesthetic factors;
- chemical and microbiological characteristics;
- quality standards;
- quality evaluation;
- grading and certification; and
- adulteration of food- detection and prevention.

12.1 INTRODUCTION

Quality is combination of attributes, properties or characteristics that give a commodity value in term of human food. Quality is overall, consumer's satisfaction and value worth, which he is paying. It is necessary for the food industry to become quality conscious and move towards attaining the international quality standards. Following are the important component of quality.

1. Appearance
2. Texture or firmness
3. Flavour
4. Colour
5. Purity
6. Nutritional quality: Foods play a very significant role in human nutrition especially as source of carbohydrate, protein, fats, vitamins, minerals and dietary fibre.

Foods are often thought of as healthy and nutritive matter having no risk of food borne illness associated with their consumption. The probability of getting sick from eating raw or processed food should not exist. Preventing contamination of fresh and processed foods from human pathogens and dangerous levels of chemicals/pesticides residues is the best way to assure that foods are wholesome and safe for human consumption.

12.2 PHYSICAL FACTORS

The defects, disease and decay can impair quality of fresh horticultural commodities. Defects can originate before harvest as a result of damage by insects, diseases, birds and hail, chemical injuries, and various blemishes (scars, scabs, rusting, rind scrapping etc.). Post harvest defects include sprouting of potatoes, carrots, onions and garlic, rooting of onions and seed germination inside fruits such as tomatoes and peppers, presence of seed stems in cabbage and lettuce and floret opening in broccoli. Physical factors also include shrivelling and wilting, mechanical damage such as punctures, cuts, scratches, splits and crushing, skin abrasions, scuffing, deformation, compression, bruising, growth cracks in fruits and vegetables.

Temperature related defects (freezing, chilling, sunburn, sunscald) puffiness of tomatoes, blossom end rot of tomatoes, tip burn of lettuce, internal breakdown of stone fruits, water core of apples, black heart of potatoes are the physiological defects.

While most of these defects reduce post harvest quality of perishables. There are examples of defects that do not influence post harvest quality of fresh produce or which may be called as consumer-tolerable defects. These include healed frost damage, scars and scabs, healed insect stings, irregular shape, healed hail damage, sub-optimal colour uniformity, colour intensity variations etc. The presence of defects frequently lowers the grade of the produce, which are other wise of good quality.

Uncontrolled cold also will damage foods. If fruits and vegetables are allowed to freeze, they suffer discolouration, changes in texture, or cracked skins, leaving the food susceptible to attack by microorganism. Carefully controlled freezing on the other hand need not cause these defects. Fruits and vegetables after harvest, like other living systems, have optimum temperature requirements. When held 'at refrigeration temperatures of about 4°C, some are weakened or killed due to chill injury and deteriorative processes follow. The deterioration includes off-colour development, surface pitting, and various forms of decay. Bananas, lemons, squash, and tomatoes are examples of products that should be held at temperatures not lower than about 10°C for maximum quality retention

12.3 APPEARANCE FACTORS

The quality of a food may simply be judged from its appearance when it is placed in front of a consumer. For example, a slight turbidity or cloudiness in orange juice is acceptable but not in apple juice, which must be crystal clear. Thus the overall eye appeal of a product is more important than taste and odour, and may determine acceptance or rejection without a trial tasting. Appearance deserve much more considerations in determining quality of a food and it includes size (dimensions, weight, volume), shape (diameter, depth ratio, smoothness, compactness, uniformity), colour (uniformity, intensity), gloss (nature of surface wax) and different external and internal defects.

Physical factors are such as size, shape, freedom from defect/damaged surface, type and extent of damaged parts. The optical properties such as colour, gloss and transparency of fruits and vegetables and the consistency of the processed products are also appearance factors that are indicative of quality. The appearance factors are highly useful and practiced in quality evaluation of fruits and vegetables, as well as in processed products.

Colour increases the attractiveness of many fruits and vegetables and used as a maturity index as colour undergo many changes as a part of the ripening process. Unripe fruit is usually green and in many types of fruit, the green colour becomes lighter during ripening and maturation owing to breakdown of chlorophyll, for example in apples, grapes, papaya. This may reveal underlying yellow or red pigments. Peel and pulp often undergo different colour changes, as in apples and bananas, In some cases, fruit colour is a strong indicator of eating quality and shelf-life, for example, tomatoes and bananas. Size and shape of fruits and vegetables are of major interest to the grower as it is directly proportional to the yield and also very useful in grading and handling during processing and transportation.

Defects may be caused by: (a) deformities caused by unfavourable environmental conditions (b) insects and microorganisms (c) mechanical injury during handling, transportation and processing such as damage, bruising and crushing (d) specks and sediments (e) foreign material or any other harmful added substance.

12.4 TEXTUAL FACTORS

Texture include various factors such softness, hardness, firmness, juiciness, grittiness or chewiness, fibrousness, mealiness and stickiness felt by the consumer when he handles the food with fingers (hand feel) or with the tongue, teeth or palate (mouth feel). Any deviation from the expected texture is said to be a quality defect. The texture of foods changes due to aging, improper processing or storage. Fresh fruits and vegetables become soggy due to over-ripening. Texture is an important factor in deciding the consumer acceptance of a food. In fact, quality of a food is mainly judged by its freshness/ripeness/ maturity or proper processing. For example, crispness of potato chips, the firmness and crunchiness of apples, and juiciness of fruit such as melons, non-sticky are indicative of prime quality of the food.

12.5 KINESTHETIC FACTORS

These are the quality factors which are judged by hands feel, mouth feel, and judged by sense of touch and tells about, chewiness, softness, juiciness, fibrousness, grittiness, mealiness, stickiness of fresh and processed foods.

12.6 FLAVOUR FACTORS

Flavour is a complex of taste and aromatic components. Total flavour can rarely be assessed by the consumer prior to purchase but it is critical in the repeat purchase of a particular product or product cultivars. Key taste components in fresh produce are sweetness, acidity, astringency and bitterness. Sweetness of some fruit may increase dramatically during ripening due to conversions of starch into sugars, for example in apples, bananas, mangoes and pears. Aroma may be fragrant, acidic & burnt and can be determined to some extent before purchase by the consumer but it tends to be important as a positive factor only in highly aromatic products such as certain cultivars of melon or mangoes.

Evaluation of flavour factor is highly subjective and depends on the discriminating ability of the consumer as flavour includes the sense of smell as well as the sense of taste as experienced by a consumer. People differ in their sensitivity to different odours and tastes as much as in their preference for various types of foods. In addition, consumers are influenced to some extent on the appearance, colour and texture of the food while evaluating the flavour characteristics.

12.7 CHEMICAL AND MICROBIOLOGICAL CHARACTERISTICS

12.7.1 Chemical Characteristics

Lipid oxidation and non-enzymatic browning are two major chemical characteristics which, affect the quality of fruits and vegetables during processing and storage and lead to a deterioration in sensory qualities.

Lipid oxidation results in production of off flavour as well as loss of ascorbic acid. It is influenced by light, oxygen concentration, high temperature, sunlight and the presence of iron and copper, and water activity. Control of these factors can significantly reduce the extent of lipid oxidation in foods.

Non-enzymic browning is one of the major causes of quality deterioration and takes place during frying, cooking, storage of dried and concentrated foods. The non enzymic browning is caused by the reaction of amino acids and reducing sugars through Mallard reaction, leading to insoluble black brown pigments which , produce bitter taste and loss in nutrients.

There is some loss of colour in fruits and vegetable during maturation, ripening, storage and processing due the degradation of chlorophyll, anthocyanins and carotenoids by oxidation. For example, dehydrated green peas and beans packed in clear glass containers undergo photo-oxidation and loss of desirable colour occur.

More than 150 reddish water-soluble anthocyanin pigments are present in the plant kingdom. Some anthocyanins form complexes with metals such as Al, Fe, Cu and Sn. by chemical reaction. These complexes generally result in a change in the colour of the pigment (for example, red sour cherries react with tin to from a purple complex) and are therefore undesirable. Since metal packaging materials such as cans could be sources of these metals, they are usually coated with special organic linings to avoid these undesirable reactions.

The carotenoids are a group of mainly lipid soluble compounds responsible for many of the yellow and red colours of food products. The main cause of carotenoids degradation in foods is oxidation. The mechanism of oxidation in processed foods is complex and depends on many factors. The pigments may auto-oxidise by reaction with atmospheric oxygen due to light, heat and the presence of pro-and anti-oxidants.

Ascorbic acid is the most important vitamin in fruits and vegetables and its stability vary markedly as a function of environmental conditions such as pH , concentration of trace metal ions and oxygen because it is oxidized in the presence of oxygen.

12.7.2 Microbiological Characteristics

The microbial action is associated with the presence of bacteria, yeasts and moulds on vegetables and fruits resulting in deterioration of quality during normal processes of aging. The microbial attack on fruits and vegetable and their processed products usually alter the appearance, texture, colour, odour, flavour or slime formation. The appearance includes colour changes, visible growth of microorganisms, formation of pockets of gas and microbial growth especially that of moulds on the surface of food products. As some foods deteriorate, they become soft or mushy. Degradation of foods results in the formation of compounds that have unacceptable odours and flavours.

The most common microbial spoilages in fruits and vegetables are mildew, brown rot, soft rot, black rot, green rot, mould rot or souring and water soaked musky areas, brown or white patches. These spoilage of quality are caused by *Penicillium italicum, Aspergillus niger, Alternaria sp., Mucor sp., Byssochlamys fulva, Botryis cinerea, Rhizopus nigricans, and saprophytic* bacteria.. Dry rots often lead to darkening and discolouring, and hardening of the surface of vegetables and fruits.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Describe quality.

12.8 QUALITY STANDARDS

Different standards are employed to control the quality of fresh and processed foods in the country. Food standards for ensuring the quality and safety of foods for human consumption have been formulated and enforced by law in India. Food standards have been also prescribed based on the International Codex Alimentarius with suitable modification to suit Indian conditions. Different quality standards are summarized below.

Different Quality Standards

Name of standard	Features
a) Legal standards	– Mandatory standard established by federal state or municipal agencies. – Set up by law or represented by appropriate act. – Concerned with freedom from adulteration and proper quality control measures i.e. insects, moulds, yeasts, pesticides, maximum limit of preservative and food without contamination.
b) Company standards	– Established by food industry. – Represent consumers image and become trademark of symbol of product quality. – Are used by private firms or supermarkets.
c) Industry standard	– Established by an organised group for any given commodity. – Become effective by pressure from market organization or specific commodity group where legal standards are not involved.
d) Consumer or grade standards	– Represent consumer's requirement of a grade/standard product. – Based on experience in use by the industry for consumers.

The different standards take into consideration intrinsic qualities of foods, nutritional aspects, hygienic values and consumer appeal. Some standards are voluntary in nature and some are mandatory.

12.8.1 Legal Standards

These are also called as Health Ministry (Government of India) standards and are mandatory in nature. They are prescribed to ensure minimum quality in the foods marketed and promulgated under the Prevention of Food Adulteration Act other Rules and Orders of Government of India which cover food items: beverages, starchy foods, spices and condiments, sweetening agents, edible fats, milk and milk products, common salt, fruit products, edible oils, cereal products, vanaspati, vinegar, sweets and confectionary, food colours, limits for preservatives, antioxidants, emulsifying and stabilizing agents, flavouring agents, pesticide residues.

Quality denotes the degree of excellence of a product. It is indicated in terms of grades, standards and specifications which are laid down by a competent authority in the country. It is an important consideration in marketing of a product. Consumers are concerned about the safety, nutritional quality, aesthetic value, convenience to use and cost of foods. An established system of quality control assures uniformity in standards and thereby ensures that each food stuff is what it possess to be and what its label declares, if there is one.

12.8.2 Market Standards

The market dictates some quality parameters in the food stuffs marketed. There can be more than one quality requirement for a particular commodity. The economic status and quality consciousness of the consumer influences the market standards and they are voluntary in nature. Examples are different, grades of fruits, vegetables, rice with more or less broken, pulses etc.

12.8.3 Industry Standards

These standards require special quality factors in the foods the consumer purchase. Wheat miller requires wheat with high milling yield. A baker will require a wheat flour with high percentage of gluten of good strength to obtain a good loaf of bread. Similarly fruit processing industry will require certain specific qualities in the fruits like colour, flavour when they are purchased.

12.9 QUALITY EVALUATION

The quality evaluation of fruits, vegetables, other foods and processed products gives useful information on nutritional and biochemical characteristics. Quality evaluation methods can be destructive or non-destructive. They include both objective (based on instrument readings) such as physical, chemical, or microbiological and subjective (based on human judgment, using hedonic scales) methods as in taste. Subjective methods are also called as sensory analysis.

The physical, chemical and microbiological analytical methods are considered to be objective. These methods are usually standard scientific tests, which, one should be in a position to reproduce with the same results by any trained technician. Physical measurements include product attributes such as; size, weight, colour, texture, headspace and even impurities such as filth and insects. Chemical methods are usually more complex and often require sophisticated instrumentation. Precise tests for moisture, total soluble solids, titratable acidity, vitamins, colour pigments, proteins, carbohydrates, ash, pectin and fiber have become standard practice. Microbiological methods are used to determine the presence of bacteria, moulds and yeasts. The details of some of the methods used in the quality evaluation are given below:

12.9.1 Appearance Quality

Appearance quality of fruits and vegetables is measured by size, shape, colour, gloss and presence physical defects.

Size: Dimension-measured with sizing rings, calipers. Weight-correlation is generally good between size and weight.

Shape: Ratio of dimensions – such as diameter/depth ratio used as indices of shape in fruits.

Colour: Uniformity and intensity-important appearance qualities. Visual matching- colour charts to match and describe colours of fruits and vegetables. Light ref1ectance is measured by Hunter Lab Colour Meters and Agtron E5W spectrophotometer. Light transmission meters are used to determine internal colour and various disorders (water core of apples and black heart of potatoes). Lovibond tintometer is also used to judge the colour and it has universal acceptance. Determination of pigments (chlorophylls carotenoids, carotene, lycopene, xanthophylls), and flavonoids (anthocyanins) is done by colourimetric procedures.

Gloss (bloom, finish): measured using a Gloss-meter or by visual evaluation.

Presence of defects (external and internal): Evaluated using a scoring system of 1 to 5 (1 = no symptoms, 2 = slight, 3 = moderate, 4 = severe, and 5 = extreme). Which may be expanded to a 1 to 7 or 1 to 9 hedonic scale.

12.9.2 Textural Quality

Yielding quality (firmness, softness): Hand-held testers - determine penetration force using testers such as the Magness-Taylor Pressure Tester and the Effegi penetrometer. Laboratory testing-fruit firmness is determined by Instron Universal Testing machine or Texture Analyser or by measuring fruit deformation using a Deformation Taster.

Fibrousness and toughness: Measured on by Instron or Texture Testing System a Fibrometer.

Succulence and juiciness: Measurement of water and extractable juice contents are the indicators of succulence and juiciness.

Sensory textural: Evaluate grittiness, crispness, mealiness, chewiness and oiliness.

12.9.3 Flavour Quality

Sweetness: Sugars are determined by colourimeteric methods. For quick measurement of glucose in field, is done by enzyme coated strips. Total soluble solids contents are (sweetness) are measured using refractometers.

Sourness (acidity): pH of juice is determined by pH meter or pH indicator paper. Total titratable acidity is determined by titrating the extracted juice with alkali to pH 8.1.

Saltiness: Salt is determined by chemical method. Saltiness can be measured subjectively by sensory evaluation.

Astringency: Determined by taste testing or measuring tannin contents.

Bitterness: Determined by taste testing or measurement of the glyco-alkaloids.

Aroma (odour): Determined by sensory panels in combination with identification of volatile components.

Sensory evaluation: Human subjects – judge and measure combined sensory characteristics (sweetness, astringency, bitterness, overall flavour intensity) of a commodity.

12.9.4 Nutritional Value

Various analytical methods are available for determination of total carbohydrates, dietary fibre, proteins, amino acids, lipids, fatty acids, vitamins, and minerals in fruits and vegetables.

Eating Quality Factors: These include sweetness, sourness, astringency, bitterness, aroma and off-flavours. Objective analytical determination of critical components must be coupled with subjective evaluations by a taste panel to yield useful and meaningful information about flavour quality of fresh fruits and vegetables.

12.9.5 Non Destructive Methods

Acoustic and vibration tests: The sound of a fruit as it is tapped sharply with a finger knuckle can change during maturation and ripening and this method is used by consumers while purchasing fruits. Melons are trapped to judge whether they are ready to be harvested.

Electrical properties: Electrical properties of the fruit change with the soundness or maturity or spoilage or physical damage of the fruit. It has been found that the capacitance of deteriorated cell increased while resistance decreased and therefore the measurements could be used to determine the freshness or age of the fruit. At 500 Hertz the dielectric constant of green and ripe peaches was 550 and 150 respectively.

Nuclear magnetic resonance (NMR): NMR is being used to find the maturity & quality of fruits and it is also correlated well to sugar content of bananas & apples, and oil content in avocado. It has been used to detect bruises on apples, peaches, pears and onions, pits in olives and prunes and insect damage in pears.

Near Infrared Reflectance (NIR): It has been studied to measure the internal qualities like sugars, acidity, soluble solids, nitrogen & calcium in apples, peaches, pineapples, mango and pear. It is used to find the fruit firmness & their storability in cold stores.

Sonic techniques: Based on the generation of resonating frequency that can be used to calculate internal resistance (hardness).

12.9.6 Summary of Methods of Determining Quality

Subjective*	– Include sense organs – Based on opinion of investigators – Past training experience of individual's power or perception – Statistical Analysis required to get meaningful results
Objective**	– Based on scientific tests – No human perception is involved
a) Physical method	– Size, texture, colour, consistency, headspace, fill and drained weight, vacuum, container, symmetry, defects, viscosity

b) Chemical methods	– Enzyme, moisture, fibre, pH, acidity, protein, specific gravity, fat/oil, carbohydrate, ash, mineral, vitamins, sugars, tannins, alcohols
c) Microbiological methods	– Mold, insect fragments, insect, excreta, foreign material – Differentiation between cell types/tissue/ microorganisms – Determination of microbial count spoilage detection in the fresh and processed products, microorganisms causing spoilage/ fermentation

**Subjective:* The human eye is used to evaluate colour.

***Objective:* An instrument is used to provide a special colour value based on the amount of light reflected-off the commodity surface or the light reflected through the commodity. e.g. Lovibond tintometer.

12.10 GRADING AND CERTIFICATION

The fruits, vegetables and other foods are graded according to size, shape, weight, colour and visible defects to obtain uniform quality and fetch good price for the fruits. This is done by hand or machines. Automatic grading machines are available in which vibrating screens or screens with various sized slots are used to separate different types of product. *Density grading* is carried out by using different concentration of brine for fruits. Grading for colour is carried out by an electronic colour-sensing device. Manual grading done by hands and is usually necessary to avoid losses or to keep losses within reasonable limits.

To ensures quality and purity, Government of India, has established different agencies like AGMARK, Indian Standard Institute to make grades of foods, vegetables & fruits and they are affixing their marks (Agmark, ISI) on the products. The quality *of* product is determined with reference to the size, variety, weight, colour, moisture and, fats content and other factors. The act defines the quality of most of the agricultural raw and processed products commodities into various grades depending upon the degree of purity in each case. The grades incorporated are grades 1, 2, 3 and 4 or special, good, fair and ordinary. The physical and chemical characteristics of products are kept in mind while formulating the Agmark specifications.

Grading of commodities like ghee, butter, vegetable oils, *atta*, spices and honey is voluntary. On the other hand, grading of spices, basmati rice, essential oils, onions, potatoes etc. that are meant for export, is compulsory under AGMARK to ensure quality. The grading of agricultural commodities has three main purposes to: (i) to protect the producers and consumer from exploitation. By knowing the quality and grade of his produce, he is in better bargaining position against the trader. (ii) serve as a means of describing the quality of the commodities to be purchased *or* sold by the buyers and sellers in the country and abroad. Which avoids the need for physical checking and handling at many points. (iii) protect the consumer by ensuring the quality of products he purchases.

Under Indian Standard Specification fruits and vegetables have three grades, super, fancy and commercial.

Super: The fruits and vegetables under this grade shall be of similar variety characters, fresh, firm, i.e. not withered or wilted, tender, succulent, well shaped, fairly smooth clean and well coloured which means that the commodity has a uniform good colour characteristics of the variety over practically the entire surface, well developed, uniform in size, free from injuries and damage by scars, insects, diseases or mechanical or other means.

Fancy: The fruits and vegetables under this grade shall be of similar variety characters, fresh, firm, tender, succulent, well shaped, fairly smooth clean and well coloured. And are free from, injuries, damage by disease, insects, mechanical or other means.

Commercial: The fruits and vegetables under this grade shall consists which do not conform to the requirements of either super or fancy grade, but the quality is fit for use of human consumption.

12.10.1 Certification

The Bureau of Indian Standards, (BIS) Act, 1986, operates a product certification scheme, including Food and Agriculture. The certification allows the licensees to use the popular ISI Mark, which has become synonymous with Quality products for the Indian markets.

The BIS certification is voluntary, and aims at providing quality, safety and dependability to the customer. All BIS certifications are carried out on Indian Standards, which have been found amenable to product certification. Presence of certification mark known as Standard Mark on a product is an assurance of conformity to the specifications. The conformity is ensured by regular surveillance of the licensee's performance by surprise inspections and testing of samples, drawn both from the factory and the market.

The Govt. of India on considerations of public health & safety, and mass consumption has enforced mandatory certifications of 135 products through Orders issued under various Acts. While the Bureau grants licenses only on application however the enforcement of compulsory certification is done by the notified authorities and the Bureau maintains a close vigil on the quality of goods certified through its surveillance operations.

The broad area of food and agriculture under certification are: processed fruits and vegetable products, spices and condiments, bakery, confectionery and nutritious supplements, dairy products, drinks and carbonated beverages, fish and fisheries products, food additives, food analysis and nutrition, food hygiene, food microbiology, food grains, livestock feeds, oils and oilseeds, pesticides residue analysis.

12.11 ADULTERATION OF FOOD – DETECTION AND PREVENTION

Food is consumed should be pure provide energy and nutrition and as such it should be wholesome and not have deleterious substances. The food adulteration implies that food lack certain standard of quality or purity and, is a great menace to public health, posing serious threat to the society.

Food adulteration is defined as the process by which the quality or the nature of a food product is adversely affected through the addition of a foreign or an inferior substance and the removal of a vital element, such as fat from milks and the addition of water to it. Adulteration of food may endanger health due to either addition of a deleterious substance or removal of a vital component. Adulteration may be intentional or unintentional. The intentional adulteration is a willful act intended to increase the margin of profit while the incidental contamination is usually due to ignorance, negligence or lack of proper checking facilities. Adulteration of food stuffs is commonly practiced in India as the consumers like to get maximum quantity for as low a price as possible. When the price of the food product is higher than the price, which the consumer is prepared to pay, seller is compelled to supply a food product of inferior quality, thus adulteration done.

12.11.1 Types of Adulterants

i) Intentional adulterants	*Substances added to food are:* sand, marble chips, stones, mud, other filth, talc, chalk powder, water, mineral oil, harmful colours.
ii) Incidental adulterants	They are pesticide residues, tin from can, droppings of rodent's larvae in foods.

We are eating foods daily laced with some toxic pesticides. Even the rodents and insects introduce into the food a high degree of filth in the form of excreta, bodily secretions and microorganisms responsible for food spoilage as well as its intoxication. The incidental poisoning can be prevented by the following:

- Regular 'market basket' surveys to warn people of dangerous build-up of toxins in food.
- Stepping up the integrated pest management programme to educate farmers about the judicious use of pesticides. No spraying should be done a week before harvest.
- Promoting the control of pests using their natural predators.
- Preventing industries from dumping poisonous effluents.
- Considering health costs while deciding pesticide policy.
- Use of safer pesticides like synthetic pyrethroides or malathion.
- Thorough washing of foods to get rid of much of toxins.

12.11.2 Detection of Food Adulteration

Few important food adulterants and simple tests to detect adulteration of foods

Substance	Adulterant	Tests
1	2	3
Tur dal	*Lakh* dal or metanil	1. *Lakh dal is* irregular in shape and of lighter, colour than turdal 2. Add concentrated HCI to moisten dal. Yellow colour Will turn into magenta red if metanil yellow is present.

Dals	Kesari dal Clay, stones, gravels Lead chromate (yellow)	Add 50 ml of dilute HCI to dal and keep on simmering water for about 15 min. The development of pink colour indicates the presence of kesari dal. Visual examination detects these adulterants. Shake 5 g of dal with 5 ml of water and add a few drops of HCI. A pink colour shows the presence of colour.
Bajra	Fungus	Immerse in saline water, fungi will come on top
Wheat, bajra and other food grains	Ergot (a fungus containing a poisonous substance) Dhatura seeds	a) Longer size purple black grains in bajra show the presence of ergots. b) Put some grains in a glass containing 20% salt solution. Ergot floats over the surface, while sound grains settle down. Dhatura seeds resemble chilly seeds with blackish brown colour which can be separated out by close examination
Tea leaves	Exhausted tea or black or bengal gram dal husk with colour	a) Tea leaves sprinkled on wet filter paper would immediately release added colour b) Spread the little slaked lime on white porcelain tile or glass plate. Sprinkling a little tea dust on the lime will show the presence of coal tar dye. In the case of genuine tea, there will be only a slight greenish yellow colour due to chlorophyll which appears after sometime.
Mustard seeds	Argemone seeds	Agremone seeds have no round structure, they are pointed and are mere blackish than mustard seeds.
Chilli powder	Saw-dust and red colour	Sprinkle on the surface of water. Saw-dust floats. Added colour will colour the water.
Edible oils	Argemone oil Mineral oil	Add concentrated nitric acid to the sample and shake carefully. Red to reddish brown colour in acid layer would indicate the presence of argemone oil. Take 2 ml of edible oil and add equal quantity of N/2 alcoholic potash. Heat in boiling water bath for 15 min and add 10 ml of water. Any turbidity shows the presence of mineral oil.

	Castor oil	Dissolve some oil in petroleum ether in a test tube and cool in ice salt mixture. Presence of turbidity within 5 min indicates the presence of castor oil.
Turmeric	Coloured saw dust, metanil yellow Starch	Take a teaspoon full of turmeric powder in a test tube. Add a few drops of concentrated HCI. There is instant appearance of violet colour which disappears on dilution with water. If the metanil yellow colour persists (an artificial dye) the presence of non- permitted coal tar is indicated. Add iodine solution to turmeric solution, it will turn violet if starch is present.
Coriander	Horse dung powder	Soak in water. Horse dung will float which can be easily detected.
Ghee or Butter	Vanaspati Mashed potatoes, sweet potato and other starches.	Take about one teaspoonful of melted ghee or butter with equal quantity of concentrated HCI in a test tube and add to it a pinch of cane sugar. Shake well for one minute and observe it after 5 min. Appearance of crimson colour in lower (acidic) layer shows the presence of ‘vanaspati’. The presence of mashed potatoes and sweet potatoes in a sample of butter can easily be detected by adding a drop of tincture of iodine. The appearance of blue colour indicates the presence of mashed potato, sweet potato or other starches.
Black pepper	Dried seeds of papaya fruit Light berries	Papaya seeds can be separated out from pepper as they are shrunken, oval in shape and greenish brown or brownish black in colour. The suspected papaya seed in black pepper sample is distinguishable by its characteristic repulsive flavour quite distinct from the bite of black pepper. Light berries float on spirit.
Rice	Marble or other stones	Place a small quantity of rice on the palm of the hand and gradually immerse the same in water. The stone chips will sink.

Wheat flour (maida)	Atta from which maida suji has been extracted	When dough is prepared from resultant wheat flour, more water has to be used and chapattis prepared out of this will blow out. The normal taste of chapattis prepared out of wheat is somewhat sweetish whereas those prepared out of adulterated wheat flour will taste insipid.

12.11.3 Prevention of Food Adulteration

To safeguard the interest of the consumer, it is necessary to have a check and control over the quality of food marketed for human consumption.

In India "Prevention of Food Adulteration Act" was promulgated by the Government in 1954 and the Rules under this act were made in 1955. The act was intended to make provisions for the prevention of adulteration in food. The act empowers the government agencies to prevent this unsocial activity and safeguard the health of the people. The implementation of the Act/Rules is done at State/Union territory level whereas the Central Government may give such directions it may deem necessary regarding execution of the provisions in the Act/Rules. For this purpose, the 'Central Committee for Food Standards' was constituted with (a) members representing concerned ministries, (b) representatives of consumers, medical professionals, agricultural, commercial and industrial organizations and hotel industry, (c) representatives of State/Union territories and (d) Directors of the Central Food Laboratories and (e) Director General of Health Services. Four Central Food Laboratories and a number of state level laboratories were established for analysis of samples collected by the state level food inspectors.

Standards under PFA Act and Rules: The standards laid down under the PFA Act and Rules are minimum standards of purity and are based on the agricultural practices, climatic conditions prevailing, and economic conditions and nutritional status of the people in the country

The standards are mandatory in nature and by government laws food articles which do not conform to the standards are considered unfit for human consumption. The Act and Rules deal with preservatives, poisonous metals, naturally occurring toxic substances, anti-oxidants, emulsifying and stabilizing agents, flavouring agents, colouring matter and other food additives, insecticides and pesticides, solvent extracted oils and edible flours, non-alcoholic beverages, starchy foods, spices and condiments and their mixes, honey, jaggery, saccharin, coffee, tea and milk, milk products, edible oils, cereals, baked products, sweets and confectionary and a range of similar products. The Act and Rules deal with the administrative procedures to be followed for reporting, analysis, prosecution, presentation of cases in a court of law and punishment to be carried out.

The adulterated food articles are defined under the Act.

12.11.4 Prevention of Food Adulteration Tips to Consumer

Despite the advantages of modern technology, illness due to adulterated/ contaminated food is one of the leading causes of sickness or death. Food-borne diseases range from acute gastroenteritis to precancerous/cancerous stage. Consumers are therefore offered tips in ascertaining quality of food by quick and simple tests for detection of common adulterants in food.

- Read label before purchasing.
- Purchase food articles from licensed vendors and insist on Bill or Cash Memo.
- Prefer foods sold in packed containers even if the cost is higher.
- Prefer foods certified by Govt. agencies like Agmark, ISI certification mark and FPO
- Avoid coloured foods especially sweetmeats or sharbats or ice candy.
- Buy foods from reputed firms.
- Do not buy cut or exposed fruits or vegetables.
- Do not use containers or packages used for insecticide chemicals or non-edible items.

12.12 LET US SUM UP

Quality of food is a combination of attributes, properties or characteristics that give a commodity value in terms of human food. The important components of quality are: appearance, texture or firmness, flavour, colour, purity and nutritional quality. Food plays a very significant role in human nutrition especially as source of carbohydrate, protein, fats, vitamins, minerals and dietary fibre. Lipid oxidation and non-enzymatic browning in fruits and vegetable are two major chemical characteristics, which affect the quality of food during processing and storage. The microbiological characteristics are associated with the presence of bacteria, yeasts and moulds on foods resulting in deterioration of quality.

Different quality standards are formulated and enforced by Government of India to ensure food quality and safety for human consumption. The quality evaluation of fruits, vegetables, other foods and processed products gives useful information on nutritional and biochemical characteristics and can be determined by destructive or non-destructive methods. These include both objective such as physical, chemical, or microbiological methods and subjective such as taste. Food adulteration is defined as the process by which the quality or the nature of a food product is adversely affected through the addition of a foreign or an inferior substance and the removal of a vital element. Adulteration may be intentional or unintentional. In India "Prevention of Food Adulteration Act" was promulgated by the Government to make provisions for the prevention of adulteration in food by law.

The fruits, vegetables and other foods are graded according to size, shape, weight, colour and visible defects to obtain uniform quality which is done by hand or machines. Automatic grading machines are available. Grading for colour, an electronic colour-sensing device is used. To ensures quality and purity, Government of India, has established Agricultural Produce Grading and Marketing Act (Agmark), and Indian Standard Institute to make grades of foods, vegetables and fruits & they are affixing the Agmark & ISI quality mark respectively on the products. The Bureau of Indian Standards, (BIS) Act, operates a product certification scheme, including Food and Agriculture. The certification allows the licensees to use the ISI Mark, which insure quality of products. The BIS certification is voluntary, and aims at providing quality, safety and dependability to the customer. All BIS certifications are carried out on Indian Standards, which have been found amenable to product certification.

12.13 KEY WORDS

Quality	:	It is a measure of the degree of excellence or degree of acceptability by the consumer.
Appearance	:	It include size, shape, colour, gloss and other visible defects of foods.
Texture	:	It include softness, hardness, firmness, juiceness, chewness, mealiness & stickiness, of the food commodity.
Flavour	:	It is a complex of taste and aroma.
Chemical characteristics	:	The lipid oxidation and non enzymatic browning are the chemical reactions of the rancidity and browning of foods respectively.
Microbiological characteristics	:	The microbiological characteristics are associated with the presence of bacteria, yeasts and moulds on foods resulting in deterioration of quality attributes
Quality standards	:	They are something that is set up and established by the authority for measuring quality.
Quality evaluation	:	The quality evaluation gives information on nutritional and biochemical characteristics of foods and determined by destructive or non-

destructive methods which can be objective or subjective.

Adulteration : Food adulteration is the process by which the quality or the nature of a food product is adversely affected by the addition of a foreign or an inferior substance.

Grading : The food products are graded according to size, shape, weight, colour and visible defects to obtain uniform quality.

Certification : The certification allows the licensees to use the quality Mark to insure quality of products and certification may be voluntary or mandatory.

Hygiene : It involves all measures to ensure the safety, soundness and wholesomeness of food at all stages of production and processing.

12.14 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:
   - Quality is combination of attributes, properties or characteristics that give a commodity value in term of human food.
   - Quality is overall, consumer's satisfaction and value worth.
   - Appearance, firmness, flavour, colour, purity, nutritional quality:
2. Your answer should include the following points:
   - Physical characteristics.
   - Chemical characteristics.
   - Nutritional characteristics.
3. Your answer should include the following points:
   - Lipid of oxidation.
   - Non-enzymatic browning.
   - Rancidity.
   - Maillard reaction.
4. Your answer should include the following points:
   - Mildew
   - Brown rot
   - Soft rot
   - Black rot
   - Green rot
   - Mould rot
   - Souring

Check Your Progress Exercise 2

1. Your answer should include the following points:
   - Different standards for ensuring the quality and safety of foods for human consumption have been formulated and enforced by law in India.
   - Legal standards.
   - Company standards.
   - Industry standards.
   - Consumer or grade standards.
2. Your answer should include the following points:
   - Intentional adulterants.
   - Incidental adulterants.
   - Prevention of Food Adulteration Act 1955.
3. Your answer should include the following points:
   - Derivative of Agricultural Marketing.
   - Agricultural Produce Act, 1937.
   - AGMARK products are free from adulteration.
4. Your answer should include the following points:
   - Uniform quality and fetch good price.
   - The grades are1, 2, 3, & 4.
   - Special, good, fair and ordinary grades.
   - Super, fancy & commercially grades.
   - BIS Act.
   - ISI mark.
5. Your answer should include the following points:
   - Physical, Chemical and Microbiological methods.
   - Objective and subjective methods.
   - Non-destructive methods.

UNIT 13 DETERIORATIVE FACTORS AND THEIR CONTROL

Structure

13.0 OBJECTIVES

After reading this unit, you should be able to:

- know shelf life and dating of food;
- explain causes of food deterioration;
- know nutritional changes in food;
- describe food borne diseases;
- know food allergies and anti-microbial agents used in food;
- explain enzyme inactivation;
- describe different treatments to keep the food safe; and
- know hygiene and sanitation.

13.1 INTRODUCTION

Deterioration of food can be defined as any decay due to physical or chemical means or undesirable decomposition of constituents by excessive growth of microorganism. Food deterioration is manifested by the reduction in aroma, flavour, textural and nutritional values of foods. In extreme cases, the foods become totally unpalatable and is unfit for human consumption. Some microorganisms are also known to release toxins that may cause damage to health.

13.2 SHELF LIFE AND DATING OF FOODS

All foods have a time of the usefulness i.e. a time limit during which they can be consumed. Shelf life is the time required for a food product to reach to an unacceptable quality. The length of the shelf life of foods will depend on the type of food, processing method, packaging, and storage conditions. It is a practice to add some form of dating system to retail packages of foods so that consumers may have some indication of the shelf life or freshness of the products they buy. Food manufacturers put code dated on their products. The dates of manufacture ("pack date"). The date the product was displayed ("display date"), the date by which the product should be sold ("sell by date"), the last date of maximal quality ("best used by date"), and the date beyond which the product is no longer acceptable ("use by date" or expiry date").

One recent system for monitoring shelf life uses labels or tags on foods that respond to a combination of time and temperature to which the product has been exposed. These are called "time-temperature" indicators and are based on the principle that both time and temperature are important in the spoilage of foods.

13.3 CAUSES OF FOOD DETERIORATION

The major factors affecting food deterioration are: (1) growth and activities of microorganisms, principally bacteria, yeast, and moulds; (2) activities of food enzymes and other chemical reactions within food itself; (3) infestation by insects, parasites, and rodents; (4) inappropriate temperatures; (5) gain or loss of moisture; (6) oxygen (7) light (8) physical stress and (9) time.

These factors can be divided into biological, chemical and physical factors and often they do not operate in isolation. Bacteria, insects, and light, for example, can all be operating simultaneously to spoil food in the field or in a warehouse. Similarly, heat, moisture, and air simultaneously affect the multiplication and activities of bacteria and chemical activities of food enzymes. At any time, many forms of deterioration may take place, depending on the food and environmental conditions. The major types of spoilage of foods are microbiological, biochemical, physical and chemical.

13.3.1 Chemical Reactions

Chemical reactions take place in the presence of atmospheric oxygen and sunlight. Two major chemical changes, which occur during the processing, and storage of fruits and vegetables are lipid oxidation and non-enzymatic browning which deteriorate sensory quality, colour and flavour.

Lipid oxidation is influenced by light, local oxygen concentration, high temperature and the presence of iron and copper, and water activity. Control of these factors can significantly reduce the extent of lipid oxidation or rancidity in foods.

Non-enzymatic browning is one of the major causes of deterioration which takes place during frying, cooking, storage of dried and concentrated foods through Maillard reaction between reducing sugars and amino acids present in the foods and formed black brown insoluble pigments.

13.3.2 Biochemical Reactions

Different biochemical reactions in foods and plants tissues are catalysed by enzymes. They are responsible for certain undesirable or desirable changes in fruits, vegetables and other foods. Examples involving endogenous enzymes include: (a) the post-harvest senescence and spoilage of fruit and vegetables; (b) oxidation of phenols in plant tissues by phenolases leading to enzymic browning; (c) sugar – starch conversion in plant tissues by amylases; (d) post-harvest demethylation of pectic substances in plant tissues (leading to softening of plant tissues during ripening, and firming of plant tissues during processing).

Factors responsible for controlling enzymatic activities are: temperature, water activity, pH, chemicals which can inhibit or enhance enzyme activity.

Enzymatic spoilage is the greatest cause of food deterioration. If enzymatic reactions are uncontrolled, the off-odours, and off-colours may develop in foods. In fruit and vegetables, enzyme-induced oxidative breakdown of unsaturated fatty acids occurs extensively which, give characteristic aromas during ripening of fruits. Enzymatic browning take place in apples and potatoes during cutting and peeling and exposed to air, due to the oxidation of phenols by peroxidase and polyphenoloxidase.

Certain changes are produced by enzymes of foods and micro-organisms that contaminate the food. Ripening of banana is due to the enzymes present but after some time the fruit becomes too soft by microorganism enzymes and become unfit to eat. Enzymes convert starch into sugars, proteins into amino acids, and pectin into pectic acids and this change the constituents of food. Enzymes can act between 0^0 and 60^0C but 37^0C is optimum temperature. All enzymes are inactivated at 80^0C.

13.3.3 Physico – Chemical Reaction

Physico-chemical reactions are caused by freezing, burning, drying and bruising of fruits and vegetables during storage, handling and transportation, which result in food deteriorations.

Food processing or storage causes some deterioration in colour of fruits and vegetables due to the degradation of the chlorophyll resulting dull olive-brown colour. Dehydrated green peas and beans packed in glass containers undergo photo-oxidation and loss of desirable colour.

In addition to chlorophyll, anthocyanins and carotenoids also give colour to fresh and processed foods. Anthocyanins form complexes with metals which results in change in the colour of the pigment. Red sour cherries react with tin and form undesirable purple complex. Carotenoid degradation occurs in foods by oxidation in the presence oxygen, light and heat.

One major undesirable physical change in dried food powders is the absorption of moisture, which results in caking. In general, moisture absorption is associated with increased cohesiveness. Caking does not occur at water activities of less than about 0.4 at ambient temperature.

13.3.4 Microorganism: General Principles, Causes and Growth

Most significant deteriorative changes occur in foods due to microorganisms present in air, soil, water, on fruits, vegetables and foods. They are so small that they can only be seen through microscope. There are three types of microorganisms which cause spoilage: (1) Bacteria, (2) Yeasts (3) Moulds.

Bacteria

Bacteria are minute unicellular microorganisms. The growth of bacteria depends upon food , temperature, pH, moisture and oxygen. Bacteria are much more difficult to kill and are the most common causes of food spoilage. They are present in active form (vegetative stage) or resting form (spore stage). In vegetative stage, bacteria are destroyed at boiling temperature but spores require application of heat (100^0C) for a long time (six hours) or 30 min at 121^0C under 10 lbs pressure.

All forms of bacteria are sensitive to acids and can be killed easily in acidic pH at a temperature of boiling water. So foods with high acid content (all fruits, tomatoes, pickles etc.) are processed at 100^0C whereas low acid foods such as corn, peas, beans and all vegetables except tomatoes have to be processed at higher temperature (116^0C) in a steam pressure to kill bacteria. The temperature maintained and the length of time, the food is held vary with kind of foods. Moist heat resistant bacteria are present in the soil, hence, preparation and processing of root vegetables require special care. *Clostridium botulinum* causes spoilage in canned foods.

Bacteria enter through stomata and lenticels. The most common bacteria causing significant reductions in shelf life of fruits and vegetables is the soft rotting species of the genus *Erwinia*. Under suitable conditions they produce large quantities of extracellular enzymes which rapidly macerate the tissue which gives unpleasant off-odours

Most of the pathogens of fruits and vegetables will grow between 6 and 35^0C. Some (*B. cinerea)* will survive and even grow at low temperatures, 1^0C, on agricultural produce, whereas *Botryodiplodia theobromae* or *Aspergillus niger* cause losses in warm regions.

Each kind of bacteria has a definite range of food requirements. Level of moisture in food is important in preventing or allowing the bacterial growth in the food. Bacteria require more moisture than yeasts or moulds. Each bacteria has an optimal temperature at which it grows best. Temperature below and above the optimum adversely affects the growth of bacteria. pH determines the kind of bacteria that well grow on the food. Most bacteria grow best at neutral, pH, however, some bacteria also grow in acid or alkaline media.

On the basis of respiration bacteria are classified as:

- **Aerobic** : They require free oxygen for growth.
- **Anaerobic** : Do not require free oxygen for growth.
- **Facultative** : Grow either with or without free oxygen.

Yeasts

Fungi usually known as yeast are microscopic unicellular organisms, which are non-motile round or oval. Yeasts reproduce or multiply by a process of "budding". The bud when fully mature, breaks away from the mother cell and becomes independent and repeats the process of multiplication. Yeasts require less moisture and acidic pH to grow and do not grow in alkaline medium. Yeasts grow under moderate temperature (25-30 C) in solution containing sugar. Most of the yeasts usually do not grow in media containing more than 65% of sugar or 0.5% acetic acid. Heating at 60 ^{0}C for a few minutes is sufficient to destroy most species of yeasts. Boiling destroys yeast cells and spores effectively. Some yeast grow well in light sugar solution and acidic medium. Some yeasts are very useful in making bread, beer, wine, vinegar and many other fermented products. Yeasts are responsible for fermentation of fruits and fruit products. Yeasts are undesirable when they grow on fruits, juices, squashes, *sharbat*, honey etc. They spoil the appearance, taste, texture and wholesomeness of fruits and fruit products. During active fermentation, yeast can be recognized by formation of bubbles or foam on the surface of the product. Some of yeasts which grow on fruits are *Saccharomyces, Candida,* etc.

Moulds

Moulds are larger and more complex in structure than bacteria or yeast. Moulds are made up of mycelium and spores. They grow in a network of hair like fibres called mycelia and send up fruiting bodies that yield spores. A piece of orange left for a time becomes covered with a whitish or grayish cottony matter

They thrive best in closed, damp and dark situation and require adequate supply of warmth, moisture and air for growth. They are aerobic in nature and require less available moisture and can grow well at 25-30 C. Moulds prefer sugar containing substances like jam, jelly, preserves and other sweet based products. They can grow at wide range of pH (2 to 8.5) but majority grow well at acidic pH. Therefore, they grow nicely on pickles, juices etc. They can grow on many kind of foods especially when temperature, air and humidity are favourable. Their growth can be seen only on the surface of food. They not only consume nutrients present in food thereby lowering the food value but also produce odd by-products, which spoil the flavour, taste and texture of food hence change the quality contents of the entire products.

Majority of moulds are sensitive to heat and are destroyed at 60 C when heated for 30 minutes. Boiling quickly destroys both moulds and their spores. Some of common moulds are *Aspergillus Penicillium*, *Rhizopus* and *Heliminthosporium*.

Insect and Pests, Rodents

The main categories of foods subjects to insects and pest attack are fruits, vegetables, grains and their processed products, and dried fruits. The presence of insects and pests and their excreta in foods may render products consumable loss, in nutritional quality, production of off-flavours and acceleration of decay processes due to creation of higher temperatures and moisture levels and release of enzymes. The products of insect and pests activities such as webbing, clumped-together food particles and holes can also reduce the food values.

Warm humid environment promote insect growth, although most insects will not breed if the temperature exceeds about 35 C^0 or falls below 10 C^0. Many insects cannot reproduce satisfactorily unless the moisture content of their food is greater than 11%.

Rats and mice carry disease-producing organisms on their feet and/or in their feces and are known to harbour *Salmonella* associated with food-borne disease in humans. Rodents contaminate the food through defecation, urination or when walk over food or food contact surfaces. These animals also destroy intensively human's foods. Rats and mice gnaw to reach sources of food and drink and to keep their teeth short. Their incisor teeth are so strong that rats have been known to gnaw through lead pipes and unhardened concrete, as well as sacks, wood and flexible packaging materials.

13.4 NUTRITIONAL CHANGES IN FOOD QUALITY

The four major factors, which bring nutritional changes in food quality, are light, oxygen, temperature and water activity. However, because of the diverse nature of the various nutrients as well as the chemical heterogeneity within each class of compounds and the complex interactions of the above variables, generalizations about nutrient degradation can not be made.

The major nutritional changes which occurred in foods are due to microbiological, enzymatic and chemical reactions.

Microbiological

- Growth or presence of toxicogenic and/or infective microorganisms.
- Growth of spoilage microorganism.

Enzymatic

- Hydrolytic reactions catalyzed by lipases, proteases, etc.
- Lipoxygenase activity.
- Enzymatic browning.

Chemical

- Oxidative rancidity.
- Oxidative and reductive discolouration.
- Non-enzymatic browning.
- Nutrient losses.

Physical

- Mass transfer, movement of low molecular weight components.
- Loss of crisp texture.
- Loss of flavours.
- Freeze-induced damaged.

One of the principal responsibilities of the food scientist is to preserve nutrients through all phases of food acquisition, processing, storage, and preparation. The key to doing this is a knowledge of the stability of nutrients under different conditions. Vitamin A is highly sensitive (i.e., unstable) to acid, air, light, and heat; on the other hand, vitamin C is stable in acid but is sensitive to alkalinity, air, light, and heat. Because of the instability of nutrients under various conditions and their water solubility, cooking losses of some essential nutrients may be greater than 75%. In modern food processing operations, however, losses seldom exceed 25%.

13.5 FOOD-BORNE DISEASE

Food-borne diseases cause food deterioration that may or may not alter a food's organoleptic properties but cause illness and disease to human beings after consumption. Food-borne diseases are classified as food infections or food intoxications. Food infections involve microorganisms present in the food at the time of consumption which then grow in the host and cause illness and disease. Food intoxications involve toxic substances produced in foods by microorganisms prior to consumption and cause disease upon ingestion. The toxin producer microorganisms need not to grow in the host to produce a disease or even be present in the food.

Staphylococcus aureus and *Clostridium botulinum* produce bacterial food poisoning by intoxication through the production of specific bacterial toxins. The toxin produced by *C. botulinum* is one of the most potent toxic substances known. Many bacteria can transmit food-borne infections capable of causing human disease. These include *Clostridium perfringens*, numerous members of the genus *Salmonella*, *Shigella dysenteriae, Vibrio parahaemolyticus, Streptococcus pyogens, Bacillus cereus, Campylobacter jejuni,* and other. A number of viral infection may also be contracted by man through contaminated food that has not been adequately processed or handled, including infectious hepatitis, poliomyelitis, and various respiratory and intestinal disorders. Over the last decade or so, several bacteria that had not been thought to be transmitted by food and cause human disease have found to do just that. Chief among these "newer" pathogens are *Aeromonas hydrophila*, *Yersinia enterocolitica*, *Listeria monocytogenes*, *Vibrio parahaemolyticus* and a particular type of *Escherichia coli* called 0157: H7 of particular importance is the recent discovery that some food-borne pathogenic bacteria can multiply at temperatures as low as 3.3^{0}C. This means that temperatures, which have been considered good for refrigerated storage, may not always keep food becoming a hazard.

Certain moulds produce mycotoxins, the best known being the aflatoxins by *Aspergillus flavus.* Aflatoxins are toxic to man and domestic animals. However, their carcinogenic properties are cause for much concern since aflatoxins can be produced in a wide range of cereals, legumes, nuts, and other products allowed to become mouldy. When such products occur in feeds, aflatoxins may subsequently be detected in the milk products of animals consuming the feed that is ultimately consumed by humans.

13.6 FOOD ALLERGIES

Food allergy may be defined as normal tissue reaction that may occur in some individuals after consuming a particular food or group of foods. Food allergens consists mostly of proteins, though some other chemical compounds present in foods may also produce allergic reaction.

Since the allergen is carried through all parts of the body, the allergies manifestations are many and varied. The skin and mucous membranes are particularly sensitive to the allergen. The sign and symptoms of allergy may include (i) Skin lesions, rash and eczema; (ii) Nausea, vomiting, diarrhoea and colitis; (iii) Headache, cold and asthma, and (iv) Redness, swelling, burning and itching of the eyes and irritation of the nasal mucous membrane. The allergy associated with consumption of orange and tomato juices is apparently due to traces of proteins present in the juice or to the peel oil.

The allergies are treated by drugs and also different types of diets are used in treatment of allergy (i) Synthetic diets, (ii) Elimination diets, and (iii) Restricted diets. Desensitization of the subject to the allergic food may also be carried out. Currently the only way to treat food allergies is to avoid the food that triggers allergic reactions.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. What is shelf-life and dating of foods?

....

....

....

....

....

....

2. Name the major causes of deterioration.

....

....

....

....

....

....

3. What are nutritional changes in the food quality?

....

....

....

....

....

4. Name the bacterial causal organism of food- borne infections.

13.7 ANTI-MICROBIAL AGENTS USED IN FOOD

Anti-microbial agents are the chemicals which inhibit the growth & development of bacteria, moulds and yeasts. They are weak acids work in the un-ionized form. They are not effective above their pKa values.

The use of anti-microbial agents depend on; **a**nti-microbial activity, pH of the food product, food composition, processing, and storage conditions, solubility, flavor, cost, marketing impact. The details of the most commonly used anti-microbial agents in food preservations are as follow:

13.7.1 Sulphite and Sulphur Dioxide

Sulphur dioxide and its derivatives have been extensively used in foods as a food preservative and anti-microbial agents. They act as an antioxidant, reducing & anti-microbial agents and prevents enzymatic, non-enzymatic reactions and microbial growth respectively. The common used forms are sulphur dioxide and sodium, potassium and calcium salts of sulphite, bisulfite or metabisulphite. The preservative action of sulphur dioxide as an anti-microbial agent in acid media, is due to undissociated compounds. It is like a biocidal and biostatic agent and is more active against bacteria than moulds and yeasts. It is more effective against Gram-negative bacteria.

13.7.2 Nitrite and Nitrate Salts

Nitrates and nitrites salts are inhibitors of toxic bacteria, involved in botulism, and considered as legal preservatives. Under regulations nitrites and nitrates are permitted as preservatives in cured meat and meat products including poultry at levels below 200 ppm. They also stabilize the colour after cooking and impart good flavour of lean meat without this the meat would be greeny brown. The use of nitrates and nitrites in the food industry is now subject to strict control.

13.7.3 Glycerol Esters

Glycerol esters show anti-microbial activity against Gram positive bacteria and yeasts. It is used as surface decontamination agents. It also inhibit *Clostridium botulinum* and widely applied in cured meats and refrigerated packaged fresh fish.

The inhibitory effect of the glyceride is due to the conduction of protons through the cell membrane, which effectively destroys the proton motive force that is needed for substrate transport. Death of cell arises due to the generation of holes in cell membranes.

13.7.4 Epoxides

Epoxides destroy all form of microorganisms, including spores and even viruses, but the mechanism of epoxides is poorly understood. They find applications in treating low moisture foods and to sterilize aseptic packaging materials. They are used in vapour state and after adequate exposure, most of residual unreacted epoxide is removed by flushing and evacuation.

13.7.5 p-Hydroxy Benzoate Alkyl Esters

The p-Hydroxy Benzoate Alkyl Esters (parabens) are widely used as anti-microbial agents in foods and pharmaceutical products particularly in baked foods, soft drinks, olives, pickles, jams and jellies and syrup. They are effective inhibitor of moulds and yeasts (0.5-0.1 %) but ineffective against bacteria, especially gram negative bacteria. In contrast to other *antimycotic* agents, the parabens are active at pH 7.0, and higher as they remain undissociated at these values.

Benzoates, sorbates, hydrogenperoxides, and propionates can also be used as anti-microbial agents.

13.8 ENZYME INACTIVATION

Some enzymes catalyze or initiate undesirable changes in colour, texture, flavour and nutrients of fruits and vegetables during storage and processing (Table 13.1). Inactivations of these enzymes prevent discoloration, improve flavour, soften tissues and loss of nutrients. Inactivation of enzymes is mainly done by blanching. Blanching is a mild treatment which expose plant tissues to steam or hot water, heating at 75-95 C for about 1 to 10 minutes, depending on the product requirements. At high temperature enzymatic proteins are denatured and make the enzymes inactive. If food processors did not blanch vegetables prior to freezing or dehydration, the natural enzymes would remain active even during frozen storage and destroy the product quality with time. Many vegetables which are not properly blanched develop a very noticeable off-odour and off-flavour.

Table 13.1: Enzymes responsible for quality deterioration in fruits and vegetables

Off-flavour development	• Lipoxygenase • Lipase • Protease
Texture changes	• Pectic enzymes • Cellulase
Colour changes	• Polyphenol oxidase • Chlorophyllase • Peroxidase (lesser extent) • Lipoxygenase*
Nutritional changes	• Ascorbic acid oxidase • Thiaminase

*hydroperoxides and radicals formed by lipid oxidation may destroy chlorophyll and carotenoids

In order to prevent undesirable changes in fruit texture, colour and flavour chemicals are used to inactivate enzymes as antioxidants. The inactivation of peroxidase is an indicator of effectiveness of blanching, and one could assume that all quality affecting enzymes had been destroyed.

13.9 TREATMENTS

The different treatments to prevent deterioration or spoilage of food should be performed so that it can be stored or preserved in fit conditions for future use. The classification of treatments of reducing deterioration is difficult because they do not act in isolation but take place together or one after the other. However the preservation procedures have two main characteristics:

- some of them are applied only to one or some categories of foods; others can be used across the board and thus a wider application (cold storage, freezing, drying/dehydration, sterilization, etc.);
- some guarantee food preservation on their own while others require combination with other procedures, either as principal or as auxiliary processes in order to assure preservation (for example smoking has to be preceded by salting).

13.9.1 Physical

It is better if the following physical treatments are kept in mind to control the spoilage.

- Heating,
- Cooling,
- Lowering of water content,
- Drying/dehydration,
- Concentration,
- Irradiation,

- Other physical means (high pressure, vacuum, inert gases),
- Salting.

13.9.2 Thermal

Heat or thermal processing includes heating and cooking, required to eliminate the potential of food borne illness. The simple act of cooking, frying, boiling or simply heating food prior to consumption are forms of food preservation. Cooked food itself can be held for several days provided it is protected from recontamination. Various methods in thermal processing include blanching, pasteurization and sterilization.

Blanching: Dipping of fruits & vegetables in boiling water or steam at temperatures around 75-95^{0}C for about 1 to 10 min, depending on the product requirements to inactivate enzymatic and biological activities. It is a necessary pre-treatment to achieve satisfactory quality in dehydrated, canned and frozen products. The process is required for reduction in enzyme activity otherwise undesirable changes in odour, flavour, colour, texture and nutritive value will occur during storage. It also helps in removal of intercellular gases to reduce the oxidative changes in food. Blanching may also result in some reduction in the microbial load and the texture may be improved.

Pasteurization: The food is heated to a temperature around 60 to 80 ^{0}C depending upon food product. The normal range is 65-75 ^{0}C at which nearly all the enzymes and vegetative microorganisms are inactivated. The heating may be done by steam, hot water, dry heat or electric currents, and then products are cooled promptly. Pasteurization does not kill all the microorganisms present in fruit juices. Some spores and spore forming bacteria like *Bacillus subtilis* can survive and multiply later.

Sterilization: Sterilization involves the use of heat at a temperature of 121°C (wet heat) for 15 min or longer to ensure total destruction of microorganisms including spores. The sterilized food must be placed in a container to prevent the entry of spoilage organisms. This is generally done with steam under pressure, as in a autoclave or commercial retort. Commercial pressure retorts operate at temperatures and for time intervals adequate to destroy large numbers of highly resistant bacterial spores within the canned food. Sterilization is not always necessary to kill all microorganisms but may be employed to destroy disease-producing organisms in the food.

13.9.3 Chemicals

Many chemicals will kill or inhibit the growth of specific microorganisms and prevent the deterioration of foods, but most of these are not permitted. A few that are permitted, in prescribed low levels in certain foods, include sodium chloride, acetic acid, sodium benzoate, sorbic acid, sodium, and calcium propionate, ethyl formate, and sulfur dioxide.

Sodium chloride: Common salt used in high concentration (15-20%) prevents the growth of microorganisms and increase the keeping quality of foods such as pickles. Salt at high concentration dehydrates microbial cells. Salt inhibits enzymatic browning and also acts as an antioxidant. Salt ionizes to yield chloride ions which, are harmful to the organisms and it also sensitizes the cell against carbon dioxide. Effectiveness of salt varies with its concentration and temperature.

Acetic acid: Acidic pH inhibits the growth of many microorganisms. Vinegar or acetic acid has germicidal and antiseptic properties and also checks aerobic and anaerobic fermentation. It is more effective against yeast and bacteria than molds. About 2% acetic acid prevents the spoilage of most products. It is used in preservation of pickles, sauces and chutney.

Citric acid: It is used in preservation of certain fruits and vegetables. It is added to jams, jellies, preserves and squashes. It increases the acidity and prevents mould growth.

Propionates: Sodium or calcium propionate is used most extensively in the prevention of mould growth. These are effective against moulds with little or no inhibition of most yeast and bacteria. Their effectiveness decreases with an increase in pH and optimal pH is 5 to 6, depending upon the food item. These are ideal preservatives for bread and baked foods to prevent contamination of loaves during slicing and/or wrapping.

Benzoic acid and its salt: Sodium benzoate as a salt of benzoic acid is used because it is more soluble than acid. It is benzoic acid molecule, which is germicidal. It is more effective against yeasts than molds. 0.06-0.10% of sodium benzoate preserves most fruit products (pH 3.5-4.0). In the long run, the benzoate may darken the products therefore, it is mostly used in coloured products of tomato, plum, watermelon, *jamun,* pomegranate and coloured grapes.

Sulphurous acid and its salts: Mostly potassium or sodium metabisulphite is used and gives characteristic sulpher dioxide smell. Sulphur dioxide retards oxidation, prevents discolouration or loss of flavour and vitamin C. It acts as a better preservative against bacterial fermentation and molds. It prevents enzymatic darkening of cut and peeled fruits and vegetables. But it cannot be used in products stored in tin cans because it causes pin holes in metals and forms incrustation of tin sulphide.

In dehydration of fruits and vegetables, burning of sulphur at levels 1000-3000 ppm preserves colour, as well as vitamin C, repels insects and destroys organisms. It bleaches colour of pigments and its use is restricted to products of fruit like mango, litchi, lime, orange, lemon, guava, etc.

Sorbic acid: It is an organic acid having anti-microbial properties and prevents moulds in preserves. The effectiveness of sorbic acid increases in acid media ($pH < 6.0$) and inhibit moulds, yeasts and some bacteria.

The sodium and potassium salts of sorbic acid are used as fungistatic agents for foods especially on surface and in wrapping materials. These are also used for the preservation of cheese, sweet pickles, etc. for the control of lactic acid fermentation.

Antibiotics: An antibiotic is a chemical produced by microorganism which, inhibit growth or destroy microorganisms. Antibiotics, subtelin and nisin are produced by *Bacillus subtilis and Streptococcus lactis* respectively and used to preserve asparagus, corn , peas, mushrooms, tomatoes and milk. They are more commonly used in canning of processed products and effectively reduce the thermal process requirements necessary to control the spoilage food products.

Chemicals preservations: Antioxidants, butylated hydroxy toluene (BHT) and butylated hydroxyanisole (BHA) are used as food preservative and they inhibit, retard or arrest the growth of microorganisms.

13.9.4 High Pressure Technology

High-pressure technology (HPT) is a new non-thermal process for preservation of fruits and vegetables. This technology is a combination of a high pressure, temperature and time. The process subjects food products to pressures between 50 and 700+ Mpa. High pressures kill microorganisms and inactivate enzymes without the use of heat that can damage the taste, texture, and nutritional value of the food. The mechanism does not promote the formation of new chemicals, "radiolytic" by-products, or free-radicals. By HPT, colour, nutrients, vitamins, and flavour are unchanged and undegraded. Moisture content of fruits and vegetables is very important because very little effect is obtained below 40%. Texture frequently can also be retained but will depend on the initial structure. The texture of high air content foods will likely be changed by HPT.

HPT is applied for the production of high quality shelf stable low acid foods. When combined with a moderate starting (pre-compression) temperatures of 70 to 95^{0}C, spoilage and pathogenic spores are destroyed within less than 1 to 2 minutes. Factors which are important to HPT are process pressure, process temperature (-20^{0}C to 121^{0}C), water activity, and pH.

Fruit based products such as jams, jellies, purees, sauces, fruit juices are processed in HPT at varying pressures 50-700 Mpa, temperature 5-20^{0}C and duration of 2-30 minutes and it improve gelation, faster sugar penetration and reduce the loss of flavour, texture, colour and aroma and nutrients. Inactivate pectinmethlylesterase, polypenoloxidase, peroxidase and lipoxygenase and pathogenic microorganism activity also. Other advantages include: reduced process times, minimal heat damage problems, retention of freshness, flavour, texture and colour and no loss of vitamin C

13.9.5 Cooling

Cooling means storage temperature above freezing and it ranges from 16C to –2.2 C. Cooling will preserve perishable fruits and vegetable for days or weeks depending upon the nature of the food by retarding microbial growth and enzyme reactions at low temperatures. The lower the temperature, the greater the retardation. Various types of cool storage are available.

Cool storage: The temperature in cool rooms where surplus food is stored is usually around 15C. Enzymatic & microbial changes in the foods are not prevented but slowed down considerably. Root crops, potatoes, onions, apples and similar foods can be stored for limited periods.

Cold store or chilling (0 to 5^{0}C): Chilling temperatures are obtained by mechanical refrigeration. Fruits, vegetables and their products can be preserved for a few days to many weeks. The best storage temperature for many foods is slightly above 0^{0}C but this varies with the product. Besides temperature, the relative humidity can affect the preservation of the food. Commercial cold storages (temp.2-5^{0}C; R.H 90-100%) with automatic control of temperature are used for storage of semi-perishable foods such as potatoes and apples and made their availability throughout the year. The growth of bacteria, yeasts, and moulds, and rate of all chemical reactions is slow at or below 10^{0}C, and becomes slower the colder it gets.

13.9.6 Freezing

At temperature below the freezing point of water (–18 to –40^{0}C), growth of microorganisms and enzyme activity are reduced to minimum. Most perishable foods can be preserved for several months if the temperature is brought down quickly and the food is kept at these temperatures. Foods can be quickly frozen in about 90 minutes or less. Quick frozen foods maintain their quality and freshness when they are thawed. Frozen foods should, always be kept at temperatures, below –5^{0}C. Properly frozen (–12 to –17C^0 by excluding air), juice retains its freshness, colour and aroma for a long time.

13.9.7 Microwave

Microwave energy produces heat in materials that absorb and heat foods in a unique fashion that largely eliminate temperature gradients between the surface and centre of food masses. Foods do not heat from the outside to the inside as with conventional heating since microwave penetration can generate heat throughout the food mass simultaneously. The microwaves can result in very rapid heating but requires special equipment, packaging materials, since microwaves will not pass through metal cans or metal foils. Microwave heating produce major differences in food appearance and other properties compared to conventional heating and reduces process time by 90%. Microwave heating increases the temperature of the interior water parts of the solid and has the following advantages: (1) A penetrating quality that leads to uniform drying. (2) Selective absorption by liquid water, which leads to uniform moisture profile within the particle. (3) Ease to control due to rapid response of such heating.

13.9.8 IQF (Individual Quick Freezing)

IQF generally refers to freezing of solid food/pieces/grains like green peas, cut beans, cauliflower pieces, meat, fish etc. While quick freezing relates mostly to liquid, pulpy or semi liquid products like fruit juices, mango/papaya concentrate and purees etc. There is no clumping together of pieces or grains. They remain individual separate pieces. Individual quick freezing have advantages:

- Smaller ice crystals are formed, hence, there is less mechanical destruction of intact cells of the food.
- More rapid prevention of microbial growth.
- More rapid slowing down of enzymatic action.

13.9.9 Ohmic Heating

Ohmic heating, has the advantage that a product containing liquid, solid, or solid-liquid mixtures can, be heated rapidly with a uniform thermal profile. This ensures significant quality retention in comparison to conventional thermal processing, where heat transfer to the interior resulting in significant quality loss. Ohmic heating eliminate bacterial spores. In ohmic heating, the food should possess at least a slight electrical conductivity. Since fats and oils do not conduct electricity, ohmic heating cannot be used in these products.

In transit, ohmic heating could be used to heat the food. The system is light weight, requires minimum space and an electrical power supply, and food packages that can be accommodated between electrodes. It is also suited to the available energy sources (electricity) in transit. This technology is used for simple heating of foods particularly which consists of particles suspended in liquids such as soups.

13.9.10 Drying and Dehydration

Both the terms "drying" and "dehydration" mean the removal of water. Drying is generally done under the influence of non-conventional energy sources like sun and wind. In sun drying, there is no temperature and humidity control. The hottest days are chosen so that the foods dry very fast, thus, preventing from getting spoiled due to souring. Quick removal of the moisture prevents the growth of the microorganisms. Dehydration means the removal of moisture by the application of artificial heat under controlled conditions temperature, humidity and airflow. In this process a single layer of fruit or vegetable, whole or slices is spread on trays, placed inside the dehydrator. The initial temperature of the dehydrator is usually 43°C which is gradually increased to 60-71 °C. Drying is economical and very useful process. Most of the foods contain enough moisture, which encourages action by their own enzymes and microorganisms growth.

Food dehydration cause minimum or ideally no other changes in the food properties and dried to final moisture of about 1-5%. Examples are dried milk and eggs, potatoes flakes, instant coffee, and orange juice crystals. Such products will have storage stability at room temperature for a year or longer. A major criterion of the quality of dehydrated foods is that when reconstituted by the addition of water they are virtually indistinguishable from the original food materials used in their preparation.

13.9.11 Irradiation

Irradiation is a non-thermal technology and involves the use of gamma rays, X-rays or electrons, and uses energy levels that assure no induction of radioactivity in the irradiated product. It retards ripening or senescence of raw fruits and vegetables, sprouting of potatoes. Irradiation will increase the shelf life of foods from 2-5 years. The product must be frozen to achieve stability without major off-flavours. A wide range of products can be preserved by irradiation but primarily it is used to preserve meats. Microorganisms are inactivated by different kinds of radiations. X-rays, microwaves, ultraviolet light, and ionizing radiations, differing in wavelength and energy have been used to preserve food. For all types of radiation, the doses required to sterilize foods, and inactivate enzymes, are generally excessive or borderline from the food quality view point, and all may cause flavour, colour, texture, or nutritional defects. Doses less than sterilizing appear more generally useful to extend storage life. Sub-sterilization doses can inactivate enzymes responsible for initiating vegetable sprouting.

Today, foods are irradiated with ionizing radiation, obtained from radioactive isotopes, which does not rise the temperature significantly and called "cold sterilization". Several foods such as spices, vegetables and fruits, and poultry have been approved for irradiation pasteurization at specific doses in India.

13.9.12 Curing

Curing is a formation of multilayered protective periderm on tuber vegetables after harvest when kept in heaps for 15 to 20 days at ambient conditions to prevent bruising during transport and handling, entry of microorganism and excessive loss of moisture. Plant tissues are covered with protective tissues, which serve to protect the plant from excessive water loss. The primary protective layer is the epidermis but if the plant organ undergoes secondary growth, a multilayered periderm may develop, for example, on apples or potatoes. The epidermis is covered with a waxy cuticle of cutin while the cell walls of periderm tissues generally become impregnated with suberin. Both cutin and suberin can reduce water losses from plant surfaces; however some water loss is inevitable.

13.9.13 Smoking

Smoke is used for preserving foods such as meats and fish. The preservative action generally comes from a combination of factors. Smoke contains preservative chemicals such as small amounts of formaldehyde and other materials from the burning of wood. In addition, smoke generally is associated with heat, which helps to kill microorganisms. This heat also tends to dry out the food, which further contributes to preservation. Smoking over a fire may be quite effective in preserving certain foods; on the other hand, today smoke may be added merely to flavour food, that is, without heat from burning. In meat products, smoke combined with other preservatives is used more for its flavour than for its preservative action.

13.10 HYGIENE AND SANITATION

'Hygiene' describes a system of sanitary principles for the preservation of health. Food hygiene is much more than cleanliness, it involves all measures to ensure the safety, soundness and wholesomeness of food at all stages from its production, processing, manufacturing, packaging, storage, distribution, display for sale and consumption. Food hygiene aims for the production, preparation processing and presentation of food, which is safe for consumer and had good keeping quality. It covers not only the proper handling of foodstuff but also cleanness and sanitization of all the utensils and apparatus used in preparation, premises of food processing unit, service and consumption to eliminate the contamination of food borne microorganism.

The food hygienic measures will involve:

- Protecting food from risk of contamination of any kind.
- Preventing any organisms multiplying to an extent which would expose consumers to risk, or result in premature decomposition of food.
- Destroying any harmful bacteria in the food through cooking or processing.

High standards of food hygiene are essential to prevent food poisoning, food-borne infections, food spoilage, loss of productivity, loss of business, food losses due to premature spoilage or damage, incorrect storage temperature or pest infestations and prosecutions for contraventions of food legislation. Hence, these standards of food must be achieved at a reasonable cost to ensure that the business remains profitable. For it, cost effective hygiene may be considered.

13.11 LET US SUM UP

Deterioration of food is a decay or undesirable decomposition of constituents by excessive growth of microorganism or by other physical and chemical causes. The deterioration factors are: (1) growth and activities of microorganisms, principally bacteria, yeast, and moulds; (2) activities of food enzymes and other chemical reactions within food itself; (3) infestation by insects, parasites, and rodents; (4) inappropriate temperatures; (5) gain or loss of moisture; (6) oxygen (7) light (8) physical stress and (9) time. Biochemical reactions in foods are catalysed by enzymes and are responsible for undesirable or desirable changes. Nutritional changes occur in foods during storage and processing due to microbiological, enzymatic and chemical reactions. Food-borne diseases cause illness and infections to humans after consumption contaminated foods. Anti- microbial agents are the chemicals which inhibits the growth & development of bacteria, moulds and yeasts. At high temperature enzymatic proteins are denatured and make the enzymes inactive. Different treatments such as thermal, chemicals, high pressure technology, cooling, freezing, microwave, individual quick freezing, ohmic heating, drying and dehydration, irradiation and smoking are done to prevent deterioration or spoilage of food so that it can be stored or preserved in fit conditions for future use. Food hygiene involves all measures to ensure the safety, soundness and wholesomeness of food at all stages: production, processing, manufacturing, packaging, storage, distribution, display for sale and consumption.

13.12 KEY WORDS

Anti-microbial agents :	Chemicals, which inhibits the growth and development of microorganisms.
Bacteria :	They are minute unicellular microorganisms.
Biochemical reactions :	Reactions catalysed by the enzymes in food and plant issues.
Blanching :	Dipping of fruits and vegetables in boiling water or exposing these to steam for a few minutes to kill enzymatic and biological activity.
Cooling :	Use of low temperature to retard chemical reaction and action of enzymes.
Drying and dehydration :	Removal of water.
Enzyme inactivation :	Stoppage of enzyme activity by denaturing them
Food-borne disease :	Disease or infection caused to humans after eating spoiled food
Food deterioration :	Decay or undesirable decomposition of food.
Freezing :	At temperature below the freezing point of water (−18 to −40° C) growth of microorganism and enzymes activity are reduced to a minimum.

High pressure technology	:	It is a non-thermal process for preservation of foods.
Hygiene	:	A system of sanitary principles for preservation of health.
Individual quick freezing	:	Means individual freezing of solid food/ pieces.
Irradiation	:	Exposure to radiation-generally used to sterilize various foods by killing microorganisms.
Microorganisms	:	Very small living beings such as bacteria, yeast and fungi.
Pasteurization	:	The process of killing harmful organisms in a food by heating at controlled temperature below 100°C.
Sterilization	:	Heating at high temperature i.e. 100°C to kill microorganisms.

13.13 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:
   - Shelf life is the time required for a food to reach at unacceptable stage.
   - The retail package of processed foods should have date of manufacture and expiry date to know the self-life.
2. Your answer should include the following points:
   - Microorganism, bacteria, yeast, moulds.
   - Activities of enzymes.
   - Chemical reactions.
   - Moisture, temperature, oxygen.
3. Your answer should include the following points:
   - Enzymatic: lipases, proteases, lipoxygenase, enzymic browning.
   - Chemical: Rancidity and non-enzymatic browning.
   - Physical: loss of texture and flavour.

4. Your answer should include the following points:
   - Clostridoium
   - Salmonella
   - Shigella
5. Your answer should include the following points:
   - Proteins
   - Chemicals

Check Your Progress Exercise 2

1. Your answer should include the following points
   - Anti-microbial agents are the chemicals which inhibits the growth & development of microorganism.
   - Weak acids and work when in the un-ionized form.
   - Sulphur dioxide and its derivatives, Nitrates and nitrites salts, Glycerol esters, Epoxides, p-Hydroxy Benzoate Alkyl Esters (parabens).
2. Your answer should include the following points:
   - Denaturation of enzymic proteins.
   - Blanching.
   - Polyphenoxidase and peroxidase.
3. Your answer should include the following points:
   - Thermal, ohemic heating.
   - Chemical.
   - Cooling, freezing, individual quick freezing.
   - Microwave, irradiation.
   - Smoking.
   - Drying.
4. Your answer should include the following points:
   - Reduction of microorganism contamination.
   - Prevention of food spoilage or decomposition.

3. Potter, N.N. and Hotchkiss, J.H. (1996) Food Science (5^{th} Ed). CBS publishers and Distributors, New Delhi.

4. Srivastava, R.P. and Kumar Sanjeev (2^{nd} Edn) (1998) Fruit and vegetables preservation: Principles and Practices. International Books Distributing Co., Lucknow, India

5. Verma, L.R. and Joshi. V.K. (2000) Post-harvest Technology of fruits and vegetables. Indus Publishing Company, New Delhi.

6. Wills, R.B.H., Mc Glasson, W.B., D. Graham Lecture, T.H. and Hall, E.G. (1989) Post-harvest: An Introduction to the physiology and handling of fruits and vegetable. Chapman and Hall, Inc, New York.

UNIT 14 QUALITY ASSURANCE: REGULATION, CODES, GRADES AND STANDARDS

Structure

14.0 OBJECTIVES

After reading this unit, you should be able to answer:

- food safety issues;
- food adulteration, contamination and their detection;
- quality control;
- grades;
- standards;
- enforcement of food laws;
- testing of samples; and
- residue analysis

14.1 INTRODUCTION

Food industry plays an important role in the national economy. For a successful food processing sector, various aspects of total quality management such as quality control, quality system and quality assurance should function for total success. In today's global market, quality and food safety have a competitive edge of enterprises producing foods and providing services to reach the global market. As a member of World Trade organization (WTO), India is signatory to the Sanitary and Phytosanitary (SPS) agreement, and hence has to adopt for international standards, guidelines and recommendations issued by FAO/WHO, Codex Alimentarius Commissions, adoption of food safety standards. The Ministry of Food processing Industries is building awareness among, producers, processors and consumers about the advantages of foods quality, safety and assurance.

14.2 FOOD SAFETY ISSUES

The safety of foods is of utmost significance and has gained a worldwide attention. People have the right to eat the safe and suitable foods. Food borne illness and injuries can be fatal to humans and can damage trade and tourism. Food spoilage is wasteful, costly and can adversely affect trade and consumer confidence. Effective hygiene control, therefore, is vital to avoid the adverse affect on human health and economic consequences of food borne illness, injury and food spoilage. Everyone, including farmers, growers, manufacturers and processors, food handlers and consumers have a responsibility to assure that food is safe and suitable for consumption. These general principles lay a firm foundation for ensuring food hygiene and should be used in conjunction with specific code of hygienic practices. Consumers should also practice clean habits in handling, cooking and storage of food to ensure complete food safety.

In order to understand "food safety" we must first know the terms *safe, hazard,* and *risk.* "Safe" means that nothing harmful happens when we consume a food. A hazard is the capacity of a thing to cause harm. We should first identify hazards related to foods or food components and then estimate the size of the risk that the hazard will cause. It is important to note that all foods have some degree of risk and that no food is absolutely "safe." The important consideration becomes the size of the risk and how the size of the risk can be reduced without eliminating the food source. The goal of food safety is to reduce the size of risks to the lowest reasonable level without severe disruption of the food supply.

14.2.1 Specific Safety Issues

Specific food safety concerns differ markedly and include:

- Additives, colours and flavours.
- Antibiotics and other food additives.
- Fertilizers and other growing aids.
- Irradiation.
- Microbiological contamination.
- Naturally occurring food toxicants.
- Nutrition.
- Pesticides.
- Pollutants.

- Processing, packaging and labelling.
- Tampering.

Consumers are most concerned about pesticides and additives as both are linked to cancer and not to microbiological contaminations, however food industry is most concerned about the microbiological safety of its products. In addition, many quality control checks are made to ensure that foods are free of extraneous matter such as glass, machine fillings and insect parts. Many food industries adopt 'Good Manufacturing Practice (GMP) and 'Hazard Analysis and Critical Control points (HACCP)'. Which assure that products manufactured under proper conditions and sanitation and hygiene will not have chance of contamination or error during processing.

14.3 FOOD ADULTERATION, CONTAMINATION AND THEIR DETECTION

14.3.1 Food Adulteration

Food adulteration is defined as the process by which the quality or the nature of a food product is adversely affected through the addition of a foreign or an inferior substance and the removal of a vital element. Adulteration of food may endanger health. Adulteration may be intentional or unintentional. The intentional adulteration is a willful act while the incidental adulteration is usually due to ignorance or lack of proper facilities.

Intentional adulterants: These adulterants are mixed with the food intentionally to increase the weight and quantity to make more money. Examples, sand, marble chips, stones, mud, other filth, talc, chalk powder, water, mineral oil and harmful colours.

Incidental adulterants: Pesticide residues, tin from can, droppings of rodents, larvae in foods. Some foods contain toxic pesticides, and the rodents & insects also introduce excreta, secretions and microorganisms responsible for food spoilage and intoxication.

14.3.2 Food Contamination

Food products are mostly contaminated with soil, air and water-borne microorganisms. Harvesting, processing, distribution and preparation generally contaminate the foods and food products which transmit certain food poisoning micro-organisms causing infections or intoxications or illness in humans. Food contaminations can be defined as the transference of any objectionable matter into or on the food. Following are 3 types of contaminations.

Contamination by microorganisms (bacteria, moulds or viruses): Generally occurs in raw foods such as vegetables grown on sewage, contaminated food premises, inadequate space and poor design. This type of contamination by microorganisms is the most serious and may result in food spoilage, food poisoning or even death.

Bacterial contamination is most significant as it results in large amount of spoilt food and large number of food poisoning cases. Bacteria are found everywhere: in soil, air, water, plants, animals, human and foods. Certain bacteria release toxins and cause death of persons consuming contaminated food. Some bacteria such as *Clostridium botulinum, Staphylococcus aureus,* *Salmonella bacteria* and *Bacillus cereus* are the common causes of food illness in humans.

Mould spores are found in atmosphere, on damp surfaces and on mouldy food. If food is stored at the wrong temperature at high humidity and in excess of the recommended shelf life, there are chances of food contamination.

Viruses like Hepatists A, Norwalk virus group and Rotavirus etc. are usually spread into food premises by food handlers who are carriers or on raw foods which have been grown in sewage polluted water and cause illness.

Yeasts grow best in the intermediate acid range, a pH of from 4.0 to 4.5. Food that is highly contaminated with yeasts will frequently have a fruity odour.

Physical contamination: Foreign bodies such as dust, dirt, stones etc. found in food may be brought into food premises with the raw materials or introduced during storage, preparation, service or display. Bolts, nuts, other pieces of metals, staples, cardboard string, polythene, rodent droppings, eggs and larvae of insects, cigarette buts, glass, wood splinters, paint or dust hair and fingernails, buttons and combs of persons handling the food are generally the sources of physical contaminations. Care should be taken that they do not contaminate the food.

Chemical contamination: Unwanted chemicals can enter the food during growth e.g. fertilizers, pesticides, environmental contaminants such as led or dioxins; during processing e.g. oil, cleaning chemicals; during transport as a result of spoilage or leakage and during sale etc.

14.3.3 Food Quality Assurance

Quality assurance includes the *planning* and *surveillance* of everything to do with quality throughout the company. Quality assurance seeks to generate confidence both within the organization and externally, among its customers, that their requirements will be fulfilled. Among the additional features acquired in the progress from quality control to quality assurance are the following:

- The definition of a quality policy and objectives;
- The development of a quality manual;
- Ensuring competency of personnel;
- Conducting periodic internal audits;
- The elimination of the root causes of the problems found; and
- Periodic reviews of the system by top management.

Above all, there is a shift in emphasis from mere detection to prevention of non-conformance. For introduction quality assurance system in the food industry good hygienic practices, a good agricultural practices, and good environmental practices for various industries should be adopted. The standards should become essential for introduction of quality assurance system in food industry in the form of potential hazards, GMP, HACCP, ISO:9000, Codex Alimentarius standards etc.

The Codex Alimentarius general principles of food hygiene are aimed to:

- identify the essential principles of food hygiene applicable throughout the food chain (production to consumption), to achieve that food is safe and suitable for human consumption;
- recommend a hazard analysis and critical control point (HACCP)- based approach to enhance food safety;
- indicate how to implement those principles; and provide a guidance for specific codes which may be needed for – sectors of the food chain; processes; or commodities; to amplify the hygiene requirements specific to those areas.

These principles are recommended to Governments, industry (including individual primary producers, manufacturers, processors, food service operators and retailers) and consumers alike.

14.3.4 Commercial Item Description

Commercial item description is defined under FPO standards (Govt. of India) for each processed food product which consists code number, whether concentrated or unconcentrated, sweetened or unsweetened, pasteurized or unpasteurized , made from ripe fresh and good quality fruits or vegetables, added water or not, and details of preservative, emulsifying, stabilizing agents i.e. name, quantity and quality (food grade). It also includes the quantity of total soluble solids, sugars, vitamins and addition of salt, colour etc. A label has to be fixed on the processed products mentioning date of manufacture, date of expiry, total weight of product, and nutritive composition the product i.e. total carbohydrate, fats, proteins, fibre, name of additive etc. Following are the few examples:

FRUIT JUICE means the unfermented and unconcentrated liquid expressed from sound, ripe fresh fruit and with or without:

a) sugar, dextrose, invert sugar, or liquid glucose, either singly or in combination;

b) water, peel-oil, fruit essences and flavour, common salt, ascorbic acid, citric acid, and preservatives.

The acidity of the finished product calculated as citric acid shall not be less than 4% in the case of pure lemon juice or pulp and not less than 5% in the case of pure lime juice but shall not exceed 3.5%t in the case of other juices.]

The total soluble solids for sweetened fruit juice (except tomato juice) shall not be less than 10%. It may also contain permitted emulsifying and stabilizing agents as prescribed in rule 61 C. It may also contain fumaric acid certified by BIS to the extent of 0.3%.

Tomato Juice means canned or bottled, unconcentrated, pasteurized juice expressed from tomatoes with a proportion of the pulp, expressed with or without the application of heat by any method that does not add water to juice, from whole, ripe tomatoes from which all stems and objectionable portions have been removed and with or without (a) salt (b) sugar, or dextrose, or both added in dry form (c) citric acid, malic acid or ascorbic acid. Provided that canned tomato juice may also contain extraneous permitted colour. The total soluble solids w/w shall be not less than 5 % ([free of salt). It may also contain permitted emulsifying and stabilizing agents as prescribed in rule 61-C. [It may also contain fumaric acid certified by BIS to the extent of 0.3 %.

Fruit Syrup means sweetened fruit juice containing, sugar, dextrose, invert sugar or liquid glucose either alone or combination, with or without:(a) water, peel-oil, fruit essences and flavours, common salt (b) citric acid, ascorbic acid.(c) permitted preservatives and colours. The total soluble solids w/w shall not be less than 65 %. The minimum percentage of fruit juice in the final product shall not be less than 25% w/w. It may also contain permitted emulsifying and stabilising agents as prescribed in rule 61-C.It may also contain fumaric acid (food grade) certified by BIS to the extent of 0.3 %.

14.4 QUALITY CONTROL

Quality control (QC) is a means of detecting whether quality has been achieved and of taking action to correct any deficiencies. QC activities include:

- Establishing the specifications of the parameters to be controlled;
- Preparing quality plans for control;
- Performing checks or inspections;
- Diagnosing and taking action on the variations observed; and
- Checking that the variations have been corrected.

The fundamental purpose of a quality control program is to acquire dependable information on all the attributes of a product which affects its quality. Quality control ensures that raw materials meet set standards, processing methods should be performed as designed, finished products meet company standards and consumer confidence in the enterprise remains high. The basic functions of a quality control programme are:

- Physical and chemical evaluation of raw materials and processed products.
- Control of
  a) Raw materials, ingredients and packaging supplies.
  b) Processing parameters.
  c) Finished products.
- Microbiological analysis and control of raw materials and finished products.
- Control of storage and handling conditions.
- Sanitation and waste products control.
- Assurance that final products are within the legal and marketing standards established.

Quality control in fruits and vegetables begins in the field with the selection of proper time of harvest for maximum quality. Each subsequent step after harvest is to maintain quality and include the following step:

Operation	**Procedures**
Harvesting	Check maturity of commodity with respect to colours size, firmness etc.
Preparation for market	• Monitor various steps such as washing, sorting, waxing, sizing, post harvest treatments etc. • Check shipping containers for compliance with grade, size and weight regulations.
Cooling	Monitor product temperature at key points in the handling system, especially before and after cooling.
Transportation	Check transit vehicle for cleanliness, before loading, loading pattern, load immobilization etc.
Destination markets	Check quality and condition of the product and shipping containers at destination market.

Quality control personnel should devote full time and attention to their duties and make needed changes in the harvesting and handling operation as and when required to maintain the desired quality.

Quality control within a food manufacturing industry demands constant vigilance at all stages in processing, so that any necessary adjustments can be made at the appropriate time. The specific responsibilities of quality control is to ensure that the system used produces a standard product with acceptable quality in respect to nutrition, purity, wholesomeness and palatability. The specific responsibilities of quality control assigned to a department or to an individual include:

- Standardizing procedure for sampling and examining raw materials. Development of test procedures.
- Establishment and implementation of quality standards for fresh and processed products.
- Setting up preventive quality control methods for in-plant liaison between manufacturing section and test laboratories.
- Examination of finished products.
- Storage controls.
- Research and development into new products and their packaging.

Quality control leads to:

- Raw material control
- Process control
- Inspection of finished products
- Sensory evaluation or evaluation of the acceptability of the final product.
- Packaging
- Labelling and storage

14.4.1 Inspection

The objective of inspection is product conformance by screening out conforming products from nonconforming products, which is done by visual checks/ measurements; then testing and reporting. Under a simple inspection-based system, one or more characteristics of a product are examined, measured or tested, and compared with specifications to assess conformity. Products that do not conform to specifications are reworked, or regraded, or accepted with concessions, or rejected. This system is used for inspecting incoming goods, checking a product at intermediate stages, or inspecting a product ready for delivery to the customer. Using inspection to improve quality is too late, too costly and ineffective. In processing fruits and vegetables for export continuous inspection is applied. The inspection of raw materials should be carried out at the commencement of each processing run to ensure that only good quality fruits or vegetables of sufficient maturity are used for processing. Sampling checks of raw materials should be carried out frequently. Raw material and ingredients must be inspected and sorted to insure that they are clean, wholesome and fit for processing. Containers and carriers (such as trucks or railcars) should be inspected to assure that their condition has not contaminated raw ingredients

14.4.2 Lab Tests

The laboratory tests used in quality control are usually standard scientific tests for physical, chemical, microscopic and microbiological analysis. By adopting these tests one should be in a position to reproduce same results by any trained quality control technician. Physical tests include product characteristics such as size, weight, colour, texture and adulterants like, glass, stone, filth and insects. The processed products should be of prescribed size, weight, colour, texture etc and devoid of physical adulterants. The chemical tests for the estimations of moisture, protein, carbohydrates, minerals, fats, vitamins and fibre contents should be standards practice from the raw material and processed products for the prescribed quality. Microscopic and microbial tests are used to determine the presence of moulds, microbes and insect fragments or foreign materials, spoilage or disease microorganisms from the raw and finished products to obtain disease free foods. The tests assure that the final products are disease free, within the legal and marketing standards established.

14.4.3 Sanitation

The raw produce, processed foods, processing units and persons working in food processing units must be kept in good sanitary conditions to minimize the possibilities of contamination by microorganism, chemicals and physicals adulterants. The persons working in food units should not have any disease and must wear clean clothes, maintain a high degree of personal cleanliness and must wash or sanitize hands thoroughly before starting work and at any other time when the hands have become soiled. The food processing plant must be free from litter, waste or refuse; potential for foot-borne filth or breeding places for insects or microorganisms.

The processing units must be kept in good sanitary condition to minimize the possibility of contaminating foods or equipment that contact food. Pesticides, insecticides and rodenticides may be used to prevent contamination by pests, insects and rodents respectively. All utensils and equipment surfaces that contact food must be cleaned and sanitized before use to prevent food contamination. When utensils or equipment are used in a continuous production operation, they must be cleaned and sanitized on a predetermined schedule. The water which comes into contact with food or processing equipment must be safe and of good sanitary quality. The disposal of sewage water should be proper so that it must flow into sewage system or disposed of through other adequate means. Toilets and hand-washing facilities must be provided inside processing centres for workers. Raw materials must be washed or cleaned to remove soil and other contamination by sanitary quality water. Food processing equipment must be kept in a sanitary condition through frequent cleaning and, when necessary, sanitizing. If ice is used and comes in contact with food products, it must be made from potable water and be in a sanitary conditions.

14.4.4 TQM (Total Quality Management)

TQM requires the creation and continual improvement of processes, along with other quality assurance activities. Companies or organizations aspiring to quality management are characterized by the widespread application of the concept that everyone in the organization has customers and that their satisfaction should be enhanced; in this way, everyone is committed to continually improving their part of the operation.

a) TQM is a process designed to focus external/internal customer expectations preventing problem building, commitment to quality in the work force and promoting open decision-making.

b) TQM is an effective system for integrating quality development, quality maintenance, and quality improvement efforts of various groups in the organization so as to enable products and services at the most economical level, which allows customer satisfaction.

c) TQM is a building, housing the quality assurance system, quality consciousness of employees as the foundation, employee's involvement and commitment as the walls, the quality policy of the management as the roof.

d) TQM is an integrated organizational approach in delighting customers by meeting their expectations on a continuous basis through every one involved with the organization, working on continuous improvement in all products/services/processes along with proper problem solving methodology.

e) Meaning of Total Quality Management

Total	Every one associated with the company is involved in continuous improvement, in all functional areas, at all levels.
Quality	Customers expressed and implied requirements are met fully.
Management	Executives are fully committed Effective utilization of resources Decision in a planned way To maintain existing level of quality To improve existing level of quality.

14.4.5 Codex Alimentarius

The Codex Alimentarius is a collection of international standards for the safety and quality of foods as well as codes of good manufacturing practice and other guidelines to protect the health of the consumer and remove unfair practices in International trade. This is based on the recommendation of FAO and WHO, a worldwide conference for food standards and guidelines that would protect consumer's health and ensure international fare trade practices. Codex standards comprise standards for processed frozen fruits and vegetable, fruit juices, fats and oils, milk products, cereals and pulses, fish and poultry products, coca products and standards methods of analysis. Codex has also brought a list of more than 1000 food additives along with their permitted levels for use in different foods. The Codex general principles of food hygiene are aimed to: a) identify the essential principles of food hygiene applicable throughout the food chain to achieve the goal of ensuring that food is safe and suitable for human consumption. b) recommend a HACCP based approach as means to enhance food safety. c) indicate how to implements those principles and d) provide a guidance for specific codes which may be needed for – sectors of food chain; process; or commodities; to employ the hygiene requirements specific to those area.

14.4.6 HACCP (Hazard Analysis and Critical Control Point)

HACCP is a management system in which food safety is addressed through the analysis and control of biological, chemical, and physical hazards from raw material production, procurement and handling, to manufacturing, distribution and consumption of the finished product. Food safety systems based on the HACCP principles have been successfully applied in food processing plants, retail food stores, and food service operations.

Advantages

- Focus on identifying and preventing hazards from contaminated food is based on scientific principles.
- Permits more efficient and effective monitoring at government level, primarily because the record keeping allows investigators to see how well a firm is complying with food safety laws over a period rather than how well it is doing on any given day.
- Places responsibility for ensuring food safety appropriately on the food manufacturer or distributor.
- Helps food companies complete more effectively in the world market
- Reduces barriers to international trade.

The HACCP is based on 7 principles, which have been universally accepted by government agencies, trade associations and the food industry around the world. These include:

1. **Assessment of hazards:** Each unit operation should be evaluated to identify potential source of microbial, chemical and physical hazards, which may be introduced into the produce. Areas, which should be evaluated, are growing and harvesting operations, packing shed operations, packaging material and storage as well as distribution. This process is best accomplished by a team of both management and production personnel.
2. **Determine critical control points (CCP) to control the identified hazards:** The next step in developing a HACCP program is to draw a flow diagram for your specific operation and then determine where each of the identified hazards may be monitored. Each point that will be monitored to control specific hazard is now designed a critical control point.
3. **Establishment of CCO limits:** Once CCP have been identified, tolerance limits must be set to determine when corrective action needs to be taken. Tolerance must be observable and measurable.
4. **Established of CCP monitoring procedures:** How often monitoring will be done, how measurements will be taken and what documentations will be prepared must next be clearly defined.
5. **Corrective action when deviations from CCP limits occur:** When a deviation from the prescribed limits occurs corrective action must be taken to eliminate the potential contamination. All deviations and corrective actions must be noted in written form.

6. **HACCP record keeping system:** All paper work related to the HACCP system must be kept in an orderly and accessible manner. Records that should be kept include:

   - Production Records
   - Supplier audits
   - Pesticides usage and testing results
   - Irrigated water test results etc.
   - Harvesting Records:
   - Harvest dates and lot numbers
   - Total number of boxed harvested, etc.
   - All critical control point monitoring records
   - Storage and distribution records
   - Temperature monitoring
   - Truck cleanliness etc.

7. **Deviation file:** HACCP deviations and corrective actions taken.

   HACCP verification: Periodic HACCP plan review including review of CCP records, deviations and random sampling to verify that the HACCP program must be done to assure that HACCP program is functioning properly. This review should be done either on a monthly or quarterly basis.

14.5 GRADES

The quality of agricultural produce, cereals, spices, oil seeds, legumes, fruits and vegetables has criterion for the categorization into various grades depending upon the degree of purity in each case. The grades incorporated are grades 1,2,3 and 4 or special, good, fair and ordinary.

Grading of some commodities like vegetable oils, *atta,* spices and honey is voluntary. The grading of commodities like tobacco, walnuts, spices, basmati rice, essential oils, onions, potatoes meant for export is compulsory under government acts to ensures the quality of produces. Grading add extra cost and hence the graded products are priced slightly higher. The grading of agri-cultural commodities has three main purposes. Firstly, it protects the consumer from exploitation. By knowing the quality and grade of his produce, he is in better bargaining position against the trader. Secondly, it serves as a means of describing the quality of the commodities to be purchased or sold by the buyers and sellers all over the country and abroad. This establishes a common trade language and avoids the need for physical checking and handling at many points. Thirdly, it protects the consumer by ensuring the quality of products he purchases

14.6 STANDARDS

Food standards for ensuring the quality and safety of raw and processed foods for human consumption have been formulated and enforced by law in India. Food standards have been also prescribed based on the International Codex Alimentarius with suitable modification to suit Indian conditions thus in India food processing and allied industries are governed by following different standards.

14.6.1 ISO (International Organization for Standardization) 9000 SERIES

ISO 9000 series are quality management and quality assurance standards. The principal of these standards is, 'if the system (input, process, output) through which the product is produced, is perfect then the product coming out of system will also be perfect'. This series of standards for quality assurances is now being adopted by most of the companies in India and abroad. More and more companies are in the queue for achieving this quality System Certificate. ISO 9000 series of standards are available which provide the guidelines for the establishment and management of quality system in the organization.

There are 4 basic models for classification of ISO 9000 Series:

ISO 9001 : Model for design, development, production, installation and servicing.

ISO 9002 : Model for production, installation and servicing.

ISO 9003 : Model for final inspection and testing.

ISO 9004 : Model for quality management and quality system element.

There are laid down guidelines on how to develop and follow systems as per the requirement of this series: The series covers the following major clauses**:** Management responsibilities, Quality systems, Contract review, Design control, Document control, Purchase, Purchaser supplied product, Product Identification and Traceability, Process control, Inspection and testing, Inspections and testing of measuring equipments control of nonconforming product, Corrective preventive action, Handling, storage, packaging and delivery: Quality records, Internal Quality audit, Training, service and statistical techniques

The main principal of achieving this certification is 'SAY what you Do and Do what you SAY'

14.6.2 Fruit Product Order (FPO)

Central Govt. formulated Fruit Product Order (1955 and 1961) which lays down statutory minimum standards in respect of the quality of various fruits, vegetables products and processing facilities. Packaging fruits and vegetables to standards below the minimum prescribed is an offence and punishable by law. Periodic inspection by inspectors is carried out to ensure conformity of standards by processors. Every manufacturer of fruit and vegetable products must obtain a license for manufacture and conform to the sanitary requirements and standard of quality specified. The inspectors are empowered to collect samples and inspect the factory and send the coded samples to Central

Laboratory. The order has laid down limits for the presence of poisonous elements. The act has laid down the standard specifications for the food products and food additives.

14.6.3 Meat Products Order (MPO)

This order regulates manufacture, quality and sale of meat and all meat products . Provisions are meant to control production, quality and distribution of raw and processed meat. This makes it illegal to transport meat unless it has been prepared and processed according to the provisions of the order and carries the mark of inspection. It provides means to (a) detect and destroy meat of diseased animals (b) ensure that the preparation and handling of meat and meat products is conducted in a clean and sanitary manner (c) Prevent the use of harmful substances in meat foods. (d) See that every piece of cut meat is inspected before sale to ensure its wholesomeness. The order also lays down the rules and conditions for procedure to be adopted for the selection of disease free animals, slaughterhouse practices and further treatment of the meat so as to maintain the meat in a wholesome manner, devoid of pathogens.

14.6.4 Cold Storage Order (CSO)

The cold storage order (CSO), 1980, promulgated under the Essential Commodities Act, 1955, has the objective of ensuring hygienic and proper refrigeration conditions in a cold store, regulating the growth of cold storage industry and rendering technical guidance for the scientific preservation of food stuffs in a cold store and prevent exploitation of farmers by cold storage owners. Agricultural Marketing Advisor to the Government of India is the licensing officer under this order.

14.6.5 PFA (Prevention of Food Adulteration Act and Rules in India)

Indian Government promulgated Prevention of Food Adulteration Act of 1954 to ensure that food articles sold to the customers are pure and wholesome. It also intended to prevent fraud or deception and encourages fair trade practices. The act was amended twice to plug the loopholes of escape and to ensure stringent punishment. The act prohibits the manufacture, sale and distribution of not only adulterated foods but also foods contaminated with toxicants and misbranded foods. A central food laboratory at Calcutta was established for the purpose of reporting on the suspected food products. A Central Committee for food standards has been constituted under the Act and has been charged with the function of advising the Central Government on matters relating to Food Standards. Provisions have been made in the Act for the appointment of Food Inspectors by the state Governments and their powers have been defined. The State Governments set up food testing laboratories and appoint Public Analysts with adequate staff to report on suspected foods. Standards have been laid under the PFA Act for various categories of food and according to PFA Act, a food shall be deemed to be adulterated if it does not meet the specified conditions mentioned in the Act.

14.6.6 AGMARK

The word ‘Agmark’ is a derivative of Agricultural Marketing. The Agmark standards were set up by the Government of India by introducing an Agricultural Produce Act in 1937. The Agmark seal ensures quality and purity. The quality and grade of product is determined with reference to the size, variety, weight, colour, moisture, fat content and other factors. The Act defines the quality of cereals, spices, oil seeds, butter, ghee, legumes and eggs and provides criterion for the categorization of commodities into various grades. The grades incorporated are grades 1,2,3 and 4 or special, good, fair and ordinary. The standards also specify the types of packaging to be used for different products. The physical and chemical characteristics of products are kept in mind while formulating the Agmark specifications. The Central Agmark Laboratory at Nagpur carrying out research and development work. The Certificate of Authorization is granted only to those in the trade having adequate experience and standing. The staff of the Directorate of Marketing and Inspection or of the State Government is generally present at the time of selection of goods, their processing, grading and packing before applying the appropriate AGMARK labels.

- Agmark products are free from adulteration and conform to the scientifically laid down principles of purity. It ensures consumer protection.
- Each batch of Agmark products is pre-tested for quality by quality control and trained chemist.
- Agmark products are always packed in food grade material never to be sold loose.
- Agmark products bear Agmark label or replica as an identification mark, date of manufacturing and expiry period.
- Free of cost replacement provided in the rules if Agmark products are found not conforming to the quality standards.
- They are not mandatory, any body can use them.

14.7 ENFORCEMENT OF FOOD LAWS

Food standards for ensuring the quality and safety of raw and processed foods for human consumption have been formulated and enforced by law in India. The laws and regulations exist to deal with food safety and consumer concerns about food contamination and adulteration, penalizing the seller of diseased, unwholesome and corrupted food products. The law defines foods, food preservatives and artificial colour, and ban the sale of food prepared under unsanitary conditions or containing any deleterious or unsafe substances. These also specify standards of quality for various classes of foods and outline the conditions under which a food would be regarded as adulterated or misbranded. Finally, there are statutory or legal obligations, which need to be fulfilled for safeguarding the health and well being of people and the establishment.

There are number of food laws being implemented by various Ministries/Departments of Indian Government. These are primarily meant for 1) Regulation of Specifications of Food, and 2) Regulation of Hygiene conditions of Processing and Manufacturing. The Government of India has also empowered several agencies and promulgated a number of acts and orders to ensure food safety. Agencies and institutes have also been created to lay down standards for quality of foods. The manner in which the food is processed and packed is also covered by a number of regulations. Some of these food quality assurance laws are voluntary and some are mandatory. The following are various food laws operating in India.

1. Prevention of Food Adulteration Act, 1954 and Rules 1955.
2. Agriculture Produce Act 1937 (AGMARK) Grading and Marketing.
3. Bureau of India Standards (BIS).
4. Environment Protection Act 1986 & Rules 1989.
5. Export Quality Control and Inspection Act, 1963.
6. Essential Commodities Act, 1955.
7. Insecticide Act, 1968.
8. Fruit Product Order, 1955.
9. Meat Food Product Order, 1973.
10. Solvent Extracted Oil, De oiled Meal and Edible Flour (control) order, 1967.
11. Milk and Milk Product Order, 1992.

PFA are enforced by the Department of Health. Under the law, slaughter houses, markets, factories, warehouses and other establishments involved in food trade may be inspected to ascertain that the raw materials as well as processing, packaging and storage facilities are sterile and ingredients meet the minimum standards prescribed by the law. Adulterated and misbranded products may be seized by inspectors, destroyed and legal action be taken depending upon the nature of the offence.

Food laws came into existence for a number of reasons:

i) To maintain the quality of food produced in the country;
ii) To prevent exploitation of the consumer by the sellers;
iii) To safeguard the health of the consumers;
iv) To establish criteria for quality of food products, since more and more foods were eaten in processed, rather than natural forms. This has resulted in the inability of the consumer to identify the quality of the contents that could be identified easily.

The legislation which is directly concerned with the protection of the health of consumers and the quality of food products marketed is the Prevention of Food Adulteration (PFA) which states that an article of food shall be deemed to be adulterated. The PFA Act, thus, lays down the guidelines for setting up standards for various food items like cereals and cereals products, pulses, ghee, etc. All processed items which, are mass-produced for public use, are expected to conform to these standards.

In addition to the mandatory acts and orders cited above, agencies such as Bureau of Indian Standards (BIS) and Directorate of Marketing and Inspection have also laid down quality standard for foods.

Operating quality systems as per quality system standards leads to doing right things on time, all the time and always to the customer's satisfaction

14.8 TESTING OF SAMPLING

The Food Health Authority (FHA) at State level is the Director of Public Health and Preventive Medicine. It is responsible for the good quality and standards of foods available to the consumers. Under FHA, the Local Health Authority appointed in each city of every State is responsible for testing of samples. The food inspector is appointed by the Central or State Government and they are trained in food inspection and sampling and have the powers to take sample of any food article from 1) any person selling such article 2) any person who is in the course of delivering or preparing to deliver such article to a purchaser or consignee 3) a consignee after delivering of any such article to him, and to send such samples for analysis to the Public Analyst (PA) of local area. When the Food Inspector wants to lift the suspected food, the shopkeeper must first be informed and there should be a witness present also. 150 g of sample is necessary to be sent for analysis but usually 600 g of sample is collected and sent to Central Food Laboratory Calcutta, and Central Food Technological Research Institute, Mysore. There is a recommended procedure to collect the sample and seal it in a bottle. The sealed bottle has a label on it in which the code number of the inspector, address of the shop, date and time of collection are written. When individuals doubt adulteration in foodstuffs they have to inform the Food Health Authority. Samples can be sent for analysis only after getting order from Food Health Authority. If the persons are found guilty of selling adulterated food, the persons involved can be convicted. A vendor found adulterating the food with ingredients injurious to health is liable for a much heavier sentence than a vendor involved in only mixing an inferior ingredient not injurious to health.

14.9 RESIDUE ANALYSIS

The foods require the absence of harmful substances like pesticides that are harmful for human health. The estimation of pesticides residues in foods is very important and the declaration of pesticides qualitatively or quantitatively has become inevitable for export and import. About 176 pesticides are listed which come into foods from their intentional or unintentional use on the crops. The maximum residue limits vary with the type of commodity. Use of many pesticides is restricted by law and the maximum residue limits commonly used pesticides are fixed by national (PFA in India) and international (Codex Alimentarius Commission) agencies.

Analysis of pesticides in foods is very cumbersome job and requires standards procedures and specific instruments. The basic steps for sampling and analysis of pesticides are given below:

Sampling ⟶ Sample preparation ⟶ Extraction of pesticides ⟶

Partitioning ⟶ Cleanup, Concentration of extract ⟶ Dilution with

appropriate solvent ⟶ Identification & estimation of pesticides

(GC, HPLC, Mass Spectrometer, GC-MS, UV-VIS Spectrometer, TLC etc.)

The sampling procedures and quantity for sampling varies with the commodity and type of sample. The sample should be drawn as uniform as possible from whole lot of produce.

Residue analysis consists of a chain of procedures. The analyst should be an experienced and competent in residue analysis. The laboratory requires an adequate range of reference standard pesticide of high purity. The range should cover all parent species and their metabolites. Chemical reagents, adsorbents and solvents should be high purity and not to interfere in the analysis. All glassware, reagents, solvents and water should be checked from contaminants before use. In a routine laboratory monitoring for compliance with national tolerances, standardized methods will be used and these should be validated periodically.

A number of instrumental procedures for estimation/confirmation are used in residue analysis. Gas chromatography (GC) is the commonly used instrument for qualitative and quantitative determination of pesticides residues. The specific columns and detectors are used for different groups of pesticides. Thin layer chromatography (TLC) is also used in some instances, confirmation of gas-chromatographic findings and identification most conveniently achieved by TLC. The advantages TLC are speed, low cost and applicability to heat sensitive materials but it has lower sensitivity than GC. High performance liquid chromatography (HPLC) can be used advantageously for the confirmation of residues initially found by gas chromatography or by other techniques and may be in certain circumstances the preferred quantitative technique. Mass spectrometers (MS**)** are generally sensitive at the nanogram level.

14.10 LET US SUM UP

The safety of foods is of utmost significance as people have the right to eat the safe and nutritious foods. Adulteration of food may be intentional or unintentional it endangers the health of consumers. Food products are mostly contaminated with microorganisms, (bacteria, moulds or viruses), and physical (dust, dirt, stones etc) & chemical (fertilizer, pesticides) contaminants. Quality assurance includes the *planning* and *surveillance* of everything to do with quality throughout the company and it generates confidence among consumers and customers. For introduction of quality assurance system in the food industry, good hygienic practices, good agricultural practices, and good environmental practices for various industries should be adopted. The standards should become essential for introduction of quality assurance system in food industry. Quality control ensures that raw materials meet set standards, processing methods perform as designed, finished products meet company standards and consumer confidence in the enterprise remains high. The specific responsibility of quality control is to ensure that the system used produces a standard product with acceptable quality in respect to nutrition, purity, wholesomeness and palatability. The objective of inspection is product conformance by screening out conforming products from nonconforming.

The raw produce, processed foods, processing units and persons working in food processing units must be kept in good sanitary conditions to minimize the possibilities of contamination by microorganism, chemicals and physicals adulterants. Total Quality Management requires the creation and continual improvement of processes, along with other quality assurance activities. The Codex Alimentarius is a collection of international standards and codes for the safety and quality of foods. HACCP is a management system in which food safety is addressed through the analysis and control of biological, chemical, and physical hazards from raw material production, procurement and handling, to manufacturing, distribution and consumption of the finished product. Food standards for ensuring the quality and safety of raw and processed foods for human consumption have been formulated and enforced by law in India. The laws and regulations exist to deal with food safety and consumer concerns about food contamination and adulteration, penalizing the seller of diseased, unwholesome and corrupted food products. The estimation of pesticides residues in foods is very important and the declaration of pesticides qualitatively or quantitatively has become inevitable for export and import foods. Identification & estimation of pesticides residues is done by GC, HPLC, Mass Spectrometer, GC-MS, UV-VIS Spectrometer, TLC etc.

14.11 KEY WORDS

Adulterated	**:**	The deliberate addition of inferior or cheaper material to a supposedly pure food product in order to stretch out supplies and increase profits.
Bacteria	**:**	Single celled microscopic organism.
Chemical sanitizers	**:**	Products used on equipment and utensils after washing and rinsing to reduce the number of disease – causing microbes to safe levels.
Contamination	**:**	The unintended pressure of harmful substances or conditions in food that can cause illness or injury to people who eat the infected food.
Critical control point (CCP)	**:**	means a point or procedure in a specific food system where loss of control may result in on unacceptable health risk.
Codex alimentarius	**:**	Is a collection of international standards and codes for the safety and quality of foods.
Disnifact	**:**	destroy harmful bacteria.
Food borne illness	**:**	An illness caused by consumption of a contaminated food.
Grade standards	**:**	Principally standards of quality to help producers, wholesalers, retailers, and consumer's in marketing and purchasing food products.
HACCP	**:**	called *hassip* is a management system in which food safety is addressed.
Juice	**:**	the aqueous liquid expressed or extracted from one or more fruits or vegetables or any concentrations of such liquids.
Sanitation	**:**	maintenance of conditions which are clean and promote good health.

14.12 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:
   - Additives, colour and flavour.
   - Microbiological contamination.
   - Pesticides, fertilizers, food toxicants, pollutants etc.

2. Your answer should include the following points:

   - *Clostridium botulinum.*
   - *Salmonlla.*

3. Your answer should include the following points:

   - Good Manufacturing Practices
   - HACCP
   - Codex Alimanterius
   - ISO : 9000

Check Your Progress Exercise 2

1. Your answer should include the following points:

   - Physical and chemical evaluation of raw & processed material.
   - Control of raw material, processing parameter and finished products, storage and handling conditions.
   - Microbiological analysis.

2. Your answer should include the following points:

   - Product conformance.
   - Grading is done for purity and quality of product.
   - Fetch better price.

3. Your answer should include the following points:

   - Collection International standards and codex for quality and safety foods.
   - Recommended HACCP to enhance food safety.
   - Identify principles of food safety.

4. Your answer should include the following points:

   - Assessment of hazards.
   - Determine Critical Control Points (CCP).
   - Established of CCP limits.
   - Established of CCP Monitoring procedures.
   - HACCP record keeping system.
   - Deviation file.
   - HACCP verification.

Check Your Progress Exercise 3

1. Your answer should include the following points:

   - Quality management and quality assistance international standards.
   - ISO:9001, ISO:9002, ISO:9003, ISO:9004 for design, production, inspection and testing and quality management etc.

2. Your answer should include the following points:
   - Agricultural Produce Act, 1937.
   - Derivative of Agricultural Marketing.
   - Products are free from adulteration.
   - Pre-tested product quality and bear AGMARK seal.
3. Your answer should include the following points:
   - Prevention of Food Adulteration Act, 1954 and Rules 1955.
   - Agriculture Produce Act 1937 (AGMARK) Grading and Marketing.
   - Bureau of India Standards (BIS)
   - Fruit Product Order, 1955
   - Meat Food Product Order, 1973.

EXPERIMENT 1 EQUILIBRIUM MOISTURE CONTENT (EMC)

Structure

1.1 INTRODUCTION

Food materials tend to absorb or lose moisture according to the environmental conditions. They will absorb moisture when partial vapour pressure of the water inside the grain is less than the partial vapour pressure of water present in environment and *vice versa*. The moisture content at the time when equilibrium is achieved by absorbing or losing moisture for specific temperature and relative humidity conditions is known as "Equilibrium Moisture Content (EMC)". The EMC plays significant role in drying and storage of food grains as well as dried fruit and vegetable products.

Objective

After studying and performing this experiment, you should be able to:

- determine the EMC (w.b.) of foods.

1.2 EXPERIMENT

1.2.1 Principle

When a moist food product is placed in a gaseous atmosphere containing water vapour, heat and water vapour exchanges occur between the two phases. The food absorbs or loses water to the atmosphere until a state of thermodynamic equilibrium is reached. Temperature and pressure are then constant and equal in both phases. The moisture achieved in this condition is EMC. In this experiment constant temperature is achieved using incubators and constant water vapour pressure of environment (relative humidity) at particular temperature is achieved using saturated salt solutions. The study is done in closed chamber in order to achieve constant relative humidity.

1.2.2 Requirements (Equipment/Machinery/ Instrument and Chemicals/ Material)

- Hot air oven
- Moisture boxes
- Analytical balance (Least count 0.001 g)
- Desiccators

- Incubators
- Salts (NaCl, K_2CO_3, etc.), as per required humidity conditions

1.2.3 Procedure

- Set the incubator at a particular temperature.
- Place saturated salt solution, (particular salt which maintains a constant relative humidity at specific temperature), in the desiccators.

Table 1.1: Equilibrium relative humidities for some saturated salt solutions

Chemical	Relative humidity %		
	22·8°C	30°C	37.8°C
Sodium chloride	75.5	75.2	75.1
Sodium nitrite	64.8	63.3	61.8
Sodium dichromate	54.1	52.0	50.0
Potassium carbonate	43.9	43.5	43.4
Magnesium chloride	32.9	32.4	31.9

- Accurately measure moisture content of the test sample by drying in an hot air oven. Then keep the sample in Petri dishes, transfer the Petri dishes into desiccators, close the lid and keep the desiccators inside the incubator.
- Accurately weigh samples after 15 days, daily and observe the increase or decrease in weight till it becomes constant.

1.2.4 Observations

Parameters	16 day	17 day	18 day	19 day	20 day
Weight of Petri dish + equilibrated sample (w3)					

Let weight of empty Petri dish was (w1), weight of Petri dish + sample was w2, initially. Based on moisture content of initial sample, the weight of water present in the sample was W4, and then EMC will be given as

$$\text{EMC} = \frac{\text{Weight of sample after equilibration} - \text{Dry matter content of sample}}{\text{Weight of sample after equilibration}} \times 100$$

$$= \frac{(\text{w3} - \text{w1}) - (\text{w2} - \text{w1} - \text{W4})}{(\text{w3} - \text{w1})} \times 100$$

1.2.5 Results

Calculate EMC using above formula. The results are always displayed along with temperature and relative humidity.

1.3 PRECAUTIONS

- Never touch the sample or Petri dishes with wet hands.
- The Petri dishes should be dried before placing the samples.
- Sample should be evenly distributed inside the moisture boxes in a single layer.
- The Petri dishes should not come in contact with salt solutions.

EXPERIMENT 2 BULK DENSITY

Structure

2.1 INTRODUCTION

It is the weight of the food material in a unit volume. It is of importance in the packaging, handling and other operations.

Objective

After studying this experiment, you should be able to:

- determine the bulk density of the food material.

2.2 EXPERIMENT

2.2.1 Principle

The finely ground material is filled in a container of known volume, and its weight is measured. The mass per unit volume is bulk density. It should be in kg per cubic meter.

2.2.2 Requirements (Equipment/Machinery/Instrument and Chemicals/ Material)

- Measuring cylinder (250 ml capacity)
- Analytical balance (Least count 0.001 g)

2.2.3 Procedure

- Weigh a 250 ml capacity measuring cylinder (Say W1).
- Fill the pre-weighed measuring cylinder with finely ground vegetable/fruit sample (30-mesh size) up to the 100 ml mark.
- Weigh the filled cylinder with sample (Say W2).
- Repeat above steps with two more lots of the same sample.

2.2.4 Observations

Parameters	Sample number		
	1	2	3
Weight of empty cylinder (W1), g			
Weight of cylinder + sample (W2), g			

2.2.5 Results

Calculate bulk density using the formula given below. Take the average of three values and report the results in kg/m^3.

$$\text{Bulk Density} = (W2 - W1) \times 10$$

2.3 PRECAUTIONS

- Filling of the cylinder up to 100 ml mark should be accurate.

EXPERIMENT 3 TRUE DENSITY

Structure

3.1 INTRODUCTION

It is the actual volume occupied by the particles of food material. It is of the importance in the packaging, handling and other operations.

Objective

After studying this experiment, you should be able to:

- determine the true density of the food material.

3.2 EXPERIMENT

3.2.1 Principle

The material is filled in a container having a liquid already filled in it of known volume. The volume displaced by the sample particles is the true volume and ratio with its weight will give true density. It should be in kg per cubic meter.

3.2.2 Requirements (Equipment/Machinery/Instrument and Chemicals/ Material)

- Measuring cylinder (250 ml capacity)
- Analytical balance (Least count 0.001 g)
- Toluene

3.2.3 Procedure

- Accurately weigh a finely ground 100 g sample (W1).
- Now fill a 250 ml capacity measuring cylinder with toluene up to the 100 ml mark.
- Transfer the weighed sample into the liquid.
- Determine the change in volume (V1).
- Repeat above steps with two more lots of the same sample.

3.2.4 Observations

Parameters	Sample number		
	1	2	3
Weight of sample (W1), g			
Weight in the volume (V2), ml			

3.2.5 Results

Calculate true density using the formula given below. Take the average of three values and report the results in kg/m^3.

$$\text{True Density} = \frac{\text{W1}}{\text{V1}} \times 1000$$

3.3 PRECAUTIONS

- Filling of the cylinder up to 100 ml mark should be accurate.

EXPERIMENT 4 MEASUREMENT OF FAT/ OIL

Structure

4.1 INTRODUCTION

Fat or oil present in any food is the source of energy. The oils and fats are insoluble in water and soluble in some organic solvents. It may be present in the food material itself as in oilseeds or it may come during processing. Determination of fat / oil content is essential to know the calorific value of food.

Objective

After studying this experiment, you should be able to:

- determine the fat content of foods.

4.2 EXPERIMENT

4.2.1 Principle

Fats and oils are soluble in organic solvents like hexane, Isopropanol etc. but other constituents are not. Hence, the fat present in the food sample is dissolved into the solvent and afterwards solvent is removed by evaporation distillation (Boiling point of solvent is much less than that of oils/fat).

4.2.2 Requirements (Equipment/Machinery/Instrument and Chemicals/ Material)

- Soxhlet apparatus
- Extraction filter paper thimble
- Analytical balance (Least count 0.001 g)
- Sample grinder
- Organic solvent (Hexane, Isopropanol or diethyl ether), acetone

4.2.3 Procedure

- Thoroughly wash the boiling flasks and rinse with commercial grade acetone to remove any residual oil/fat.
- Dry the flasks by placing in hot air oven for 3-4 hours

- Weigh the flasks and label them.
- Weigh the extraction filter paper thimbles (in duplicate) and label them.
- Transfer 2-5 g samples in pre-weighed thimbles and determine their accurate weight.
- Plugged these thimbles with non-adsorbent cotton and place them straight in the soxhlet extraction tube.
- Fill the extraction tubes with solvent sufficient enough so that the siphon system starts working.
- Now fix the Soxhlet assembly properly and switch on the heaters.
- As soon as the initiation of boiling is indicated start the water connected to condensers and allow the extraction for 8 hours.
- After 8 hours switch off the heaters and allow cooling.
- The solvent is evaporated using vacuum oven at 50^{o}C or a water bath and then flasks with oil are weighed.

4.2.4 Observations

Parameters	Sample number		
	1	2	3
Weight of empty flask (w1)			
Weight of empty thimble (w2)			
Weight of thimble + sample (w3)			
Weight of flask + oil (w4)			

Fat / oil content is calculated by using the following formula.

$$\%\text{Fat / oil (w.b.)} = \frac{(w4 - w1)}{(w3 - w2)} \times 100$$

4.2.5 Results

Calculate oil/fat content using above formula. Take the average of three values and report the results as percentage.

4.3 PRECAUTIONS

- The water supply should not stop during the experiment. If so, the heaters should be put off.

- Take care that solvent should not come in contact with any heated surface as it is highly inflammable.

EXPERIMENT 5 CRUDE PROTEIN (TOTAL PROTEIN)

Structure

5.1 INTRODUCTION

Proteins are fundamental food components, both functionally and nutritionally. Dietary protein is supplied from plant and animal sources. Proteins are needed to build and repair body tissue and for the metabolic functions of our bodies. The crude protein is determined by estimating total nitrogen in any food material.

Objective

After studying this experiment, you should be able to:

- determine the total protein content of foods.

5.2 EXPERIMENT

5.2.1 Principle

Total nitrogen in all the samples is determined by the Kjeldahl method. It is a three step experiment as given below;

1. **Digestion:** It results in complete hydrolysis of the sample converting all protein and other nitrogenous compounds into ammonia.

2. **Distillation:** Distillation of the digested sample is the process during which the ammonia is released which is trapped in boric acid solution to yield ammonium borate.

3. **Titration:** The solution containing ammonium borate is titrated against 0.1 or 0.01 N HCI.

The protein content is estimated by multiplying % Nitrogen by a '**Protein factor'** as given below. In case factor is not known, 6.25 is commonly used.

Protein/product type	Protein factor
Egg	6.25
Milk	6.38
Meat	6.25
Rice	5.95
Barley	5.83
Wheat (whole)	5.83
Wheat (flour)	5.70
Maize	6.25

5.2.2 Requirements (Equipment/Machinery/Instrument and Chemicals/ Material)

- Conc. sulphuric acid
- Catalyst powder: Contains Cupric sulphate (penta-hydrate) and potassium sulphate (1:5 w/w).
- Sodium hydroxide solution (50%)
- Boric acid – indicator solution.

  Solution A: It is prepared by dissolving 40g boric acid in 1.95 litres hot distilled water.

  Solution B: It is prepared by dissolving 0.01 of bromo cresol green in 10ml of 95% ethyl alcohol.

  Solution C: It is prepared by dissolving 0.05 g methyl red in 50 ml of 95% ethyl alcohol.

  Finally solutions B and C are mixed and 50ml of this solution is made up to 2 litres with boric acid solution.

- Digestion assembly including Kjeldahl flasks / tubes.
- Distillation assembly
- Burette, pipette, conical flasks etc.

5.2.3 Procedure

1. Digestion of sample

- Accurately weigh 50 to 100mg sample (in duplicate) and transfer into two different Kjeldahl digestion tubes and label them.

- Add 4 ml conc. sulphuric acid and 100mg of catalyst powder to each digestion tube.

- Place the tubes on a heater to allow digestion at slow heat (100^{o}C) for 30 min. and gradually increase the temperature to 200^{o}C in about 1hour and finally to 420^{o}C until the colour of the content changes from dark brown to bluish green.

- The digested samples are then removed from heater and allowed to cool.

2. Distillation of sample

- Thoroughly clean the distillation unit and allow preheating.
- Now add 10 to 15 ml distilled water to each Kjeldahl tube/ flask.
- Close the stopcock and fill the reservoir with water to 2/3 its volume.
- Now transfer the diluted digested sample into the sample funnel and open the stopcock to allow the sample to drop into the mixing chamber.
- Rinse the Kjeldahl tubes with 10-15ml of distilled water and add the wash water to mixing chamber.
- Close the stopcock of the sample addition funnel and add sodium hydroxide (50%) solution to the sample funnel.
- Place the receiver conical flask containing 10 ml of boric acid with indicator with the outlet tube properly submerged into the solution.
- Now allow the sodium hydroxide solution to drop slowly into the mixing chamber by gently opening the valve of the sample addition funnel. Add 15-20ml of distilled water to the sample addition funnel and allow it to drop into the mixing funnel. Now close the sample addition funnel leaving some residual water in the funnel to work as water seal.
- Start heating of the content of the mixing chamber and continue for 20-30min, or until the colour of the indicator solution is changed from bluish purple to bluish green. Collected 15-20 ml of distillate.
- Finally slow down the heating intensity and gently remove the receiver flask while rinsing the outlet tube.

3. Titration

- Now titrate the distillate against 0.01 N HCl till the bluish green colour changes to pink.
- Run a blank preparation which has been identically prepared except that it does not contain the sample.

5.2.4 Observations

Parameters			
Sample titration value, ml			
Blank titration value, ml			

% Nitrogen is calculated as follows:

$$\%\text{Nitrogen} = \frac{(\text{Sample titre} - \text{Blank titre}) \times N \times 14 \times 100}{\text{mg of sample}}$$

N = Normality of HCl

% Crude protein = %Nitrogen × Protein factor.

5.2.5 Results

Calculate crude protein using above formula. Take the average of three values and report the crude protein content in percent.

5.3 PRECAUTIONS

- The digestion should be done in a closed cabinet so as to avoid inhalation of the fumes.

- During distillation, the outlet tube must be submerged into boric acid.

EXPERIMENT 7 FREE FATTY ACIDS (FFA)

Structure

7.1 INTRODUCTION

A small quantity of free fatty acids (FFA) is usually present in oil / fat along with the triglycerides. The content of FFA is known as acid number / acid value. It increases during storage of oil / fat as such or on oil/fat rich foods. Oil used for food purposes should have FFA level less than 1.5% as its keeping quality relies upon the FFA content.

Objective

After studying this experiment, you should be able to:

- determine the free fatty acid content of oil.

7.2 EXPERIMENT

7.2.1 Principle

The content of FFA in an oil is estimated by titrating it against KOH in the presence of phenolphthalein indicator. The acid number is defined as the amount (in mg) of KOH required neutralizing the free fatty acids in 1g of oil sample.

7.2.2 Requirements (Equipment/Machinery/Instrument and Chemicals/ Material)

- Solvent (Mix 100ml of 95% aqueous ethyl alcohol with 100ml of diethyl ether. Neutralize the solvent with 0.1N using phenolphthalein indicator).
- Potassium hydroxide, 0.1N
- Indicator dye (Dissolve 500mg phenolphthalein in 50ml 95% ethyl alcohol)
- Water bath
- Analytical balance

7.2.3 Procedure

- Transfer 10g accurately weighed sample of oil into 250ml Erlenmeyer flask and add 50 ml of neutralized solvent. Add a few drops of phenolphthalein indicator.
- Keep in water bath at 50°C for 15min with continuous agitation.
- When the content is properly mixed titrate the content against 0.1 KOH until the appearing pink colour persists for 15 sec.

7.2.4 Observations

Parameters	**Sample number**		
	1	**2**	**3**
Titre value, ml			

7.2.5 Results

Calculate FFA content in terms of acid value using the formula given below. Take the average of three values and report the results.

$$\text{Acid value} = \frac{\text{Titre value} \times \text{Normality} \times 56.1 \text{ of KOH}}{\text{Weight of the sample (g)}}$$

7.3 PRECAUTIONS

- Continuous agitation is required while titrating.

UNIT 1 IMPORTANCE OF POST HARVEST MANAGEMENT

Structure

1.0 OBJECTIVES

After reading this unit, you should be able to:

- understand how post harvest management can reduce losses after harvest and increase food availability thereby provides food and nutritional securities;
- state proper post harvest care can add value and provide benefit to the producers and consumers;
- explain efficient post harvest operation can generate employment and bring rural industrialization;
- highlight the role of post harvest technology for better economy of the country through export earning; and
- demonstrate how appropriate post harvest management and processing can utilise unmarketable produce and processing waste for gainful purpose hence reducing pollution and city garbage.

1.1 INTRODUCTION

India is a vast country and a wide range of variety of fruits and vegetables are cultivated in different regions. There has been a phenomenal rise in production of fruits and vegetables in our country since Independence. As per the data for 2000-2001, the production of fruit is about 45.37 million metric tonnes and vegetable about 93.92 million metric tonnes available in India and going to be doubled by 2011 and is considered to be the second largest producer next to china in the world. Unfortunately, unlike other horticulture rich countries, average Indians do not get the basic daily requirement of fruits and vegetables and our Human Development Index is very low. This is because a considerable amount of this valuable produce is lost due to improper post harvest management. High moisture content, living nature and presence of readily utilizable nutrients make fruits and vegetables highly perishable commodities.

Spoilage mainly occurs due to microbial attack, auto-oxidation and insect pest attack. According to a study, at least 25 to 30 percent of the production of fruits and vegetables in the country is lost due to wastage and value destruction. The wastage cost was estimated to be Rs. 67,500 crores each year. Even if 1% of this could be saved by converting them into value added products, there will be a saving of Rs. 67.5 crores annually. Further, the cost of reducing spoilage is much lesser than the production of the same quantity and quality produce. Post harvest management of horticultural produce is therefore the need of the hour in order to feed ever-growing population of the world in general and India in particular. The most important advantage of post harvest management and processing is the reduction of post harvest losses of fruits and vegetables.

1.2 INCREASE FOOD AVAILABILITY

It is well known fact that fruits and vegetables are perishable in nature due to its high moisture content, high rate of physiological activity viz. respiration and ripening, microbial attack, rapid bio-chemical changes such as enzyme activity, softening of the texture and many other biotic and abiotic factors. Harvesting season of almost all fruits and vegetables is very narrow lasting only for 1-2 months. During this short period, availability of that particular fruits and vegetables is abundant but at the end of harvesting season, products availability decreases rapidly and may be completely out of market within 1-2 months. Here, therefore comes the role of Post harvest management of horticultural commodities like proper handling, packaging and storage at safe low temperature, maintenance of cool chain during transportation and marketing, pre and post harvest treatments in order to increase self - life and reduce the overall spoilage etc. These practices make fruits and vegetable available through out the year. Many modern technologies such as refrigerated storage and transportation, Controlled and Modified storage, irradiation, processing into value added products are some of the ways to extend the availability of fruits and vegetables beyond the end of the harvesting season. In this way, the food already produced can be saved for consumption by applying the techniques of post harvest management and indirectly increase food availability. Attention to the concept of post-harvest food loss reduction as a significant means to increase food availability was drawn by the World Food Conference held in Rome in 1974. The seventh session of the U.N. General Assembly in 1975 passed a resolution calling for a 50 percent reduction of post harvest losses by 1985. In the FAO, after consultation with its Governing Body food loss prevention became a priority area and an Action Programme became operational in early 1978. The Food Loss Prevention Programme of FAO till recently focussed mainly on the durable food grains, because of the prominence in daily diet. Only in May 1980, an Expert Consultation on Food Loss Prevention in Perishable Crops mainly covering fruit and vegetables was held in Rome.

1.3 NUTRITIONAL SECURITY

Fruits and vegetables constitute an important part of human's food. Even though they are generally not considered as a staple food yet they help in intake of cereal foods by making them more palatable in nature. Fruit and Vegetables in general, except for a few, are not considered to be the primary source of carbohydrate, protein and fat. However, some of them with storage roots and tubers are rich in carbohydrate, particularly starch, in amounts comparable to the cereal crops, and the leguminous vegetables supply as much as 14 per cent protein, dry seeds supplying still more. The lipid content in most vegetables is less than 0.1 per cent. Most fruit, vegetables and root crops are rich in minerals, carotene (Pro-vitamin A) and vitamin C. Besides, there are some trace elements required by the body like copper, manganese and zinc, which act as coenzymes. These are found in appreciable quantity in fruit and vegetables. The amount of nutrient can vary with fruit and vegetables, cultural practices, stage of maturity, post-harvest handling and storage conditions. Once they are harvested, their composition goes on changing as a result of physiological and biochemical activities, which are natural processes. Fruits and vegetables are the rich source of vitamins, minerals, and trace elements, deficiency of which leads many diseases such as scurvy, beriberi, night blindness etc. In addition, most of the fruits and vegetables are also loaded with antioxidants and fibers. Antioxidant neutralizes free radicals produced in the body that is found a possible cause of cancer and also prevents faster aging. At the same time fiber controls many cardiovascular diseases and movement of foods in the digestive system. Several vitamins and minerals that are scarce in cereals and animal products are present in abundance in fruits and vegetables. Beside this, fruits and vegetables also supply carbohydrates and protein and fulfill the essential nutrients in human diet. Therefore, human health is protected if fruits and vegetables or their processed products are consumed regularly. Fruits and vegetables are therefore considered as protective foods. Further, several vitamins, minerals and phyto-hormones found in fruits and vegetables have now assumed the status of functional food. These substances are capable of providing additional physiological benefit, such as prevention or delaying onset of chronic diseases, as well as meeting nutritional requirements. Keeping in view the nutritional quality of fruits and vegetables, post harvest management of these perishable commodities is the only solution for nutritional security to ever growing population of the country.

1.4 EMPLOYMENT GENERATION

Employment generation of Indian Youth is becoming more and more difficult with increasing in population. It has been observed that job opportunities in government sectors are shrinking day by day and private companies closing fresh recruitment. For rural youth, it becomes more and more difficult to get a good or moderate employment in rural areas as a result unemployed rural youth are rushing towards towns and cities to do any sort of work. This type migration of population from rural to urban area is detrimental to the society. In addition, this situation is creating a big problem in metro cities. Therefore it is the need of the hour that these youth start their own ventures that should not only be remunerative and attractive in nature but also easy to operate. Post harvest handling and processing of fruits and vegetables is one such area that can provide great possibility for employment generation. During harvesting season, people can get employment in harvesting, pre-treatments if any, packaging and transportation of fresh produce to towns and cities. The surplus production and cull fruits and vegetables can be converted into pulps and value added products during the season and later it can be used to prepare various tertiary processed products. All these operations require human resources in large quantity.

A fruit and vegetable processing factory having a capacity of 10qt/month can engage 4-6 people for the whole year. In addition in order to handle freshly produced fruits and vegetables properly grading and packing stations and quality control laboratory have to be developed to keep the pace of development process. Further, as ancillary industries manufacturing units for food processing machinery, packaging materials both for fresh and processed fruit and vegetable products will also develop side by side and generate employment. Other relevant industries and establishments, such as, retail outlets etc, will also provide additional employment. In our country 90% of fruit and vegetable produced are marketed by the farmers compared to only 20% of cereals/food grains production of India.

Employment potential of food processing industries is much higher compared to many other relevant industries. For example per 1,000 crores of investment employment potential in food is 54,000 compared to textiles –48000 and paper –2500. It has been reported that there is a 4 fold indirect employment on investment in food and it provides 60% employment in small towns and rural areas. Our aim is to increase processing from present level of 2% to 10% by 2010 that will involve an investment of Rs.1,40,000 crores generating direct employment 77 lakh and indirect employment 3 crores.

1.5 VALUE ADDITION

Horticultural produce in general and fruits and vegetables in particular generate a large amount of valuable waste such as inedible plant parts as such for human food that end up as garbage. However, if they are gainfully utilised at the proper time they can produce value added products. Vegetables such as cauliflower, peas, leafy vegetables, etc. can be primarily/minimally processed so that inedible parts are removed before being sent on to the metropolitan city markets. They should be unit packed at packing stations situated at appropriate points in every district. This process will reduce the transportation and handling cost of inedible parts and help the consumer by providing a convenience food. The consumers particularly the working women would be willing to pay higher prices because these ready to use products save lots of time, in kitchen besides labour and space. Similarly, bananas should be transported in hands as is done in other countries. Each packing station should have the facility for processing. Physically damaged fruit and vegetables that are without infection but would be spoiled on storage can be made into durable and value added processed products at this point. Utilization of physically damaged fruits and vegetables into value added processed product could considerably reduce the price of main product as a result more processed food products will come within the reach of common people.

Fruits and vegetables are perishable in nature, it can not be stored for longer period. It has been observed that about 25-30% of total production are not fit for fresh marketing and called culled produce. These produce are undersized, oversized and malformed/deformed and physically damaged fruits and vegetables but microbiologically sound at the time of harvest. The produce of this category either sold at throw away prices or left to spoil as such. Thus a huge quantity of horticultural produce in the form of cull fruits and vegetables occurs every year which otherwise could be utilized, if processed into various value added by products. Fruits and vegetable processing units also generate large amount of valuable waste such as peel, stones and other inedible plant parts that are generally not utilsed properly and rejected as such in our country and finally end up as garbage. However, if they are gainfully utilised at the proper time they can become value added products. Some of theses waste are rich source of vital constituents like carbohydrates, protein, fat, minerals, edible fibres, etc. and also constituents of commercial use such as pectin, starch, colours/ pigments, essential oils, sugars, vinegar, alcohol, and many compounds useful in food and beverage industries. In addition the waste may be used as cattle feed that is in short supply in our country. These waste processing not only gives value added products but also reduce the price of the primary processed products that are sold at a premium price in our country beyond the means of the common people. In general, it improves the overall economy of the country. Premature fruit drop due vagaries of climate such dust or hailstorm is also a big problem in India. As a result a substantial quantity of fruits and vegetables are lost before they attend proper maturity stage. These produce can be utilized usefully if processed into value added products such as pulp, pickle, chutney, dried powder etc.

During peak harvesting season a good amount of quality fruits and vegetables are available in abundant quantity resulting in market glut and all of these quality produce can not be marketed in the fresh form. As a result, there is huge spoilage and wastage of fresh fruits and vegetables. This wastage can be reduced if they are timely processed into different value added products or preserved by different methods during harvesting season. Now it can be used throughout the year and can be transported to distant market. Value added products not only palatable but also nutritious and gives economic gain. Nutritional value of these products can be increased many folds through fortification particularly of protein, vitamins and minerals. Processing serves as an outlet for surplus production and therefore acts as price stabilizer. Fruits are generally consumed as fresh but mostly vegetables are cooked before consumption expecting a few ones like cucumbers, tomatoes etc. Value addition also includes peeling, slicing, cutting into pieces, processing and packaging. All such activities increase value of the products.

India has a wide range of indigenous fruits that are underutilized. Most of these fruits are tropical/subtropical in nature and grow even under adverse agro-climatic conditions. A large number of these fruits are known for their therapeutic/medicinal and nutritive value and have excellent flavour and very attractive colour. Some of these fruits are not easy to eat out of hand e.g. baelfruit that has a hard shell, mucilaginous texture and numerous seeds; as a result it is not popular as a dessert fruit. Kokum is not acceptable as a fresh fruit because of its high acidity, only its thick outer rind is used in beverage industry or for culinary purpose in the dried form. Similarly aonla as a fresh fruit is not liked because of its strong astringent taste. All these fruits have a great potentiality to processing into a value added fruit products of commercial importance. So that the growers get a remunerative price and consumers get the opportunity to enjoy the indigenous fruit products. A shrink-wrapped fruit and vegetable fetches more prices compared to non shrink-wrapped ones because of value addition.

It has already been mentioned that less than 2% of production of fruits and vegetables in India goes for processing. As a result, value addition in food sector is low at 7%. The production of fruits and vegetables in our country is now 66% of food grains. It is expected that this figure is likely to be 80% by 2010. With proper infrastructure facility for post harvest handling and processing, value addition will correspondingly go up from 7% to 35 % resulting in increases in GNP.

1.6 EXPORT EARNING

It is known that about 84 different fruits and 63 items of vegetables are traded in world market. In addition a large number of fruit and vegetable products are also marketed. India by virtue of its varied agro-climatic conditions has the advantage of producing most these fruits and vegetables and processing them into products that can be traded in the world market. In order to achieve export potential, following fruits have been identified as having good market potential viz. Mango, Grapes, Banana, Lychee, Exotic fruits Chikoo, Ber, Pomegranate, Amongst vegetables the items identified as having good export potential are - Onion, Potato, Green vegetables. The following two categories of vegetables also has great potentiality: a) Traditional - okra, bitter gourd, chili and other seasonal vegetables; b) Non-traditional - asparagus, celery, broccoli, bell pepper, sweet corn and baby corn; green and lima beans.

India has vast resources of indigenous fruits and vegetables that have established medicinal and therapeutic values apart having high nutritive value, attractive color and excellent flavor viz. aonla, baelfruit, jamun, kokum, phalsa etc. There is always a demand all over the world for new, nutritious, attractive and delicately flavoured products. Also, the trend today is a return to the natural and a preference for the therapy provided by nature. Consumers today are becoming increasingly conscious of the health and nutritional aspects of their food. The tendency is to avoid chemicals and synthetic foods and choose therapy and nutrition through natural resources. The underutilised fruits of India have an important role to play in satisfying the demand for nutritious, delicately flavored and attractive natural foods of high therapeutic value. The development of these fruits can considerably contribute to crop diversification, farm income and the improvement of nutrition and also provide valuable exports and additional employment. Therefore, among these indigenous fruit lies an untapped potentiality for processing into value added products that can attract export market. For example, Bael and Aonla are indigenous fruits having highest riboflavin (Vit. B2) and vitamin C respectively. Increased health consciousness in the masses will boost their consumption in India and in International market. Any Aonla products can be exported as they are rich in vitamin- C. Therefore, export of these indigenous fruits and vegetables and their processed products can earn valuable foreign exchange. Though some fruit products, are being manufactured at present on a small scale, inspite of such favourable possibilities no systematic approach has been made to utilise the potential of the indigenous fruits on a large scale mainly because of the lack of the requisite amount of raw material. Organised orcharding and systematic collection of raw material is of utmost importance. Kiwi fruit that was practically unknown in the world market a few years back, is now in the forefront of international fruit trade. The New Zealand Kiwi Fruit Marketing Board highlighted the plus points of Kiwi Fruit such as thirst quenching, highly nutritious, rich in Vitamin -C, good for maintaining health, slimming effect etc. to make it popular among the consumers the world over. There is no reason why we can not achieve similar success. Instead of trying to compete in a market where other countries are already established and far ahead we must break new ground and create markets for our indigenous fruits where no other country can compete with us.

Freezing is rated as the best technique available for food preservation since it maintains the natural properties by reducing post harvest changes and microbial deterioration to the barest minimum without any influence on the original qualities. The rate of freezing plays a great role on the quality of frozen fruits and vegetables; faster freezing rate is required to obtain better quality. Liquid nitrogen is the most common cryogenic substance fused in food freezing. Ultra quick freezing rate, minimum dehydration less, freedom from oxidative changes, minimum freezing damage of freeze sensitive products, maximum quality retention of texture, colour and flavour of sensitive fruits and vegetables during freezing and the inert nature of the freezant are the advantages of liquid nitrogen freezing. A systematic establishment of quick freezing industry can boost export trade of our country. Methods have been standardized under laboratory conditions for the manufacture of cryogenically frozen, crack free, peeled ripe mango slices having excellent retention of quality attributes, well comparable with those of fresh mangoes in ready-to-serve form and cent-per-cent edible portion. This will have a great potentiality in export trade. The problems generally facing the export of fresh mangoes, like short storage life, added bulk of stone and peel, hidden disorders like spongy tissue and stone weevil can be successfully overcome by producing the cryogenically frozen mango slices.

Hardly there is any fruit that is not cultivated in this country. At present only few established fruits and vegetables are exported. Government has already recognized it as one of the major thrust for augmenting the countries export. Lack of proper post harvest management and infrastructure facilities are the major hurdles for export of horticultural produce. Countries like Indonesia, Malaysia, Thailand etc. are far behind in production of fruits and vegetables compared to India but their exports are many folds higher than our country. It is mainly because of good post harvest management practices, quality maintenance through out the marketing channel and basic infrastructure for export

1.7 RURAL INDUSTRIALISATION

Post harvest management and processing of fruits and vegetables is the backbone of the horticulture industry as it takes care of gluts and all possible wastage that occur during handling, storage, distribution and marketing. Most growers are rural people. During peak harvesting season, always there is glut. There is no preservation unit, grading and packinghouse in rural areas. They can not hold their produce, even for few days due to lack of storage facility and they are unable to preserve their produce. This situation forced them to sale their good quality produce at very low price to middleman. Cull fruits and vegetables are generally goes waste or sold at a throw away price. After harvesting season is over, again rural people become jobless. They generally migrate to cities in search of any sort of job. Setting up of small and cottage level preservation factory at village level not only reduces losses due to glut but also provides jobs for rural people. It can always fetch an additional income to the grower and help in stabilizing the prices and providing economic return. Hence, fruit and vegetable processing industry should be encouraged and developed in rural areas, a way of rural industrialisation

1.8 BENEFICIAL TO PRODUCERS AND CONSUMERS

In a country like India, transportation facilities are not so good, rural electrification is also in infancy stage and huge production of horticultural produce occur in different parts of the country particularly in the rural areas and under developed areas. There is always abundance of produce at the production site but scarcity of the same produce at consumption places.

Growers at production site sale their produce at the lowest minimum price due to fear of spoilage. However, the consumers purchase the same commodities at a very high price in cities and urban areas due to involvement of middle man. In this way, both producers and consumers suffer and middle man only get advantage. To overcome this situation, growers should be trained properly about post harvest management, storage and processing of fresh Fruits and vegetables. There must be on farm storage facilities viz. pusa zero energy cool chamber for short duration storage. Cottage and small scale level fruit and vegetable processing unit must be encouraged so that cull fruits and Fruits and vegetables can be converted into value added products, properly stored and processed products can be transported to the places of scarcity during their harvesting season and after the season is over. In this way a glut like situation can be avoided in production areas. Growers will get a good price for their produce and consumer will have to pay a reasonable price only.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. What are the major factors responsible for spoilage of fruits and vegetables?

1.9 LET US SUM UP

Fruits and vegetables are highly perishable in nature that results in rapid spoilage and deterioration in quality. However, proper post harvest management can reduce this spoilage. The cost of reducing spoilage is much lesser than the production on additional land. A good post harvest management reduces spoilage by preserving seasonal surplus and cull fruits and vegetables, which often lie rotting on the roadside. Processing and value addition increases food availability, generates cattle feed by converting factory waste thus reduces garbage accumulation. Growers get remunerative price of their produce and consumers buy it at reasonable price. Many indigenous fruits and vegetables, which are not generally marketed, as fresh can be processed into value added products for export. These products are in demand in national and international market due to its medicinal and therapeutic properties. Fresh as well as processed fruits and vegetables is rich source of vital nutrients like vitamins, minerals, fibers etc. It gives nutritional security forever growing population and protects their health.

1.10 KEY WORDS

Post harvest management : Methods and techniques applied to increase the shelf life and retain quality of horticultural

		produce either as fresh or processed into different products.
Post harvest losses	:	Losses of horticultural commodities in quality and quantity after harvesting till consumption.
Food availability	:	Availability of fruits, vegetables and their processed products beyond their harvesting season or round the year.
Irradiation	:	Exposure of biological materials to radiation such as X-ray, gama-ray, electron beams etc.
Antioxidants	:	Substances which prevent oxidative reaction in foods.

1.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - High moisture content.
   - More physiologically active.
   - Soft texture and rich nutrients invites microbes and insect pest.
   - Susceptible to rapid enzymatic oxidation.

2. Your answer should include the following points:

   - Post harvest losses reduction at different stages increases food availability.
   - Processing of surplus fruits and vegetables into value added products.
   - Utilization of cull fruits and vegetables into processed products.
   - Increases shelf-life of fruits and vegetables by improved post harvest management.

3. Your answer should include the following points:

   - Fruits and vegetables processing industry utilizes surplus and cull produce.
   - It provides more employment and occupation for rural people.
   - It saves farmers from distress selling.
   - Ideal in rural areas due to cheap availability of raw material and local labour.

4. Your answer should include the following points:

   - Indigenous fruits and vegetables having medicinal and therapeutic properties.

   - Cull and surplus produce can be utilized for preparation of various products instead of throwing for spoilage.

   - Waste generated during processing can be processed either into animal feed or for use in related industry.

- It generates employment, animal feed and prevents garbage accumulation.
- Earns valuable foreign currency and saves Indian currency paid for import of processed fruits and vegetables products.
- Fulfills Defense requirements.
- Improves overall Indian economy.

5. Your answer should include the following points:
   - Better post harvest infrastructure for export purpose.
   - High tech processing like cryogenic freezing and aseptic packaging.
   - Fresh vegetables rich in anti-oxidant medicinal value.
   - Processing of indigenous tropical fruits rich in nutrient and therapeutic value.

6. Your answer should include the following points:
   - Fruits and vegetables are rich source of vitamins which prevents diseases like scurvy, Beriberi, night blindness etc.
   - They are also rich source of antioxidants neutralizes free radicals formed in human body that causes sometimes cancer and accelerates faster aging.
   - Minerals found in fruits and vegetables take part in various biochemical reactions.

1. Cruess, W.V. (1997) Commercial Fruit and Vegetable products, Allied Scientific Publishers.
2. Lal, G., Siddapa, G.S. and Tandon, G.L. (1986) Preservation of Fruits and Vegetables. India Council of Agricultural Research, New Delhi.
3. Ranganna, S. (2000) Hand Book of Canning and Asceptic Packaging, Tata McGraw Hill Publishing Company Limited New Delhi.
4. Srivastava, R.P. and Kumar, Sanjeev (1998) Fruit and Vegetable preservation, (Principles and Practical), International Book Distributing Co: Lucknow.
5. Verma, L.R. and Joshi, V.K. (2000) Post harvest Technology of Fruits and Vegetables. Volume 2, Indus Publishing Company: New Delhi.
6. Woodroof, J.G. and Luh, B.S. (3rd Ed.) (1986) Commercial Fruit processing, AVI Publishing Company; Westport.

UNIT 2 CAUSES OF PRE AND POST HARVEST LOSSES OF FRUITS AND VEGETABLES

Structure

2.0 OBJECTIVES

In this unit we will discuss the pre- and post-harvest factors for post-harvest losses of fruits and vegetables.

After going through this unit, you should be able to know the:

- role of cultural practices (irrigation, nutrient deficiency) and maturity index in post-harvest losses of fruits and vegetables;

- infestation of pest and disease and their contribution to post-harvest losses;
- role of environmental factors such as soil condition, climate, frost, hail, pollutants etc. in post-harvest losses; and
- improper handling, storage, transportation and socio-economic factors and their impact in post-harvest losses.

2.1 INTRODUCTION

Fruits and vegetables not only provide nutritional security, but also generate a high income to growers. Better production practices, careful harvesting and proper packaging, storage and transport contribute to the good quality produce. Once a crop is harvested it is impossible to improve its quality. Because of high moisture content, fruits and vegetables are inherently more liable to deteriorate. After harvest, they are also biologically active and carry out transpiration, respiration, ripening and other biochemical activities, which deteriorate the quality of the produce. In India, the post harvest losses of fruits and vegetables is varying from 25-40% /depending upon the kind of produce and its pre and post-harvest practice. This can occur in the field, in packing houses, in storage, during transportation and in the wholesale and retail markets. Severe losses occur because of poor infrastructure, poor pre and post harvest management, marketing of the produce.

Biological causes of deterioration of fruits and vegetables include metabolic changes (respiration, ethylene production and action, compositional changes), mechanical injuries (cuts, bruises, abrasions, etc.), incidence of physiological disorders, and pathological breakdown. The rate of biological deterioration depends on various environmental factors including temperature, relative humidity, and concentrations of ethylene, oxygen, and carbon dioxide.

The loss in food value of fruits and vegetables may be attributed after harvesting through several ways:

- Water content is reduced with time as the continuation of living processes within the produce and as result the commodity gets shrivelled and loses its turgidity.
- Vitamin C content decreases with time after harvest.
- Cooking partially destroys water soluble vitamins B and C.
- Peeling may cause significant loss of food value, since most of the nutrients are in engrossed in epidermis skin especially in potatoes, where the protein content is just adhering to skin.
- Water used in cooking vegetables dissolved minerals and trace elements.

2.2 PRE-HARVEST FACTORS IN POST HARVEST LOSSES

2.2.1 Choice of Cultivars and Planting Materials

The healthy crops will only come from healthy and good quality planting materials. The market quality of the produce is determined by selecting the crops, their cultivars, and the production system. It is well known that some cultivars have better palatability apart from better transport quality and longer shelf life than others. While selecting planting materials following points should be taken into consideration.

What Needs to Do?

- Choose cultivars that will have better quality attributes and as per the demand of the consumers.
- Use clean, healthy, high quality planting materials.
- Grow off-season cultivars of the same crop to extend harvest period.
- Choose cultivars that are well suited to the specific climate, day length, soil and growing conditions.
- Always select seed from the good quality produce or source.

2.2.2 Cultural Practices

Cultural practices can also affect post-harvest quality. Produce that has been stressed by too much or too little water, high rates of nitrogen, or mechanical injury (scrapes, bruises, abrasions) is particularly susceptible to post-harvest diseases. For example, mold and decay on pumpkin and squashes caused by the fungus *Rhizoctonia* results from the fruits lying on the ground. Cauliflower curds are susceptible to post-harvest rot caused by the bacteria *Erwinia* if nitrogen is applied as foliar spray. Beets and radishes are susceptible to soil-borne diseases when the soil temperature reaches 80º F. The finger rot in banana and stem end rot in mango caused by *Botryodploidia theobromae* is more severe when temperature is above 30^0C and 20^0 C and bow the growth of the fungus is poor.

Several diseases outbreaks in the field may cause food borne illnesses which have been traced to contamination of produce in the field.

What Measures to Take?

- Follow only recommended practices in terms of variety, season its manure/fertilize doses, irrigation level and the care during growing and after harvesting.

2.2.3 Irrigation

Growing plants need a continuous water supply for both photosynthesis (the process by which plants convert light to chemical energy and produce carbohydrates from carbon dioxide and water) and transpiration (the giving off by a plant of vapour containing waste products). If banana is allowed to mature fully before harvest and harvesting is shortly after rainfall or irrigation, the fruit can easily split during handling operations, allowing micro-organism infection and post-harvest rotting.

Bad effects can be caused by:

- The use of irrigation methods that spray water on foliage or excessive rainfall can increase incidence of disease and fungal infections.
- Excess rain or irrigation during growing and before harvesting can contribute to loss of flavour in many crops and increased susceptibility to bruising and decay in storage, respectively.
- Lack of rain or irrigation during growing can cause low juice content and thick skin in citrus fruit.

- Dry conditions followed by rain or irrigation, give rise to growth cracks or secondary growth in potatoes and growth cracks in tomatoes.

Judicious application of water during the maturity will reduce the post-harvest losses of fruits and vegetables.

2.2.4 Nutrient/Mineral Deficiency

Lack of plant nutrients in the soil can seriously affect the quality of fresh produce at harvest. On the other hand, too much fertilizer can harm the development and post-harvest condition of produce. Crops which contain high levels of nitrogen have poorer keeping quality than the same variety of crop with lower nitrogen levels. The problem of fertilizer balance in soils and its effect on crops is complex and depends also on other conditions such as temperature, moisture, acidity of the soil and reactions among different fertilizer chemicals. Imbalance of fertilizers can result in several physiological disorders which alter the appearance and ultimately consumer's acceptance of the fruit and vegetable produce during post-harvest period.

Nutrient deficiency	Physiological disorder
Calcium	blossom end rot in tomato and capsicum, internal browning in Brussels sprout, internal tip burn in cabbage, cavity spot and cracking in carrot, black heart in celery, hollow stem in cabbage, cauliflower and Brussels sprouts, bitter pit in apples, calyx en rot in persimmon, leaf drop in peach etc.
Boron	cracked stem in celery, root split in carrot, brown heart or root canker in beet, browning of curd in cauliflower, lumpiness in papaya, internal necrosis in mango, fruit cracking in pomegranate, russeting and internal cork in apple etc.
Molybdenum	whiptail in cauliflower, yellow spot diseases in oranges
Manganese	marsh spot in peas and beans
Nitrogen	stunted growth or yellow-red discoloration of leaves in green vegetables
Magnesium	Interveinal chlorosis in apple

2.2.5 Other Cultural Practices

- Pruning and thinning – improves sun penetration and ventilation which is important for uniform fruit colour development, increase in fruit size and quality, but yield decreases slightly. Encouraging plants to grow upward on trellises also lowers relative humidity and reduces incidence of disease.

- Weed control – weeds are commonly alternative hosts for crop diseases and pests. Weeds also compete with crops for nutrients and soil moisture and thereby reduce the quality of fruits and vegetables.

- Crop hygiene – decaying plant residues, dead wood and fruit and vegetables wastes are all reservoirs of infection causing post-harvest decay. Their collection and removal are important to keep your crop safe from bacterial and fungal infection.
- Use cultivation practices that are recommended and appropriate for the region and climate.
- Pesticides and herbicides can damage by causing spray burns and leave poisonous residues if used incorrectly.
- Growth-regulating chemicals are used mainly to improve marketability of fruit by controlling the time of fruit set and promote uniform ripening. They require specialist knowledge.

2.2.6 Improper Harvesting

A critical time for growers of fruit and vegetables is the period of decision on when to harvest a crop. Normally fruits and vegetables are harvested when they have developed to the ideal condition for consumption. This condition is usually referred to as harvest maturity. Confusion may arise because of the word maturity since, in the botanical sense, this refers to the time when the plant has completed its active growth (vegetative growth) and arrived at the stage of flowering and seed production (physiological maturity).

Maturity whether viewed as physiological maturity or harvestable maturity can have a pronounced influence on the quality of fruits and vegetables. Optimum maturity at harvest depends on the market or intended use (storage, fresh consumption and processing). For many vegetables the optimum eating quality is reached at tender stage e.g. leafy vegetables, cucumber, bottle gourd, green peas, beans, okra etc. Delayed harvest will lead to fibre development. The good quality fruits are obtained when harvesting is done at proper stage of maturity. Immature fruits when harvested will give poor quality and erratic ripening. For example the fruits of mango are harvested based on fullness of cheeks, colour in pedicel end whereas banana fruits are harvested based on fullness of fingers and disappearance of angularity on the surface.

Method of harvesting is as important as time of harvesting. Faulty harvesting and rough handling at the farm directly affect market quality. Injury to peel may serve as entry port for the micro-organisms and lead to rotting. For example, banana bunches should be cut leaving 30 cm of stalk.

2.2.7 Post-harvest Physiology

The quality of the harvested fruits and vegetables depend on the condition of growth as well as physiological and biochemical changes they undergo after harvest. Fruit and vegetable cells are still alive after harvest and continue their physiological activity. The post harvest quality and storage life of fruits appear to be controlled by the maturity. If the fruits are harvested at a proper stage of maturity, the quality of the fruits shall be good. Poor quality and uneven ripening are due to early and late harvesting may result in extremely poor shelf life.

Respiration generates heat as sugars, fats, and proteins in the cells of the crop are oxidized. The loss of these stored food reserves through respiration means decreased food value, loss of flavour, loss of saleable weight, and more rapid deterioration. The respiration rate of a commodity strongly determines its transit and post-harvest life. The higher the storage temperature, the higher the respiration rate will be.

Respiration plays a very significant role in the post harvest life of the fruits. In most of the fruits, the rate of respiration increases rapidly with ripening. The sudden upsurge in respiration is called the 'climacteric rise', which is considered to be the turning point in the life of the fruit. After this the senescence and deterioration of the fruit begin.

Climacteric fruits	**Non-climacteric fruits**
Apple, banana, papaya, mango, guava, jackfruit, fig, sapota, tomato, musk melon, water melon etc.	Litchi, pineapple, grapes, pomegranate, lemon, orange, lime, cucumber etc.

To extend the post harvest life of the fruits its respiration rate should be reduced as far as possible. Thus an understanding of the factors, which influence the rate of respiration, is indispensable to post harvest technologies for manipulating the storage behaviour of fruits and vegetables.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Match the following:

Nutrient deficiency	**Physiological disorder**
(a) Calcium deficiency	i) marsh spot in peas and beans
(b) Boron deficiency	ii) Inter-veinal chlorosis in apple
(c) Molybdenum deficiency	iii) browning of curd in cauliflower
(d) Manganese deficiency	iv) whiptail in cauliflower
(e) Magnesium deficiency	v) bitter pit in apples

(a)	
(b)	
(c)	
(d)	
(e)	

2. Critically analyse the role of cultural practices in post harvest losses of fruits and vegetables with suitable examples.

………………………………………………………………………………

………………………………………………………………………………

2.3 BIOLOGICAL FACTORS

Heavy post-harvest losses are occurred by the invasion of fungi, bacteria, insects and other organisms. Microorganisms attack fresh produce easily and spread quickly, because the produce does not have much of a natural defense mechanism after the harvest and has plenty of nutrients and moisture to support microbial growth. Almost all post-harvest pests originate from field infestations, and if the storage condition is conducive they can multiply on.

2.3.1 Pathological

Plant pathogens cause substantial losses of fruits and vegetables during production. Specific pathogens also resulted in undesirable post-harvest losses. For example, bacterial spots in tomato caused by *Xanthomonas campestris* pv vesicatoria; white mould *(Sclerotinia sclerotiarum)* produces white mycelium in blossom end of cucurbits.

Viral disease like Zucchini Yellow Mosaic virus of summer squash *(Cucurbita pepo)* resulted small distorted fruit and tomato mosaic virus causes discolouration of mature tomato fruits. Black mould rot caused by *Aspergillus niger,* bulb rot by *Fusarium solani* and bacterial rot by *Pseudomonas* sp. infection during cultivation of onion may cause damage during storage. Preharvest infection of fungi, *Botryodiploidia theobromae* and *Glomerella cingulata* cause stem end rot and anthracnose disease, respectively, in mango which usually develop as the fruits ripen. These diseases are also to be effectively controlled before harvest otherwise act as inoculums for post harvest loss.

2.3.2 Entomological

Feeding by different insect generally resulted in distinctly undesirable appearance of the produce. For example, cabbage loopper *(Trichoplusia nii)* create holes in foliage and head becomes unacceptable. Some insects cause primary damage by developing larva that tunnel throughout interior portion of the produce as sweet potato weevil, *Cylas formicarius*. Another form of damage produced through lack of or incomplete pollination resulting in misshapen fruits. For example, cucurbits exhibit small, distorted fruits that are generally shed before reaching harvestable maturity when pollination is inadequate. In the fruits of mango, the insects like fruit flies (*Bactrocera dorsalis*) and mango stone weevil (*Sternochetus mangiferae*) those invaded at the time of flowering, remained inside the fruits till the ripening of fruits. These fruits are unfit for consumption and cause the damage even during storage.

2.4 ENVIRONMENTAL FACTORS

The environmental factors such as soil type, temperature, frost, and rainy weather during growing and at harvest can have an adverse effect on storage life and quality. For example, carrots grown on muck soils do not hold up as well in storage as compared to carrots grown on lighter, upland soils.

2.4.1 Climate

Temperature during growth affects cucumber fruit length and thus repressing development. Likewise, cucumber fruit curvature is increased with increasing temperature. High temperature during pollination resulted in puffiness of fruit in tomato.

2.4.2 Chilling Injury

Chilling injury is often associated with storage but it also occurs prior to harvest. In sweet potato, chilling injury increases rotting and the formation of 'hard-core' a condition where a woody core forms in the storage root. When young cucumber fruits are exposed to chilling temperature, the surface of the fruit is scarred and an undesirable curvature develops. Similarly, when banana fruits are exposed to chilling temperature, there is increase in tannin content, hardening of central placenta, inhibition in starch/sugar conversion and reduction in ascorbic acid content. There is skin pitting, inhibition in conversion of sucrose to reducing sugar in papaya fruits when store in chilling temperature. This type of damage is more acute in other tropical fruits also. Thus, the tropical fruits are to be protected from their chilling in field condition and stored at their appropriate storage temperature.

2.4.3 Frost Damage

Frost occurs through sublimation of water vapour on objects that are below 0^0C. Frost causes damage to the foliage of leafy vegetables as burning symptoms.

2.4.4 High Temperature Stress

Pre-harvest high temperature (during growing) causes losses in post-harvest quality of fruits and vegetables. The losses due to temperature variation vary with species, cultivars, stage of development etc. Direct effects of high temperature stress include damage to cellular membrane, proteins and nucleic acids. Indirect effects include inhibition of pigment formation and degradation. In addition, high temperature causes premature ripening in pumpkin. The oranges grown in the tropics tend to have higher sugar and total solids content than those grown in sub-tropics. However, the tropical grown oranges tend to develop less colour as compared to sub-tropics grown oranges.

2.4.5 Hail Damage

Hail storm size, and its exposure to crop growth stage and duration time are critical factors affecting the degree of damage. Hail damage results in a direct effect on the physical quality of the product, increases the incidence of damage and diseases like bacterial spot (*Xanthomonas campestris* pv. vesicatoria) of sweet pepper.

2.4.6 Soil Condition

The effect of soil on the vegetable produce is largely through its textural properties, drainage, soil reaction and nutrient availability. Soil texture is especially, important for root and tuber crops e.g. hard and compact soil resulted in root forking and stunted growth of carrot and radish.

2.4.7 Pollutants

The toxic elements such as Ag, Cd, Co, Mg, Mn, NI and Zn cause serious damage to vegetables. Air-polllutants such as ozone causes surface blistering of spinach *(Spinacea oleracea* L) leaves, nitrogen dioxide results in marginal and interveinal collapse of lettuce leaves.

2.5 IMPROPER HANDLING, PACKING, STORAGE AND TRANSPORTATION

2.5.1 During Post-harvest Handling

Harvest should be completed during the coolest time of the day, which is usually in the early morning, and produce should be kept under the shade in the field. Crops destined for storage should be as free as possible from skin breaks, bruises, spots, rots, decay, and other deterioration. Bruises and other mechanical damage not only affect appearance, but provide entrance to decay organisms as well.

Improper container for packaging capsicum

Owing to their tender texture and high moisture content, fresh fruits and vegetables are very susceptible to mechanical injury. Poor handling, unsuitable containers, improper packaging and transportation can easily cause bruising, cutting, breaking, impact wounding and other forms of injury. Post-harvest rots are more prevalent in fruits and vegetables that are bruised or otherwise damaged. Mechanical damage also increases moisture loss. The rate of moisture loss may be increased by as much as 400% by a single bad bruise on an apple, and bruised potatoes may lose three to four times as much weight as non-bruised potatoes.

2.5.2 During Storage

Storage is one of the most important aspects of the post harvest handling of fruits and vegetables. A substantial quantity of fruits and vegetables go waste in our country due to lack of proper storage. The primary purpose of storage is to control the rate of transpiration, respiration, ripening and also any undesirable bio-chemical changes or disease infection. Improper storage resulted in deterioration in fruits and vegetables in following ways:

- Aging due to ripening, softening, and textural and colour changes
- Undesirable metabolic changes and respiratory heat production
- Moisture loss and the wilting
- Spoilage due to invasion by bacteria, fungi, and yeasts and insect pests
- Undesirable growth, such as sprouting of potato

Need and Importance

The field heat of a freshly harvested crop should be removed as quickly as possible before shipping, processing, or storage. Refrigerated trucks are not designed to pre cool fresh commodities but only maintain the temperature of pre-cooled produce. Likewise, most refrigerated storage rooms have neither the refrigeration capacity nor the forced air movement needed for rapid cooling. Rapid pre-cooling to the product's lowest safe temperature is most critical for crops with both inherently high and low respiration rates commodities.

Crops with high respiration rate	Crops with low respiration rate
Artichokes, Brussels sprouts, green onions, snap beans, asparagus, broccoli, mushrooms, peas, sweet corn etc.	Nuts, apples, grapes, garlic, onions, potatoes (mature), sweet potato etc.

Pre-cooling methods and appropriate storage temperature and relative humidity for fruits and vegetables are important operations just after harvesting of the produce in order to reduce the post harvest losses.

2.5.3 Storage Temperature

Many vegetables and fruits store best at temperatures just above freezing, while others are injured by low temperatures. Both time and temperature are involved in chilling injury. Damage may occur in a short time if temperatures are considerably below the danger threshold, but some crops can withstand temperatures a few degrees into the danger zone for a longer time. The effects of chilling injury are cumulative in some crops. Low temperatures in transit, or even in the field shortly before harvest, add to the total effects of chilling that might occur in storage. Crops such as cucumbers, eggplant, pumpkin, summer squash, okra, and sweet potato are highly sensitive to chilling injury. Similarly, the tropical and sub-tropical fruits like mango, banana, papaya, pineapple etc. are also sensitive to chilling temperature. Moderately sensitive crops are snap bean, muskmelon, sweet pepper, winter squash, tomato, and watermelon. These crops may look sound when removed from low temperature storage, but after a few days of warmer temperatures, chilling symptoms become evident: pitting or other skin blemishes, internal discoloration, or failure to ripen. Tomato, squash, sweet pepper that have been over-chilled may be particularly susceptible to decay such as *Alternaria* rot.

2.5.4 Relative Humidity

Relative humidity is also important in the storage of fruits and vegetables. The relative humidity of the storage unit directly influences water loss in produce. Water loss can severely degrade quality-for instance, wilted greens may require excessive trimming, and grapes may drop loose from clusters if their stems dry out. Water loss also leads to saleable weight loss and reduced profit. Most fruit and vegetable crops retain better quality at high relative humidity (80 to 95%), but at this humidity, disease growth is encouraged at higher temperature level.

2.5.5 Storage Sanitation

Sanitation is of great concern to produce handlers, not only to protect produce against post-harvest diseases, but also to protect consumers from food borne illnesses. *E. coli*, *Salmonella*, Hepatitis, and *Cyclospera* are among the disease-causing organisms.

2.5.6 Ethylene Evolution

Ethylene, a natural hormone produced by some fruits as they ripen. It promotes additional ripening of produce when exposed to it. Damaged or diseased apples produce high levels of ethylene and stimulate the other apples to age too quickly. As the fruits age or ripen, they become more susceptible to diseases. Ethylene "producers" should not be stored with fruits, vegetables that are sensitive to it. The result could be loss of quality, reduced shelf life, and specific symptoms of injury.

Bad effects of ethylene during storage include:

- russet spotting of lettuce along the midrib of the leaves;
- loss of green colour in snap bean;
- increased toughness in turnips and asparagus spear;
- bitterness in carrots and parsnip;
- yellowing and abscission of leaves in broccoli, cabbage, Chinese cabbage, and cauliflower;
- accelerated softening of cucumbers, acorn and summer squash;
- softening and development of off-flavour in watermelon;
- browning and discoloration in eggplant pulp and seed;
- discoloration and off-flavour in sweet potato;
- sprouting of potato; and
- increased ripening and softening of mature green tomato.

Ethylene producers include apple, apricot, avocado, ripening banana, honeydew melons, ripe kiwifruit, nectarines, papayas, peaches, pears, persimmons, plantains, and tomato. By and large, more matured and ripened commodities produce more amount of ethylene production.

In regard to reduce cross-transfer of odours, combinations that should be avoided in storage rooms include:

- apples or pears with celery, cabbage, carrot, potato, or onion
- celery with onion or carrot
- citrus with any of the strongly scented vegetables

Pear and apple acquire an unpleasant, earthy taste and odour when stored with potato. It is recommended that onion, nuts, citrus, and potato each be stored separately.

2.5.7 During Transportation

Inland transportation of horticultural crops is usually by rail or by truck. Overseas transportation is by sea or air. A limited amount of high-valued produce is sometimes transported overland by air. The basic requirements for conditions during transportation are proper control of temperature and humidity and adequate ventilation. In addition, the produce should be immobilized by proper cushioning in packs, packaging and stacking, to avoid excessive movement or vibration. Vibration and impact during transportation may cause severe bruising or other types of mechanical injury.

Transportation through trucks

Plastic crates suitable for packaging tomato

Refrigerated containers and trailers are more often used for long distance shipping, whether by sea, rail or truck. Shipping by refrigerated trucks is not only convenient, but also effective in preserving the quality of product. However, both the initial investment and the operating costs are very high. Another possibility is insulated or properly ventilated trailer trucks. Pre-cooled products can be transported through well-insulated non-refrigerated trucks for many hours without any significant rise in product temperature. There are considerable cost savings without any sacrifice of quality if trucks are only insulated, rather than refrigerated, for short-distance shipping. If the product is not pre-cooled or if the shipping distance is long, a ventilated truck is a better choice than an insulated truck without ventilation and without refrigeration. Ventilation alone does not usually provide a uniform cool temperature, but it may help dissipate excessive field heat and respiration heat, and thus avoid high temperature injury.

2.6 SOCIO-ECONOMIC FACTORS

2.6.1 Marketing Systems

Growers can produce large quantities of good-quality fruits and vegetables, but if they do not have a dependable, fast, and equitable means of getting such commodities to the consumer, losses will be extensive. This is further accentuated by lack of communication between producers and receivers, and lack of market information.

Marketing cooperatives should be encouraged among producers of major commodities in important production areas. Advantages of marketing cooperatively include providing central accumulation points for the harvested commodity, purchasing harvesting and packing supplies and materials in quantity, providing for proper preparation for market and storage when needed, facilitating transportation to the markets, and acting as a common selling unit for the members, coordinating the marketing program, and distributing profits equitably.

Alternative distribution systems, such as direct selling to the consumer (roadside stands, produce markets in cities, local farmers' markets in the countryside, etc.) should be encouraged. The Farmer's Market system is to be developed for selling their own fruits and vegetables directly to the consumers. Production should be encouraged as close to the major population centres as possible to minimize transportation costs.

Overcrowded market

Wholesale markets in India are in desperate need of improvement in terms of facilities and sanitation. They are overcrowded, unsanitary, and lack adequate facilities for loading, unloading, ripening, consumer packaging, and temporary storage.

2.6.2 Roads

In India, roads are not adequate for proper transport of horticultural crops. Also, transport vehicles and other modes, especially those suited for fresh horticultural perishables, are in short supply during the season. This is true whether for local marketing or export to other countries. Efficient transport system can go a long way not only in reducing post harvest losses of fruits and vegetables but also in stabilizing the price fluctuation of the same commodity available in different parts of the country.

2.6.3 Government Regulations and Legislation

The degree of governmental controls, especially on wholesale and retail prices of fresh fruits and vegetables, varies from one state to another. In many cases, price controls are counterproductive. Although intended for consumer protection, such regulations encourage fraud and provide no incentive for producing high-quality produce or for post harvest quality maintenance due to non-implementation. On the other hand, regulations covering proper handling procedures and public health aspects during marketing are, if enforced properly, very important to the consumer.

2.6.4 Use of Specific Tools and Equipment

Even if growers and handlers of fresh fruits and vegetables were convinced of the merits of using some special tools and/or equipment in harvesting and post harvest handling, they most likely will not be able to find them in the domestic market. This is true of harvesting aids; containers; equipment for cleaning, waxing, and packing; and cooling facilities. Most of these tools are neither manufactured locally nor imported in sufficient quantity to meet demand. Various government regulations not permit direct import by producers of their needs. It is imperative that the tools that will enable handlers to use recommended technology for a given situation be available for them to use. In many cases, such tools can be manufactured locally at much lower costs than those imported.

2.6.5 Awareness among Common People

The human element in post harvest handling of horticultural commodities is extremely important. Most handlers involved directly in harvesting, packaging, transporting, and marketing in developing countries, have limited or no appreciation for the need for, or how to maintain quality. An effective and far-reaching educational (extension) program on these aspects is needed critically and will continue to be essential in the future.

2.6.6 Maintenance of Equipment

In developing countries like India, some good facilities those were built a few years ago are currently "out of order" or not functioning properly because of lack of maintenance and unavailability of spare parts. This problem is especially true of public-sector facilities. Any new project should include in its plan adequate funds for maintenance to ensure its success and extended usefulness.

   ………………………………………………………………………………

2.7 LET US SUM UP

In this unit, we studied association of both pre and post harvest factors with post harvest losses of fruits and vegetables.

Fruits and vegetables are living entities. The quality and marketable life of these commodities depends on both pre and post-harvest factors. The factors which influence the quality include harvest maturity, choice of cultivars/varieties, climate and soil in which it is grown, pre-harvest infection or infestation of micro-organisms and insects, storage conditions etc. The level of damage suffered by the crop during harvesting and handling can also affect the marketable life. Hence in order to maintain a level of freshness of fruits and vegetables from the field to the dinner table presents many challenges. A grower, who can meet these challenges, will be able to expand his or her marketing opportunities and be better able to compete in the marketplace. The causes of losses occur at different times during the production and post harvest cycle of the crop should be clearly understood before taking control measure. If it is clear that loss is due to infection of micro-organisms the control measures will depend on the type of micro-organisms, the time of infection, the reason for the success of the infection and legislation governing possible control measures.

2.8 KEY WORDS

Physiological maturity : It refers to the stage in the development of the fruits and vegetables when maximum growth and maturation have occurred.

Harvest maturity : It refers to the stage of development when plant or plant parts posses the pre-requisites for utilisation by consumers for a purpose.

Pre-cooling : It refers to the process of quick removal of heat just after harvesting of fruits and vegetables by forced air cooling method.

Climacteric fruits : Fruits where there is upsurge in their respiration after the harvest.

Non-climacteric fruits : Fruits where there is no upsurge in their respiration rate after the harvest.

2.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. a) v b) iii c) iv d) i e) ii

2. Your answer should include the following points:

   - Role of irrigation
   - Role of mineral or nutrient deficiency
   - Other factors such as weed, crop hygiene, plant protection and use of growth regulators etc.

3. Your answer should include the following points:

   The basic criteria are as follows:

   - Choose cultivars that will have better quality attributes and as per the demand of the consumers.
   - Use clean, healthy, high quality planting materials.
   - Grow off-season cultivars of the same crop to extend harvest period.
   - Choose cultivars that are well suited to the specific climate, day length, soil and growing conditions.
   - Always select seed from the good quality produce or source.

4. Your answer should include the following points:

   Definition of climacteric and non-climacteric fruits and write few examples as given in sub-section 2.1.2.2.4.

Check Your Progress Exercise 2

1. A) iv B) iii C) i D) ii

2. Your answer should include the following points:

   i) Climate
   ii) Chilling Injury
   iii) Frost Damage
   iv) High Temperature Stress
   v) Hail Damage
   vi) Soil Condition
   vii) Pollutants

Check Your Progress Exercise 3

1. Your answer should include the following points:

   - Storage Temperature
   - Relative Humidity
   - Storage sanitation
   - Ethylene

2. Your answer should include the role of ethylene in fruit deterioration (bad effects) and measures to take as mentioned in Sub-Section 2.1.2.5.2.4

3. Your answer should include the following points:

   - Marketing System
   - Road
   - Government Regulation and Legislation
   - Use of Specific tools and Equipments
   - Awareness among Common People
   - Maintenance of Equipment

4. Your answer should include the following points:

   i) Mention the proper stage of harvesting of both the crops
   ii) Mention the rate of respiration, ethylene evolution etc. during storage
   iii) Write all about insect damage with suitable example as given in Sub-Section 2.1.2.3.2

2.10 SOME USEFUL BOOKS

2. Bose, T.K., Som, M.G. and Kabir, J. (1st Ed.) (1985) Vegetable Crops, Naya Prokash, Kolkata.

3. Thompson, A.K. (1st Ed.) (1996) Post harvest Technology on fruits and vegetables, Black Well Science Ltd., UK.

UNIT 3 MATURITY INDICES AND HARVESTING PARAMETERS

Structure

3.0 OBJECTIVES

After studying this unit, you should be able to:

- understand what is maturity;
- distinguish between physiological and commercial maturity;
- determine maturity of important fruits and vegetables; and
- know harvesting time methods, and equipment.

3.1 INTRODUCTION

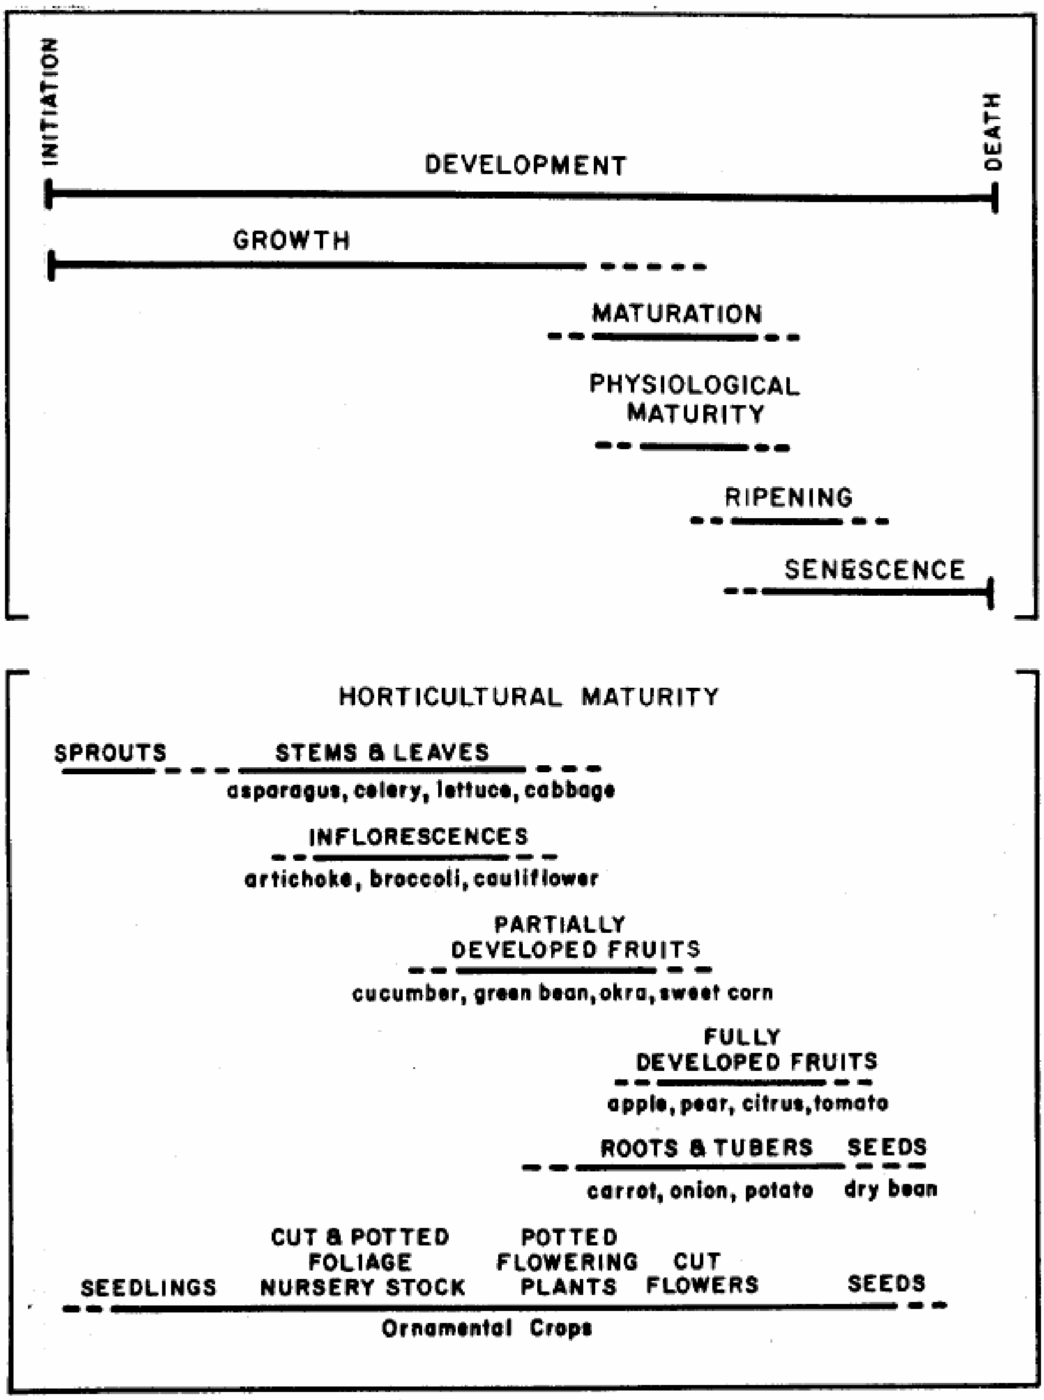
The maturity of fruits and vegetables is an indication of the development of the crop and its progress for becoming a marketable product. Selection of right stage of maturity for harvest is an important aspect, which has considerable influence on storage life and quality and final acceptance by the consumer.

Definition

To most of us 'mature' and 'ripe' means the same thing when describing fruit. But in post-harvest technology mature can be defined as "that stage at which a commodity has reached a sufficient stage of development that after harvesting and post-harvest handling (including ripening, where required), its quality will be at least the minimum acceptable to the ultimate consumer."

Maturity can be of two types – physiological maturity and commercial maturity. Physiological maturity refers to the point in the development of an organ (*e.g.* fruit, leaf) or organism (*e.g.* ornamental plant) when maximum growth has been achieved and the organ or organism has matured to the extent that the next development stage can be completed. In case of fruit, ripening can be considered as the next development stage, preceding the senescence stage.

The commercial or horticultural maturity is the characteristic state of a plant organ required by the consumer. It is concerned with the timing of the harvest to meet particular market requirements. Commercial maturity bears little relation to physiological maturity, and may occur at any stage during development, maturation, ripening or senescence. Examples of commercial maturity include bean sprouts (during early stage of development), cucumber (during maturation) and tomato (during ripening). Chilli can be harvested (commercially mature) at 'green stage' of fruit for 'green chilli' market and at 'red ripe' stage for drying to be used as spice. At both these stages, chilli fruits are commercially or horticulturally mature. The term 'immaturity', 'optimum maturity' and 'over maturity' can be related to these market requirements. To a green chilli market, a red ripe chilli is 'over mature' and to the red ripe chilli market green chilli is 'immature'. Some examples of commercial maturity in relation to physiological age are shown in Figure 3.1



3.2 DETERMINATION OF MATURITY

Determination of the stage of maturity at which a fruit or vegetable should be harvested is important for its subsequent quality, storage and marketable life. Combination of both subjective and objective methods are used to assess maturity of the produce for harvesting. In the former, the appearance; texture, smell, taste comprise the criteria. For the later, the instruments are used to measure colour, ºBrix, sugar, acidity, protein, tannins etc., chemical and physical analyses like determination. These methods can be grouped into physical, chemical, physiological, computation, electronic etc. based on the principles used for measuring the various parameters.

3.2.1 Physical Method

Skin colour

Change of skin colour of many fruits is a valuable guide to maturity. There is gradual loss of intensity of colour from dark green to light green and then development of yellow and/or red pigment (*e.g.* tomato, papaya, litchi, mango). Some fruits like some cultivars of mango, apple, and peach develop red blush colour (i.e. additional colour on the ground colour) as they mature on tree and can be used as maturity index. The assessment of harvest maturity by skin colour changes usually depends on the judgment of the harvester. Colour charts are used for apple, tomato, peach *etc.* Instruments are available for measurement of colour of fruits, and they are mostly used on harvested fruit. On-line commercial colour sorter is used in many crops.

Shape

The shape of fruit and vegetable can change during maturation and this can be used as a criterion to determine harvest maturity For example, some cultivars of banana becomes less angular and more rounded in cross-section. Mango changes shape during maturation on the tree. The shoulder of immature mango fruit slopes away from the fruit stalk and as the maturity advances the shoulder level or becomes raised with the point of attachment with the fruit stalk.

Size

In most crops, size is frequently used to determine when it should be harvested. Sometimes it is related to the market requirement. For example, if a market requires a bottle gourd of 30 cm length, the fruit should not be allowed to grow beyond that limit though the cultivar may be having the potentiality to grow much longer. In banana, the length or width of individual finger can be used to determine harvest maturity. Size also gives rise to volume and is often expressed as weight to determine harvest maturity of many fruits and vegetables like mango, watermelon, pumpkin. When we divide weight by volume it gives density (g/cm^2) and is used as maturity index in potato. The size is also used for grading of many fruits and vegetables and machines have been developed for size grading.

Firmness

As fruits mature and ripen, they soften because of dissolving of pectin comprising the middle lamella of cell wall. This softening can be estimated subjectively by the finger feel of commodity. It can objectively be measured using a fruit hand held pressure tester (also called penetrometer). These testers measure the pressure at which flesh yields to the penetration of a standard diameter plunger inserted to a standard depth. More sophisticated tests can be carried out using machines such as Instron Universal Testing Machine. But these machines are mainly used for experimental studies.

Specific gravity

Specific gravity is the relative gravity or weight of solids or liquids compared to distilled water at 62°F (16.7°C). To determine specific gravity the fruit or vegetable is weighed in air and in distilled water and its weight in air is divided by the loss of weight in water. As fruits mature their specific gravity increases. This parameter is rarely used in practice to determine when to harvest, but can be used as a sampling technique. It is used, however, to grade the produce into different maturity groups after harvesting. To do this, fruits or vegetables are placed in a tank of water, those that float are less mature than those that sink. To increase effectiveness sometimes salt is added to the water at 1% to 2% concentration.

Aroma

Most fruits synthesise volatile chemicals as they ripen. These give the fruit its characteristic flavour and can be used to determine whether fruit is ripe or not.

3.2.2 Chemical Method

Sugars

As the fruit ripens, starch is broken down to sugars. Measurement of sugars can provide an indication of the stage of maturity or ripeness. In practice, the soluble solids, also called degree brix, are measured in the fruit juice. Usually the sugars constitute the major portion of soluble solid of the fruit juice. So measurement of total soluble solid (TSS) can give a reliable estimate of sugar in fruit juice. This is done using a refractometer or a brix hydrometer, which provide quick and easy methods for assessment of ripeness. This can be used in grape, muskmelon, mango etc.

Starch

Measurement of starch content in the developing fruit of pear and apple provides a reliable method for assessing their harvest maturity.

Acidity

The acidity of many types of fruit changes during maturation and ripening. In citrus, mango, pineapple and many other fruits acidity progressively decrease as the fruit matures on the tree. Taking samples of these fruits, extracting the juice and titrating it against a standard alkaline solution give a measure of acidity, which can be related to determine harvest maturity. Normally, acidity is not used singly; it is related to soluble solids, giving what is called sugar acid ratio.

3.2.3 Physiological Method

Climacteric fruits, in which there is a distinct rise in respiration during ripening, can be sampled, kept at a relatively high temperature and respiration rate measured. By doing this, it may be possible to predict the number of days the fruit would have taken to commence the climacteric rise if left on the tree.

3.2.4 Computation Method

The time required between flowering and fruit being ready for harvesting may be measured by 'heat units' or 'degree days' in a particular environment. It has been found that a characteristic number of heat units or degree days is required to mature a crop. Maturity will be advanced under warm conditions or delayed under cooler conditions. The number of degree days to maturity of a particular crop or a variety is determined over a period of several years by obtaining the sum of the difference between the daily mean temperature and a fixed base temperature (commonly the minimum temperature at which growth occurs). For example:

20-15°C (minimum base temp.) × 1 day = 5
25 -15°C = 10 × 2 days = 20; total 25 degree days

Likewise the computation is continued and when the total number of degree days reaches say 1000 for a particular crop it is presumed that the crop is ready for harvest. As maturity approaches the correct stage of the crop may be checked by other means. This method is helpful in planning planting, harvesting and factory management programme for annual processing crops such as pea, tomato *etc*.

3.2.5 Electronic and Other Methods

Electronic principles are used in various machine used in determining the maturity.

Electronic colour sorter

This machine is used in packing houses to sort out fruits on the basis of colour *e.g*. in apple, orange *etc*.

Acoustic and vibration test

The sound of a fruit when tapped with the knuckle of the finger, changes during maturation and ripening. Consumers often use this method for testing when purchasing watermelon. Farmers also use this for determining maturity. Sophisticated machines have been developed to measure the sound of tapping for precise determination of maturity.

Electromagnetic method

Nuclear magnetic resonance (NMR) spectroscopy is used in human pathology to provide images of the inside of the body. Such instrument has been found to be useful in determining maturity by examining internal structure of fruit.

3.3 MATURITY INDICES OF COMMERCIALLY IMPORTANT FRUITS

Mango

The various criteria recommended for judging maturity are red blush colour development on the shoulders, falling off of one or two ripe fruits from the plant naturally, the specific gravity of fruit ranging from 1.01 to 1.02 and in general fruits attain maturity 90-120 days from the fruit set stage. Sometimes maturity indices like change in pulp colour from white to pale yellow and slowing down of latex flow from the stalk of plucked fruits also serve the purpose.

Banana

The fruits are usually harvested when the ridges on the surface of the skin change from angular to round *i.e.* after the attainment of the ¾ full stage. The maturity of fruits can also be adjudged by some other physical characters and chemical analysis. The physical characters like change in skin colour or development of blush or visually lighter colour is also taken into account to determine the maturity of fruits. In addition, fruits attain the size specific to variety on maturity. However, for long distance transport attainment of ¾ maturity is taken as harvesting index.

Citrus

The fruits are generally harvested when the changes in rind colour take place. The colour break stage (change in colour from green to yellow) is taken as criterion for judging the maturity of lime and lemon. In citrus, total soluble solid (TSS): acid ratio is considered to be a good index for judging maturity, which varies from variety to variety.

Papaya

The fruits should be left on the tree until they mature fully. Usually the fruits are harvested when they are of full size, light green with a tinge of yellow at apical end. On ripening the latex becomes watery from milky.

Pineapple

The fruits are usually harvested when the surface colour is between colour break and quarter yellow for shipment by sea and a half to three-quarter yellow colour for transportation by air. Harvesting for local market and distant market should be done at the full maturity stage and 75-80 per cent maturity stage, respectively. At maturity, the eyelets get flattened.

Grapes

In grapes, the basal berries mature and ripen first and the harvesting of immature berries are never advisable as these do not ripen after harvest. The physical appearance like change in colour from dark green to light green, yellow or red or purple depending upon the type of cultivars, glossyness and softness of berries are also taken as indices for judging maturity. The estimation of TSS: acid ratio is also taken as criteria for judging the maturity. The TSS and acidity of berries are determined by refractometer and titration, respectively.

Sapota

In sapota, various criteria have been suggested for judging the maturity *e.g.* development of a dull orange colour or potato colour, showing light yellow streak instead of a green streak when scratched and disappearance of browny scales on the fruit surface.

Guava

Guava fruits mature 4-5 months after flowering. At maturity the specific gravity varies from 0.95-0.96, while TSS and acid content ranges from 12-13° Brix and 0.36 to 0.41% respectively.

Jackfruit

Several indices are commonly used to determine the optimum time to pick the fruits. A dull, hollow sound is produced when the fruit is tapped by the finger; the fruit spines become well developed and wide spaced; the spines yield to moderate pressure and lastly there is development of aroma. For distant market, fruit should be harvested when still firm and without any aroma.

Pomegranate

The fruits are ready for harvest in 5-6 months after flowering. The fruits are picked when the skin turn slightly yellow and the fruit gives a metallic sound when tapped. Likewise, the ripe fruits give a distinct cracking sound of grain cracking when pressed slightly on the slices.

Apple

Apple may be harvested when a fruit separates easily from the branch, retains firmness of pulp and taste which are desirable. On maturity the skin colour changes from green to yellow or red depending upon the cultivars. The days from complete flowering can also be taken as a criterion to assess the maturity, which varies from 90±4 days in early maturing varieties to 180±5 days in late maturing varieties.

Pear

Pear is harvested when firm and green for canning, while fully mature fruits are harvested for fresh consumption. Days from full flowering, TSS and firmness can also be used for judging the maturity.

Peach

Various criteria have been advised for judging the maturity of peaches like fruit size, shape, firmness, starch content of fruits *etc*. Usually peaches are picked when they are still hard as they can ripen well in storage or in transit.

Plum

Change of ground colour of fruits from green to yellow or red depending upon the varieties, firmness and TSS content of fruits and days from full flowering are used to assess the maturity of fruits.

Strawberry

Strawberries are generally harvested when half to three-fourth of skin develops colour. For distant shipment green or white and still hard berries are harvested.

3.4 MATURITY INDICES OF COMMERCIALLY IMPORTANT VEGETABLES

Broccoli

The best stage of harvesting is before the buds begin to open, the heads remain compact and the yellow petals have not come out. The total length of the stalk and the head can be 15 to 25 cm depending on the variety. The axillary shoots grow and form smaller heads sometime after harvest of the main head. These can also be harvested for marketing.

Cauliflower

Stage of maturity is determined by curd size and its compactness. If harvesting is delayed, the curds become loose and discoloured. If the produce is meant for storage, it is better to harvest when the curds are not fully exposed and still covered with central whorl of leaves.

Cabbage

Solidity and firmness of the heads are the usual maturity characteristics used. Colour of the head is used as an added index. The head turns a lighter shade of green when full development is attained.

Celery

Generally, celery requires blanching, although some growers prefer to sell it green. There is no specific time of harvest for celery though some like to harvest it as early as possible to take advantage of higher price. Blanching of the petioles and stalks and slight enlargement of the heart and inner leaves are used as picking indices.

Carrot

Depending on the variety, the attainment of desired size is the primary consideration. Marketing of roots begins as soon as they attain acceptable size even though they have not attained full size specific to the variety. The roots must be harvested before emergence of the seed stalk.

Cucurbitaceous vegetables

In general, cucurbit fruits mature faster. In such kind of vegetables like summer squash, Indian squash (tinda), bitter gourd, small (gherkin) cucumber and long melon, fruits reach optimum maturity stage within a week or so after fruit set. In other kinds of vegetables like sponge and ridge gourds, bottle gourd, snake gourd, pointed gourd *etc*., picking is done in about 12 to 15 or even 20 days after fruit set. In sponge and ridge gourd the flesh should not turn fibrous. In bittergourd, fruits should not turn yellow or yellowish orange in transit, hence, these are to be harvested at green stage. In musk and watermelon, 30 to 40 days will be required for the fruits to reach harvest maturity.

Picking of fruits at the right edible maturity stage is dependent upon individual kinds and varieties. In salad or slicing cucumber, dark green skin colour should not turn into brownish yellow and white spine colour will also be an useful indication of edible maturity. Over-mature fruits will show carpel separation (development of gap in the flesh) in transverse section.

In muskmelon, there are two groups of cultivars which behave distinctly. In one group, the fruits when mature slips out easily from the vine with little pressure or jerk or if not it will remain separated from the vine next day. This is called full slip stage. Most cultivars including Indian varieties and cantaloupes of the USA behave in this way. The cantaloupes can be picked at ¾ slip stage for long distance transport. There is another group of melon like Honey Dew and Casaba, the fruits of which do not separate at maturity and they have to be picked on the basis of external colour. In some Indian cultivars, green stripes on the skin begin to turn yellow which is an indication of full maturity. Muskmelon is a climacteric fruit which ripens during transit and storage and hence it is harvested before it is fully ripe.

In watermelon, maturity is judged by taking into consideration of several factors: (i) dull sound when the fruit is thumped, in contrast to metallic sound, (ii) withering of tendril at the fruit axil, (iii) ground spot turning yellow, (iv) rind of the ripe melon yields to pressure. Cumulatively all these criteria will help judge correct stage of picking.

Eggplant

Fruits should be picked as soon as they have attained the desired size, before they harden or show streaks of unusual colour. The skin should be bright and glossy and seeds undeveloped.

Tomato

Harvesting depend upon the purpose for which it is grown and time to be taken for reaching the destination. Six maturity stages are recognized. These are mature green, breaker, turning, pink, light red and red. In 'breaker' stage only up to 10% of the fruit surface especially at the blossom end is pink or red and in 'red' stage more than 90% of the fruit surface is red. In India fruits, for a distant market, are harvested at 'breaker' stage and they ripen during transit. For nearby market and for processing, it is better to harvest at a latter stage.

The colour of the fruit can be measured by a colour chart or a colour measuring instrument using light transmittance technique.

Potato

Setting of skin, starch content and leaf senescence are harvest indices. To catch early market and to get high price, potatoes are also harvested before attaining full maturity. These tubers are not fit for storage and should be disposed of quickly.

Garlic and onion

Onions are harvested depending upon the purpose for which the crop is grown. It requires 45 to 90 days from field setting for green onions and 90 to 150 days for bulb depending upon the variety. Onions should be harvested one week after 50% crop shows neck fall. Garlic is ready for harvesting when the tops turn yellowish or brownish and show signs of drying up and bend over.

Okra

Fruits are harvested when they are tender and exhibiting maximum growth rate. At this stage, the blossom end of the fruits, when bent, breaks easily. It takes 7 to 8 days to become ready for harvesting after fruit set. Frequent picking promotes fruit development and increases yield.

Pea

Quality of pea depends on sugar content and tenderness. With increasing maturity and size, sugar declines rapidly with an increase in starch and protein. Thus a high sugar content is an indication of high quality. The appearance of the pod is an added indication of maturity. Since firmness increases with maturity, a tenderometer is used to measure tenderness. Calculation of degree days is also done for mechanical harvesting.

Radish

The crop matures in 3 to 4 weeks in case of quick growing varieties and in 8 to 10 weeks in case of the Chinese varieties. The crop is harvested when the roots are still tender before they become pithy and fibrous.

3.5 HARVESTING

The objective of harvesting is to pick the fruits or vegetables at the proper stage of maturity, with a minimum damage, as rapidly as possible and at a minimum cost. This objective is best achieved by hand harvesting in most fruits and vegetables.

3.5.1 Hand Harvesting

Hand harvesting is the most advantageous method. It offers several advantages:

1. Selection of proper stage of maturity is accurate.
2. Humans can handle fruits and vegetables with minimum damage.
3. Multiple harvesting is possible.
4. Requires less capital investment.

Need and Importance

Care in harvesting and handling is necessary to preserve subsequent quality. Bruises and injuries may later show up as black or brown patches, making the commodity unattractive. As far as possible, harvesting should be done during cooler part of the day and the harvested material should immediately be removed to a shady place. Harvesting immediately after rain dew/snow should be avoided as it creates conditions most favourable for multiplication of decay causing pathogens.

a) Fruits

Soft fruits such as strawberry which are borne on low growing plant, are simply removed from the plant and are put into a suitable container. Sometimes they are directly put into the consumer carton for sending to the market. Fruits which are borne on tall or medium tall trees such as mango, citrus, sapota, guava, apple *etc*. are difficult to harvest and the process is time consuming. A long pole with some cutting device and a bag at the end is commonly used. Some improved harvesters have been developed in India by ICAR institutes and SAU'S viz. IARI, New Delhi, IIHR, Bangalore, KKV, Dapoli and CISH, Lucknow. These harvesters have been tested successfully in several crops and have been found to be more efficient and economical than manual harvesting by hand only. It has also been reported that fruits harvested by cutting the fruit stalk rather than twisting and pulling, had lower incidence of rotting during subsequent storage.

b) Vegetables

Most vegetables are hand harvested even in the developed countries. Root crops like potato, onion, garlic, colocasia and tapioca are dug out with the help of fork or spade. Other root crops like radish, turnip, carrot and beet are pulled out of the soil. All damaged roots should be sorted out as early as possible. Fruit vegetables like okra, brinjal *etc*. require some cutting device like krives/siezzer/sickle sickle. Tomato usually does not require such device and pulling by hand can detach the fruits. Muskmelon at full-slip stage does not even require any pulling by hand. At half-slip stages a little jerk may be required in Pumpkin, bottle gourd, bitter gourd, sponge gourd, ridge gourd etc. require some cutting device for harvesting. Cauliflower and cabbage are harvested by cutting the stalk with some sharp tool. Leafy vegetables like amaranth, spinach, spinach beet (Palak), *Trigonella* (Methi) *etc*. may be harvested by picking the leaves or by cutting with sickle depending on the market requirement.

3.5.2 Mechanical Harvesting

Mechanical harvesting has certain advantages:

1. It is a quicker method.
2. Problem associated with labour management is less.

There are certain disadvantages too:

1. It damages perennial crops (e.g. damage to bark by a tree shaker)
2. There may be a lack in processing and handling capacity to handle high rate of harvest.
3. There is less chance of selection of fruits.
4. Damage due to mechanical injury is more.
5. It is more expensive.

a) Fruits

Very little fruit destined for fresh market is harvested by machines because the likely damage could result in rapid deterioration of quality. Fruits for processing may be harvested mechanically. Oranges for juice extraction may be removed from the trees by powerful wind machines being dragged through the orchard followed by collecting oranges from the ground mechanically or manually. Tree shakers are also used. These methods may cause considerable damage to fruits. Grapes can be harvested for wine making using tractor-mounted machines with combing fingers made of rubber which are run up the stems, pulling up the fruit bunches along with leaves. In banana, bunches are cut manually and then conveyed by hanging conveyor rope. Sometimes conveyor belts are also used.

b) Vegetables

Mechanical aids to harvesting vegetables such as cauliflower, cabbage, lettuce involve cutting by hand and placing them on a conveyer of a mobile packing station which is slowly conveyed across the field. Peas for processing are harvested by combine. Tissue damage during harvesting has been reported to develop off flavour due to enzymatic reaction in pea. Mechanical harvesting of French bean may cause breaking of the tips. In potato, mechanical harvester removes the tubers from the soil and by mechanical shaking, soil clods are broken into fine pieces for easy removal of potato from the soil. In developed countries the entire operation of digging and removal of potato is done by machine. In India, in some parts of the country, mainly digging is done by the potato harvester. In some countries, onion is harvested mechanically after cutting the tops mechanically before harvesting. Similar harvester can be used for sweet potato. Harvesters for tapioca and yam have been less successful. Tapioca harvesters for processing are common but the roots must be processed quickly after harvest to avoid deterioration.

3.6 LET US SUM UP

In this unit, you have read about maturity of fruits and vegetables, methods of determination of harvest maturity, maturity indices of important fruits and vegetables and their harvesting methods. It has given you an idea about the advantages and disadvantages of hand and machine harvesting. It has also highlighted the simple and commercially followed methods for determining maturity stage for harvesting.

3.7 KEY WORDS

Maturity : It is a phenomenon by which a commodity (fruit or vegetable) reaches a sufficient stage of development that after harvesting and post-harvest handling; its quality will be at least the minimum acceptable to the ultimate consumer.

Physiological maturity : It refers to the point in the development of an organ or organism when maximum growth has been achieved and the organ or organism is ready for the next development stage to be completed.

Horticultural or commercial maturity : It is the characteristic state of a plant organ required by the consumer. It is concerned with the timing of the harvest.

Maturity indices : These are the criteria which are used to determine whether a crop has reached a proper stage for harvesting.

3.8 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - Definition of maturity.
   - Classification of maturity into two types – physiological and commercial and differences between them.

2. Your answer should include the following points:

   - Grouping of methods of determination of maturity into physical, chemical, physiological, computation, electronic and others.
   - Description of methods grouped under physical group.

Check Your Progress Exercise 2

1. Maturity indices of important fruits are to be written.
2. Maturity indices of important vegetables are to be written
3. Merits and demerits of hand and machine harvesting are to be discussed.

3.9 SOME USEFUL BOOKS

1. Kader, A.A. (ed.) (1992) Post-harvest Technology of Horticultural Crops (2nd edition), University of California, Berkley.

2. Thompson, A.K. (2003) Fruits and Vegetables: Harvesting Handling and Storage, Blackwell Publishing, UK.

3. Watada, A.E., Herner, R.C., Kader, A., Romani, R.J. and Staby, G.L. (1984) Terminology for the description of Developmental stages of horticultural Corpp. Hort. Science, 19: 20-21.

4. Wills, R., McGlasson, B., Graham, D. and Joyce, D. (2004) Post-harvest (4th edition), CAB International, U.K.

UNIT 4 PACKAGING OF FRUITS AND VEGETABLES

The main objective of packaging is to keep the fruits, vegetables and root crops in good condition until it is sold and consumed. Good packaging gives more choice to consumers in terms of food availability and encourages the customers to purchase the product. Packaging also enhances the income of rural producers from surplus produce.

Structure

4.0 OBJECTIVES

After studying this unit, you should be able to:

- know the types of post harvest losses;
- select good packaging material for fruits, vegetables and root crops;
- describe different types of packaging material;
- know the types of cushioning material; and
- explain how post-harvest handling and marketing can be improved through better packaging.

4.1 INTRODUCTION

Do you know that India now occupies first place in the world in the production of fruits and vegetables. But increased production of fruits and vegetables will have significance only when they reach the consumer in fresh and palatable condition at a reasonable price. Due to heavy post harvest losses, there is a considerable gap between production and availability of fruits and vegetables to consumers. Post-harvest losses are occurring in the period between harvesting and consumption. The term losses include all types of losses for the farmers, traders and consumers (e.g. weight loss, quality loss, financial loss,

loss of goodwill, loss of marketing opportunities, loss of nutritional value, etc.). Hence there is an urgent need to adopt proper post harvest management practices by adopting improved packaging, handling and efficient transportation methods.

Packaging is

- Assembling the produce in convenient units for transport, distribution, storage, retailing and end use.
- Ensuring safe delivery to the consumer in sound condition at minimum cost.
- It must prevent losses, increase marketability and decrease the handling and transportation cost.

Packaging of fresh fruits, vegetables and root crops is one of the most important steps in the long and complicated journey from grower/farmer to consumer. Packaging extends the shelf-life to local surpluses of food and thus allows the food to be distributed to other areas.

Good packaging has two purposes, which are functional and aesthetic. Functional purpose aim at extending the shelf life to the product by protecting the produce from the hazards of transportation, microbial, insect/ pest damage and physiological and biochemical changes. Aesthetic aspect of packaging aims at attracting the consumer in terms of shape, size, colour and convenience etc of the packaging and identifies the product in the market, which enhances brand loyalty.

Most predominately used packaging materials for fruits, vegetables and root crops are wood followed by jute, bamboo, and corrugated fibre boards. More recently the use of plastics are becoming more convenient due to maximum reusability.

There are mainly two categories of packaging: (i) Retail packaging and (ii) Bulk shipment packaging.

Retail packaging: The materials used for retail or small unit packaging are different in different ecological locations, subject to availability around the producing centres. For example Polyethylene films (HDPE, LDPE), boxes, bags, tray type containers etc.

Bulk Shipment packaging: Corrugated boxes, molded pulp trays, foamed polystyrene trays are used for bulk shipment.

The type of package used depends upon the shape and the perishability of the product. Based on this, there are five main classifications:

Produce	Common Package Recommended
Soft fruits	Semi-rigid containers
Hard fruits	Open tray
Stem products	Bags or wrappers
Root vegetables	Polyethylene bags
Green vegetables	Polyethylene or Polystyrene bags

4.2 SELECTION OF PACKAGING MATERIAL

How to select packaging material for a particular commodity? What are the points we should consider to select the packaging material?

Package is selected in accordance with the product characteristics. Now what is the product characteristics based on which the package is selected? They are physical and physico-chemical.

Packaging material is selected on the basis of:

- The commodity itself.
- The systems of production, storage, handling, transportation.
- Cost factor involved in producing packaging material
- Market requirement
- Consumer attitude.
- Requirement of recycling, re-use disposal etc.

The important considerations in selecting packaging material for fruits, vegetables and root crops are:

1. Easy to open and close
2. Easy to fill
3. Easy disposal
4. Easy to recycle
5. Pilfer-proof
6. Eye appeal
7. Should withstand rough handling
8. It must provide adequate ventilation to contents for rapid cooling during transport and storage.
9. It must be readily available.
10. The package should be large enough to hold melons and pumpkins, but should also be suitable to hold smaller produce.
11. It must be cost-effective in terms of the market value of the commodity for which used;
12. Its dimensions and design must be suited to the available transport in order to load neatly, firmly with full capacity.
13. It should be easily transported when empty and occupy less space than when full.

Packages should be of a size, which can be easily handled. The ratio of weight of the container to that of the produce it contains is important. Where transport charges are calculated on a weight basis, heavy packaging can contribute significantly to the final cost of the saleable product. The shape of packages is also significant because of the loading factor, the way the load is positioned on the transport vehicle for maximum capacity and stability. Round baskets hold considerably less produce. A cylindrical basket contains only 78.5 percent by volume compared with a rectangular box occupying the same space.

Suitable packaging for any product requires good ventilation to prevent the build up of heat and carbon dioxide (Heat and carbon dioxide decreases the keeping quality of the produce and leads to development of off-flavour of the produce). The ventilation of produce is very important with adequate air flow through stacked packages. The effectiveness of ventilation during transport also depends upon the air passing through the load. Sacks and net bags must be stacked so that air can circulate through the contents.

…………………………………………………………………………………

…………………………………………………………………………………

…………………………………………………………………………………

4.3 FUNCTIONS AND PROPERTIES OF PACKAGING MATERIAL

What are the primary functions of packaging? Why do we pack a particular commodity in a specific package?

Two main functions of packaging are:

1. To assemble the produce into convenient units for handling.
2. To protect the produce during distribution, storage and marketing.

Packaging materials used serve the following purposes.

1. Serves as an efficient handling unit
2. Protects from mechanical damage
3. Protects against moisture loss
4. Provides clean and sanitary storage
5. To prevent pilferage
6. Provides sales and service motivation
7. Reduces cost of transport and marketing

Need and Importance

The basic functions of packaging are:

a) Containment – protects the loss of produce by holding together a definite quantity as per market requirement.

b) Protection against climate, water vapour, oxygen, light, transport shock, vibration, decay etc.

c) Preserving quality (microbial, freshness & aesthetics attributes)

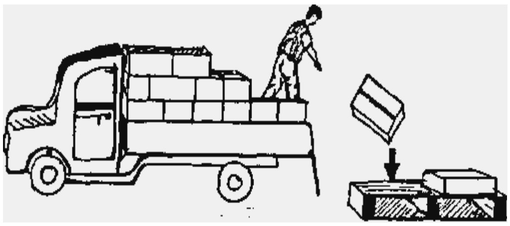
d) Information about the products, producer, content and legal requirements.

Packaging serves as an efficient handling unit to carry produce from field to consumer. It must allow removal of metabolic heat during storage and transport, and may have to contain the perishable produce throughout its ripening process. Proper ventilation is essential for this. Some commodities (e.g. avocados) that are highly sensitive to ethylene (ripening gas) require packages that permit effective ventilation so as to avoid excessive gas build up in transit.

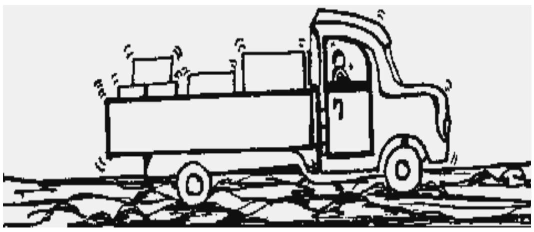
The package should also protect the produce against rotting. Perforated polyethylene liners that allow gas exchange are used for some produce. The special treatments given to certain produces (e.g. sulphur dioxide treatment of grapes and in-package use of ethylene absorbents) must be taken into consideration in package design.

Packages must protect against possible damage. Various kinds of impact and other shocks must be taken into consideration in the design of the package and its fittings to minimize this risk. Impact damage (bruising) result from dropping the individual products or letting the package fall onto a hard surface. Such damage may be avoided by careful handling, use of inserts and improvements in cushioning materials. Damage caused by compressions results from overfilling, and from incorrect and unsuitable packaging.

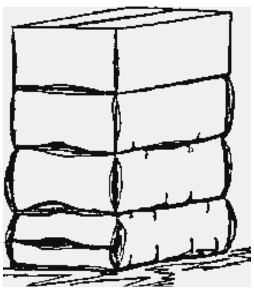
Transportation hazards



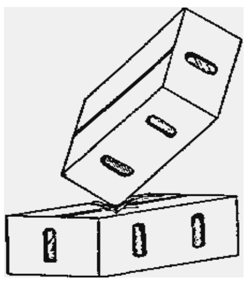
Package falling onto a hard surface



Damage caused by improper filling



Compressions results from overfilling



Damage by puncturing

(Source: FAO)

4.4 PACKAGING MATERIALS FOR FRUITS, VEGETABLES AND ROOT CROPS

There are many different types of package in use throughout the world. Packaging for fresh produce is of several types:

4.4.1 Basket made of woven strips of leaves, bamboo, plastic etc.
4.4.2 Sacks: flexible, made of plastic or jute.
  i) Bags: small size sack
  ii) Nets: sacks made of open mesh
4.4.3 Wooden crates
4.4.4 Fiberboard boxes
  i) Solid fiberboard boxes
  ii) Corrugated fiberboard boxes
4.4.5 Plastic crates
4.4.6 Biodegradable plastics
4.4.7 New innovations in packaging of fruits, vegetables and root crops
4.4.8 Pallet boxes and shipping containers.

4.4.1 Baskets

Baskets are made from woven strips of leaves, plastic and bamboo. Bamboo baskets of different shapes and sizes are used for number of perishable commodities. As the dimensional stability and ability to withstand stacking load is low, they are suitable for head load only and for very short distance transportation only. These packages are not strong enough to withstand rough handling and they are not rigid enough to take the stacking load of more than two or three baskets.

4.4.2 Sacks and Nets

The materials used for sacks and nets may be woven natural fibre (jute, cotton), woven synthetic (polypropylene, polyethylene), knitted natural fabric (cotton), knitted synthetic (polyethylene) or non-woven synthetic (propylene).

Plate 1: Jute bags

Advantages and disadvantages of sacks and nets

The advantages of using sacks and nets are merely financial. The sacks and nets are cheap, have a low weight/volume ratio and, if made of a synthetic material, will not rot. The disadvantages include a low protection against puncturing, compression, vibration and impact injuries such as dropping, difficult stacking, and the need of special stitching equipment. In general, nets are only suitable for hard produce such as coconuts and root crops (potatoes, onions).

4.4.3 Wooden Crates

Commonly used are wire bound crates for citrus/potatoes, wooden trays for tomatoes and wooden field crates.

The advantages of wooden crates are:

1. The crates can be manufactured and repaired locally.
2. Wood is relatively resistant to different weather conditions and water.
3. Wooden crates are often reused and have a higher efficiency for larger fruits, e.g. watermelons.
4. Most crates have good ventilation.

Disadvantages of wooden crates are:

1. Untreated wood can easily become contaminated with fungi and bacteria.
2. Treatment of wooden crates with paint or other chemicals may cause produce deterioration.
3. The material may be too hard or rough for produce like soft fruits, and therefore liners of a soft material may be needed.
4. Manufacturing of wooden crates puts an extra claim on the natural forest resources.

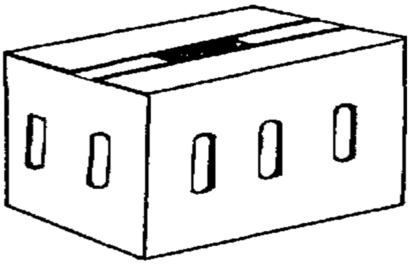
A wooden crate consists of rigid corners with planks nailed or stitched against those corners (e.g. apple or pear crate, field crate).

Plate 2: Wooden crate

4.4.4 Solid and Corrugated Fibreboard Boxes

Fibreboards are of two types viz. CFB (Corrugated Fibre Board) and SFB (Solid Fibre Board). Fibreboard boxes are frequently used because of their low weight, their range of sizes and shapes and their availability.

Solid fibreboard boxes (cartons): The boxes are used for tomato, cucumber and ginger transport. Most of them are printed with attractive colours, a brand name and a label. The information can be stamped on this label after filling the box.



Advantages of solid fibreboard boxes

- Low weight and easy to handle.
- The box can have any design, although it is recommended to use sizes fitting on the standard design of pallets.
- The boxes are delivered flat and assembling boxes can be done locally.
- The box has a low purchase cost.

Disadvantages of solid fibreboard boxes

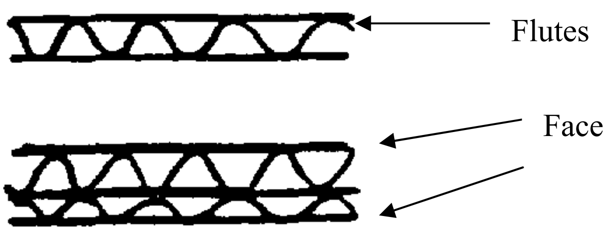
- Moisture and high humidity can seriously weaken the box. Washed produce should be made free from surface moisture before putting it into the box. Empty boxes should be stored in a dry place preferably flat on top of pallets and not for long periods of time.

- The low rigidity causes the lower stacking strength compared to wooden or plastic crates. The fibre-board boxes are easily damaged by rough handling and ropes and too much weight on top of the box can crush the perishable produce inside.

- Ventilation holes are usually small, because large holes would seriously influence the strength of the box. It is advised that the hole surfaces area is kept at least 5 percent of the total surface area of the box. Decreasing the size of the holes by not properly closing telescope boxes or not properly stacking the boxes will decrease heat exchange, resulting in higher temperatures of the produce and increased spoilage. Vertical oblong slots, instead of round holes, have the advantage that the hole stays partly open even when the telescope box lid is not completely closed.

- The boxes are not re-usable.

Corrugated Fiberboard (CFB): Corrugated fiberboard is manufactured in many different styles and weights. Because of its relativity low cost and versatility, it is the popular produce container material and will probably remain so in the near future. The flat surfaces of CFB boxes are known as 'face' and the corrugated surfaces are known as 'flutes'. The strength of CFB primarily depends on the GSM (g/m^2) of kraft paper used, no. of flutes/ meter and the height of the flutes.



The advantages of corrugated fiberboard boxes are:

Low weight, easy to handle, *cushioning* effect due to relatively soft walls. The CFB box can be fabricated to any design, the boxes are delivered flat and assembling of boxes can be done locally. They also have good printability. Above all they are most eco-friendly package due to their *biodegradability*.

Plate 3: Corrugated fibreboard boxes

However, low rigidity and poor stacking strength, high moisture absorbance, and low re-usability are the major disadvantages of CFB boxes. While packaging of fresh horticultural commodities, attention must be given for proper gaseous exchanges by providing required ventilation holes. As a rule, ventilation area should be at least 5 per cent of the total outer surface area of the box. Vertical/ oblong slots are better than round holes. Sometimes coatings with wax or poly linings are also used in CFB boxes in order to make them moisture proof.

4.4.5 Plastic Crates

In general, plastic crates are more expensive than wooden crates or carton boxes, initially but in long run they work out to be cheaper because of their more usability and longer life span. Plastic crates are usually made of high-density polyethylene (HDPE) or polypropylene (PP).

Advantages of plastic crates:

- As a strong, rigid crate, these plastic crates can be used for many journeys, making the cost per journey relatively low.
- Different sizes and shapes are available to suit different customer needs. Colours can be used for marketing purposes.
- The containers are easy to clean and disinfect.

Plastic crates are strong and water resistant and therefore, the containers can be used in humid areas and during hydro cooling.

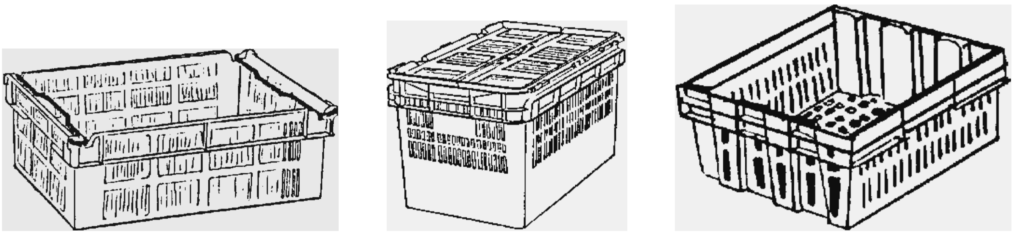
Disadvantages of plastic crates:

- The hard surfaces can damage the produce and it is advised to use liners at the bottom and side.
- The high purchase cost combined with the risk of pilferage could make this type of crate a financial risk.
- Because this crate can be used several times, the extra cost for the return trip should be included in the total running cost.

- The loss of space (40-80 mm on the sides and around 10 mm from the height).

a) *Stacking crates*

Because of the squared design with only the corner slightly rounded, an efficient use of available space is possible.



Plastic Crates (Source: FAO)

4.4.6 Bio-degradable Plastics

Plastic recycling is usually not as straightforward as for the other packaging materials. Many companies/institutions make considerable effort to produce biodegradable packaging. Biodegradable materials can be made from biological, renewable raw materials and from fossil non-renewable raw materials.

Traditionally plastics are made from petroleum-based materials that are produced from non-renewable oil (fossil fuels). A further disadvantage is that traditional plastics are not biodegradable.

Polymers of biological origin are now being used as raw materials for plastics. These bioplastics are a new generation of plastics which are claimed to be more environmentally friendly than those made from fossilfuels. Starch - a renewable degradable carbohydrate polymer that can be purified from various sources by environmentally sound processes. It is found in high amount in plants like corn (maize), potatoes, and wheat.

Starch, by itself, has a severe limitation in that it is water soluble, and articles made from starch will swell and deform upon exposure to moisture. Therefore starch is chemically modified or blended with hydrophobic synthetic polymers – which often are not biodegradable.

4.4.7 New Innovations in Packaging of Fruits and Vegetables

Designs and material used for packaging may be different under various condition viz. controlled atmosphere, modified atmosphere, ripening chambers etc. and shipping container.

4.4.8 Pallet Boxes and Shipping Container

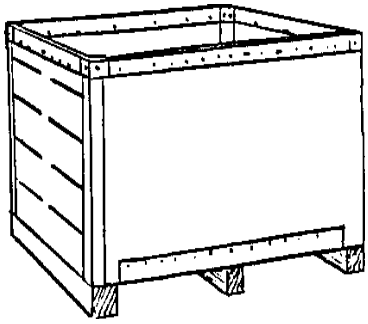
Loading and unloading is one of the very important steps in the post-harvest packaging of fruits, vegetables and root crops. Post-harvest losses can be considerably reduced by using pallets. All the subsequent handling and transportation operation become very easy once the boxes are placed on pallets. Pallets literally form the base on which most fresh produce is delivered to the consumer.

Advantages of a pallet box system:

- Less manual handling and thus reduced cost in loading, filling and unloading.
- More efficient use of available storage as compared to smaller crates.
- Increased speed of mechanical harvest.

Disadvantages of a pallet box system:

- The return volume of most of the pallet boxes is the same as the full load.
- The system requires higher investments in forklift trucks, trailers and handling systems to empty the pallet box.
- Because of the larger volumes, the produce is more easily injured during filling and unloading and the top layers will have made more movements during transport than when packed in smaller boxes.



The material can be printed to give the box a pleasant and recognizable appearance. Also the label can be included in this print.

4.4.9 Packaging Material for Fruits and Vegetable

Generally the fresh produce packed in jute bags or baskets and plastic crates for short distance transportation and CFB boxes and wooden crates for long distance transportation. The fruits and vegetables meant for super market sale are generally packed in polyethylene bags with 200 g and 500 g material.

Gunny bags	Ber, Lemon, Lime, Raw mango, Sand Pear, Sweet Orange, capsicum, cabbage, peas, potato, sweet potato
Bamboo basket	Grape, Guava, Mango, Papaya, lemon, okra, radish, carrot
Earthen Pots	Custard apple, grape
Wooden boxes	Apple, Apricot, Cherry, Litchi, Mango, Mandarin, Pear, Plum, Sapota, tomato, capsicum,
CFB	Apple, Cherry, Grape, Pomegranate and fruits for export, capsicum, chilli
Rigid plastic crates	Loose fruits for public distribution system

Packaging of fruits

1) *Mangoes:* Baskets made of bamboo with paddy as cushioning materials are used as packaging for mangoes in India due to its low cost, but they result in high spoilages of fruits. These a days, corrugated fibre boxes with

different types of cushioning materials like paddy straw, wood wool, vinylite and pliofilms wrappers, paper cuttings, newsprint, tissue paper and polyethylene films etc are used.

2) *Banana:* Conventionally bananas are transported as whole bunches wrapped with banana leaves. Use of polyethylene film bags for wrapping whole bunches for transport is found to be most suitable to reduce wastage. For export purpose bananas are packed in telescopic type corrugated fibre board boxes of different dimensions with good ventilated holes. The banana hands packed into the boxes in the lengthwise manner with their cushion resting on the bottom of the box and fruit finger tips pointing towards the lid. Stacking of these boxes is done lengthwise.

3) *Mandarins:* For long distance transport, wooden packing cases have been recommended. Here corrugated fiber board pieces are uses as liners. CFB boxes are also used with ventilation.

4) *Grapes:* 3 ply corrugated fibreboard boxes which can hold 2 to 4 kg of grapes are generally used for domestic purpose. The boxes are perforated and line with newspapers. The fruits can be protected against decay by placing sulphur treated paper such as ‘Grape guard’.

5) *Apples:* Traditionally apples are packed in wooden cases with newsprint as wrapper and pine needles or paddy straw as filler material. Now-a-days, CFB boxes provided with trays with cavities for holding apples is used. Each tray can hold 20 apples and four such trays can be placed on top of each other in the cartoon.

6) *Guava:* Guava are packed in boxes or baskets with a lining off newspapaer.

7) *Papaya:* The fruits are normally packed in baskets and individual fruits are wrapped in newspaper and the space between the fruits are stuffed with straw or saw dust.

8) *Ber:* Packed in gunny bag, cloth bag, bamboo baskets, wooden, plastic crates.

9) *Phalsa:* packed in baskets in small quantities being very perishable fruit.

10) *Pomegranate:* Usually CFB cartons are used for pomegranate packing.

11) *Bael:* Bael fruits are packed in gunny bags or plastic crates.

12) *Fig:* Fig fruits are packed in ventilated CFB boxes with fresh fig leaves as lining material.

13) *Custard apple:* Packed in earthen pots with grass and custard apple leaves as liners.

Packaging of vegetables

The vegetables are packed and transported in baskets, bags/ sacks or boxes.

1. *Tomatoes:* Tomatoes are usually packed in bamboo basket. Wooden boxes are also used of different size and shape in case of long distance transportation.

2. *Potatoes:* Commonly used packaging materials for potato are fibre mesh sacks, plastic film sacks, burlap bags. Tinted plastic bags are used to reduce light transmission to the tubers. Tubers in the transparent film bags should be protected from direct sunlight to avoid greening of the tubers.

3. *Onions:* Thin Hessian bags or bamboo baskets are used.

4. *Tuber crops:* Cassava tubers are dipped in 1% Mertect and packed in polyethylene bags and sealed to prevent microbial damage.

5. *Brinjal:* Bamboo baskets and gunny bags are used.

6. *Chilli and Capsicum:* Gunny bags, wooden boxes and CFB boxes are used.

7. *Cauliflower:* Generally packaging material are not used in cauliflower in India. Leaves protect the curd from direct exposure to sunlight. They are send in gunny bags to distant market.

8. *Watermelon:* Transported without any packing.

9. *Bottlegourd:* Baskets or crates are used.

10. *Bitter gourd:* Crates, jute bags are generally used and for supermarket sale, polythene bags are used.

11. *Pumpkin:* Baskets and gunny bags are used.

12. *Potato:* Graded and packed in gunny bags.

13. *Spinach:* Spinach is cut above root, washed, trimmed, graded and bunched or bagged.

14. *Cabbage:* Packed in crates and sacks.

15. *Pea:* Baskets, gunny bags and wooden boxes.

16. *French beans:* Wooden baskets, gunny bags.

17. *Okra:* Jute bags, baskets

18. *Muskmelon:* Transported without any individual packing in trucks.

19. *Cucumber:* Baskets, jute bags.

Root crops: Washed, graded and packed in gunny bags.

1. *Radish:* Trimmed, washed and packed in gunny bags.

2. *Carrot:* Packed in polyethylene bags after trimming tops, washing and size grading for super market display.

3. *Beetroot:* Mature roots are detopped, washed, graded and packed in gunny bags. For supermarket sale, packed in polyethylene bags.

4. *Turnip:* Gunny bags.

5. *Potato:* Graded and packed in gunny bags.

6. *Sweet potato:* Jute bags.

4.5 CUSHIONING MATERIALS AND WRAP

The cushioning material used for packaging fruits and vegetables are dry grass, paddy straw, leaves, saw dust, paper shreds etc. For the cushioning material to be useful, it should dissipate the heat of respiration of the produce. It should be free from infection so that it should not pass on the same to the fruit and vegetables. It is also important that the cushioning materials itself should be physiologically inactive. Moulded pulp tray, honeycomb portion, cell pack are used replacing the cushioning material. Cassia leaves as packaging materials are reported to be most effective in reducing physiological loss in weight (PLW), spoilage, retaining fruit colour and chemical quality.

Need and Importance

Damage caused by vibration and abrasion is generally a result of product movement within the package. While the damage may be superficial, it can adversely affect the market value of the commodity. Containers should not be filled either too loosely or too tightly for best results. Loose products may vibrate against each other and cause bruising, while over-packing results in compression bruising. Proper filling along with cushioning can minimize rubbing damage. Overfilling may lose all the benefit provided by suitable cushioning. Adding a simple cardboard liner to a crate will make it less likely to cause abrasion to produce. Shredded newspaper is inexpensive and a lightweight filler for shipping containers (if the ink used for newspaper print is non-toxic). Packaging materials such as trays, cups, wraps, liners and pads may be added to help immobilize the produce.

Plate 4: Use of cushioning material for packing (Source: FAO)

One of the newest trends in produce packaging is the shrink-wrapping of individual produce items. Shrink-wrapping has been used successfully to package apples, mangoes and a variety of tropical fruits. It is reported that seal packaging of individual citrus fruits film doubled the storage life as compared to control without packaging. Packaging of strawberries is done in various types of baskets and film over wraps to improve freshness and shelf-life. Shrink-wrapping with an engineered plastic wrap can reduce shrinkage, protect the produce from disease, reduce mechanical damage and provide a good surface for stick-on labels.

The main advantages of film wrapping of fruits and vegetables are-(i) reduced weight loss extended shelf-life (ii) minimized fruit deformation (iii) reduced chilling injury (iv) reduced decay by preventing secondary infection of fruits packed in the same box.

4.6 PRE-PACKAGING

The term “pre- packaging” covers all packaging of products in consumer units before its presentation to the end consumer. This simple technique involves cleaning, trimming, cutting of the fresh produce and packing the same in unit packages in polyethylene bags. Bean, carrot, brinjal, green chilli, root crops, leafy vegetables, and fruits like orange, lemon, banana, grape can be pre-packaged to obtain 1 to 2 times extension in shelf life in polyethylene bags under normal conditions without any refrigeration. The pre-packed produce presents better consumer appeal, longer shelf life and has considerable handling advantages in transport and marketing. The major facility required at the farm level or in orchards is a packing shed.

Pre-packaging is generally defined as packaging the produce in consumer size units either at producing center before transport or at terminal markets.

Packaging of fresh produce in consumer unit packs protects the produce against the damage and excess moisture loss.

1. It reduces the transportation cost eliminating unwanted and inedible portion of fruits and vegetables.
2. The space required for shipping and storage is less.
3. It has a better eye appeal as the produce is prepackaged in attractive film and the quality of the product can be seen from outside without opening the pack.
4. Pre packaging reduces the shopping time of the consumer as the produce is graded before being packaged.
5. It saves labour costs and produce is easy to handle.

Over-wrapping with plastic films such as polyethylene or PVC, often in the form of shrink-wrap, stretch film or cling film; bags made of paper, perforated polyethylene or polypropylene film, plastic net or cotton mesh; shallow trays of moulded pulp, paperboard, thermoformed plastic or expanded polystyrene, covered with plastic film; baskets, made of peeled wood, moulded pulp, paperboard and thermoformed or injection-moulded plastic, covered with plastic film. Among the different types of packaging films, polyethylene film finds the maximum use. Shelf life of asparagus, brinjal, okra, whole or segmented cauliflower can be increased by pre packaging in perforated or non-ventilated polythene bags.

4.7 LET US SUM UP

Adopting improved packaging, handling and transportation methods can successfully avert huge post harvest losses. The product requirements, the marketing system and the personnel preference will determine the type of packaging to use.

4.8 KEY WORDS

Post harvest losses : Losses incurred after harvesting till it reaches to the consumer for final consumption. This includes losses occurring during handling, transportation, storage, distribution etc.

Packaging : Putting the material in suitable containers for better handling, transportation, and storage.

Fiberboard : Board consisting of one or more sheets of fluted or flat paper stuck to a flat sheet of paper or board or between several liners. When fluted sheets are used, it is called corrugated fibre board and when flat paper sheets are used, it is called solid fibre board.

Cushioning material : Padding material used in between the package and the product to protect against abrasion, vibration and thereby damage. The most popular cushioning materials are paper shreds, paper liner, cardboard liner, leaves etc.

Pre-packaging : Pre-packaging covers all operations include cleaning, trimming, cutting, and packaging in unit packages.

4.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISE

Check Your Progress Exercise 1

1. Post-harvest losses are losses occurring after harvest, loss of weight, quality, nutritive value, financial loss, loss of market and goodwill.

2. Packaging material is selected on the basis of: commodity, the systems of production, storage, handling, transportation, cost factor involved in producing packaging material, market requirement, consumer attitude, requirement of recycling, re-use disposal etc.

Check Your Progress Exercise 2

1. Packaging materials used serve as an efficient handling unit, protects from mechanical damage, protects against moisture loss, provides clean and sanitary storage, sales and service motivation, prevent pilferage, reduces cost of transport and marketing

2. There are many different types of package in use throughout the world. Packaging for fresh produce is of several types: Sacks, wooden crates,

carton or fibreboard boxes, plastic crates, pallet boxes and shipping containers, baskets.

3. The advantages of corrugated fiberboard boxes are: Low weight, easy handling and stacking, cushioning effect due to relatively soft walls, so minimum bruising. CFB box can be fabricated to any design, the boxes are delivered flat and assembling of boxes can be done locally, also have good printability. All they are most eco-friendly package due to their biodegradability, economical transportation

   Disadvantages of wooden crates are: Untreated wood can be contaminated with fungi and bacteria, treatment of wooden crates with paint or other chemicals may cause produce deterioration, material may be too hard or rough for produce like soft fruits, and therefore liners of a soft material may be needed, disposal of the crates after use, manufacturing of wooden crates puts an extra claim on the natural forest resources.

Check Your Progress Exercise 3

1. The cushioning material used for packaging fruits and vegetables are dry grass, paddy straw, leaves, saw dust, paper shreds etc.

2. Pre-packaging is generally defined as packaging the produce in consumer size units either at producing centre before transport or at terminal markets. Packaging of fresh produce in consumer unit packs protects the produce against the damage and excess moisture loss, reduces the transportation cost, the space required for shipping and storage is less, better eye appeal as the produce is pre-packaged in attractive film and the quality of the product can be seen from outside without opening the pack. Pre packaging reduces the shopping time of the consumer as the produce is graded before being packaged and lower labour cost.

UNIT 5 TRANSPORTATION OF FRESH PRODUCE AND CONTROL OF LOSSES

Structure

5.0 OBJECTIVES

After going through this unit, you should be able to:

- know which mode of transport is suitable for particular condition;
- explain how transportation can influence storage life and the quality of fresh produce;
- discuss proper loading and unloading techniques for different commodities; and
- explain the advantages of Palletisation/ unitization.

5.1 INTRODUCTION

In this unit, we will discuss about transportation of fresh produce. Transport refers to carrying a produce from one place to another. Rapid and reliable transport of fresh fruits and vegetables is of critical importance to successful marketing. The delay in transport not only affects shelf life and the quality of fresh produce, but also reduces its value in the market. Transport is an important link in the handling, storage and distribution of fruits and vegetables. The transport of produce starts from the field to the assembly points or collection centres. From these places, bulk transport is undertaken by retailers, middlemen, wholesalers, processors, exporters and importers at packing stations, storage plants and shipping points. Several modes of transport are used to move fresh fruits and vegetables from farm to final consumer. They include head load, bullock carts, bicycle, rikshaw, autorikshaw, lorry, boat, ship and aeroplane. All these methods have their own advantages and disadvantages. Head load is mostly used for moving small quantities to a nearby market. This mode of transport is usually in practice in interior areas where proper roads are not available. Bullock Carts, Bicycle, rikshaw and autorikshaw are also used for short distance transport, but adequate cushioning should be provided to the transporting material for avoiding impact damage to fruits and vegetables in such mode of transport. Boats are used for inland transport, where as ships carry produce globally. High value products and the most perishables are always air lifted to the destination market. Knowledge of these pros and cons of each mode of transportation will help us to select the suitable mode of transport for an individual commodity.

5.2 PRE-OPERATIONS AND TREATMENTS

5.2.1 Packinghouse Operation

The basic operations in a packinghouse are sorting, sizing, grading and packing. Depending on the kind of produce, additional activities may include degreening, curing, washing, bunching, chemical treatments and pre-cooling. The sequence of activities varies with different crops. These operations are essential preparatory steps for transportation and subsequent marketing.

5.2.2 Curing

Potato, sweet potatoes, taro, onions, garlic and similar crops are cured prior to storage or marketing. Injured or bruised surfaces are allowed to heal by holding for a few days at ambient temperatures. The healing process is necessary so as not to shorten storage life. Periderm formation during healing is favoured by high temperature and high humidity. In sweet potatoes, this condition is most rapid at 30^o C with an RH of 95 to 97%. Potato tubers, on the other hand are held above 20^o C for about 2 days and then at $8\,^o$ to 15^o C for 10 to 12 days at 90 to 95% RH. Another change that occurs during curing is the reduction of moisture content, especially in onions and garlic. Properly cured potato tubers have as much as 50% longer storage potential than those uncured or improperly cured. Curing also reduces rotting. Curing appeared to be generally more effective at ambient temperature than in cold storage.

5.2.3 Degreening

Degreening is the process of decomposing the green pigments in fruits usually by applying ethylene (C_2H_4) or other similar metabolic inducers to give a fruit its characteristic colour as preferred by consumers. It is applicable to bananas, mangoes, citrus and tomatoes. The length of time required to degreen a fruit depends upon the degree of natural colour break and maturity. The lighter the green colour and the more mature a fruit is, the less time is required to reduce the chlorophyll to a desirable level.

The degreening process is carried out in special treating rooms with controlled temperatures and humidity in which low concentrations of C_2H_4 (about 1:50,000) are applied. The C_2H_4 can be supplied either as the chemically pure gas in cylinders or by the old and risky method of using the fumes from the incomplete combustion of kerosene. The room is thoroughly ventilated to keep the CO_2 at levels (below 1%) that will not hinder colouring. The degreening time by this system is 24 to 48 hr. When kerosene fumes are used, the burners are placed outside the degreening room. The fumes enter the room through ducts by forced ventilation. Despite the fire hazard involved, the kerosene fumes produce better coloured fruits than pure C_2H_4, and it is suggested that this may be due to the good ventilation provided in the method. The best degreening temperature is 26°C. It has been found that higher temperatures delay degreening. The RH should be from 85 to 92%. Humidity levels high enough to cause condensation during degreening are associated with slow degreening and increase in decay. Low humidity, although it checks decay, causes excessive shrinkage, shrivelling and peel breakdown.

5.2.4 Pre-cooling

High temperatures are detrimental to the keeping quality of fruits and vegetables. However, elevated produce temperature is inevitable, especially when harvesting is done during hot days. Pre-cooling is a means of removing this field heat. The general aim is to slow down the respiration of the produce, minimize the susceptibility to attack of microorganisms, reduce water loss and ease the load on the cooling system of the transport vehicle or ship's cargo space. Various methods of pre-cooling may be used.

a) Air cooling

The temperature difference between the coolant and the commodities or packages must be reduced fast for pre-cooling to be effective. Cooling may be done fast by the use of coolants such as air, iced water, ice or vacuum. The temperature of the cooling air must not be below 0°C to avoid freezing. Prompt storage is essential to achieve the benefits of pre-cooling.

Pre-coolers using air are cold rooms and tunnels. A cold room has a very intensive air circulation, high refrigerating capacity and fairly low ceilings. The cold room is advantageous for large-scale operations. Pre-cooling tunnels are long, narrow cold rooms in which air circulates at high speed.

In forced air pre-cooling, the pre-cooler forces air through the void spaces of the fruit. The final air temperature is 0 to 1.5°C. Weight loss by forced air cooling is less than 1%. The pre-cooling operation may take 1 to 1 ½ hr.

b) Hydro-cooling

Hydro-cooling quickly extracts field heat from the produce. It has been used with advantage for leafy vegetables to retain texture and freshness. For citrus and some fruits, fungicide in the cooling water may be added to hold decay within tolerable levels. Fruits cooled with water are apparently more susceptible to decay upon warming. Sometimes it may lead to chilling injury (oranges) or damage due to water soaking (citrus). The hydro-cooling equipment consists of a large tank of iced water, a high capacity pump for circulating the water to a sprinkler system, and a conveyor belt for carrying the produce to the sprinkler.

c) Vacuum cooling

Vacuum cooling is the most rapid method of pre-cooling for leafy vegetables. The principle of vacuum cooler is evaporative cooling. At 29.9 in pressure, water evaporates at 100°C. At 0.018 in water will be vaporized at 0°C. There is 1% water loss for every 6°C reduction in temperature, therefore some water must be added to compensate for this loss.

5.2.5 Washing

As consumers demand clean produce, most fruits and vegetables are washed after harvesting. Washing improves the appearance of the produce and reduces the residues of fungicides and insecticides. Washing is not done on soft delicate and perishables fruits like strawberries. Muskmelons, cucumbers, and sweet potatoes are usually cleaned by brushing or wiping dry, rather than by washing.

5.2.6 Drying

Drying removes excess surface water from the fruit or vegetable. This is facilitated by heated air blown on the fruits or vegetables as they pass through sponge roller conveyors. Drying may also be done by a series of rotating brush dryers made of soft bristles. Minimum heat and dryer brush speed should be used to avoid injury to the fruits.

5.2.7 Waxing

Fruits and vegetables have a natural waxy layer on the outer surface, which is partly removed by washing. An extra discontinuous layer of wax is applied to the fruit, which provides the necessary protection against decay organisms. Waxing is especially important if tiny injuries and scratches on the surface of the fruit or vegetable are present. These can be sealed by wax. Waxing also enhances of the gloss of fruits or vegetables. Appearance is therefore improved, making the produce more acceptable to consumers.

5.2.8 Grading

Fruits and vegetables show considerable variations in quality due to genetic, environmental and agronomic factors. Therefore grading is necessary to get suitable returns commensurate with quality.

Grades are based on soundness, firmness, cleanliness, size, weight, colour, shape, maturity and freedom from foreign matter and diseases, insect damage and mechanical injury. Whatever the classification, the produce must possess the minimum qualifications established by the regulatory agencies.

5.2.9 Sizing

After grading, the produce is sized for uniformity. Hand sizing is useful for small-scale. For large operations, various sizing devices are used, based on either shape or weight of the produce.

For regular-shaped commodities like citrus, sizers are of many types. Longitudinal belt and roll sizers are used for some citrus varieties. Size adjustment can be made quickly from oranges to tangerines to grapefruit. Central longitudinal belt and roll sizers are of many types or variations, such as transverse roll and drop roll. The different sizes drop through the canvas distribution belts and are transported to the packing stations. Perforated belt sizers consist of a belt or chain having certain size holes or meshes in each section. Commodities may be moved about on the sizers. Shaking screens with varying sizes of holes can be used for sizing. Fruits can be vibrated along the screen and collected in different sized holes. For small products such as peas and cherries, a rotating cylinder may be used. The surface of the cylinder contains many holes or slots formed by metal rods. Commodities such as cucumbers, pineapples and large root vegetables are sized by diverging belt or rope grader. For commodities with irregular shapes, sizing is done by weight of the produce.

5.2.10 Disinfestation Treatment

One of the most important pests in crop production are fruit flies. Papayas, mangoes, melons and many other fruits are highly susceptible to fruit fly attacks. Disinfestation treatments do not vary much among fruits. The disinfestation methods for export of papayas include the vapour heat and EDB fumigation treatments. An irradiation treatment needs the government clearance before use.

The vapour-heat treatment, in addition to disinfecting the fruit, controls storage decay, but it is a relatively expensive operation in terms of initial investment for equipment and operational cost. Further, it takes a long time of approximately 15-20 h, and even in properly treated fruits, vapour heat causes a reduction in the aroma of the fruit pulp.

The fumigation treatment is more economical than the vapour-heat treatment. The entire treatment time is only about 4 hr, much less than that required for the vapour-heat method. Furthermore, most of the fruits are not damaged by the treatment, and storage decay is controlled. Cold treatment is also used for this purpose but in case of fruits where there is no injury at low temperature.

5.3 FACTORS AFFECTING TRANSPORTATION OF FRESH PRODUCE

Many opportunities for damage to fruits occur during its transport from field to the destination market. Impact bruises can occur when bins are dropped during loading or unloading. Stacking of overfilled containers may cause compression bruises in fruits and vegetables. Abrasion or vibration bruises may occur when fruits move or vibrate against rough surfaces or each other during transport. Bruises and injury reduce saleability of the fruits and vegetables and reduce the quality and shelf life by enhancing senescence.

The time of harvest or maturity of a product can influence the temperature required during transit. During harvesting and packaging, several factors may affect the physiological behaviour of the commodity during transit. These are (a) maturity at harvest, (b) field temperature and humidity at harvest, (c) mechanical injury, (d) time between harvest and cooling, (e) type and rate of pre-cooling, (f) sanitation of packing facilities and (g) use of brushes, dips, sprays and fumigants.

Factors affecting transportation depend upon

- Product handling
- In-transit temperature and humidity
- Air circulation and ethylene removal
- Compression/abrasion during movement

Poor handling of produce during loading and unloading of transport vehicle results in high post-harvest losses. In our country, containers, rail wagons and road vehicles are loaded by hands, implying that each package is manually lifted and dropped 4-10 times between harvest and consumption. Further, most often casual labours are hired for this work. As casual labours have no or little knowledge of handling fresh fruits and vegetables, the risk of quality deterioration of fruits and vegetables increases.

Each commodity must be transported under optimum conditions of temperature and humidity. Fruits should be protected from high temperature in the field after harvesting. Wherever possible, harvested fruits should be moved to the shade until transport. During transport, speedy handling is done for the protection of the commodity.

Fresh fruits and vegetables in packages have two environments, one inside the package and other one outside. Controlling outside environment does not necessarily control the environment inside the package. Mostly fresh produce is packed in corrugated fibreboard, which is a poor conductor of heat. When the produce generates heat and gives off water, it may affect the packaging material resulting in collapse of carton. When such a package is transferred in cold environment, and if the rate of heat production exceeds the rate of heat transfer, the product will get hotter, and the increased respiration rate will result in higher vapour production. If the walls of package become colder than the air inside the package, moisture given off by the produce can condense on the inside of package walls resulting in collapse of carton. Therefore, circulation of air inside package is important to maintain uniform temperature through out the package. Further, air circulation helps in removal of ethylene from the produce, which is necessary for maintaining the optimum quality of fruits and vegetables.

Packing and mode of transport selected should be such that it causes no or minimum vibration and bruising injury to the product. Vibration and bruising are the major causes of spoilage of fruits and vegetables during transport. To avoid vibration and bruising injury, cushioning material should be used.

Shipping containers

Packaging for shipping and handling requires appropriate engineered containers to protect produce from bruising, vibration and the weight of other stacked containers. The ideal pack consists of a tight fill without a bulge in a lidded container having sufficient stacking strength to protect the contents under all handling conditions. Any shipping container should be designed to meet the specific requirements of the particular fruit or vegetable.

In more developed countries, many shipping containers are used only once, and are not returned to the shipper. In less developed countries, baskets and boxes are often returned for reuse.

Shipping containers should be labelled with large print to specify the commodity, variety, weight or count, grade and source.

Wooden containers can be the strongest and most rigid type of shipping container, but strength depends on the thickness of materials used. Common types include: nailed wooden boxes and crates, wire bound boxes and crates, ply wood boxes, bulk bins or pallet boxes and wooden pallets. Pallets are platform devices used as a base for assembling, storing and handling or shipping other containers in a unit load. The base may be a 2-way or 4-way type to allow entry of types of powered forklift or hand pallet trucks.

Fiberboard (corrugated) cartons are becoming popular for shipping both tropical and subtropical produce. Their light weight and low cost are advantages. However, they have the disadvantage that some types absorb moisture and lose strength and thus stacking height may be limited in areas or in storage where RH is high. The strength of fiberboard cartons may be increased with stronger base materials, with internal dividers, extra liners or by using full telescope type cartons with two outer walls. Strength and moisture resistance may also be aided by resin and paraffin wax coatings. Waxed cartons filled with produce may be hydro-cooled and top iced or have packaged ice enclosed.

Fiberboard cartons are also common for mature green tomatoes and avocados and as master containers for consumer-packaged vegetables, such as cellophane-wrapped cauliflower, trays of tomatoes and polyethylene bags of carrots or other root crops.

Mesh, burlap and multi wall paper bags may be used to ship onions, cabbage and potatoes. Some types of paper bags have special wet strength properties that allow use of package ice for non pre-cooled carrots and sweet corn.

Bulk packs

Bulk boxes or pallet bins occasionally are used as shipping containers for fruits and vegetables going to terminal market warehouses to be repacked in consumer packages. Fruits and vegetables for processing, such as tomatoes, carrots, sweet potatoes, citrus and pineapples are often shipped in bulk boxes. Bulk boxes may be constructed of plywood, sawn lumber, wirebound veneer, fiberboard, wire or combinations of these materials.

The advantages of bulk boxes over field boxes of equivalent capacity, are lower cost, rapid loading of transport vehicles and replacement of costly manual labour. Also with bulk boxes, storage or warehouse facilities can be utilized more fully and properly designed bins easily withstand stacking loads.

Consumer packages

Consumer-sized packages for produce consist only of having a supply of paper or plastic bags available for customers to select, package and weigh their purchases. With such packaging, standard sized units are packed after washing or grading. Each unit is labelled as to commodity, weight or count, brand, source and other information and the consumer units are packed in master shipping containers usually made of fiberboard.

Consumer packages are of the following types: (a) bags made of paper, film or cotton or plastic mesh; (b) trays of moulded pulp, paperboard, plastic or foamed plastic; (c) folding paperboard cartons, sometimes with a clear plastic window or with dividers for individual fruits; and (d) small rectangular or round baskets, punnets or cups of moulded pulp, plastic, veneer or coated or waxed paperboard. Moulded vacuum-formed plastic trays may be made of polystyrene or polypropylene. Foamed plastic trays are usually of polystyrene.

Stacking containers

The nature of the container and the manner of stacking are important factors that influence cooling in storage or transport. An elaborate system for air distribution is useless if poor stacking prevents airflow; air follows the path of least resistance. Generalizations on stacking arrangements are difficult with the large variety of containers in use for different commodities. A distance of 2-3 inches between rows of boxes or cartons is desirable. Rows should be laid out so that the direction of airflow is along rather than across the rows. Loaded pallets or pallet boxes in storage should be formed in straight lines to provide about 4 to 6 in of space between rows.

Special precautions should be taken in stacking containers on pallets so that as much container surface as possible is exposed to moving air to speed cooling. With fiberboard cartons, cooling may be more difficult because, having no bulge or slats, as do many wood containers, they may be stacked too tight. Produce in unventilated cartons cools very slowly and often stays appreciably warmer than the surrounding air during storage. Bulge packed cartons or boxes should not be stacked so that the weight rests on the produce, but should be stacked on their sides; or wood cleats or stripping may be needed to avoid crushing or bruising the products.

5.4 MODES OF TRANSPORT

The mode of transport of fresh horticultural commodity depends on distance to market, perishability and value of product, and the cost of transportation method. Before selection of the mode of transport a consideration must be given to

- Kind, variety, and condition of commodity
- Distance to market
- Price of the commodity
- Transit environment
- Cost of the transport

Different modes of transport used for horticultural crops include:

- Road transport
- Rail transport
- Water transport
- Air transport

Road transport

The most common transport used world wide, and because of its flexibility, door-to-door delivery, fast, easy to load and unload; and general improvement in road conditions its use has been in rise. However, this method is energy intensive, expensive and needs a relatively developed road infrastructure.

In our country land transport is mostly done with open non refrigerated trucks. It results in high losses of produce due to warming. But for short distance transport natural ventilation is always sufficient to prevent losses due to heating. It is advisable to use refrigerated van for long distance transport.

Need and Importance

Transport by road is the most important, and will continue to be the predominant mode of transport in the developing countries. It offers the benefits of great flexibility in operation, suitability for short hauls and possible door-to-door service with all the implied conveniences of loading and unloading. However, it depends upon road conditions, transport service available and organization of transport services. Connecting roads may be inaccessible during rainy months and bridges may become unsafe. Because of inadequate roads, high freight rates may be charged to transporters.

Another difficulty is that in produce transported by public vehicles, handlers and passengers have no regard for the safety and quality of the product. Often, if commodities are carried together with passengers, public vehicles deviate from direct routes to get more passengers, and there is delay in transport.

For more systematic and advanced transport facilities, e.g. refrigerated truck vans, are required. Although, use of modern facilities will increase the cost of the product in the markets, it can be compensated by supply of quality product to the consumers. For short trips, the product can be washed, disinfected, dipped in cold water and immediately placed in ice cold insulated vans. Sometimes the short periods transport can be done in a non-refrigerated but pre-cooled vehicle also. If the distance to the market is such that product temperature would be undesirably high despite provision for pre-cooling and insulation, dispensable refrigerants such as ice, dry ice, eutectic solutions or liquid nitrogen may be used. Application of these refrigerants depends not only on the duration of trip and transport temperature but also on the cost and availability of the refrigerant. If still longer transport time is expected, then the use of mechanical refrigerating machinery in the vehicle should be done.

The fundamental considerations for transport over short and long distances are as follows:

1. In transport of short duration, the product should be protected against mechanical injury and exposure to extreme temperatures. The produce should be moved in a direct and consistent direction as much as possible and should not retrace its tracks.

2. For transport over long distances, there is an added risk of product deterioration due to excessive heating and wilting, inception of decay causing organisms, chilling, softening of succulent commodities or ripening of fruits. Hence, provision for more sophisticated facilities is recognized more than ever and is one of the many urgent problems in the tropics, despite the high capital investments involved.

Rail transport

Although slower than road transport, it can provide vibration free ride at relatively less cost. However, this system of transport is declining significantly due to its less versatility and inaccessibility with production site. For short distances the rail transport is usually completed within 5 hour, which can help in avoiding refrigeration. For long distances, the rail transport is often preferable to road transport provided it is frequent and dependable. Refrigeration is needed and is more easily arranged by rail than by road. Because it is imperative to protect the product during this long shipment, refrigeration principles and practices must be followed.

Water transport

River transport is slow, but it can be used for non-refrigerated commodities. Sea transport is usually used for long distances, and use of refer containers offers a cheap method of transport in comparison to air transport.

Facilities of boats and vessels should be made available for river and sea transport. Frequent and improper commodity handlings often offset any cost advantage of water transport. With the advances in containerization the improvements in the international sea transport are happening. Refrigerated vans or trailers are now being used, which are crane-lifted to the ship, and greatly minimizing dock-to-ship handling.

Air transport

One of the most dramatic developments in the transportation of perishables is airfreight. Air transport is mostly done on passenger airplanes with a little quantities of crop being carried on cargo. Products can be sold in markets thousands of kilometers away only a day after harvest. This transport is relatively fast, making it suitable for very perishable commodities, but cost incurred in transportation is very high.

Use of air transport is very limited despite its speed due to:

a) the high cost per kg,

b) disruption of flight schedules due to bad weather,

c) traffic in handling of produce at air terminals,

d) the distance from the production or consignment centres to the airport and then from the airport to the market upon arrival at destination,

e) uncertain amount of cargo space available on scheduled flights and

With the advent of jet and jumbo planes, however, air transport offers vast possibilities. The lower operating cost per ton/km with even faster schedules has already resulted in an increase in air-transported fruit and vegetables. Prospect of air transport should not be evaluated solely on the basis of reduced operating cost, but also on the gains from premium consumer prices due to better quality of vine- or tree-ripened produce. Airport product-handling facilities and ancillary services are expected to improve as a result of current developments in aviation technology.

5.5 LOADING AND UNLOADING

It is very important to have proper loading and unloading procedure, as both the steps can damage the product integrity and render it unfit for human consumption. The product must be packed in appropriate container. Weak packages and their enclosed contents are more prone to damage during transport. There must be minimum damage to the product during loading and unloading operations.

5.6 PALLETISATION/ UNITIZATION

In advance countries almost all horticultural packages are unitized for handling. The packages must be designed for secure palletisation. The package must withstand expected stresses in the stacking column. If the packages are cross-stacked, their vents must be located on both ends and sides to allow air circulation through all packages on the pallet. The package dimensions must be compatible with pallet dimensions.

Some advantages of palletization include:

a) Savings in handling costs averaging 40 to 45%;

b) reduced handling time;

c) fewer personnel accidents by substituting mechanical or manual handling and lifting;

d) more efficient utilization of storage space;

e) reduced product damage; and

f) uniform stacking of produce.

5.7 LET US SUM UP

Transport of fresh produce is necessary to make sure its availability to the consumers. Although several methods of transport are available, a suitable method is selected based on value of the crop and distance of market. It is of paramount importance to have proper handling before and during transport to avoid any injury to the produce and to have more shelf life.

5.8 KEY WORDS

Transport	:	Movement of the product
Ethylene	:	A colourless flammable gas which stimulates ripening
Respiration	:	Process of hailing oxygen and exhaling carbon-di-oxide
Pre-cooling	:	Process of cooling fruits and vegetables immediately after harvesting
Waxing	:	Coating of fruit surface with food grade paraffin
Refer container	:	Containers used for transport of fruits and vegetables, which can be cooled to refrigerated temperature.
Perishable	:	Commodity having short life cycle
Pelletization	:	Stacking the product in a definite area as a single unit
Unitization	:	Stacking the product in a definite area a single unit

5.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answers should include following points:

   - Road
   - Rail
   - Ship
   - Aeroplane

2. Your answers should include following points:

   - Temperature regulation
   - Ethylene removal

3. Your answers should include following points:

   - Proper cushioning
   - Infrastructure development

4. Your answers should include following points:

   - Air
   - Fast quality deterioration

5. Your answers should include following points:

   - Road
   - Rail

6. Your answers should include following points:

   - Impact injury
   - Quality deterioration

7. Your answers should include following points:

   - Uniform stacking
   - Proper ventilation
   - Avoids injuries

8. Your answers should include following points:

   - Air
   - Sea

UNIT 6 CLEANING, SELECTION, SORTING, GRADING AND PACKAGING

Structure

6.0 OBJECTIVES

After studying this unit, you should be able to:

- understand different operations in handling of fresh fruits and vegetables;
- learn usefulness of these operations in maintaining quality; and
- know about containers and packing line.

6.1 INTRODUCTION

After harvesting of the crop and before marketing or storage of the produce several operations like cleaning, sorting, grading *etc.* are done. These post-harvest operations increase attractiveness, maintain quality for a longer period and increase storage life. In the developed, countries these operations are done in the packing houses, therefore are called packing house operations. In India these operations are not usually done except in case of fruits of commercial importance. In this chapter, we will learn these operations and their usefulness in post-harvest management of fruits and vegetables.

6.2 CLEANING

Soil and other materials are removed from the surface of fruits and vegetables by washing, brushing or sometimes both to improve their appearance, to prevent wilting and to remove inoculums of pathogen causing post-harvest diseases.

6.2.1 Washing

The produce is washed with clean water usually by putting in a water tank having a continuous flow of water and agitation. Use of chlorinated water containing about 200 ppm of chlorine helps in surface disinfection. If the water is recycled, chlorination is must. This helps in checking spread of the diseases especially bacterial diseases. Washing under a shower with pressurized water is more helpful in removing soil from root vegetables like carrot, radish, turnip *etc*. Rotary drum machine or barrel washer is used for potato and other root vegetables. Brush washers take care of cleaning of individual fruit or vegetable. After washing excess water should be removed. This can be done manually or with a machine.

6.2.2 Dry Cleaning

This is done with the help of machines with brushes and is used in crops that can be adequately cleaned without water. Brushes loosen any leaf or lightly attached particle and give a polishing effect with the option of aspirating afterwards. Aspirators are simple machines consisting of a vibrating mesh belt conveyer which carries the produce across the upward vertical air blast. Any light chaff or leaf is lifted off and removed. Root vegetables often need some degree of abrasion before aspiration. Machines are available with spring or rubber or spiral rollers for this action.

6.3 TRIMMING

Removal of unwanted leaves, stems or roots prior to packaging and storage is done in vegetables like lettuce, cabbage, cauliflower *etc*. It improves attractiveness of the produce and also reduces storage space by eliminating unwanted material.

6.4 SELECTION

The desirable characteristics of a fruit or vegetable are dictated by its intended use. Since the main outlet of fruit and vegetable is usually the fresh market, the acceptability of the produce is determined by consumer preference, attractiveness and organoleptic quality. The same criteria do no necessarily apply to the raw materials for processing. The processor is primarily interested for colour, flavour and texture. The grower is more concerned with least cost of cultivation, high marketable yield and maximum profit.

All these aspects constitute quality of the produce and are important for selection of the commodity. Quality may, therefore, be defined in terms of end use. Important factors in quality for the consumers are (i) appearance including size, shape, and colour (ii) condition and absence of defects, (iii) texture, (iv) flavour and (v) nutritional value.

Overall quality of the fresh produce cannot be improved after harvest. Controlled ripening can improve the colour of the produce like tomato, mango, banana *etc*. or modified storage environment can extend the storage life, but only as much as the pre harvest conditions of the crop allows. Thus the ultimate market quality of the produce will be influenced by the growers as soon as the crop or the variety is selected. If there is no domestic or nearby market for a particular crop and the grower has no facility for allowing distant transportation, there is no point in growing that crop. It is often more profitable for the growers to grow unusual vegetables like lettuce, broccoli, Brussels sprout, cherry tomato, gherkin, yellow or red capsicum *etc*. and fruits like strawberry, Kiwi *etc*. and sending them to metropolitan markets for meeting the requirements of economically higher strata of the society and foreigners. Off-season production of fruits and vegetables also fetch a good return to the grower. Production of vegetables like okra, bittergourd, cucumber *etc*. during winter and capsicum, tomato *etc*. during summer are very remunerative and can fetch higher return in metropolitan cities.

Selection of a particular variety to be grown will depend on a few aspects as discussed below.

a) The variety should match the consumer preferences of the market to be served. This is especially true in case of vegetables like brinjal, tomato and onion, and fruit like banana. In brinjal, shape (round, long, oblong), colour (purple, green, white, variegated) and size (large-round, small-round) determine the preferences among the consumers of different regions. In tomato, sour and juicy varieties are preferred in some areas over non-juicy firm varieties. In some areas white onions are preferred over other types and in some multiplier onion is preferred over the common types. In areas where red bananas are preferred, the yellow ones do not fetch good price.

b) Good seed of genetically pure variety is very important because it will ensure uniform produce of proper maturity at harvest, minimising greatly post harvest problems. This important aspect is very often overlooked.

c) In case of hybrids especially of tomato, long distance transportation could be more remunerative and fetch higher return. Thick skinned (pericarp) hybrids fetch higher prices in the markets located in distant places as they are less susceptible to damage during transit as compared to the varieties with thin pericarp.

d) If the crop is grown for processing, the variety should be selected as per specific requirements of the processing industry. In mango, varieties with more pulp content like Totapuri is preferred for processing. In tomato, varieties with high total soluble solid (TSS) are preferred for manufacture of tomato products. In onion, white varieties with high TSS are required for dehydration.

6.5 SORTING

Sorting is almost entirely a manual operation because human sight and dexterity have not been replaced satisfactorily by machines. Sorting is generally done in a packing house as a part of a cleaning, sorting and sizing on packing line. The purpose of sorting is (i) to remove items which are under size, over or under ripe, misshapen and damaged, and (ii) to meet requirements of a grade established by the centre, state or marketing agreement authority. Sorting improves attractiveness of the produce and reduces the quantity to be handled during subsequent operations like grading, packaging *etc*., by eliminating unwanted materials. By removing the damaged produce before hand, it reduces loss due to post harvest diseases during transport and storage.

Culled fruits and vegetables which do not conform to the specific quality attributes may be utilized for extraction of essential oil and pectin from citrus peel, starch from mango seed kernel and potato, natural colour from grape, *jamun*, p*halsa*, carrot *etc*. They can be effectively utilized for production of animal feed. Some of the fruit and vegetable wastes can be usefully diverted for biogas generation and making field manure.

6.5.1 Sorting Equipment

The produce for sorting generally moves over a belt or roller conveyor. A roller conveyor, which turns the produce as it moves forward, is preferable to a belt because it allows the sorter to see all sides of each item. Each sorter on the line picks out those products, which are not suitable for high marketing. Sufficient light above the sorting table is also essential for high efficiency of the operation.

6.6 GRADING

Buying of fruits and vegetables is done on the basis of grade and size. Fruits and vegetables show considerable variation in quality due to genetic, environmental and agronomic factors. Grading is necessary to get suitable returns commensurate with quality. Most countries have their own set of standards for domestic trade. Grades are based on soundness, firmness, cleanliness, size, weight, colour, shape, maturity, freedom from disease, mechanical injury, insect damage *etc*. Usually there are two to three grades for most of the products as extra grade, grade 1 and grade 2. Grading may be done manually or mechanically.

6.6.1 Grading Equipment

Grading machines fit into four main categories depending on the quality to be graded, viz., size, mass, colour and profile. Other machines that have been considered include those which measure a range of acoustic and optical properties, firmness and resilience. Size graders may incorporate an element of shape by which it can select fruits or vegetables with specific shape. Size graders are available in several different forms which have different numbers of contact points and different shaped apertures. The major limitation is that in most graders measurement of the produce is two dimensional and items may be upended to pass through. Other important aspects are utility of the machine to handle different crops, gentle handling of the produce and initial capital cost.

Different types of available graders suitable for individual crop are discussed below:

Screen grader

In this machine the produce is conveyed along with a series of belts having holes of different sizes. Any item smaller than the hole size of the belt drops down onto a chute or crosswise conveyor below. The machine will have two or three belts with holes of different sizes. The first belt will have smallest holes to remove the smaller sizes first. The size of mesh (hole) increases with subsequent belts and the largest fraction would be the carry-over from the larger mesh belt. The shape of the hole in the belt is usually square, but hexagonal are also available. This is usually a harsh method and is not suitable for fruits like apple, peach etc., which require gentle handling. Continuous shaking of the belt provides easy cleaning of the holes and faster movement of the produce.

Barrel screen grader

These graders have cylindrical screens in place of flat belt screens as in screen grader. A typical barrel grader will have three cylindrical screens. The smaller holes are at the upper end of the sloping barrel and the larger holes are at the lower end. The barrel is tilted at about 5^o so that the produce passes down by gravity. This type of grader is suitable for onion, carrot, beet, citrus, gladiolus bulbs *etc*.

Diverging belt grader

The grader operates on the basic principle of diverging elements. The produce is conveyed along a narrow channel, the width of which increases gradually as it travels along until it is so wide that the produce drops through the gap by gravity on a belt or chute below. The smaller ones drop through first and the larger ones are carried further. Graders working on this principle are available for different crops.

Roller grader

This is working on the principle of diverging elements where the produce is conveyed by a series of rollers which get wider and wider as it moves along. The smaller fruits or vegetables drop down first and the larger ones are carried forward. The main drawback of this machine is that it cannot differentiate between a longer and a shorter produce. It is suitable for spherical shaped fruits like orange, apple, tomato *etc*.

Link grader

It works almost in the same way as that of the roller grader. But instead of rollers, it carries the produce between the links which move along diverging rails. It gives more precise grading than the roller grader.

Iris grader

This is the grader where round hole mechanism has been used, and instead of having only two links, it has a set of elements arranged in an iris with a central hole. The irises pick up one fruit each at the entry point of the machine and then move along a track. The irises widen as they move along providing increasing diameter of the hole to the fruit. The fruits while passing through the holes drop at the appropriate place.

Mass grader

This is different from other grades where the produce is graded on the basis of weight, whereas most fruits and vegetables are bought and sold by both size and weight.

6.6.2 Optical Methods of Grading

Several crops are bought on the basis of colour, for e.g. tomato, pepper and apple. The usual colour to be sensed is green, yellow and red, which can be readily sensed by photoelectric techniques by the grader. The principle of operation is that light is taken from at least two sources at the fruit or vegetable and the reflected light is received by photoelectric cells. A reflector behind the item shows one of its colours, for e.g. a red apple might have a red reflector. In this case, the sensor or photoelectric cell would not recognise any difference between the apple and the reflector. If a green apple comes, it will receive a different reflected signal and the green one will be removed mechanically from the lot.

6.6.3 Manual Inspection and Grading

In spite of advances in the development of sophisticated equipment for grading, majority of fruits and vegetables are graded manually by hand and eye, even in the developed countries. Some fruits and vegetables have unusual physical characteristics, which demand manual grading. For example, grapes and bananas have unusual shape and invariably sold in bunches or clusters. Machine grading is not possible in such cases. Bananas are to be carefully graded in terms of ripeness, colour, length and blemishes, all of which are carried out manually.

Manual inspection is usually done by workers who sit along side a moving flat belt or preferably a series of rollers so that the produce is turned over continually in order to see each side of it. The workers inspect and group the produce into different grades.

6.7 PACKAGING

Assembling of the produce into convenient units for handling is called packaging, and it provides protection to the produce during transport, storage and marketing. Sometimes the produce is enclosed in smaller individual packages of consumer units (Wraps, bags, trays etc.), which is called as pre-packaging and then the individual units are put into the bigger container.

6.7.1 Pre-packaging

Many materials are used as pre-packages for different produce *e.g.* plastic films like polyethylene, polypropylene, polyvinyl chloride and polystyrene, nylon net bag, paper bag, pulp tray, open-weaven hessian bag *etc*. Plastic films have heat shrink characteristics and can be used for shrink wrapping under controlled temperature and tension in a specialized machine. They may be used separately or as wrap over moulded polystyrene or pulp trays. The produce in a package (usually consumer unit) should be of comparable weight, size, maturity and grade. Some packaging involves enclosing a single product unit (a curd of cauliflower or a head of cabbage), while in other packaging, several product units are enclosed in a single consumer unit (radish, carrot). Packaging is done manually or by a machine. However, such additional packaging increases cost. Therefore, it must be compensated by reduced wastage and increased selling price. A given quantity (count or weight) of individual packages is then packed in a larger container for transportation and distribution. Such containers may be bags, wooden boxes, bamboo (or other plant twig) basket, corrugated fibreboard boxes, plastic crates *etc*.

6.7.2 Qualities of a Package

Modern packages and packaging should meet the following requirements.

i) They should be strong enough to protect the contents during handling and transport.

ii) They should stabilize and secure the product against movement within the package during handling.

iii) The packages should maintain shape and strength under high humidity and when wet.

iv) They must facilitate rapid cooling of contents and/or offer a degree of insulation from external heat or cold.

v) They should have sufficient permeability (in case of plastic films) to gases and vapours produced during respiration by the contents.

vi) The packages should be cost effective and attractive and amenable for containing details of printing the label.

vii) The material of construction must not contain chemicals which could be transferred to the produce and be toxic to human being.

viii) The security of the package or its ease of opening and closing might be important in some marketing situation.

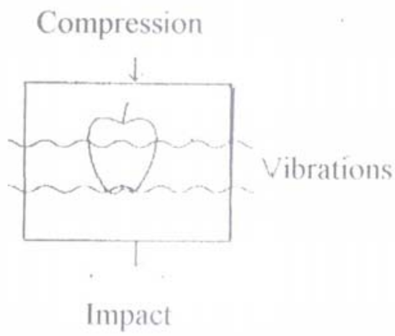
ix) The package might be required to aid retail presentation.

x) The package might need to be designed for ease of disposal, re-use or recycling.

It is becoming important to standardize the size and shape of the packages for unitization (*e.g.* use of pallets) and mechanical handling (*e.g.* fork lifting). An optimum length to width of the package is about 1.5:1.0. As per recommendations by the International Labour Organisation, 30 litre (about 20 kg of produce) and 15 litre packages are becoming standard for fruits and 36 litre packages for some vegetables.

6.7.3 Prevention of Mechanical Damage

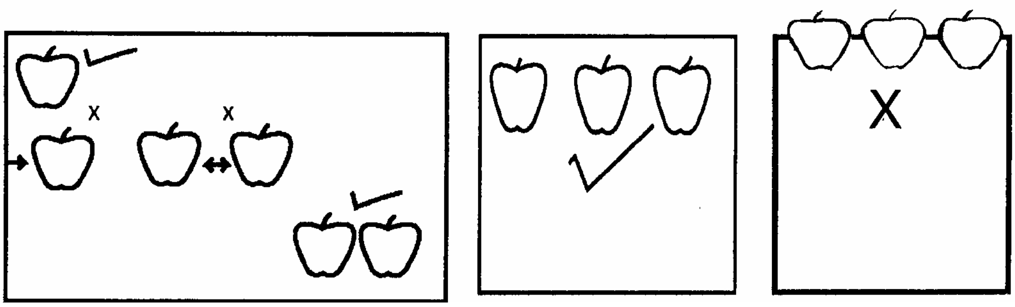
- Four different causes of mechanical injury are
  - cuts
  - compression
  - impacts
  - vibrations (rubs)



- **Cuts:** Handle produce carefully. Avoid cuts.
- **Compression:** Except certain so called 'hard' vegetables such as pumpkin, potato or onions, the package must be strong enough to carry the stacking loads, otherwise there will varying degree of compression bruising.
- **Impact:** Dropping of packages or impact shock in transport
- **Vibrations:** Common during transport, causes abrasions ranging from light rub marks to removal of not only skin but also some of the flesh. All these injuries turn brown during exposure of the material to air. The produce is disfigured and its market value is reduced. These injuries are avenues of infection, increase respiration, enhance the rate of deterioration and cause immediate loss of edible material because of the need to trim damaged portions.

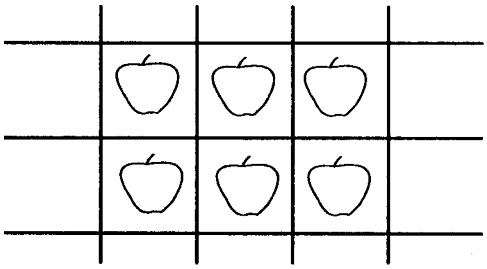
Avoiding vibration injury

- Individual specimen should not move with respect to each other or the walls of the package.



- Packaging should be full without overfilling.
- Packing too tightly increases compression and impact bruising.

- Individual wrapping.
- Isolating each piece as in cell pack.



- Tray packing 
6.7.4 Some Important Aspects

There are some other important considerations in packaging which are given below:

- Cushioning materials are provided to absorb vibration and compression during transport and to prevent movement of the produce in pack or packaged units within the container. Various cushioning materials such as paper shreds, thermocole, dry grass, paddy straw *etc*. used as bottom pads or between layers of fruits and vegetables are effective in absorbing impact and reducing bruising of the produce. The cushioning material (i) should have ability to dissipate the heat of respiration of the produce, (ii) should be free from infection which is likely to be passed on to the produce, (iii) should not injure the soft fruit, and (iv) should be physiologically inactive.

- Water loss of the produce in packages can be reduced by using plastic films with ventilating holes as pre-packaging or consumer packaging material. Ventilating holes (small perforations) prevent condensation of moisture inside packages and also allow some gas exchange for respiration, thereby preventing anaerobic respiration which otherwise would have caused off-flavour development. Polyethylene film lined corrugated fibreboard boxes with ventilating holes serve as a good container of pre-packaged units for fruits and vegetables.

- Fruits on ripening release ethylene gas which causes ripening of other fruits in the package. If early ripening is not desired, it is necessary to remove ethylene developed within the packages as quickly as possible. This is done by ethylene scrubber using blocks or sachets of high surface area materials *e.g.* foam, blotting paper *etc*. impregnated with potassium permanganate solution. Potassium permanganate oxidises ethylene to carbon dioxide and water. Some commercially formulated material like Purafil is available for scrubbing ethylene from the packages.

6.7.5 Packing Line

The method of packaging depends on the type of the produce, size of the package and operation time. High value crops such as avocado, peach, apple and kiwi fruit are often packed by hand. Hand packing helps in proper orientation of fruits in a box and thus improves overall protection and appearance. Large scale operations are often done in a packing machine. The automatic machines are arranged in multiples up to about 10 along a belt conveyor. The produce is fed into the reception hopper from where it is elevated and distributed to different machines. A gate linked to each filling station deflects the produce down a chute and into a tilted, waiting box. As the box becomes full, it lowers gradually and the preset weighing machine closes off the feed gate. The box is then carried on a short roller conveyor onto a further main conveyor with all boxes from other machines. Each box takes about one minute to fill and needs no supervision. The boxes then pass through an automatic box sealing and printing machine. Though this is a convenient method of packaging, it causes damage to sensitive fruits. It is, therefore, popular for more robust fruits like citrus and for fruits for local market. Automatic pallet loading by palletizer may then follow, or else the boxes may be manually stacked for transport.

6.8 LET US SUM UP

In this unit, you have read about post harvest operations like cleaning, trimming, selection, sorting, grading and packaging of horticultural produce. It has given you an idea of different machines used for grading and packaging.

6.9 KEY WORDS

Cleaning	:	Removal of soil and other materials from the surface of the produce by brushing or washing.
Sorting	:	Removal of under size, over or under ripe, misshapen and damaged products from the lot to meet requirements of a grade.
Grading	:	Grouping of the produce into different lots on the basis of size, weight, colour, shape, maturity.
Packaging	:	Assembling of the produce into convenient units and it provides protection to the produce during transport, storage and marketing.

6.10 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - Purpose and methods of cleaning of horticultural produce

2. Your answer should include the following points:

   - Definition of selection and sorting
   - Improvement of the produce by sorting

Check Your Progress Exercise 2

1. Your answer should include:

   - Grading and its importance

2. Your answer should include:

   - Definition of packaging
   - Qualities of a good package

3. Your answer should include:

   - Methods which help in preventing water loss and anaerobic respiration of the packaged produce
   - Use of ethylene scrubber

UNIT 7 TREATMENTS: PRE-COOLING, CURING, INHIBITION OF SPROUTING AND FUNGICIDE APPLICATION AND RIPENING

Structure

7.0 OBJECTIVES

This unit shall analyze the problems related to checking post harvest losses of fruits and vegetables. Here the issues of appropriate post harvest treatments with particular reference to curing, pre-cooling, checking sprouting and rotting of fresh fruits and vegetables will be discussed.

After studying this unit, you should be able to:

- cooling requirement of horticultural crops and pre-cooling techniques;
- concepts of curing;
- effects of sprouting and its inhibition;
- waxing and surface coating of fruits and vegetables;
- post harvest disease management and fungicide application; and
- control of ripening.

7.1 INTRODUCTION

Ever since the civilization of mankind, efforts have been directed towards accumulating and storing foods when they are in plenty in order to meet needs during the days of scarcity. In case of food grains not much problem was faced due to nature's noble way of reducing the moisture level as the grains mature and further drying after harvest. However, in case of fruits and vegetables, long term storage in their fresh form was not possible (until development of modern methods) primarily due to their high degree of perishability owing to high moisture content of these commodities at the time of harvest.

Storage of fruits and vegetables in their fresh form prolongs their usefulness and in some cases improves their quality. It also checks market glut, helps in orderly marketing, increases financial gain to both the producers and consumer and preserves quality of produce for much longer time. Horticultural produce like fruits, vegetables and cut flowers are living respiring tissues separated from the parent plant. Therefore, the aim of storage is to control various physiological and biochemical processes viz. respiration, transpiration and other metabolic activities to keep produce in maximum usable form. Hence pre-treatments viz. Curing, Pre-Cooling, Inhibition of sprouting and fungicide application plays an important role to prolong the storage life of horticultural produce.

7.2 IMPORTANCE AND METHODS OF PRE-COOLING

Pre-cooling is the process of rapid removal of field heat/respiratory heat usually practiced for fresh fruits, vegetables and cut flowers immediately after harvest, before shipment, before cold storage or before processing depending on the commodity. This is the first step of good temperature management. The primary advantages of pre-cooling are: (a) Inhibition of the growth of decay causing organisms, (b) restriction of the enzyme activities, (c) reduction of water loss, (d) reduction in rate of respiration and C_2H_4 liberation and (e) rapid wound healing. The production and action of ethylene from harvested fruits, vegetables and flowers are temperature dependent. Harvested produce kept at 25^0 C with 30% RH shows a tendency of 36 times more water loss as compared to that stored at 0^0C with 90% RH. Hence pre-cooling serves as an essential practice in any successful cool chain management of horticultural produce. The two most important factors in pre-cooling are temperature and time, i.e. fruit or vegetable must be cooled in the shortest possible time. Product cooling follows a logarithmic function, with initial rapid cooling followed by a slower rate. Since it is difficult to remove all the field heat, pre-cooling to $7/8^{th}$ of the recommended storage temperature is advisable. The product can then be placed in storage where the remaining $1/8^{th}$ of the heat can be gradually removed with less energy cost. If several products are being handled, then a system must be selected that is compatible to all of them. Highly perishable products, which have a high respiratory rate, e.g., asparagus, broccoli, spinach and sweet corn, need fast cooling and require high refrigeration capacity and fast pre-cooling methods.

In order to predict the end point of pre-cooling, it is essential to know the "half-cooling time". Half-cooling time is the time required to reduce the temperature difference between commodities and the coolant by one-half. This is independent of the initial temperature of the commodity.

The speed of cooling depends upon the following factors: (i) Accessibility of product to the refrigerating medium. (ii) Difference in temperature between the product and refrigerating medium. (iii) Velocity of refrigerating medium and (iv) Type of cooling medium. The shape, density, and surface area/volume ratio of the fruit or vegetable and the type of container are important in determining the appropriate type of cooling medium, i.e. air, water or ice.

Some products do not tolerate exposure to water. In general, the greater the amount of packaging the slower the cooling rate. If the packaging is exposed to water, packaging in paper-based material is not recommended unless it is waxed.

There are basically five methods of pre-cooling used for horticultural commodities. These are (i) Room/air cooling, (ii) Water/hydro cooling, (iii) Forced air-cooling, (iv) Vacuum cooling, and (v) Package icing.

7.2.1 Room/Air Cooling

In room / air-cooling heat transfer takes place by means of conduction. Produce is placed in an insulated room equipped with refrigeration units. This method can be used in most commodities, but it is slow compared with other options. Containers should be stacked in such a way in the room so that cold air can freely move around them, with adequate space between stacks. The cost of room / air-cooling is a relatively low.

7.2.2 Hydrocooling

By hydrocooling, the product is cooled by immersing in cold water or by showering cold water on it. Heat transfer in hydrocooling takes place by both conduction and convection mechanism. It is faster than air-cooling and does not dehydrate the product. It can be used if the product is not damaged by exposure to water. The critical factors for effective hydrocooling are water sanitation and use of water-tolerant packaging that makes it more expensive. Hydrocooling has the advantage over other pre-cooling methods in a sense that it helps to clean the produce thereby reducing the primary inoculum load. The water is normally cooled by mechanical refrigeration but if this is not available an alternate source of cold water could be clean one source of water.

7.2.3 Forced-Air/Pressure Cooling

This method is a modification of room cooling in which pre-cooling is achieved by "pulling" cold air through the stacked product (Figure 7.1). In a properly designed forced-air system, the evaporator coils in the refrigeration system have more surface area than conventional coils, allowing for more rapid heat removal. Although the cooling rate depends on the air temperature and the rate of airflow, this method is usually 75-90% faster than room cooling. Fans should be equipped with a thermostat that automatically shuts them off as soon as the desired product temperature is reached. If mechanical refrigeration is not available, passing it through a water soaked pad that will remove heat can cool the air by evaporative cooling. Since evaporative cooling will cool the air to only 1-2°C above the wet bulb temperature of the air, it is most appropriate in dry climates and for chilling-sensitive products. Another alternative to mechanical refrigeration is to pre-cool the produce only at night when the air is colder. The main disadvantage of forced air-cooling system is desiccation of the produce due to very high velocity of air. To reduce this effect the cold air is humidified using appropriate air handlers.

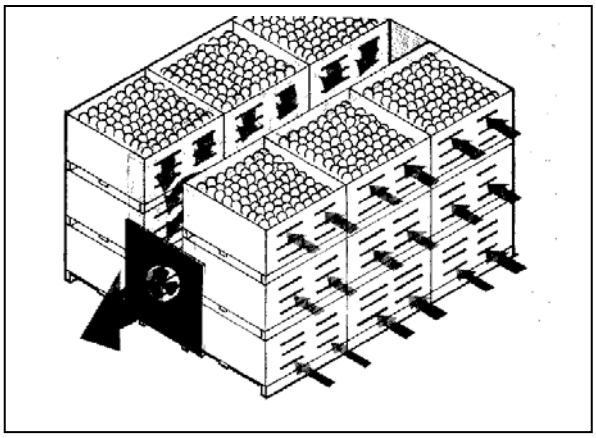

Figure 7.1: Technique of forced air cooling

7.2.4 Vacuum Cooling

This is the most rapid and energy efficient form of pre-cooling. Here the cooling is achieved by the latent heat of vaporization of water. Packaged product is placed inside an airtight chamber and the air is evacuated, which lowers the pressure and the boiling point of water. At a reduced pressure of 4.6 mm Hg, water on the surface of the product rapidly evaporates, which removes the field heat. Although this method can cool product in less than 30 minutes, it is only efficient on products with a high surface area/volume ratio. Crops having a relatively thick waxy cuticle e.g. tomatoes, grapes etc. are not suitable for vacuum cooling. Vacuum coolers are in limited use because they are expensive to purchase and operate and can only be used on a limited range of products.

7.2.5 Package-Icing

It is commonly applied to boxes of produce by placing a layer of crushed ice directly on top of the crop. The ice melts and the cold water runs down through the produce and is cooled. The main use of top icing is for road transport and it can be applied shortly after harvest to begin pre-cooling as soon as possible. By this method product is cooled faster than forced-air but the product must tolerate contact with water and ice. Although the easiest method is to add flaked ice on the top of the container, greater contact with the product can be achieved by injecting slurry of water and ice into the package. Care must be taken to ensure complete distribution in the package. Containers must be water-tolerant with holes for water drainage.

7.2.6 Alternate Methods of Pre-cooling

Several alternate methods of pre-cooling can be practiced in order to achieve the partial goal of pre-cooling in places where procurement and installation of expensive pre-cooling equipment are difficult. Some of the examples of the system could be (i) Radiant cooling by use of solar collector during night, (ii) High altitude cooling by utilizing naturally cool surrounding (about 10 c fall in temperature is recorded in every 1000m higher altitude.

7.3 ROLE AND METHODS OF DRYING AND CURING

One of the most important methods of reducing post-harvest losses in many root crops such as yam and sweet potato and also for onions, is the use of surface drying and curing processes. Curing is a natural wound healing process in which harvested root and tuber crop replace and strengthen damaged areas by forming a corky layer which protects against water loss and infection by decay organisms. In contrast, the curing of onions, and garlic is mainly a drying process where excess moisture is removed from the outer skin and neck of the onion. At the same time, by exposing the onion to higher temperatures, the colour of the skin gets darkened and natural fungicidal compounds accumulate in the skin. Both processes together ensure the formation of protecting layer which greatly reduces water loss and serves as a physical and chemical barrier to infection.

Let us examine the mechanism involved in curing:

In most of the root and tuber crops suberization is the key process of curing. “Suberin” – a group of fatty acids imparts initial protection to water loss and infection to the harvested produce. The next important mechanism is the formation of periderm which is located below the suberized cells and formed by layer of meristematic cells. This is also called ‘cork cambium’ since it produces new cells that seals off the damaged areas. In the curing process deposition of suberin (suberization) in the parenchymatous cells (periderm) takes place simultaneously. The speed of suberization depends on: temperature, relative humidity and use of chemical sprout suppressant. Few cases showing the relation of temperature and humidity to the period of suberization are given below:

Factor	Effect
Curing Temperature $\geq$ 21°C	I day for suberization
Curing Temperature = 15°C	2 days for suberization
Curing Temperature = 10°C	5-8 days for suberization
Curing Temperature = 2.5°C	> 8 days for suberization
High R.H.	Better suberization
Low R.H.	Poor suberization
Use of chemical sprout suppressant	Inhibit suberization

The term curing is also sometimes used for citrus fruits. Generally, lemons are cured at 56º to 58º F (13.33–14.4º C) and 85-90% relative humidity. Green fruits may be held for 4 months or more, while the peel becomes yellow and thinner, the pulp juicier (6-80%) and the proportion of soluble solids higher (7-24%).

7.4 EFFECTS OF SPROUTING AND ITS INHIBITION

Roots, tubers and bulb crops have one common feature i.e. inflated storage organs. Containing a substantial amount of carbohydrate, protein and vitamins and minerals. Like many other fruits and vegetables, they remain active after harvest and carry out all the vital physiological and metabolic processes until its death. The high respiration rate of these crops after harvest not only brings about the compositional changes but also builds up temperature around it which in turn creates favourable conditions for the growth of microorganisms already present on these commodity. Although, these crops are not considered to be highly perishable, the severe problem of sprouting and rooting in storage limits their successful marketing.

Now, let us analyze the typical case of onion and potato. Commodities like onion and potato have buds that enter a dormant state at maturity. In this dormant stage, the plant can survive periods unfavourable to plant growth. This coincides with the appropriate stage of harvesting of these produce for orderly marketing for several months by storing them under appropriate conditions. The duration of post harvest dormancy in potato is commonly known as 'rest period'. The rest period is influenced by pre-harvest factors, maturity and variety. This is not dependent on temperature of the storage chamber in which the commodities are stored. Once the rest period ends, the sprouting begins and this is dependent on temperature of the storage environment. Sprouting of potato occurs rarely below 4°C, but storage at this temperature results in conversion of starch to sugars making the potatoes sweet. The sweetening of potato is not desirable from the point of view of processing or fresh marketing. Presence of sugars in potato adversely affect the quality of potato chips. Moreover, the consumers do not prefer the potatoes that are sweet in taste for even culinary purposes. Again, if the potatoes are stored at temperature above 4°C sprout growth will begin after 2-3 months storage. Sprouts are the new growths and comprise of highly active tissues. Therefore, sprouted potatoes quickly loose moisture, gets shrivelled and become prone to several microbial infection. Thus sprouting results in a huge post harvest losses. Apart from physical loss due to sprouting, the quality of sprouted potatoes became poor due to high respiratory utilization of substrates. Hence the control of sprouting becomes a first step in successful marketing of potato after harvest.

We will explain you the various methods of inhibition of sprouting. They are two common practices can suppress the sprouting. i.e. Use of chemical sprout suppressant either applied in the field i.e. pre-harvest application or after the harvest of the produce i.e. post harvest application and ii) Use of ionizing radiation. Maleic Hydrazide (MH-40), Nonylalcohol, 3-chloroisopropyl – N – phenylcarbamate (CIPC), Isopropyl phenylcarbamate (IPPC), methyl napthaleneacetic acid (MENA) and 2,3,4,6 tetrachloronitrobenzene (TCNB) are commonly used as sprout inhibitors. However, legal restrictions on usage of these chemical and their residual toxicity limit their use based on the legislation prevailing in a particular country. Out of these, MH is predominantly used as pre-harvest spray to control the sprouting of onion during storage.

As onions mature, tops begin to fall and dry. Sprout inhibitors are applied when onions are intended for long term storage. They are applied when tops are about 50% down, and there are 5 to 8 green leaves per bulb to absorb and translocate the sprout inhibitor. These are not applied when temperatures exceed 26-29°C to avoid crystallization on leaf surfaces. Use of a spray adjuvant is suggested. Avoid early sprays before maturity to reduce spongy onions. Maleic hydrazide (Royal MH-30) @ 0.9 Kg ai/Acre is most commonly used. Apply in sufficient water to insure adequate coverage. Most of the other chemicals are normally used as post harvest application. One should remember the fact that CIPC is one of the very stong sprout inhibitor used as post harvest application for long term storage of potato. It is applied as dust, water dip, vapour or thermofogging formulation. A normal dosage of 50 ml per one metric ton of potato is normally recommended. Potatoes become safe for consumption after about 30 days after treatment with CIPC depending on the temperature of storage. The most important advantage of CIPC treatment is the economy in saving electrical energy in cold storage since the potatoes could be safely stored at higher temperature of 10^{o}C without any sprouting or quality deterioration. Since CIPC interferes with the periderm formation, we must take care of its application only after proper curing. So far we have learnt about the chemical sprout suppressant.

Now let us learn about the use of ionizing radiation treatment to control sprouting in onion and potato. Under the present situation, use of gama irradiation @ 0.02- 0.15 kGY has been widely accepted by many countries for successful sprout inhibition of onion and potato without affecting the other quality attributes. However, the major limitation for use of irradiation is the high cost of specialized equipment, training and further more the consumer acceptability due to the fear of induced radioactivity and formation of harmful radiolysis products in irradiated produce. The report of world health organization (WHO, 1981) clearly concluded that irradiation to any food commodity to an overall average dose of 10 kGY had no toxicological hazards.

7.5 WAXING AND SURFACE COATING

Fruits and vegetables have a natural waxy layer on the outer surface which gets partly removed during the washing process. An extra discontinuous layer of wax applied artificially with sufficient thickness and consistency in the following objectives:

- Replacement of natural wax
- To reduce the water loss during shipment and storage
- To give a cosmetic appeal
- To cover up the minute injuries caused during post-harvest handling
- To use as a carrier of fungicide/inhibitor for better shelf life and
- To protect against decay organisms.

Sugarcane wax, carnuaba wax, shellac and various resins are common types of waxes used for-the preparation of wax-emulsion. Recently, sucrose polyester waxes are gaining popularity due to their water solubility and biodegradibility. Waxes are generally applied by foaming, spraying, dipping brushing and foaming. Foaming is a very satisfactory method since it leaves a very thin coating.

Apart from the above mentioned objectives use of surface coating and waxing creates a modified atmospheric condition between the cuticle and the coating material which reduces the physiological and metabolic activities in certain fruits. Some of the common surface coating materials used are: Semperfresh, Sta-Fresh, Citrashine, Waxol, etc.

7.6 POST HARVEST DISEASE MANAGEMENT AND FUNGICIDE APPLICATION

Different types of micro-organisms can cause spoilage in storage houses. However, bacteria and fungi are the most common. Bacteria are generally propagated by direct contact between perishable goods or with contaminated surfaces, or else with the water used during treatment before or after storage**.** Some of these bacteria can be pathogenic for human as well, for e.g. as *Listeria monocytogenes.* Vegetables are mostly spoiled by bacteria due to their high pH (4.5-7.0) whereas many fruits particularly the acidic fruits (pH < 4.5) inhibits the growth of bacteria but encourage fungal spoilage. A relative humidity less than 94 to 95 % is considered low enough for growth of bacteria. Majority of the soft rots causing bacteria have their optimum temperature for growth around 30°C. The following are the major bacterial species that infect the fruits and vegetables.

Sl. No.	**Commodity**	**Disease**	**Causal organism**
1.	Potato	Soft rot	*Erwinia cartovora* *Bacillus subtilis* *Clostridium sp*
2.	Onion	Rot	*Pseudomonas capacia*
3.	Cabbage, Lettuce	Rot	*Pseudomonas cicorii*
4.	Cauliflower, cabbage, tomato, bean, radish	Bacterial rot	*Xanthomonas spp*
5.	Mango, plum, cherry, peach	Bacterial rot	*Xanthomonas campestris*
6.	Pineapple, papaya, Guava	Bacterial rot	*Ewrinia spp*
7.	Apples and pear	Bacterial rot	*Pseudomonas spp*

Bacteria like Erwinia and Xanthomonas are mainly disseminated by leafhoppers.

Control of bacterial diseases: Chlorine compounds added to water as chorine gas or as hypochlorite solution could be used to kill bacteria rapidly. In commercial practice, 2 per cent Na-hypochlorite or 50 to 100 mg of chlorine or 1-1.5 g/litre chlorine dioxide are frequently used to control the bacteria. Low temperature storage is considered to be the best method for controlling the bacterial diseases.

Several fungal rots are considered to be of major importance causing severe post harvest losses to fruits and vegetables. The fungus forms acervulli from which single celled conidia arise. Acervulus is a clamp or cushion of conidia bearing on hyphae called conidiophore. The conidium on germination produces aspersorium, which helps in adhering of conidia to the skin. When the hyphae from the germinating conidia penetrate the surface of the fruits (unripe) these cause rotting. Hyphae that arise from aspersoria when the fruits start ripening can colonise the tissue and cause rot. This dormancy of aspersoria has been attributed to phytoalexin production or non-availability of nutrients in unripe fruits. This process of existence of fungal organism in the dormant form called latent or quiescent infection. Some of the examples of quiescent infections are mentioned below.

Sl.No.	Commodity	Causal organism
1.	Apple	*Gloeosporium perennans,* *Diplodia perniciosa,* *Nectria galligena*
2.	Citrus	*Colletotrichum gloeosporoides*
3.	Mango	*Colletotrichum gloeosporoides*
4.	Strawberry	*Botrytis cinerea*

In quiescent infections the development of fungus is stopped at the stage of aspersoriaor colonization.

Control of Quiescent infection in fruits:

i) Strict sanitation in pack house to reduce conidial rot

ii) Avoidance of injury

iii) Post harvest dips with systemic fungicides

a) Benlate @ 100 ppm
b) Benomyl @ 100-400 ppm
c) Thiabendazole @ 200 ppm

iv) Pre-cooling or cool chain management

The other fungal diseases include:

Finger rot of banana: this is caused by Botryodiplodia theobromae. The infection starts from the tip of the finger. The infected fruits soon become soft and brown. An aqueous dip in Thiabendazole @ 200-500 ppm for few seconds can control the disease.

The next important disease of banana is the crown rot caused by several organisms viz, *Cremonium spp, Botryodiplodia theobromae, Ceratocystis paradoxa, Colletotrichum musae, Fusarium pallidoroseum, Verticillium theobromae* etc. Treating with any of the systemic fungicides mentioned above could do successful control of this disease.

Dark brown spots with concentric rings on ripe banana may be due to Monilial disease caused by *Monilia fructigena or M. lexa*. Benomyl dip @ 0.2% or Thiabendazole @1200-2400 ppm dip could successfully control the disease.

Two major diseases of mango observed during post harvest stage are: I) anthracnose: caused by Glomerella cingulata (conidial stage *Colletotrichum gloeosporoides*). The symptoms appear on ripe fruits as black spots or streaks. Hot benomyl dip @0.1% at 52°C could successfully control the disease. The stem end rot of mango is associated with Botryodiplodia theobromae and or Aspergillus niger. Typical lesion of black to brown spots extending the stem is the major symptom of the disease. Thiabendazole @ 0.1% is the best control measure of this disease. Among the other pathogen Penicillium expansum is responsible for causing diseases to many fruits and vegetables e.g. apples, citrus etc.

Three major fungal organisms are mostly associated with post harvest diseases of vegetables. These are: (i) Fusarium spp causing rots in tinda, bean, cowpea, chilli, tomato, cauliflower, potato, cucumber, pointed gourd and pumpkin. (ii) Geotrichum diseases caused by Geotrichum candidum in tomato, pointed gourd, watermelon and muskmelon. As a thumb rule, the foods containing lactic acid are attacked by this fungus and (iii) Pithium diseases caused by Pithium spp. that attack okra and cucurbits. The following are the time temperature combinations for control of the fungal organisms:

Organism	**Temperature (°C)**	**Time/duration**
Botryodiplodia. Gloeosporium, Colletotrichum, Rhizopus	43-49 (Papaya)	20
Colletotrichum, Diplodia, Aspergillus, Bortyodiolodia, Rhizopus	47-55 (Mango)	10-20
Monilia, Rhizopus	49-84 (peaches)	1.5-3.5
Alternaria, Geotrichum	48-57 (Tomatoes)	5-10

The development of mould on walls or ceilings of the storage chamber may indicate insufficient insulation or a perforated or poorly installed vapour seal. Many of these organisms feed on perishable goods and organic matter. In the absence of nutrient sources, they can survive on other materials, such as wood and plastic. When they attack organic matter, bacteria and fungi can give off foul odours (ethylene and other volatile substances) that can change the taste or accelerate the maturation of stored fruit and vegetables. Although it is difficult to completely eliminate these micro-organisms, preventive measures and an appropriate clean-up plan can control their proliferation and greatly reduce the infection rate of perishable goods in storage houses. Micro-organisms, which are present in the storage house, also on fruit and vegetables, can be eliminated with an appropriate clean-up plan. The presence of any residue of plant material in the storage chamber can allow bacteria and fungus spores to survive between two storage periods. For a clean-up plan to be effective, it must follow certain steps in a specific order. These steps are cleaning, disinfecting, rinsing and drying. The techniques and products used to carry out each step must be adapted to treatment systems and storage facilities, whose main components.

Floors, walls, ceiling, doors and structural beams; refrigeration systems electrical fixtures; water and air pipes and channels and their components (drains, grill); wooden and plastic containers reused for storage of fruit and vegetables; pallets used to handle containers; machinery used in the storage house; waste containers.

7.7 CONTROL OF RIPENING

Ripening is a dramatic event in the life of a fruit. It transforms a physiologically mature but inedible plant organ into a visually attractive taste and smell sensation. Ripening marks the completion of development of a fruit and the commencement of senescence, and it is normally an **irreversible** event. Ripening is the result of a complex changes, many of these probably occurring independently of one another. The changes that may occur during the ripening of freshly fruit are: Seed maturation, Colour changes, abscission (detachment from parent plant), Changes in respiratory and ethylene evolution rates, alteration in tissue/cell permeability, softening, changes in organic acids, Protein changes, production of flavour volatiles and development of wax on the skin.

On the basis of the respiratory pattern and ripening behaviour fruits are classified into two classes viz. **climacteric fruits** and **non-climacteric fruits**. As a thumb rule, the fruits which are harvested at optimum maturity and undergo ripening after harvest are grouped under Climacteric fruits; whereas another group of fruits that ripen on the tree itself and does not undergo much change after harvest or undergo further ripening are grouped under non-climacteric fruits. You observe the rise in respiration during ripening of the climacteric fruits but you don't find such trend in non-climacteric fruits. Some of the examples of both the groups of fruits are mentioned below:

Climacteric fruits are:

Apple, Apricot, Avocado, Banana, Blueberry, Fig, Kiwi fruit, Mango, Papaya, Passion fruit, Peach, Pear, Persimon, Plum, Muskmelon, Watermelon and tomato.

While Non-climacteric fruits are:

Cherry, Cucumber, Grapes, Lemon, Pineapple, Mandarins, Strawberry etc.

Climacteric and non-climacteric fruits may be further differentiated by their response to applied ethylene and by their pattern of ethylene production during ripening. It has been clearly established that all fruit produces minute qualities of ethylene during development. However, on ripening, climacteric fruits produce much larger amounts of ethylene than non-climacteric ones. Ethylene, applied at a concentration as low as 0.1–1.0 micro litres per litre for one day, is normally sufficient to hasten full ripening of climacteric fruits. However, the magnitude of climacteric is relatively independent of the concentration of applied ethylene. In contrast, applied ethylene merely increases the respiration of non-climacteric fruits, the magnitude of the increase being dependent on the concentration of ethylene. There are two different systems of introduction of ethylene in the ripening room. These are:

a) ***Shot system:*** Accurately measured quantity of ethylene is introduced into the ripening room at regular intervals using a gauge which registers the discharge of ethylene in cft/min. thorough ventilation is essential.

b) ***Trickle system:*** In this system the ethylene is introduced into the room continuously, rather than intermittently, as done in the shot system.

There are three major sources of obtaining ethylene for use in the ripening room:

i) Ethylene generators: In this a liquid (probably ethanol) produces ethylene when heated in the presence of a catalyst. This is used widely for supplying ethylene in the ripening room.

ii) Ethephon: It is commercially available as Ethrel or CEPA. To release l cft of C_2H_4 requires about 7 fluid ounces of active ingredient of ethrel. The solution of ethrel should be alkaline in order to release ethylene from ethrel. The ratio of Caustic soda: ethrel is approximately 3g: 20ml for effective release of ethylene.

iii) Ripe gas: This is compressed ethylene gas in mixed with CO_2 available in compressed cylinders. The normal concentration of ethylene in the ripe gas is 6% and CO_2 is used to make it non-inflammable.

Temperature and RH management of the storage rooms are the major factors responsible for control of ripening of fruits. The commodity should be stored at appropriate temperature and RH condition for extending its green life. These stored commodities can be ripened artificially by proper combination of temperature, RH and ethylene concentration in the ripening room. Besides temperature and RH management use of Controlled Atmosphere or Modified Atmosphere packaging or storage are proved to be successful in delaying the ripening of many fruits and vegetables and thereby extending the green life for orderly marketing practices.

The ideal condition for ripening by using ethylene in some important fruits and vegetables are mentioned below:

Fruit	Temperature (°C)	Ethylene Treatment (ppm)	Time (hours)
Avocado	18-21	10	24-72
Banana	15-21	10	24
Cantaloupe	18-21	Nil	
Honeydew melon	1821	10	24
Kiwi fruit	18-21	10	24
Mango	29-31	10	24
Papaya	21-27	Nil	
Pear	15-18	10	24
Pershimon	18-21	10	24
Tomato	13-22	10	Continuous

Ethylene is a colourless gaseous hydrocarbon with a faint sweetish smell having molecular weight 28.05; its boiling point at 760mmHg is −103.7°C. The flammable limits ranges from any composition between 3.10 to 32.00 %. It is a plant growth substance and a key to ripening of fruits and Vegetables. Its production is increased during leaf fall, flower senescence and fruit ripening. In addition, stress factors such as wounding, flooding, chilling, disease, high temperatures and drought seem to induce ethylene biosynthesis.

Threshold limit for ethylene action in various fruits varies from the type of commodity, but in most cases it ranges between 0.1−1.0 ppm. The duration of exposure may vary from 12 h to 72 h for initiation of ripening but full ripening may take several days. The effectiveness of ethylene in achieving proper and more uniform ripening depends on three important factors viz. (i) stage of maturity, (ii) temperature and RH in the ripening room, and (iii) concentration and duration of exposure to ethylene. In general, the ripening of fruits occur at 18-25^{0}C, 90-95% RH with 10-100 ppm ethylene and 24-72 h exposure depending on the commodity. Ethylene can be applied through ethylene generator using ethanol or by use of ethrel/ ethephon (2-chloroethyl phosphonic acid). One must remember the fact that ripening of fruits can be initiated by many other hydrocarbons viz. acetylene, propylene etc. But the efficacy of ethylene is considered to be 100 times more than acetylene. Calcium carbide was used for ripening fruits in India as a commercial practice. However, due to its deleterious effects on human health, it has been banned in India for use in ripening.

While storing fruits and vegetables care should be taken in such a way that the actively ethylene producing commodities should not be stored along with other fruits, vegetables, or flowers that are sensitive to it. The result could be loss of quality, reduced shelf life and specific symptoms of injury. Some examples of ethylene effects include: (i) Russet spotting of lettuce along the midrib of the leaves, (ii) loss of green colour in snap beans, (iii) increased toughness in turnips and asparagus spears, (iv) bitterness in carrots and parsnips, (v) yellowing and abscission of leaves in broccoli, cabbage, Chinese cabbage, and cauliflower, (vi) accelerated softening of cucumbers, acorn and summer squash, (vii) softening and development of off-flavour in watermelons,

(viii) browning and discoloration in eggplant pulp and seed, (ix) discoloration and off-flavour in sweet potatoes, (x) sprouting of potatoes, (xi) increased ripening and softening of mature green tomatoes and (xii) shattering of raspberries and blackberries.

7.7.1 Biological Effects of Ethylene

Some of the very important biological effects of ethylene observed in plant tissues are mentioned below:

- **Respiration –** Ethylene increases the rate of respiration in both climacteric and non-climacteric fruits
- **Ripening** – The change in fruit physiology from maturation to ripening is initiated when cellular quantities of ethylene reach a threshold level
- **Flavour** – Ethylene exposure results in development of bitter taste in carrot and beetroot
- **Toxicity** – Pea pods exposed to 0.2 to 20 ppm ethylene developed *pisatin* (a phenolic phytoalexin), which is anti-fungal compound.
- **Colour** – Ethylene exposure cause rapid breakdown of chlorophyll, increase in carotenoid and lycopene content, so colour of petals of cut flowers can be affected by ethylene.
- **Disease –** High decay was observed in presence of ethylene in celery, brinjal, cabbage, and strawberries. Ethylene stimulated spore germination of fungi, which cause rotting.
- **Sprouting –** Ethylene has an opposite effect on dormancy and stimulates the activity of other growth regulators such as gibberellins.
- **Growth –** Ethylene can stimulate the growth of harvested crops which lead to undesirable effects e.g. loss of compactness foe to increase in inter node growth in Brussels sprout.
- **Texture –** Sweet potato and asparagus develop hard texture due to increase in fiber production. In orange and pineapple softening is hastened with ethylene levels of 1.0 ppm in the store.
- **Abscission –** Fruit stalk abscission increases in the presence of ethylene.
- **Floral senescence –** Hastening of senescence of cut flowers takes place when exposed to ethylene. Sleepiness in carnation is due to presence of ethylene causing the buds failure to open. Petal abscission and blueing of rose is also due to presence of ethylene.

Besides all these deleterious effects ethylene is highly beneficial and recommended for artificial ripening and degreening of fruits without posing any health hazard. Ethylene exposed fruits show more ascorbic acid content than unexposed fruit. Hence for the purpose of extending the storage life (green life) the removal of ethylene from the storage atmosphere plays a critical role for orderly marketing. However application of ethylene finds a good place on removal from store and during marketing.

Ethylene from the storage chamber can be removed by the following means: (i) elimination of source i.e. IC-engines, (ii) ventilation (iii) use of chemical scrubbing system e.g. $KMnO_4$ impregnated vermiculite / celite blocks (purafil), ozone, brominated or activated charcoal (iv) use of bacterial system e.g. *Mycobacterium* (v) hyobaric storage (vi) controlled atmosphere storage and (vii) by use of specific antiethylene compounds e.g. Silver nitrate. (Hydroxy quinolene citrate)HQC, HQS (H Hydroxy quinolene sulfate), Rhizotoxin and its analogues.

7.8 LET US SUM UP

We should clearly remember that the fruits, vegetables and flowers after harvest remain alive and undergo high rate of physiological and metabolic activities i.e. increased rate of respiration, transpiration. Hence pre-treatments viz. Curing, Pre-Cooling, Inhibition of sprouting and fungicide application play a very crucial role to prolong the storage life of horticultural produce.

Pre-cooling is the process of rapid removal of field heat/respiratory heat, usually practiced for fresh fruits, vegetables and cut flowers immediately after harvest, before shipment, before storage or before processing depending on the commodity. This is the first step of good temperature management.

Curing is a natural wound healing process in which harvested root and tuber crop replace and strengthen damaged areas by forming a corky layer which protects against water loss and infection by decay organisms. In contrast, the curing of onions, and garlic is mainly a drying process where excess moisture is removed from the outer skin and neck of the onion. Sprouting results in a huge post harvest losses. Apart from physical loss due to sprouting, the quality of sprouted potatoes became poor due to high respiratory utilization of substrates. Hence the control of sprouting becomes a first step in successful marketing of potato after harvest

Vegetables are mostly spoiled by bacteria due to their high pH (4.5-7.0) whereas many fruits particularly the acidic fruits (pH < 4.5) inhibits the growth of bacteria but encourage fungal spoilage. A relative humidity less than 94 to 95% is considered low enough for growth of bacteria. Majority of the soft rots causing bacteria have their optimum temperature for growth around 30°C.

Ripening marks the completion of development of a fruit and the commencement of senescence, and it is normally an **irreversible** event. Temperature and RH management of the storage rooms are the major factors responsible for control of ripening of fruits.

Fruits and vegetables have a natural waxy layer on the outer surface which gets partly removed during the washing process. An extra discontinuous layer of wax applied artificially with sufficient thickness and consistency in the following objectives: Replacement of natural wax; to reduce the water loss during shipment and storage, to give a cosmetic appeal to the consumer, to cover up the minute injuries caused during post-harvest handling, to use as a carrier of fungicide/inhibitor for better shelf life and to protect against decay organisms.

7.9 KEY WORDS

Curing : Curing is a natural wound healing process in which harvested root and tuber crop replace and strengthen damaged areas by forming a corky layer which protects against water loss and infection by decay organisms.

Pre-cooling : Pre-cooling is the process of rapid removal of field heat/respiratory heat usually practiced for fresh fruits, vegetables and cut flowers immediately after harvest, before shipment, before storage or before processing depending on the commodity.

Sprouting : Commodities like onion and potato have buds that enter a dormant state at maturity. The duration of post harvest dormancy in potato is commonly known as 'rest period'. Once the rest period ends, the sprouting begins. This process of breaking the dormancy is known as sprouting.

Latent infection : The process of existence of fungal organism in the dormant form called latent or quiescent infection.

Climacteric fruits : As a thumb rule the fruits which are harvested at optimum maturity and undergo ripening after harvest are grouped under Climacteric fruits.

Non-climacteric fruits: Group of fruits that ripen on the tree itself and does not undergo much change after harvest or undergo further ripening are grouped under non-climacteric fruits.

Ripening : Ripening is a dramatic event in the life of a fruit. It transforms a physiologically mature but inedible plant organ into a visually attractive taste and smell sensation.

Waxing/surface coating : An extra discontinuous layer of wax applied artificially with sufficient thickness and consistency in order to replace natural wax lost during washing, reduce the water loss, give a cosmetic appeal, cover up the minute injuries, use as a carrier of fungicide and protect against decay organisms.

7.10 ANSWERS TO CHECK YOUR PROGRESS EXCERCISES

Check Your Progress Exercise 1

1. i) × ii) √ iii) √ iv) √
2. See sec 7.2. Your answer should include hydro cooling, room cooling, forced air cooling, package icing, vacuum cooling, alternate cooling. Definition of half-cooling time.

Check Your Progress Exercise 2

1. Your answer should include sprouting, rooting, rotting; See sec. 7.4.
2. See sec 7.4, Your answer should include increase in sweetness, loss in marketability, shrivelling, increased respiratory rate and aggravate rotting
3. See Sec. 7.4, your answer should include i) Use of chemical sprout suppressant as pre-harvest application or post harvest application and ii) Use of gama irradiation @ 0.02- 0.15 kGY. Maleic Hydrazide (MH-40) 3-chloroisopropyl–N–phenylcarbamate (CIPC), Isopropyl phenylcarbamate (IPPC), methyl napthaleneacetic acid (MENA) and 2,3,4,6 tetrachloronitrobenzene (TCNB).
4. See Sec. 7.4 , your answer should include high cost of specialized equipment, training , consumer acceptability due to the fear of induced radioactivity and formation of harmful radiolysis products in irradiated produce.

Check Your Progress Exercise 3

1. i) √ ii) √ iii) ×

2. See Sec. 7.5.

Check Your Progress Exercise 4

1. i) × ii) × iii) √

2. See Sec. 7.5. Your answer should include: sanitation of pack house, avoidance of injury, post harvest dips with systemic fungicides, pre-cooling or cool chain management.

Check Your Progress Exercise 5

1. i) Climacteric, Non-climacteric; ii) development , senescence

2. See Sec. 7.6, your answer should include use of ethrel, ethylene gas and calcium carbide, different methods of application of ethylene, temperature effect etc.

3. See Sec. 7.5, your answer should include (i) elimination of source i.e. IC-engines, (ii) ventilation (iii) use of chemical scrubbing system e.g. $KMnO_4$ impregnated vermiculite/celite blocks (purafil), ozone, brominated or activated charcoal (iv) use of bacterial system e.g. *Mycobacterium* (v) hyobaric storage (vi) controlled atmosphere storage and (vii) by use of specific antiethylene compounds

UNIT 8 FACTORS AFFECTING STORAGE LIFE

Structure

8.0 OBJECTIVES

After going through this unit, you should be able to:

- know why low temperature is helpful in increasing storage life;
- tell the role of relative humidity in the maintenance of product quality;
- differentiate between climacteric and non-climacteric fruits; and
- explain the effect of low O_2 and high CO_2 concentration on fruits.

8.1 INTRODUCTION

Storage of fruits and vegetables is one of the most important aspects of post harvest management. It is estimated that about 30 percent of fruits and vegetables produced annually is lost in India due to inadequate post harvest management. Reduction in post harvest losses could increase the availability of fruits and vegetables without increasing production. One of the reasons for the post harvest losses of fruits and vegetables is lack of proper storage facilities. Refrigerated cool store is considered to be the best method for storing fruits and vegetables. But this method is not only highly energy intensive but also involves huge capital investment. The Expert, Consultation on Food Loss Prevention in perishable crops held at FAO, Rome in May 1980 recommended that the use of proper temperature management includes simple and low cost cooling system and the use of evaporative cooling for storage of fruits and vegetables.

Storage of fresh fruits and vegetables prolongs their usefulness and in some cases improves their quality: it also checks market glut, provides wide selections of fruits and vegetables throughout the year, helps in orderly marketing, increases financial gain to the producers, and preserves the quality of the commodities. The principal aim of storage is to control the rate of transpiration, respiration and disease infection and to preserve the commodity in its most usable form for consumers.

Storage life may be prolonged by proper control of post-harvest diseases, regulation of the atmosphere, chemical treatments, irradiation and refrigeration. To date, refrigeration is the only known economical method for long term storage of fresh fruits and vegetables; all the other methods of regulating ripening and deterioration are at best only supplemental to low temperature. In fact, other quality maintaining methods will not work satisfactorily without refrigeration. In a hot tropical climate, CA storage, waxing and use of polyethylene bags are not advisable if not combined with refrigeration, as deterioration would be fast due to rapid build up of heat and CO_2.

Storage life of the fresh horticultural product is affected by many factors; most important of them are temperature and relative humidity. Fresh fruits and vegetables are living tissues and continue to respire after harvest. Storage temperature is the most important environmental factor affecting the senescence of fruits and vegetables because it regulates the rate of all associated physiological and biochemical processes. Many physiological processes are affected by temperature after harvest. Changes in quantity and quality affect horticultural crops between harvest and consumption. While some of the changes are desirable, most are not. Senescence is the final stage in the development of plant organs during which a number of changes take place that lead to breakdown and death of the plant cells, and storage life of produce is terminated.

8.2 PRINCIPLES OF STORAGE

8.2.1 Control of Undesirable Plant Processes

Since all fruits and vegetables are living tissues, the tendency after harvest is a continuation of all life processes. The aim of storage is to minimize the rate at which these processes take place. Thus, proper and adequate storage conditions must be supplied to the product; otherwise, the following undesirable plant processes may occur.

Sprouting

This can be a serious cause of deterioration, especially in onions, ginger, garlic sweet potatoes and potatoes. Sprouting is related to dormancy and rest. Dormancy is a condition of quiescence due to some internal or external factors. Rest is a phenomenon in which sprouting does not occur in spite of a favourable environment. Of the crops mentioned above, only sweet potatoes have no state of rest.

Elongation of Existing Structures

This process may be exemplified by products such as asparagus, carrot, beet and kohlrabi.

Rooting

Rooting may be initiated by a condition of elevated humidities, which may result in rapid decay, shrivelling and exhaustion of food reserves, especially in roots and tubers.

Seed Germination

During storage, seed germination within mature fruits is favoured. This process is observed in tomatoes, papaya and pod bearing vegetables. In most cases this may not be objectionable, but is detrimental in canning of whole tomatoes.

Greening

Exposure of potatoes to light during storage may produce green tissues. These portions contain solanine, which has some toxic properties. Thus, during storage, light should be minimized.

Toughening

Green beans and sweet corn may toughen when storage is unduly prolonged due to the development of spongy tissues.

Tropic Response

Response to gravity and light may cause bending of tissues. Products of uneven shapes are difficult to package. Appearance of the product, when offered for sale is also affected.

8.2.2 Control of Transpiration

Of the environmental factors, temperature, RH and vapour pressure difference (VPD) are important in transpiration. Low temperature, high RH and small VPD are necessary to minimize shrinkage of the product. A 5% loss in weight of a fruit is enough to produce shrivelling which makes it unattractive for sale. In using high RH during storage, care must be taken not to allow the development of surface moulds and other decay organisms due to condensation of moisture on the surface of the products. It can be controlled by proper packaging, use of protective coatings and by keeping the refrigerant as close as possible to the desired air temperature.

8.2.3 Control of Respiration

The basic principle in cold storage is the retarding effect of low temperature on respiration. Respiration is a breakdown process and means to minimize this process should be provided. Controlled atmosphere storage has proved to be a good commercial supplement to refrigeration. Its feasibility in the tropics should be explored.

Ventilation is indirectly related to respiration. Usually, the heat generated by respiration accumulates at the centre of the storeroom, and if provisions are not made for its exit, the rate of respiration of the stored products will be increased. It will be noted that since respiration and storage life are intimately related, whatever factors affect one will also influence the other.

8.3 TYPES OF STORAGE OPERATION

The enormous increase of fruit and vegetable production, owing to larger acreage and high yielding varieties, requires sufficient storage space. Accordingly, storage operations have been developed into a skilful job with a wide range of variations depending on the existing facilities and the nature, kind and quantity of products.

Storage operations may be either temporary, short term or long term. Temporary storage operation is needed for highly perishable products which require immediate marketing. It may be installed with or without refrigeration. This is extremely important for road side stands, market gardens, railway stations, shipping yards and retail stores. Mid term storage operation is aimed at checking the market glut without much deterioration in quality. This may extend from 1 to 6 wk, depending on the need. Mango, banana, papaya, cabbage, brinjal, tomatoes, cauliflower and beans are transferred to short term storage rooms when their quality is still good, and held there until a reasonable market price is attained. They are constantly inspected. Crops like apples, oranges, pomelos, pears, squash, potatoes, colocasia, sweet potatoes, carrots, onions, garlics and pumpkins are stored for a longer period of time. Long term storage operation is principally influenced by economic factors. The products are stored during their peak periods of production and marketed continuously during the rest of the year when producers and dealers can obtain reasonably high prices.

Storage operation may be classified as either natural or artificial. Artificial storage operation may be divided further into 4 types: (a) mechanical or structural, (b) controlled atmosphere, (c) chemical and (d) radiation. Natural storage operation keeps the products in situ without any artificial treatment. The aim is to let the fruit or vegetable mature and ripen on the plant for as long as possible. Harvesting is therefore delayed. Artificial storage operation, on the other hand, attempts to provide all possible artificial storage conditions to prolong the usability of the product.

8.3.1 Natural Storage

In India, particularly in West Bengal, vegetables like potato, yam, sweet potato, garlic and ginger are kept in situ for several months after they attain maturity. These are removed keeping in view the market rate. Staggering the harvest is easy and economical because it does not involve any extra expenditure and fabrication for storing. The vegetables are generally, removed before the rainy season to prevent rotting and sprouting.

8.3.2 Artificial Storage

Vegetables are stored in pits and trenches by mounting soil on the surface. Pits are used for storing beets, potatoes, carrots, turnips, cabbage, parsnips, sweet potatoes etc. Except for cabbage and parsnips, the vegetables are first covered with hay, straw or litter and then with soil to protect the surface from water leakage and freezing.

The small trenches should be dug at right angles to each other to facilitate ventilation. Wooden planks or boards are often placed above. The soil, about 4 to 5 in thick is filled with hay or straw and the products are piled inside the trench. A similar cover of straw or hay is placed above the commodity and plastered with mud. Several small trenches are better than one or two large ones. When a trench is opened all the stored products should be removed at a time. The location of the trenches should be on well drained high land. There should be no surface drain near the trench.

Untopped beets are stored underground, 12 to 16 inches deep in regions of mild winter. At the start of severe cold, 2 adjacent rows are placed in covered with soil. In this way, beets, which are neither too young nor too mature, can be kept for 5 to 6 months. In British Columbia, a cover of 4 to 5 inches is enough, but in the southern states, from 8 to 10 in is usually necessary.

Underground field storage offers the advantage of being convenient for the grower, as it can be done anywhere at anytime. Space is not restricted. It is most suitable for short term storage operations. However, many disadvantages render this type of storage unfavourable. It is expensive in terms of labour charges from digging the pit to removal of the product. Weather and soil conditions influence the operation. Heavy losses may occur since climatic conditions cannot be controlled. Deterioration can be faster for vegetables not removed before cold and wet weather.

8.3.3 Low Cost Storage Structures

Low cost storage system has a great significance in our country since other advanced storage systems work ought to be extremely expensive. Most of the low cost storage structures are built by taking the advantage of natural cooling.

i) Clamps

The clamps are commonly used for potatoes, turnips, beet etc. and vary in design. An area of land at the side of the field which is not prone to water logging is selected. The width can be any convenient size but normally it ranges between 3'-7'5" and it can be any suitable length. These dimensions are marked out and the vegetables piled on the ground. Occasionally straw is put on the ground before keeping the vegetables. The height of the pile should be about 1/3 of its width. The pile is covered with whole wheat or rice straw to about 6-8" thick, when compressed. In colder climates, more straw and soil may be added.

ii) Cellar

These are underground or partly underground structures usually below a house. They are used for years as storage for fruits and vegetables. The cellar temperature is approximately equal to the average annual air temperature. Cool under ground spaces work well for storing already cooled produce but not for removing field heat.

iii) Night time cooling

In some parts of our country there are significant differences between night and day temperatures allowing night time ventilation to be a good source of cool temperature.

iv) High altitude cooling

High altitude can be a source of cold. As a thumb rule air temperature decreases by 10°C for every 1 km increase in altitude.

v) Zero energy cool chambers

It is based on the principle of evaporative cooling. Evaporative cooling is not only one of the simplest and cheapest methods but also does not involve any conventional energy source or power to operate. Evaporative cooling is widely used for comfort cooling of living and working spaces in hot, dry climates and has considerable potential for pre-cooling and even storage of fruits and vegetables in such climates.

The basic principles are evaporation of water produces considerable cooling effect and the faster the evaporation, the greater the cooling. Evaporative cooling occurs when air that is not already saturated with water vapour is blown across any wet surface. Thus an evaporative cooler consists of a wet porous bed through which air is drawn, cooled and humidified by evaporation of water. Theoretically the lowest temperature that can be reached by the evaporation of water is the wet bulb temperature.

8.3.4 Ventilated Storage

a) **Above ground warehouse:** This is a common type of structure built above the surface of the ground and extensively used by rural farmers in the Indian peninsula. A dwelling house may be used for this purpose. The nature and type of construction depend on the area and nature of the product to be stored. In cold regions, greater insulation is needed, whereas in warm areas proper ventilation is essential. A storage structure for sweet potatoes differs from that for onions, leafy vegetables, crucifers or mangoes.

   This structure has the following advantages over the other types: (a) special construction is not needed, since a dwelling house will satisfy the conditions provided it is provided with necessary fittings suited for the particular type of fruits or vegetables; (b) products are easily handled during storage and removal; (c) grading, storing and packing of fruits and vegetables are facilitated.

b) **Controlled atmosphere storage:** Artificial atmospheres have been maintained in storage rooms in several ways. The respiration by the fruits increases the concentration of CO_2 and decreases the O_2 in the room. Proper levels are maintained by CO_2 absorbers, usually NaOH. Water is also used for absorbing CO_2 from CA storage when the concentration becomes too high. This method was less expensive and less noxious than with NaOH.

8.3.5 Refrigerated Storage

Although costly, the advantages of refrigerated or low temperature storage are well known. The following general principles should be considered during planning the refrigerated warehouse.

Site selection: The site of a storage plant should be selected bearing in mind its accessibility to highways, production areas, shipping points and distribution centres. Availability of fuel, telephone systems, electricity, water and sewer should also be considered. The site should be levelled so that costs of excavations and steep driveways are minimized.

Utilization of space and equipment: Mechanical product handling and newer methods of construction tend to give single story design greater capacity per rupee of investment than multi story refrigerated warehouse. In a one-story structure, high ceilings are provided; thus ducts, refrigeration units, pipes, sprinklers and other overhead obstructions should be placed so that they do not interfere with the use of vertical space. Small columns on wide centres permit palletized storage with comparatively little lost space.

Insulation requirement: A good insulating material must have low thermal conductivity, permanence, ease of application, reasonable cost and moisture-resisting qualities. The best insulating medium possible is two silver-coated surfaces separated by a perfect vacuum. This is used in small units (e.g. Thermos bottles) but is impractical in a larger scale. Still air is the second best insulator, but in practice this is not realized because of convection currents carrying heat. Other insulating materials include granulated cork, charcoal, cellular ebonite, glass fiber, kapok, cane fiber boards, silicate cotton (slag wool), cellular plastics, balsa wood, saw dust, rice husk and coconut fibers. However, they are not as efficient as slab cork. Usually they absorb moisture readily, causing decreased resistance to heat flow and structural deterioration.

To protect the insulator against entry of water vapour, a vapour barrier is needed. Since this travels inward, from the warmer to the colder side, the vapour seal should be placed on the outer surface of the insulator. Plastic film, metal foil, rigid metal sheets or hot mastics will provide adequate vapour seals.

Insulation is not usually placed on floors if the ground water level is more than 12 ft below the floor surface. Dry ground is a fairly effective insulator. Insulation thickness varies with the average and extreme temperatures of the location and temperature of the room. For cold storage of fruits and vegetables in the tropics, 4 to 5 in of cork insulator are sufficient.

Ventilation: Storage rooms should be provided with a forced air distribution system, which will allow uniform airflow throughout the pile of commodities. Air should circulate from the centre of the room outward to the walls, down through and between the rows of commodity and back up through the centre of the room. This is made possible by providing ducts or blowers and proper stacking of containers to permit airflow in a pre determined direction.

Refrigeration doors: Doors should permit easy access in and out of the room and at the same time minimizes undue loss of refrigeration. Bumper doors (or air doors) are convenient because they are self-closing and can easily be opened by dumping them with a fork lift truck. A hinge-insulated door opening should have at least 12 inch clearance on both sides of a pallet. The recent tendency is to use 10 feet as the standard height to accommodate all types of stacking lift trucks.

8.4 FACTORS AFFECTING STORAGE LIFE

8.4.1 Temperature

All fresh commodities contain water in their tissues and therefore are subjected to desiccation, which makes them susceptible for deterioration by other factors, such as microbial infection. Further elevated temperature influences the deterioration rate of harvested commodities. For each increment of 10°C, the rate of deterioration increases by two-to-three fold. Exposure to undesirable temperature results in many physiological disorders. Temperature also influences the effect of ethylene, reduced O_2 and elevated CO_2. Temperature can also influence the incidence or severity of pathogens.

8.4.2 Relative Humidity

In addition to temperature, relative humidity (RH) is the other factor which influences water loss from the product. It is important to maintain the RH level to optimum as lower RH may cause desiccation of the product, and higher RH may lead to condensation of water on fruit surface which may invite a host of problems.

8.4.3 Atmospheric Composition

Reduction of O_2 and elevation of CO_2 can either delay or accelerate the deterioration of fresh horticultural produce. The extent of these effects depends on commodity, cultivar, physiological age, O_2 and CO_2 level, temperature and duration of holding.

8.4.4 Physiological State-Respiration Rate and Ethylene Evolution

Respiration rate and ethylene evolution are major factors determining the storage life of harvested commodity. Respiration is the process by which stored complex materials are broken into simple products and energy is released. While respiration is essential to maintain the state of living of the produce, it causes deterioration due to losses in food reserves, food value, flavour, and dry weight. Further, a good amount of energy is released during respiration. The rate of deterioration of harvested produce is generally proportional to their respiration rate.

Ethylene is the natural ripening and senescence hormone, which is physiologically active at very low concentration (0.1 ppm). While all the plants produce ethylene, its production varies greatly. Generally ethylene production rate increases with maturity at harvest, physical injury, disease incidence, increased temperature and water stress. It can be controlled by storing at low temperatures and reduced O_2 and elevated CO_2 atmosphere.

8.4.5 Initial Infection and Physical Condition of Produce

The produce should be in good condition before storage. Harvesting should be done in a manner that it doesn't cause impact, bruising or injury to the product. Bruising may stimulate respiration and enhance ethylene production that accelerates ripening and associated changes. The bruised or cut sites may invite microbial infection, which ultimately reduces the life of the product.

8.4.6 Pre-harvest Factors

The prevailing climatic conditions and cultural practices determine the quality of the produce. The incidence of infection at the time of harvest will determine the storage life of a commodity. A sizable proportion of stored produce is spoiled by these infections.

Storage life partly reflects the cultural and environmental conditions to which the produce is exposed before harvesting. The environmental factors include temperature, RH, light, soil texture, wind, elevation, and rain fall; whereas cultural factors are mineral nutrition, soil management, pruning, thinning, chemical spray, rootstocks, planting density and irrigation.

I) Climatic influences

Temperature: The metabolism and composition of the fruit are affected by temperature. Tomatoes grown at high night temperature have higher respiration rates than those, which grow at lower night temperature and ultimately have lower shelf life.

Light: The duration, intensity and quality of light affect the quality of fruit and vegetable at harvest and have influence on the shelf life. In tomatoes leaf shading of fruits produces a deep red colour, and the fruits exposed to the sun are lighter in weight with thinner rind. Such fruits are more susceptible to mechanical damage and have higher transpiration rate; and lower shelf life.

Water supply: Water supply to plant during growth also affects the storage life. Fruits and vegetables grown under water deficit condition may not develop properly and will have shorter shelf life. Similarly under water logged conditions may cause development of water soaked areas on commodity reducing the storage life.

Wind: Wind may damage the leaves of the vegetables or cause abrasions on fruit surface, which reduces their shelf life. High wind velocity may have a deleterious effect on plant growth.

II) Cultural practices

Several factors before harvest affect quality of horticultural crops after harvest. The quality of the seed or the plant material is an important factor that controls the fruit produced. Besides this genetic makeup of plant also determines the quality of the product. All cultural practices have direct effect on final quality of the produce.

Seeding or planting period: Many species are very sensitive to environmental conditions, so optimum quality of produce cannot be expected when crop is grown under adverse conditions.

Planting density: Planting density can affect both quality and quantity of produce. In high density planting competition among plants is increased which reduces light availability, and thus may decrease its quality. Low density planting leads to large sized fruits with good colour. But larger fruits are commonly more susceptible to physiological disorders.

Environmental conditions during growth: High temperature, light intensity, wind rain, hail, storm and snowfall are the environmental conditions that may influence the quality of the produce.

Irrigation: Irregular watering usually reduces fruit size, increases splitting and physiological disorders, and it reduces water content in fruit or plant.

Fertilization: Poor fertilization increases chances of physiological disorders due to deficiency of some minerals, or excess may lead to toxicity of some minerals. Nutrition of the plant is the most studied factor affecting the quality of harvested produce and its storage life. Many physiological disorders are the result of depleted nutrient status or nutrient toxicity in the soil. High level of nitrogen promotes stem end rind breakdown in citrus, and cracking in sweet potato, where as deficiency of nitrogen causes stunted growth. Deficiency of potassium leads to black spot in potatoes. Calcium deficiency causes reduction in firmness besides causing cavity spot in carrots. Besides the major nutrients, micronutrient deficiency also affects product storage life. Fruits of citrus become hard and grow to irregular shape and contain brown gummy discoloration in the albedo if grown in boron deficient soil.

Pruning: Pruning reduces the load in plants, and leads to good fruit development in the plant. Fruits from well pruned tree can be expected to have more storage life than unpruned tree due to proper growth and development.

Thinning: Thinning reduces the competition between fruit trees, and therefore promotes a good balance between the vegetative parts and fruit, which results in improvement of quality.

Disease and insect control measures: Incidences of pathogens and insects have negative effect on fruit quality. Poor management of plant protection programs has the potential of not only reducing yield, but quality also.

Hormone and growth regulators used during growing season: Many hormones and growth regulators are sprayed during growth season to improve the quality of fruit/vegetables.

Chemical sprays: Chemical sprays during pre-harvest are done for control of weeds, insects and pests, and control of nematodes. Timely and adequate concentrations of these sprays improve the quality of the produce.

Rootstock: The effect of genetic material on storage potential after harvest is well documented. Different cultivars of same fruit vary in their storage requirement and storage life.

Other cultural practices: Any factor that affects plant growth also influences the quality of harvested produce. Age of the tree also influences the size and quality of the fruit, as in orange the older trees have smaller fruits with thin rinds, but high TSS. Further interactions among different levels of climatic and cultural factors during growth may affect the fruit quality and its storage potential.

8.4.7 Harvesting and Handling Practices

These likewise influence storage behaviour and quality. Merely dropping the fruit to the ground from a height of only a few inches will cause an outburst of CO_2 production, which may not be immediately counteracted by low temperature storage. Bruises, punctures, scratches and other mechanical injuries can be expected to produce even greater damage. Hence, careful handling and prompt storage should be practiced.

8.5 LET US SUM UP

Being a live tissue, fruits and vegetables continue to perform metabolic activities even after harvesting, which is the major cause of their spoilage. Therefore proper storage after harvest is necessary to maintain the product quality after harvest. The product should be stored under optimum conditions of temperature to reduce its respiration and ethylene production, which leads to senescence. Maintaining proper humidity and alteration of product environment during storage also helps in extending the storage life of fresh produce.

8.6 KEY WORDS

Relative humidity	:	The relative amount of moisture in the atmosphere
Desiccation	:	Removal of water from the surface
Harvesting	:	Detaching the edible portion from the plant
Impact	:	To hit with force against a hard surface
Bruising	:	To injure the surface without breaking the skin, but causing Discoloration.
Microbial infection	:	Growth of microorganism on a product
Ethylene	:	A gas which stimulates ripening
Respiration	:	Process of inhaling oxygen and exhaling carbon-di-oxide

8.7 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answers should include following points:
   - Rate of chemical and biochemical reactions
   - Severity of pathogen infection
2. Your answers should include following points:
   - Temperature regulation
   - Ethylene removal
3. Your answers should include following points:
   - Desiccation
   - Pathogen infection
4. Your answers should include following points:
   - Reduced respiration
   - Reduced ethylene production

- Low pathogen incidence
- Enhanced shelf life

5. Your answers should include following points:

   - Loss of storage material
   - Ethylene production
   - Heat production

6. Your answers should include following points:

   - Respiration
   - Ethylene production

7. Your answers should include following points:

   - Death of tissues
   - Termination of metabolic activities

8. Your answers should include following points:

   - Enhanced ethylene production
   - Site for pathogen attack
   - Blackening of surface

UNIT 9 STORAGE STRUCTURE

Structure

9.0 OBJECTIVES

After reading this unit, you should be able to:

- explain orderly marketing of fruits and vegetables thereby increase the period of availability;
- understand the role of temperature, humidity and atmospheric gases during storage;
- state different high-tech and low cost traditional storage techniques;
- demonstrate the principle of evaporative cooling and the role of Zero Energy Cool Chamber; and
- highlight the importance of refrigerated/cool stores for the benefit of the producers and consumers.

9.1 INTRODUCTION

Storage of fruits and vegetables is very much essential, because of their highly perishable nature. Their storage can be extended by various treatments applied to them after harvest. The most important of these is temperature management. Orderly marketing of these perishable commodities requires some storage facility in order to balance day to day fluctuation between product harvest and their sale.

Fruits and vegetables are grown in many parts of the country but not uniformly. During harvesting season, availability is abundant in one region but generally scarcity in other parts. The season lasts for few days to few weeks and this situation creates a glut in growing area and the growers do not get a remunerative price of their valuable produce. As a result, they encounter more spoilage and force to undertake distress selling at the instance of unscrupulous traders. Considerable difference exists in marketing of perishable fruits and vegetables and that of durable cereal grains. Consumers generally prefer to buy a small / requisite quantity of vegetables daily or once/twice a week because of their perishable nature. While in case of other items of food viz. cereals, pulses, vegetable oil, spices etc are normally procured once in a month as they are durable in nature primarily because they contain less moisture compared to fruits and vegetables. In order to extend marketing of these perishable commodities beyond the end of harvest season, proper storage of fruits and vegetables become essential.

A proper storage system reduces physiological activity of horticultural commodities by maintaining lowest safe temperature that will not cause chilling or freezing injury. It also reduces growth of spoilage causing microorganisms. With some commodities, the storage facility may also be used to apply special treatments like curing of tuber and other fruits and vegetables. For example potatoes and sweet potatoes are held at high temperature and high relative humidity for few hours/days to cure wounds sustained during harvest, drying of scaly leaves of onion and garlic, and degreening of oranges and lemons and application etherals for uniform ripening before marketing or shipment.

9.2 REFRIGERATED/COOL STORAGE

Fruits and vegetables if stored at low temperature remain fresh and nutritious for a longer time. Low temperature reduces physiological activity rate of the product like respiration, transpiration, ethylene production and other biochemical reactions responsible for rapid ripening and senescence. It also minimizes attack of pest and diseases and prevents product dryness with the help of humidifier in the storage room. Refrigerated storage is one such type of storage structure where temperature can be brought down with the help of mechanical refrigeration. This system doesn't produce cooling but removes heat from the storage that we feel is cooled. Refrigeration cycle in the compression system is by far the most popular and most widely used system of refrigeration. It consists of four important units namely compressor, condenser, cooling coil and expansion valves.

A good refrigerant changes into vapour phase upon heating and in liquid state upon cooling. The refrigerant (Fereon-12) or ammonia takes out the heat from the room and changes into vapour. The expansion valve controls the amount of refrigerant. The expanded gas is then compressed in compressor and thus the heat is removed from the compressed gas by means of running water or circulating cool air over the cooling coils containing the hot gas. The hot gas changes into liquid in condenser. Once the refrigerant is returned to the liquid state, it is again ready to be admitted through the expansion or the pressure-reducing device on to the evaporation. This cycle of actions in the compression system is repeated continuously so long as the compressor is in operation and with such a system accurate temperature control is possible. The ideal condition in the cool store is the lowest minimum temperature that does not cause chilling injuries to the produce.

Table 9.1: Recommended cool store temperature and relative humidity of some important fruits

Fruit	Temperature °c	Relative humidity%	Storage (days)
Apple	-0.1- +4	90-95	30-50
Banana	13-15	85-90	30-45
Grape	+1 -	90-95	60-90
Guava	5-10	90	14-21
Lemon	10-14	90	60-150
Lime	9-10	90	30-60
Litchi	1.5	90-95	21-35
Mango	13.3	85-90	15-25
Orange	4-6	85-90	45-80
Papaya	12.2	85-90	7-21
Pineapple	10-13	90	21-28
Sapota	12.2	85-90	14-21

9.3 CONTROL/MODIFIED ATMOSPHERE STORAGE

It is an advance technology for storage of fruits and vegetables. In these systems, storage environment is different than the normal. Controlled atmosphere (CA) storage utilizes the correct amount of gas combination during storage. In CA, oxygen is reduced from 21% to 2-5% and CO_2 is increased from 0.03 to 1-5%. These results slow down of physiological activity of fruits and vegetables such as rate of respiration, ethylene production and other bio-chemical reactions. The reduced rate of these activities actually decreases the ripening and senescence process considerably. Construction and running of CA storage needs special attention such as it should be gas tight, mechanical refrigeration should be attached to maintain a temperature of 30-32 ^{0}F. Nitrogen and CO_2 gas are introduced into the storage and excess CO_2 must be removed by dry hydrated lime because high CO_2 is not tolerated by many commodities. No doubt, CA storage has many advantages but few harmful effects have also been recorded. For example, Initiation of black heart in potatoes, brown stains on lettuce, irregular ripening of banana, pear, tomato and development of off-flavour at very low O_2 concentration.

Modified atmosphere inside the package develops due to the respiration of fruits and vegetables. Inside the package O_2 decreases and CO_2 increases with the uptake of O_2 and release of CO_2. In MA storage, a very low degree of control gas concentration is possible. However, a desired gas combination can also be obtained by placing absorbers and adsorbers of O_2, CO_2 and ethylene. The MA and CA differ mainly in degree of control of gas concentration. Advances in the design and manufacturing of polymeric films with wide range of gas permeability increased the efficiency of MA storage.

9.4 ICE BANK COOLER

In efficient cooling system cooled air passes over the stored fruits and vegetables at a very high velocity as a result desiccation of the crop takes place. In order to avoid this, various methods of humidifying the cooling air have been developed. A recent development in refrigeration is the Ice Bank Cooling system with positive ventilation. The system positively directs ice cold air through the boxes or crates containing fresh fruits and vegetables. In this way quicker cooling is possible and large amount of heat can be removed in a relatively short period of time. In this system, a bank of ice is built up with the help of a small refrigeration plant. The ice is accumulated on extended surface plate, which are suspended in a tank of water. The water surrounding the ice is pumped to the top of a cooling tower and falls through the tower passing over the extended surface, giving a large surface area of heat exchange. The air leaving the tower maintains high relative humidity. Once initial cooling is complete the store maintains a temperature of 0.5 - 0.8^{o}C and relative humidity of 98 per cent. In view of the continuous humid cool air circulated through the stored commodities this system of storage is found very useful for storage of fresh horticultural produce. This will be preceding step for cool storage of fruits and vegetables.

9.5 HYPOBARIC STORAGE

Fruits and vegetables can be stored under less than atmospheric pressure. This technology is called hypobaric storage. Fruits were held at about 0.2 to 0.5 atmospheric pressure at 59 to 75°F and humidified air was passed through the chamber in order to maintain humidity and to remove ethylene and other volatile compounds given off by the fruits and vegetables. There is reduction of ethylene in the fruit tissues and O_2 in the chamber. As a result, products respiration and ethylene production decreases which results increased shelf - life. Many volatile compounds evolved by the produce and from other sources may accumulate in the storage atmosphere. Ethylene is the most important volatile compound accumulated in the storage room. Its accumulation above certain level may reduce storage life. Therefore, its removal becomes necessary. Hypobaric storage is a form of controlled atmosphere storage in which the produce is stored in partial vacuum. In hypobaric storage system, the commodity is placed in a vacuum tight and refrigerated container and air is evacuated by a vacuum pump to the desired low pressure. This is a very expensive method and used in case of high value commodities.

9.6 LOW COST STORAGE

Low cost storage structures are the best alternative for rural areas and in all such places where electric facility is not available. It is easy to install and run by unskilled people. These low cost storage systems have a great significance in our country since other advanced storage techniques work out to be extremely expensive. Most of the low cost storage structures are build by taking the advantage of natural cooling and all of them are not only environment friendly but also energy saving.

Clamps

These have been used from time immemorial as a traditional method of storage. The clamps vary in design and commonly used for potatoes, turnips, beet etc. An area of land at the side of the field that is not susceptive to water logging is selected. The width can be any convenient one but normally it ranges between 3' – 7. 5' and it can be any suitable length. These dimensions are marked out and the vegetables piled on the ground. Occasionally straw is put on the ground before the vegetables. The height of the pile should be about 1/3 of its width. The pile is covered with unbroken what or rice straw to about 6.8" thick, when fully compressed, laid upright from ground to ridge and capped at the top with bent over straws. About 2 weeks after the clamp is covered with a layer of soil, usually in the order of 6-8" thick when compressed. In colder climates more straw and soil may be added.

Pits

Normally pits or trenches are dug at the edges of the field where the crop is grown. One should remember that the site of pits or trenches in the field should be at higher points particularly in high rainfall regions. These are lined with straw or any other organic matter before filling with the commodities to be stored and then covered with a layer of organic matter and then with a layer of soil. Sometimes wooden boards are placed on the surface before the soil is put on. Some times lack of ventilation may cause rotting problems. This can be avoided by providing ventilation hole at the top in such away that it allows only air to pass out but no rain to penetrate.

Cellar

These were underground or partly underground structures usually below a house. This location provides good insulation as a result they are protected from excessively low temperatures in cold climates. They were used for years as storage for fruits and vegetables. The crops are usually spread out thinly on shelves in order to ensure good air circulation. The doors of the cellars are generally kept open at night to ensure that the temperature in store remains low. It has often been observed that the cellar humidity remains low that may induce desiccation. In order to avoid such situation precaution is taken to keep the floor of the store wet. As a general rule, the cellar temperature is approximately equal to the average annual air temperature. Cool under ground spaces work well for storing already cooled produce but not for removing field heat.

Night time cooling

This is also called as air cooled storage system. This method actually should consist of an insulating room from all the sides with air inlet and out let for exchange of air. During night open these pores and allow the cool air to come inside. By putting an exhaust fan at out let will increase the efficiency of nighttime cooling. It will facilitate more sucking of cool air inside for faster air circulation and rapid cooling. During daytime both inlet and outlet are kept closed. The trapped cool air will keep the produce cool. The relative humidity can also be maintained by sprinkling water on the floor or by providing mechanical humidifier. Fruits and vegetables can be stored for few days to a few weeks depending on the out side temperature. In some parts of the world, there are significant differences between night and day temperatures allowing night time ventilation as an efficient system of storage of fruits and vegetables. In hilly areas also night temperature falls as high as 15 to 20°C. Low night temperature can be used to reduce field heat simply by harvesting the produce during early morning hours.

Well water

In some areas, well water can be an effective source of cold. The temperatures of the ground at depths greater than about 2m (5feet) below the surface is equal to the average annual temperature. Well water temperatures are usually very near to this.

Naturally formed ice

This is an old method of refrigeration and very useful for cold countries where water of lakes, ponds are frozen in winter season. The ice is harvested and stored in insulated houses and used for pre-cooling, storage and transportation of horticultural commodities. Before the development of mechanical refrigeration, refrigeration was provided by ice formed naturally in shallow ponds during winter. The ice was insulated from spring and summer heat with straw and transported to cities as needed. But the cost of transportation was found very high as compared to electrical cost for refrigeration. Generally one Kg of ice takes 325 Kilo Joules of energy for complete melting. The heat comes form the commodities and its immediate surroundings that results cooling. But this method requires a large quantity of ice and creates problem of disposal of melt water. However, cooling facilities in climates where winter ice making is feasible can store for summer use. In case of few fruits and vegetables, it is best suited for transportation along with ice.

High altitude cooling

High altitude can also be a source of cold. As a thumb rule, air temperature decreases by 10°C (18°F) every 1Km increase in altitude. It is not possible to bring this air down to ground level because it naturally heats up as it drops in altitude. However, in some cases it may be possible to store the commodity at high altitude in mountainous areas.

Underground storage

Cellars, abandoned mines, and other underground storage have been used for years for storage of fruits and vegetables. The temperature inside storage is approximately equal to the average annual air temperature. It should be noted that cool underground spaces work well for already cooled produce but not for removing field heat. The soil has a poor ability to transfer heat. Once the cold is depleted from an area it will not regenerate rapidly. Use of soil at the top for insulating the underground pit is important in order to avoid run-off and rain water to enter into the pit. A small tube is generally inserted inside the pit for gaseous exchange.

Ventilated storage/onion storage structure

The conventional storage structures used in India for onion are primarily made of bamboo or similar plant material with a thatch on top. All attempts are made to provide side and bottom ventilation, but unfortunately due to indiscriminate piling of onion heat pockets develop because of improper ventilation of onion stack. As a result of inadequate ventilation, spoilage is accelerated. Therefore, air movement is essential for onion storage. Considerable reduction of spoilage of onion could be achieved by modifying the existing storage structure and introducing pile ventilation with the help of perforated bamboo pipes. It was observed that storage of onion in perforated plastic crates stacked in a ventilated room/shed could reduce the storage losses due to spoilage to a considerable extent. The big size cool chamber can be used as an ideal onion storage structure if the water is withdrawn from the system.

9.7 EVAPORATIVE COOLING/PUSA ZERO ENERGY COOL CHAMBER

Evaporative cooling is Nature's very own method. The ancient Egyptians used a primitive form of evaporative cooling, dating back to about 2500 BC and so did the Mughals a few centuries ago. Evaporation of water produces a considerable cooling effect and the faster the evaporation the greater is the cooling. Evaporative cooling occurs when air, that is not already saturated with water vapour, is blown across any wet surface. Thus evaporative coolers consist of a wet porous bet through which air is drawn and is cooled and humidified by evaporation of water. Theoretically, the lowest temperature that can be reached by the evaporation of water is the wet bulb temperature. Evaporative cooling is widely used for comfort cooling of living and working spaces in hot, dry climates and it has a considerable potential for pre-cooling and even storage of fruits. The principles of evaporative cooling can be gainfully utilized for storage of fresh produce, particularly in rural India, as it can be constructed even in a remote village.

This is a low cost storage structure, based on the principle of evaporative cooling. The most important advantage of this low cost technology lies in the fact that it requires very minimal electricity or power to operate and all the construction material of cool chamber are available easily and cheaply. It can be installed by low skill persons as it does not require any specialised skill. Only the place / site should have a permanent source of water. The raw material required for the construction of cool chamber are bricks river bed sand, bamboo, khaskhas, rice straw (or any material of similar nature), gunny bags/cloths etc. Its construction is also very simple. First of all floor is made with a single layer of bricks and the side wall are made with a double layer of bricks leaving a cavity of approximately 7.6 cm space in between the two layers of bricks. This cavity is filled with river bed sand free from stones and other materials. The top cover is made with khaskhas or gunny bags in a bamboo frame structure. About 400 bricks are required to built a cool chamber for 1 quintal of fruits or vegetables. After construction, wall, floor sand and top cover should be wetted fully by water. Once the chamber is fully saturated with water, sprinkling of water once in the morning and once in the evening is enough to maintain the temperature and humidity. These cool chambers can reduce the temperature by 17-18°C during the peak summer months and maintain a very high humidity of about 95 per cent throughout the year even when the atmospheric relative humidity falls below 20 per cent. The improved system of watering by single drip in zero energy cool chamber was found to be efficient in maintaining slightly lower temperature compared to the conventional system. It also helped in saving considerable amount of water and labour. Few precautions should be taken to run this chamber successfully, that there should be a permanent source of water, it should be constructed under shade and the site should not be prone to water logging condition. Spray recommended insecticide/ fungicides before storage. The shelf life of fruits and vegetables could be increased from a few days to few weeks in these chambers.

Commercial size cool chamber

The low cost big size cool chamber has been designed and constructed with the double brick wall having cavity filled with riverbed sand. The bottom of the chamber is provided with four ducts that are submerged in wet sand. The floor of the chamber is made of wooden planks with provision of the entry of fresh air through the duct. An exhaust fan has been provided at the top for ventilation purpose. The trial with big size cool chamber showed that it could bring down the temperature by 8-10°C. The study revealed that the temperature could be brought down efficiently by judicious operation of the exhaust fan.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Why do we need storage of fruits and vegetables?

9.8 LET US SUM UP

Storage of fruits and vegetables is essential to extend the period of availability for orderly marketing, pricestablization, spoilage reduction and distribution to the places of scarcity. Many biotic and abiotic factors effects the storage life of fruits and vegetables after harvesting. In order to control these factors many, high-tech storage systems are developed such as refrigerated storage, Controlled/Modified atmosphere storage, Hypobaric storage etc. However, such high-tech storage are costly, requires power to operate and skilled persons which a small farmer can not afford. On the other hand, low cost storage systems are found very useful for on farm. Pusa Zero Energy Cool Chamber is one such low cost storage system. It requires very low or minimal electricity or power to operate nor any skilled person to operate, maintains low temperature and high humidity. Small and marginal farmers can adopt this low cost storage to store his daily harvesting instead of selling to middlemen at cheapest rate. In addition commercial size cool chamber can be constructed in a in village hat for storage purpose.

9.9 KEY WORDS

Evaporative cooling : Evaporative cooling occurs when air that is not saturated with water vapour is blown across any wet surface.

Zero energy cool chamber : Low cost storage structure for storage of horticultural perishable.

Relative humidity : Ratio of weight of water vapour present in the air and the weight of water vapour required to fully saturate the air, expressed in percentage.

Processing : Sterilizing process by the application of heat.

9.10 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - It regulates market price and facilitates orderly marketing of fruits and vegetables.
   - Increases availability of fruits and vegetables during off-season.
   - Extend the shelf-life of fruits and vegetables beyond the harvesting season.
   - Increases the marketing period of fruits and vegetables.
   - Beneficial to both the producers and the consumers.

2. Your answer should include the following points:

   - Underground storage such cellars, abandoned mines, caves etc.

- Cooling by naturally formed ice
- High altitude cooling
- Night time cooling
- Storage in clamps

3. Your answer should include the following points:

   - It does not require any electricity or power to operate.
   - All the construction material of cool chamber are available easily and cheaply.
   - Any person can install it at any place/site (with a permanent source of water).
   - It maintains high humidity and low temperature which is essential to preserve freshness and prevents desiccation of horticultural produce during storage.
   - It increases shelf-life of fruits and vegetables and preserve their nutritional quality.

4. Your answer should include the following points:

   - Refrigerated storage
   - Controlled atmosphere storage.
   - Modified atmosphere storage.
   - Hypobaric storage
   - Ice Bank cooler

5. Your answer should include the following points:

   - Expansion valve
   - Compressor
   - Condenser
   - Cooling coil
   - Refrigerant

6. Your answer should include the following points:

   - CA maintains required level of gases in the storage, which is not possible in MA.
   - In CA required amount of gases are maintained by injecting or removing but not in MA.
   - In MA respiration of fruits or vegetables modifies gases composition.
   - Packing of fruits and vegetables in a polyethylene pouch is an example of MA.
   - CA requires airtight room with refrigeration and gases controlling facility.

UNIT 10 MARKET AND MARKET MECHANIZATION

Structure

10.0 OBJECTIVES

After reading this unit, you should be able to understand:

- concept of markets;
- what role markets play in economic development?;
- various classifications of markets and marketing channels;
- various types of market functions that are performed in the marketing and role of market middlemen;
- marketing efficiency and how to measure marketing efficiency; and
- what is meant by market mechanization, its role and scope?

10.1 INTRODUCTION

In the traditional subsistent society, most of the people earned their livelihood from land and had little left for marketing. This marketable surplus was exchanged locally only. The distance between producers and consumers was less. Small quantities of commodities were transported as head loads to places of demand. There were limited varieties of commodities brought to market. The commodities were normally sold in raw form and seasonally only. Roads were not developed and time was not properly valued. All the marketing services were performed manually. However, slowly and slowly market centres developed where bulk of commodities started flowing in. The urbanization further helped in establishing big markets. However, with a larger proportion of commodities moving to urban markets and more proportions available for commercial markets, certain kinds of problems, characteristic to the stage of development, also became apparent.

With the stage of development, the income of the people increased the demand for better markets and better marketing services also increased. A wide range of variety of commodities also developed. Those producers who could meet the consumers' demands, gained. The part of gain was further invested for improving marketing facilities and services. Government also helped in establishing the modern markets.

However, there were many problems too. With the increase in population and further increase in income and urbanization, the demand for fast marketing services increased. The limited supply of increased marketing services could not keep the pace with demand. Thus the need for the mechanization of the markets was felt to meet the demand, promptly.

Transportation in the market itself became fast. Well developed countries today have mechanical grading, packing, stitching and loading and unloading of the commodities in the market places. The weighing machines immediately weighs the commodities accurately even to fractions. A similar mechanized system is needed to move manufactured inputs to farm from urban areas where they are produced.

10.2 CONCEPT AND DEFINITIONS

In any market oriented economy, the production is mainly for sale to the consumers. The direct sale of the producer to the consumer can bring higher price to him. But the search of consumers for direct sale is normally costly. The direct sale to consumers is not possible by every producer especially when producer faces shortage of labour and time. The market place serves a better outlet, in such situation, where more amounts can be sold with less labour and time. It is in this context that the formal markets with modern facilities, especially for agricultural produce are of paramount importance in agricultural countries like India.

Traditionally, a "market" was a physical place where buyers and sellers gathered to exchange goods. A market includes any area/place where the people assemble for sale and purchase of the commodities that satisfy their demand. Thus, it is an area in which the demand and supply forces operate.

Economists describe a market as a collection of buyers and sellers who transact over a particular product. But marketers view the sellers as constituting the industry and the buyers as constituting the market. Business people often use the term markets to cover various groupings of customers such as product markets (the shoe market); demographic markets (the youth market); and geographic markets (the Indian market).

The traditional boundary of the market in terms of place is now relaxed. We can distinguish between a marketplace and a market space. The marketplace is physical, as one goes shopping in a store; market space is digital, as when one goes shopping on the Internet. Many observers believe that an increasing amount of purchasing will shift from the marketplace. Today, each nation's economy and the global economy consist of complex interacting sets of markets linked through exchange processes.

Thus, the term market means not a particular market place in which things are bought and sold but the whole of any region in which buyers and sellers are in such a free intercourse with one another that the prices of the same good tend to equality, easily and quickly. Therefore, a market is defined in terms of existence of fundamental forces of supply and demand and is not necessarily confined to a place.

Some necessary conditions for a market to exist are:

- Reference of the commodity
- Existence of buyers as well as sellers
- Existence of business relationship between buyers and sellers.
- Medium of exchange.

Thus, market is an arena for organizing and facilitating business activities and for answering the economic questions: What to produce, how much to produce and how to distribute? The marketing on the other hand is performance of all business activities involved in flow of goods and services associated with inputs and output from initial point of production to ultimate consumers.

10.3 ROLE OF MARKETS

The markets provide most convenient outlet for producers and consumers. These provide livelihood to various people who perform different kinds of activities /functions. Since, the commodity prices are principal factors affecting the level of living of both producers and consumers in developing counties, it is often desirable to measure the returns to the farmers and also lower cost to consumers in order to raise their standard of living. Well organized/ regulated and managed market does not permit malpractices.

Free markets play a very important role in the development of a country by providing the right direction to the resources' use and fulfil the demand of all types of consumers and producers of variety of goods. They operate to make a variety of products to targeted consumers at various places in desired form and conditions and deliver to those who are willing to pay reasonably.

Well developed marketing system in rural areas will further add to increase the market for industrial goods. Thus, a good marketing system acts as a motivating force for development of a country. The market demand will signal the, production and the employment and profitability.

It is important to note that an efficient, viable marketing system can not be realized without institutions which provide financing , assume risk, aid exchange by impartially mediating set weight and measures, grades and standards and help to disseminate market facts.

10.4 TYPES OF MARKETS

Markets are of various types and can be divided on various bases. Some of the basis on which, agricultural markets can be classified are given below:

Classification of Markets:

10.4.1 On the Basis of Location

On the basis of the place or location or operation, markets are of the following types:

a) *Village markets:* A market which is located in a small village, where major transactions take place among the buyers and sellers of a village, is called a village market.

b) *Primary wholesale markets:* These markets are located in big towns near the centres of production of agricultural commodities. In these markets, a major part of the produce is brought for sale by the producers-farmers themselves. Transactions in these markets usually take place between the farmers and traders.

c) *Secondary wholesale markets:* These markets are located generally in district headquarters or important trade centres or near railway junctions. The major transactions of commodities take place between the village traders and wholesalers. The bulk of arrival in this market is from other markets.

d) *Terminal markets:* The terminal markets are those in which goods produced are finally either sold to the consumers/processors or assembled for export. Such markets are located either in cities or near sea ports.

e) *Seaboard markets:* These markets are located near seashore. These are mainly for exports/imports. Such markets are Mumbai, Kolkata and Chennai.

10.4.2 On the Basis of Area Covered

On the basis of the area from which buyers and sellers usually come for transactions, markets may be classified into the following four classes:

a) *Local or village markets:* This covers a village/local area. In this type of market the buying and selling activities are confined among the buyers and sellers drawn from the same village or nearby villages. The village markets exist mostly for perishable commodities in small lots, e.g., egg market, local milk market or vegetable market.

b) *Regional markets:* Regional market is one in which buyers and sellers for a commodity are drawn from a larger area than the local markets. Regional markets in India usually exist for food grains such as Moga market for wheat.

c) *National markets:* A market in which buyers and sellers are at the. National level. National markets are found for durable goods like spices, jute and tea.

d) *World market:* The buyers and sellers are drawn from the whole world. These are the biggest markets from the area point of view. These markets exist in the commodities which have a worldwide demand and/or supply, such as coffee, machinery, gold, silver, etc.

10.4.3 On the Basis of Time Span

The markets can be classified on the basis of the duration for which they work.

a) *Short-period markets:* The markets which are held only for a few hours are called short-period markets. The highly perishable commodity/ products assemble at a place near village or city to market the produce like fish, vegetables and in these markets, the prices of commodities are governed mainly by the extent of demand for, rather than by the supply of, the commodity.

   There are weekly markets in many places where all commodities including agricultural commodities are sold at a particular day in a week.

b) *Long-period markets:* These markets are held for a longer period than the short-period markets. The commodities traded in these markets are less perishable and can be stored for longer time. These are food grains and oi1seeds. The prices are governed both by the supply and demand forces.

c) *Secular markets:* These markets are of a permanent nature. The commodities traded in these markets are durable in nature and can be stored for many years. Examples are markets for machinery, manufactured goods.

10.4.4 On the Basis of Volume of Transactions

The markets on the basis of volume of transactions at a time can be divided into two.

a) *Wholesale markets:* A wholesale market is one in which commodities are bought and sold in large quantities or in bulk. The farm produce from far off places is normally sold to wholesaler here. However, transactions take place between traders also.

b) *Retail markets:* Transactions in these markets take place between retailers and final consumers. The retailer purchase in wholesale market and sell in small lots to the consumers as per their requirements. These markets are very near to the consumers.

10.4.5 On the Basis of Nature of Transactions

The markets can also be classified on the basis of nature of transaction. These markets are of two types

a) *Spot or cash markets:* A market in which goods are exchanged for money on the spot is called the spot or cash market.

b) *Forward markets:* A market in which the purchase and sale of a commodity takes place at time ‘t’ but the exchange of the commodity takes place on some specified date in future i.e., time t + 1. Sometimes even on the specified date in the future (t + 1), there may not be any exchange of the commodity. Instead, the difference in the purchase and sale prices are paid or taken.

10.4.6 On the Basis of Degree of Competition

The market can be classified on the basis of competition of exchange of commodity between buyers and sellers. On the basis of competition, markets may be classified into the following categories:

Perfect Markets: A perfect market is one in which the following conditions are satisfied:

i) Large number of buyers and sellers exist.

ii) All the buyers and sellers in the market have perfect knowledge of prices.

iii) Prices of homogeneous goods at any time are uniform over a geographical area, plus or minus the cost of getting supplies from surplus to deficit areas.

iv) The prices are uniform at any place over periods of time, plus or minus the cost of storage from one period to another.

v) The prices of different forms of a product are uniform, plus or minus the cost of converting the product from one form to another.

vi) There is free entry and exit of the buyers and sellers.

Imperfect Markets: The markets in which perfect competition conditions lack are characterized as imperfect markets. The following situations, each based on the degree of imperfection, are normally identified:

a) *Monopoly market:* Pure Monopoly is a market situation in which there is only one seller of a commodity. He exercises sole control over the quantity or price of the commodity. In this market, the price of a commodity is generally higher than in other markets. But when there is only one buyer of a product, the market is termed as a Monopsony market.

b) *Duopoly market:* A duopoly market is one which has only two sellers of a commodity. They mutually agree to charge a common price which is higher than the hypothetical price in a perfect market. The market situation in which there are only two buyers of a commodity is known as the duopsony market.

c) *Oligopoly market:* A market in which there are more than two but still a few sellers of a commodity is termed as an oligopoly market. A market having a few (more than two) buyers is known as oligopsony market.

d) Monopolistic competition: When a large number of sellers deal in heterogeneous or differentiated form of a commodity, the situation is called monopolistic competition. The difference is made conspicuous by different trade marks on the product. Different prices prevail for the same basic product. Examples of monopolistic competition faced by farmers may be drawn from the input markets. For example, they have to choose between various makes of insecticides, pump sets, fertilizers and equipment.

10.4.7 Classification of the Market on the Basis of Public Intervention

Based on the extent of public intervention, markets may be placed in anyone of the following two classes:

a) *Regulated markets:* Markets in which business is done in accordance with the rules and regulations framed by the statutory market organization. Standards, grades and charges in such markets are fixed.

b) *Unregulated markets:* There are no official rules, regulation and public controls. The market rules etc. are made by the private parties only, in these markets.

10.5 MARKETING FUNCTIONS

Each of marketing function is a major specialized activity performed in accomplishing the marketing process. The list of the marketing functions differs among the writers. However, we shall follow a fairly widely accepted classification of functions, as follows:

A. *Exchange functions:*

1. Buying (assembling)
2. Selling

B. *Physical functions:*

1. Storage
2. Transportation
3. Processing

C. *Facilitating functions:*

1. Standardization
2. Financing
3. Risk-bearing
4. Market intelligence

The ***exchange functions*** are the activities involved in the transfer of title to goods. They represent the point at which price is determined during marketing. These functions are never performed in our economy without a judgment of value, usually expressed at least partially as a price, being placed on the goods. Both the buying and selling functions have as their primary objective, the negotiation of favourable terms of exchange.

The ***buying*** *function* is largely, one of seeking out the sources of supply, assembling of products, and the activities associated with purchase. This function can be either the assembling of the raw products from the production areas or the assembling of finished products into the hands of other middlemen in order to meet the demands of the ultimate consumer.

The ***selling*** *function* includes most of the physical arrangements of display of goods. Advertising and other promotional devices to influence or create demands are also part of the selling function. The decision like proper unit of sale, the proper packages, the best marketing channel, the proper time and place to approach potential buyers can be included in the selling function.

The ***physical functions*** are those activities that involve handling, movement, and physical change of the actual commodity itself. They are involved in solving the problems of when, what, and where, in marketing process.

The *storage function* is primarily concerned with making goods available at the desired time. The owners of a product hold large quantities of raw materials until they are needed for further processing. It may be the holding of supplies of finished goods as the inventories of processor, wholesalers and retailers.

The *transportation function* is primarily concerned with making goods available at the proper place. Adequate performance of this function requires the weighing of alternatives of routes and modes of transportation as they affect transportation costs. It includes the activities involved in preparation for shipment, also.

The *processing* function is often excluded in the list of marketing functions because it is a form-changing activity. However, in the broad view of agricultural marketing this activity cannot be omitted. The processing function would include all those essential manufacturing activities that change the basic form of the product, such as converting fresh peas into canned or frozen peas, or wheat into flour and finally into bread.

The ***facilitating*** **f*****unctions*** are those that help in smooth performance of the exchange and physical functions. These activities are not directly involved in either the exchange of title or the physical handling of products. However, without them, the modern marketing system would not be possible. These functions serve as the grease that makes the wheels of the marketing machine go round.

The *standardization function* is the establishment and maintenance of uniform measurements. These may be measurements of both quality and quantity. This function simplifies buying and selling, because it makes the sale by sample and description, possible. It, therefore, is one of the activities that make possible mass selling. Effective standardization is basic to an efficient pricing process. A consumer directed system assumes that the consumer will make his wants known largely through price differentials. These differentials must then be passed back through the marketing channel so that marketing agencies and producers can know what is wanted. Well-defined units of quality and quantity of a commodity can fetch a better price. Standardization also simplifies grouping of similar lots of commodities at producing points. After their establishment, the use of standards must be policed. Such activities as quality control in processing plants and inspections to maintain the standards in the marketing channel can be considered part of this function. In addition, certain aspects of the packaging activity are a standardization procedure of units of sale as well as being part of the merchandising activity of the selling function.

The *financing function* is the advancing of money to carry out the various aspects of marketing. The capital is tied up between the time of the first sale of raw products and the sale of finished goods to the ultimate consumer. Someone must finance this holding of goods. The period may vary from 3 months for perishable and more than six months for semi perishable products. Financing may be from various lending agencies or owner's capital resources. In either instance, it is a necessary activity in modern marketing.

The *risk-bearing function* is the accepting the risk of loss in the marketing of a product. These risks are physical risks and market risks. The physical risks are those that occur from destruction or deterioration of the product itself by fire, accident, wind, earthquakes, cold, and heat. Market risks are those that occur because of the changes in value of a product as it is marketed. An unfavourable movement in prices might result in high inventory losses. A change in consumer taste might reduce the desirability of the product. A change in competitors marketing situation might result in a loss of customers. All these risks in varying degrees must be borne in the marketing of a product. Risk-bearing may take a more conventional form, such as the use of insurance companies in the case of physical risks or utilizes the future exchanges in the case of price risks. Or, as is often true, the entrepreneur himself may bear the risk without the aid of any of these specialized agencies. The function of risk-bearing is often confused with the function of finance. Their differences can be kept clear, however, if it is remembered that the need for financing arises because of the time lag between the purchase and sale of products, thus the need for risk-bearing arises because of the possibility of loss during the holding period (unlike the function of financing which is because of time lag between purchases and sales).

The *market intelligence function* involves collecting, interpreting, and disseminating the large variety of data necessary for the smooth operation of the marketing processes. Efficient marketing cannot operate in an information vacuum. An effective pricing mechanism depends on well-informed buyers and sellers. Successful decisions on how much to pay for commodities or what kind of pricing policy to use in the sale require a large amount of market knowledge. Adequate storage programs, an efficient transportation service, and an adequate standardization program, all depend to a considerable extent on good information. As with other functions, this function may be performed by those who specialize in its performance. On the other hand, everyone in the marketing process who buys and sells products, evaluates available market data and therefore tries to perform this function efficiently.

10.6 MARKETING CHANNELS

Marketing channels may be defined as alternative route of product flow from producer to consumers. Or, we may define marketing channels as the set of various agents/ firms/ individuals that take title or assist in transferring goods/services as it moves from producer to the final consumer.

The analysis of marketing channels is intended to provide a systematic knowledge of the flow of goods and services from their origin (producer) to their final destination (consumer). This knowledge is acquired by studying the "participants" in the process, i.e., those who perform physical marketing functions in order to obtain economic benefits. In carrying out these functions, marketing agents achieve both personal and social goals. They earn a (personal) financial reward by performing an activity desired by society. They add value to product and in doing so help satisfy customers' needs. The price the consumer pays for the goods (the physical commodity) and services (e.g., storage, transportation, bulk-bearing, grading) rendered, compensates the marketing agent for his efforts. This price also serves as a signal to all the actors in the marketing channel, i.e., producers, rural assemblers, transporters, wholesalers, and retailers etc.

Producers and consumers are part of all marketing channels. The number of intermediaries in between these two will indicate the length of channel. For example:

Zero level – producer → consumer

One level – producer → whole seller → consumer

Three level – producer → miller → whole seller → consumer

The following marketing channels for general food grains in India.

Some common marketing channels for wheat have been identified as follows:

a) Farmer to consumer;
b) Farmer to retailer or village trader to consumer;
c) Farmer to wholesaler to retailer to consumer;
d) Farmer to village trader to wholesaler to retailer to consumer;
e) Farmer to co-operative marketing society to retailer to consumer;
f) Farmer to a government agency (FCI, etc.) to fair price shop-owner to consumer;
g) Farmer to wholesaler to flour miller to retailer to consumer.

The channels of paddy-rice and pulses are broadly the same, except that rice millers or dal millers come into the picture before the produce reaches retailers or consumers.

10.7 THE PERFECT MARKET CONCEPT

The general nature of these market structures is familiar- perfect knowledge, no lag, large no. of firms, stadardised or homogenous products, and no exercise of monopoly powers. Actually the requirements for a perfect market are some what less restrictive. The essential conditions are:

1. Large no. of buyers and sellers are there in the market
2. Perfect knowledge by all buyers and sellers
3. Each buyer and seller acts in an economically "rational" way, disregarding any influence of his actions on price, and
4. Free entry in all directions.

Of course, all markets in real life operate with some degree of imperfect knowledge and with lags and frictions, and some have important elements of monopoly. In spite of this, the concept of the perfect market is important. Its abstraction permits us to focus attention on and to understand the general nature of many market forces. It is a fair approximation to reality in some markets and, perhaps, especially for many agricultural markets. It has some "normative" values associated with the concept of economic efficiency and so, may be useful in economic planning. Finally, it provides an essential background for understanding imperfect markets.

10.8 ROLE OF MIDDLEMAN

Middlemen are those individuals who specialize in various marketing functions involved in sale and purchase of goods as the commodity moves from producers to consumers. They may operate as individual, partner proprietors, co-operatives or non cooperative corporations. The activities and functions that most people visualize as "agricultural marketing" are those related to the movement of commodities from primary producers through to ultimate consumers. Some farm commodities move directly to ultimate consumers, but most of products require some additional sorting, grading, storing, and processing before they are ready for consumption. Transportation and handling takes place as commodities move from one stage to another in the marketing system. Storing and processing may take place at several different stages. This involves expenditure. In fact, marketing process is expensive. Nearly 40 percent of costs are the marketing costs. In case of perishables, the marketing cost is very high.

Many people in developing countries see the activities being performed by middlemen, add little value but charge heavily. It is reported in many studies that there are excessive "hands" in the marketing process, but most recognize that the marketing functions of transporting, storing, and processing, and the provision of place, time, and form utility, are essential – whoever performs them.

Often, marketers or middlemen are looked upon as parasites in the economy. They do, however perform essential functions and the system should permit equitable earnings for those performing needed services. Thus, The marketing systems provide a livelihood for people who perform the various marketing activities, and should yield reasonable returns to the capital and management skills devoted to them. Transportation and storage provide place and time utility--bringing goods to the people where and when they want it. Processing increases form utility—preserving the life of commodities like food and making them available in more convenient ways. It matters little who performs these kinds of functions—the farmer himself or his wife who sells their commodities in the market place, his cooperative association or a marketing board, the trucker or miller or baker. All have a right to expect payment for their services and some return on their investment in facilities needed to perform the services. As marketing organizations grow in size, requiring more capital and specialized management, returns on investment and payment for management skills become increasingly important in the interest of efficient market performance.

In India, various middlemen, in agricultural marketing, who perform marketing activities in between producers and consumers can be classified as

I. Agent Middlemen
   1. Brokers
   2. Commission agents

II. Merchant middlemen
   1. Wholesale traders
   2. Retailers

III. Speculative middlemen

IV. Processors and manufacturers

V. Facilitative middleman.
   1. Hamals/Labour
   2. Weighmen
   3. Transporters
   4. Graders
   5. Communication agencies
   6. Advertising agencies

Their description is as follows:

I) ***Agent Middlemen:*** These are those individuals/agencies which act as representatives of their clients like traders or producers. They earn their income through sale of their specialised services. They charge commission/ brokerage in sale or purchase activities. These are of two types namely brokers and commission agents. The difference between two is very little.

1. *Brokers:* These agents work for a commission on behalf of other participants. They operate at all levels in marketing chain. Typically, they work for a flat rate or percentage (of the selling price)/ commission. They charge brokerage from buyers/sellers or both depending on services provided by them. They bring together the sellers and buyers. They do not work in regulated markets and where the sale is through open auction method. They do not have establishments in the markets.

2. *Commission agents:* They are usually granted broad powers by those who send commodities to him. They normally take over physical handling of products, arrange for the terms of sale, deduct their fee from the sale proceeds and remit the balance to sellers/farm producer. They also advance loan to the farmers/itinerant traders on the condition that produce to be sold will be routed through them. Commission agents are of two types namely Kuchha Arhtya and Pucca Arhtya. Pucca Arhtyas normally acts on behalf of wholesalers/traders/ processors/oil millers who purchase the quantity in bulk through these commission agents. They have their shop, godown and also some times guest house of their own for the farmers in the markets, they act as 'A' class traders.

II) ***Merchant Middlemen:*** These are those individuals who purchase and sell the products on their own and bear the market risk. These are mainly of two types:

1. *Wholesalers:* These traders purchase in bulk either at their own in the market or from producers/ itinerant traders or through commission agents. They sell to the retailers/processors or dispatch to other markets also. They bear the market risk.

2. *Retailers:* Retailers are those traders who normally purchase from the wholesalers either on cash or credit. They divide up large amount of produce purchased and sell it to consumers in small units. They also bear the market risk.

   Itinerant traders/village merchants are also in this category who purchase the produce from those producers/farmers, who do not want to go to markets for various reasons, and sell produce in the nearby market on some profit. They keep them aware of daily market prices.

III)***Speculative Middlemen:*** These **are** those who speculate and take advantage of price movement in the market. Speculative middlemen seek out and specialize in taking price risks and usually do not handle and merchandise. They often attempt to earn their profits from short-run fluctuations in prices. Purchases and sales are usually made at the same level in the marketing channel. For example, a speculator merchant may buy a product/commodity today and sell it back either today or tomorrow in the same market. They may buy and sell commodities in futures several times within the same day. They are professional risk takers unlike merchant middlemen.

IV) ***Processors and Manufacturers:*** These undertake processing activities and thus add form utility in raw or semi-finished products. They many times, use their own buying agents in the producing areas. This group may undertake processing or manufacturing and then wholesaling of their finished products to retailers. Many processors attempt to reach the ultimate consumer through advertising.

The restaurant most often is a retailing establishment in that it sells to final consumers. However, some of these businesses operate as wholesalers, preparing food in large quantities and selling to other retail outlets. And of course these businesses are, because of their preparation and cooking activities, processors.

V) ***Facilitative Organizations:*** These organizations aid the various middlemen in performing their tasks. They do not directly participate in the marketing processes either as merchants, agents, processors or speculators. One group of these organizations furnishes the physical facilities for the handling of products. They also aid in grading, arranging and transmitting payment etc.

1. *Hamal/labour:* These load/ unload the products from vehicles and move them in the markets. They receive their incomes from their physical labour use.

2. *Weighmen:* The weighmen weigh the products in the market and get payment for that.

3. *Transporters:* These move commodities from production point and transport those to consuming points.

4. *Graders:* These facilitate in making the products uniform for better pricing. They charge for their labour used in grading.

5. *Communication agencies:* They help in providing information on various aspects of marketing, including price and arrival information in a market or at different markets.

10.9 MARKETING EFFICIENCY

Marketing efficiency is a degree of market performance. Marketing efficiency is the ratio of market output (satisfaction) to marketing input (cost of resources). An increase in this ratio represents an improvement in the efficiency. The reduction in the cost for same level of satisfaction or an increase in the satisfaction at a given cost results in the improvement in the efficiency. Clark, defined marketing efficiency as having following three components:

i) The effectiveness with which a marketing service is performed.

ii) The cost at which the service is performed.

iii) The effect of this cost and the method of performing the service.

10.9.1 Types of Marketing Efficiency

Traditional efficiency of the marketing system has been looked at two angles:

a) *Pricing efficiency or allocative efficiency*

The pricing efficiency is concerned with improving the operation of buying, selling, and pricing aspects of marketing process, so that it remains responsive to the consumers' directions. The best measure of the consumer satisfaction obtained, from marketing systems output, is what the consumers are willing to pay for it in the market place. If markets are operating efficiently, the prices of the different commodities are related to space, time and form. The prices should not differ among geographical regions, transportation cost and storage cost. Similarly it should not exceed more than the cost of processing. If it differs more than that, then the pricing efficiency is low.

Therefore, pricing or economic efficiency relates to functional deficiency or degree of competition or monopoly. Government needs to police the conduct to prohibit collusion or any other act that hurts the competitive performance.

b) *Operating or technical efficiency*

It indicates use of technology in providing marketing services. In contrast to pricing or economic efficiency, operational or technical efficiency assumes that the output of goods and services is given and focuses on reducing the costs of providing them. For example more efficient use of machine for sorting and grading will reduce the cost of grading. If these costs are lowered, keeping the services at the same level, bulk transport using efficient mode of transport, will reduce the operational cost. Both of above two types of efficiencies reinforce each other for better efficiency.

For example, if in market A cost of say grading is Rs 1.00 per kg and in market B cost of grading is Rs 1.20 per kg, then market A is operating efficiently in respect of grading.

10.9.2 Methods to Measure Marketing Efficiency

Both types of above efficiencies can be reflected in terms of value added and the costs. The marketing services provided will add to the value and the cost involved in providing the service. Thus we can work out the index of output to input for any of the market in order to assess the marketing efficiency. However it is very difficult to assess the services provided in value terms. In other words, it is difficult to assess the value added by an activity during the marketing. However, evaluation of cost is relatively easy.

Index of marketing,

$$E = O/I$$

Where E is the index of marketing efficiency, O is the output (value added or the services provided) and I is the input cost.

Total value added in a marketing system can be taken as the difference in the price of product paid by the consumer and the price received by the producer. If we want to compare the efficiency for two different markets located at a distance, we need to work out this index for both market and see which of the two is an efficient market. Obviously, wherever the index will be more, that market will be efficient comparatively, provided, same type of services are provided. The difference in output and also in input may be due to difference in the technology used or the market competition itself. We also need to find the imperfection in competition. In imperfect market, the prices of output are more due to undue profit charges.

A modified version of marketing efficiency (ME) as given by Shepherd is given below:

$$ME = (V-I)/I$$

Where V is Price paid by consumer, I is the input cost. In this method the difficulty in value added by marketing services is overcome. However, the formula remains the same if approximation is used for value added.

We compare the efficiency of different markets, marketing channels using this method.

10.10 MARKET MECHANISATION – CONCEPT, ROLE AND SCOPE

Mechanization of marketing operations has become popular in almost every human activity. However, the pace of mechanization in India in respect of marketing is slow. Mechanization in crop production has been spectacular especially on large farms. It has also saved farmers from the drudgery of farm operations. Mechanical market operations differ for different commodities. In view of urgency, the farmers have now become commercial minded and therefore the production has also increased. The marketable and marketed surplus of all types of crops has increased. This has created over crowding and congestion in the markets, especially those of food grains.

10.10.1 Role

Higher marketed and marketable surplus of almost all agricultural commodities including fruits and vegetables has expanded the arrivals in the markets. But Indian markets are normally congested. High arrivals have made them more congested especially when commodities do not move faster due to slow and time consuming marketing operation. Mechanisation of various marketing operations in such situation (like that in crop production) is the only answer for swift movement and clearing the markets. The role can be easily seen through followings:

1. The precision in operation by manual labour is not possible. This calls for mechanization so that more uniform goods are available to consumer. This will also facilitate other marketing operations.

2. The operations by manual labour are very costly. But the mechanical operations perform these various activities at reasonable cost. This will help the consumer more.

3. Fast transport of commodities from very far-off places is possible through rail and highways. This will also help the farmers in taking advantage of higher price in a particular market.

4. Drudgery of marketing operation drastically reduces.

10.10.2 Scope

Market mechanization in India is very slow and need special attention for providing variety of services. Today, variety of services with swiftness and that too at low cost are extremely important. All of these could be achieved, provided we go for mechanization. The mechanization for different commodities may differ. The perishable commodities like fruits and vegetables need different kind of mechanization compared to food grains.

Sorting, grading weighing, bagging, stitching and use of conveyor will be very effective in improving operations in the markets. While time saving mechanization is important in perishable commodities like fruits and vegetable etc. less costly operation are needed for non-perishable commodities which are dealt in bulk. Mechanical operations at all marketing stages including mixing of chemicals in the commodities kept in storage (if needed) will reduce the cost tremendously. Thus, there is tremendous scope for marketing mechanization which will enable the marketing functionaries to provide the marketing services with swiftness, at low cost and well in time. It will also help in decongestion of the agricultural markets to a large extent.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. a) Define a market.

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

b) What are the necessary condition for market to exist?

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

c) What is the role of markets in farm economy in India?

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

2. a) Classify the markets on the basis of location.

....

....

....

....

....

b) Write in brief the concept of perfect market.

....

....

....

....

....

3. a) What is meant by marketing channels?

....

....

....

....

....

....

b) Write various marketing channels of vegetables in nearby market in your area/ district.

....

....

10.11 LET US SUM UP

Markets are very important in smooth conduct of buying and selling operations of any goods and services. These markets play a very important role by giving, directions to the resource use. In fact, a perfect market situation maximizes the welfare of producers as well as consumers'.

Market Prices are the signals that direct and coordinate the decisions of producers, consumers and food marketing firms. These prices are the result of supply and demand forces operating within the framework of an open exchange freely competitive marketplace. There is a tendency for farm prices to return to the supply and demand equilibrium point when disturbed. Shifts in the supply and demand, results in new equilibrium prices.

Competition plays a key role in harnessing the rivalry and the profit- seeking of the marketplace in order that it may serve the public interest. The competitive state of the agricultural markets disciplines firms' conduct, behaviour and practices; encourage new technologies and products; and regulates prices and profit level.

10.12 KEY WORDS

Market	:	Market is an arena for organizing and facilitating business activities and for answering the economic questions: What to produce, how much to produce and how to distribute.
Marketing	:	Marketing is performance of all business activities involved in flow of goods and services associated with inputs and output from initial point of production to ultimate consumers.
Perfect Market	:	A market characterized with large no. of buyers and sellers all engaged in sale and purchase of homogenous products with perfect knowledge of market prices and quantities and no discrimination. Perfect competition is a market structure having above characteristics.
Marketing functions	:	These are specialized business activities necessary to the marketing process.
Marketing channels	:	Alternative routes of product flow from producer to the consumers.
Brokers	:	An agent middleman who facilitate trade but does not physically handle the produce. He is paid fee by the sellers or buyers.
Marketing efficiency	:	A ration of market output (satisfaction) to marketing inputs (cost of performing functions). An increase in this ratio represents improved efficiency, a decrease indicates decrease in efficiency.

Market Mechanization : Performing various marketing functions including loading and unloading using mechanical means is market mechanization.

10.13 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. a) Your answer should include definition of market.

   b) The conditions included are existence of commodity, buyers and sellers and medium of exchange.

   c) Your answer should indicate/explain how the market gives direction to produce more beneficial commodities, through price.

2. a) Your answer should include the explanation village, primary, secondary, terminal and sea board markets.

   b) Your answer should include the definition of perfect market and also the conditions for perfect market

3. a) Your answer to this question should include definition of marketing channels (routes through which agricultural produce passes from farmers to ultimate consumers.

   b) Explain the various marketing channels of commodity sale to consumer such as

   Farmer —> co-operatives —>wholesaler —> retailers —>- consumer

   Farmers —> consumer

   Farmers —> Commission agent & or —> wholesaler —> consumer etc.

   From your own experience you should write which of the channels in prevalent in your nearby market.

4. a) The answer to this should includes exchange function, physical function and facilitating function along with sub functions of each of these.

   b) Your answer should include the help in smooth sale and purchases (as valuation becomes easier), both farmers/intermediaries and exporters gain through this and gives income and employment.

5. a) Your answer should include operational and technical efficiencies along with examples.

   b) The answer should include formula for marketing efficiency index including revised version of marketing efficiency.

6. a) The answer should include the meaning/definition of market mechanization with some example.

   b) Under this you should explain fastness, economic, uniformity and better pricing through mechanization.

3. Jobber, David (1998) Principals and Practices of Marketing. McGraw-Hill Publishing Company, London.

4. Kohl R.L. and Joseph N. Uhl (1980) Marketing of Agricultural Products. Cillier Macmillan Publishers. London.

5. Ramaswamy, V.S. and Namakumari, S. (1999) Marketing Management Planning, Implementation and Control. MACMILLAN India Limited, Delhi.

6. Saxena, Ranjan (1997) Marketing Management. Tata McGraw Hill, New Delhi.

UNIT 11 MARKET INFORMATION SYSTEM

Structure

11.0 OBJECTIVES

After reading this unit, you should be able to:

- explain concept of market information system;
- describe importance of Marketing information system to various people engaged in marketing;
- know why information system is needed and what is the existing marketing information system in India;
- explain difference in marketing information and marketing intelligence;
- know various agencies providing marketing information in India, lacunae in marketing information system and how it can be improved; and
- describe components of marketing environment and various sub-systems of marketing information system.

11.1 INTRODUCTION

In traditional subsistence economy the farmers had little marketed and marketable surplus which they sold in the local markets only. They knew their customers first hand. They knew consumers' preference and their paying capacity etc. by being around them. Today, the consumers are wide spread in domestic and international markets with better paying capacity. This has offered a good market opportunity to the farmers. The remarkable development of roads, transport and communication have further added to the market opportunity. An agricultural commodity producer located in a corner of the country can plan the sale of his agricultural products through out the country or even globally. But for better prices he must have knowledge of potential buyers and prices in various markets. This information provides him opportunities for high sale prices and greater profit. In fact, we can say that market knowledge is the power for higher income even to the small farmer or a tiny producer. Thus, a farmer / manufacturer can harvest rich returns if he is able to take right marketing decisions, given the market information. All producers, manufacturers, and all other marketing intermediaries, include the organizations providing marketing facilities, utilise marketing information to run the business more profitability. However, Market information requirement of various groups of people engaged in marketing may vary.

Farmers, businessmen, administrators, and legislators have come to rely more and more on statistics to tell them what's happening, to show where their economic problems are, and to assist them in finding answers or serving as a guideline both for current activities and planning ahead.

11.2 CONCEPT AND DEFINITION

Marketing information system is system of collecting and analysing information related to marketing of goods and services. It consists of people, equipment, and procedures to gather, sort, analyse, evaluate, and distribute pertinent, timely and accurate information for use by marketing decision makers. A marketing information system collects the information on various related aspects of marketing environment such as marketing channels, competitors, prices, arrivals, grades, standards etc.. For international marketing it collects information on prices, quality, standard, grades and legal aspects for products sale in importing countries.

It combines this external information with his own business information including his capacity and capability (internal) to take the right decision on what, where, when and how to sell (from farmer's point of view or any other seller's/manufacturer's point of view).

Market information may be defined as a information on all marketing aspects important from selling or buying point of view. It includes all facts, estimates, opinions and other information which affect the marketing of goods and services.

Authentic market information is the life blood for profitable marketing/sales. Market information agencies judge the pulse of Market (whether price is high and sale is active or sluggish?), measure the temperature of markets (prices whether rising or fallings?), and monitor the market's pressure (whether supplies are adequate, short or in glut?). The market's history is recorded in statistical data series, and agencies offer a prognosis or estimate of the markets' future health.

Market information is a facilitating marketing function, and market intelligence is essential to a smooth and efficiently operating marketing system. Accurate and timely market information facilitates market decision, regulates the competitive market process and lubricates the marketing machinery.

All those who produce, buy and sell agricultural products are continuously amassing, revising and using market information on prices, supplies, demand, and other market conditions.

11.3 IMPORTANCE AND NEED OF MARKETING INFORMATION SYSTEM

11.3.1 Importance

After learning the definition you should be able to understand the role and need of MIS to various groups of people engaged in marketing. Information for management of commercial farming is very important from profit point of view. In fact, to manage a business very profitably is to plan and manage its future, but to plan and manage future is to manage the relevant information. Its importance for various group of people can be judged from the following:

a) *Farmer-producers:* Market information helps in improving decision-making power of the farmer. A farmer is required to decide when, where and through whom he should sell his produce and buy inputs. Price information helps him to take these decisions.

b) *Market middlemen:* Market middlemen also need market information to plan the purchase, storage and sale of particular commodity. On the basis of market information/ data, they project their estimates and take decisions about whether to sell immediately or to stock goods for some time, whether to sell into the local market or go in for import or export, whether to sell in their original form or processed form. The loss/failure of business can partly be attributed to either the non-availability of market information or its inadequate availability, analysis and interpretation of market information. Co-operative marketing societies operating as commission agents make use of market information for advising their members so that they may take decisions on when to sell their product.

   Processors make use of market information and plan their purchases so that they may run their plant continuously and profitably. They can also work out the inventory of a product that should be maintained for a particular period of time.

c) *General economy:* In fact, market information is also beneficial for whole economy. There is always need for a competitive market process for all commodities. The competitive process contributes to the operational efficiency of production and marketing. However, a perfectly competitive system is difficult to obtain; but the availability of market information contributes towards the competitive situation. In the absence of this system, different prices will prevail, leading to the profiteering by specialized agencies. The business of forward trading is based on the availability of market information.

d) *Government:* Market information is essential for the government in framing its agricultural production policies, in the regulation of markets, buffer stocking, import-export, prices, mechanization and control policies.

11.3.2 Need of Marketing Information System

During the past century three developments have taken place that necessitated need for more and better marketing information system.

a) *Markets expanded from local to national and international marketing*. The fast infrastructure development has remarkably expanded the market. The producers can take the advantage of this expanded market. When the commercial farmers expand their business or area of operation to meet demand, they need more formal system for collecting market information and analyzing it. The WTO has opened a new chapter for developing countries for export of agricultural products in global market provided developed countries do follow the code of conduct and help in establishing fair trading system.

b) *Change from buyers needs to buyer wants*. As the income of the buyers increase they become more choosy and need variety of goods. In fact, today, consumers need more diversified food basket. The increase in number of buyer also result in large opportunities. However, seller find it harder to predict buyers response to different features. Obviously more detailed information on consumers' wants can help the business enterprises.

c) *Change from price to non-price competition*. As sellers increase the use of branding, products differentiation, advertising and sales promotion, they require more information on effectiveness of these marketing tools.

Marketing information need can be assessed through the following questions:

- What type of decision you are normally required to take?
- What type of information you need to take these decisions?
- What type of information do you regularly get?
- What additional type of information you need?
- What information you want daily, weekly, monthly and annually?
- What five most important improvements can be made in the present marketing information system?
- What information do you need for export of specific product?

Both government and non government organizations are engaged in collecting and disseminating the information world wide. Better endowed Farmers/Traders/ firms collect the market information through their own resources.

A rational farmer or trader will try to maximize his profit through sale by integrating all the markets information. Market information pertaining to a set of markets helps the users in taking decision on what, where, when and how to sell. An intelligent farmer/trader monitors the movement of price as well as demand and supply of different agricultural commodities overtime and across various markets including international markets and then takes the decision to the best of his advantage under national and international macro environment. Such market information on commercial agricultural products normally consists of different products, grades, standards, factors affecting market forces, prices in different markets for different grades and the competitors of similar products. Thus, this will include information on all the micro and macro, socio-economic and political factors that affects the decision-making in agricultural trade.

The role of the marketing information system is to assess the information needs of farmers and traders, develop the needed information and distribute the information in time to the various clienteles i.e. farmers, processors, traders and consumers. The needed information can be developed through collection of information by survey, marketing intelligence activities, marketing research and marketing decision support analysis.

Different countries have developed marketing information systems with variations depending on the amount of money invested in the system. Those systems are also related to planning priorities, and the type of commodity produced. Most countries in Asia operate a marketing information service with the express aim of promoting efficient marketing and raising farm incomes. The form it takes varies according to the level of economic development, and especially the extent to which agriculture has changed from subsistence to commercial farming.

11.3.3 Need for Marketing Information In India

India has varied agro-climatic conditions which enables it to produce all kinds of agricultural crops in various parts of the country at different period of times in an year. But, the forward linkage is India is very poor and the farmers sell the produce in nearby/local markets or in the village itself. Many a times heavy supplies come to the local market which leads to low price and thus low profit while price in other/distant markets is high. This high price in other markets can be a fortune for any farmer. But the farmers not have the information on such prices. The local market traders also exploit the poor farmers through various mal practices.

National marketing information systems usually provide price information through the mass media, such as newspapers and radio. However, it is not clear how useful such information is to the farmers. It is believed that information is either not available or available in different forms.

The need for market information on agricultural products and markets is more important in agricultural economy like India where large amount is produced by crores of small and marginal farmers. Their income depends on the sale proceeds of agricultural commodities. Thus, marketing information will help Indian farmers and other market functionaries make profit oriented decisions through what, how, when and where to market produce and what price to expect under prevailing conditions. The farmers who understand market trends and market opportunities have a better chance of getting potential returns and success. As a matter of fact, marketing information plays a vital role in the functioning of the whole market system. Helping farmers in India through market information ensure that produce goes to markets where there is a demand for it. It shortens marketing channels and cuts down on transport costs. It helps ensure that each marketing transaction is a fair one, and that all participants share the risks and benefits. However, this does not happen if marketing information is distributed unequally, as is generally the case in India where large number of small size farmers sell to local traders or to the markets with few traders for various reasons especially lack of resources and market information. The farmers then end up bearing the greater part of the risk, while the dealers end up with the greater part of the profits.

Recent advances in information technology will help small farmers, large farmers or traders with the marketing information they need to make right decision. However, farmers may not benefit from sophisticated facilities, if the system is poorly managed or not designed for their needs in terms of infrastructure. It is not enough for marketing information to be collected: it must also be disseminated in a form accessible to clients and adapted in their decisions.

In many marketing information systems, regional data is transmitted to a central national facility where it is processed and amalgamated with similar data from all over the country. The result is useful to those working for central government agencies, who need to know what is happening over the whole country. It is of less value to the farmers or consumers in the rural areas. Farmers are interested mainly in prices in local markets where they sell their goods. Big traders, Associations/ houses take advantage of such national and international marketing information.

11.3.4 Central Scheme for Marketing Information in India

In India, the Directorate of Marketing and Inspection (DMI) headed by the Agricultural Marketing Advisor, Department of Agriculture & Co-operation (DAC) implements agricultural marketing policies and programmes of the Government of India. It undertakes:

- Standardisation, grading and quality control of agricultural and allied produce
- Market research and surveys
- Provides technical support in regulation, planning and designing of physical markets.
- Training of personnel in agricultural marketing in the country
- Promotion of cold storages
- Administration of Meat Food Products Order
- Marketing extension, consumer education etc.
- Market Information network.

It also liaise with the State Agricultural Marketing Boards and Directorates for Agricultural Marketing Development in the country, which have been established to ensure proper planning and development of agricultural marketing including implementation of State Marketing Legislations which define local market practices, market charges payable to various functionaries, license the functionaries and promote the development of orderly marketing. The dissemination of market information is common function of Agricultural Produce Marketing committee (APMC), which is performed through displaying of the prices prevailing in the market on the notice boards and broadcasting through All-India Radio, etc. This information is also supplied to State & Central Government from important markets. The statistics of arrival, sales & prices etc. are generally maintained by APMCs of various markets in India.

By and large the States and Union Territories are providing some market information in one form or the other for the benefits of market users like producers, traders and consumers. However, the information is collected and disseminated by use of conventional methods which cause delay in communicating the information to different target groups, adversely affecting its utility. The farmers are also not able to know about the prices prevailing in other markets. Many Market Committees still disseminate information in respect of their own markets only. The farmers are, therefore, left with no alternative but to dispose of their produce in the nearest market, even at throw away prices, because of either not available or delayed market information.

Therefore there is an urgent need to bring improvement in the present marketing information system by linking all APMCs, State marketing Board and State Directorates of Agricultural Marketing and DMI of Ministry of Agriculture. It is felt that investment on network of about 7000 Whole sale Agricultural Produce Markets in the country will facilitate globalisation of Indian farmers. In view of this importance, the Department of Agriculture and Co-operation in Ministry of Agriculture Government of India (GOI), under DMI, has sanctioned a Central Sector Scheme named as Agricultural Marketing Information Network (AGMARK-NET) at an estimated project cost of 10 crores to link at present 770 agricultural markets besides 40 Agricultural Marketing Boards/Directorates in the beginning during 2000-02. The objectives of this Scheme are:

- To establish a nation-wide information network for speedy collection and dissemination of market information for its efficient utilisation.
- To computerise data on market fee, market charges, total arrivals, arrivals by agencies, prices (variety wise / quality wise), storage, dispatches with destination, mode of transportation, costs, sold and unsold stocks, sources of supply with destination, method of sale, payment, weighment, grading facilities, quantities graded, market personnel (trained/ untrained), market functionaries, market finance, development programmes, infrastructure facilities, constitution/composition of Market Committee, income and expenditure and other activities of the Agriculture Produce Market Committees, State Marketing Boards and Departments.
- To ensure flow of regular and reliable data to producers, traders and consumers to derive maximum benefit of their sales and purchases.
- To increase the efficiency in marketing by effecting improvement in the existing market information system

11.4 TYPES OF MARKET INFORMATION

Market information is of two types:

i) *Market intelligence:* Marketing intelligence is different from regular marketing information or marketing research data. It may form part of marketing information system but it is special in the sense that it gives strategic information in a flash and is quite often related to competitors' activities. The nature of the marketing job necessitates a good intelligence system. Broadly, marketing intelligence furnishes information on changes in market conditions, changes in customers' requirement, emerging strategies of competitors and emerging opportunities in the business Marketing intelligence may be gathered by marketing executives directly or through field sales managers. Occasionally, it is also purchased from external agencies which provide marketing intelligence services. In what so whatever manner it is collected, it is essential to have a reliable and efficient system for gathering and using the intelligence. If there is too much delay in the process, the marketing intelligence loses its significance.

If it is gathered and used properly, marketing intelligence will serve as a pathfinder.

ii) *Market news:* This term refers to current information about prices, arrivals and changes in market conditions. This information tips the farmers to take decisions about when and where to sell his produce. The availability of market news in time and with speed is of utmost value. Sometimes, a person/trader who gets the first market news has a substantial advantage over his fellow-traders who receive it late. Market news quickly becomes obsolete and requires frequent up dating.

11.5 AGENCIES PROVIDING MARKET INFORMATION

The collected information has no meaning until it reaches the persons who need it. The agencies/ sources through which market information is disseminated are:

a) *Personal contacts:* This is the most important source of dissemination of market information. Information is given orally, i.e., by one businessman to another businessman, by a businessman to a farmer, or by one farmer to other farmer.

b) *Post and telephone:* Businessmen get information from other markets on the telephones. Commission agents convey the information on the prices of different commodities to their client-farmers on postcards. They fill the rates on these postcards and post them daily or some time at intervals.

c) *Newspapers:* The newspapers in English, Hindi and regional languages publish the wholesale prices of important agricultural commodities in the selected markets of the country/State. In addition, the Economic Times and the Financial Express contain a lot of information on the various aspects of marketing including prices.

d) *Magazines:* Magazines, such as the Eastern Economist, Commerce and Capital, are important weekly trade journals, which collect information on trade.

e) *Government agencies' reports:* The regulated markets, the Agriculture Marketing Department in the States, the Directorates of Economics and Statistics in the States, the Directorate of Marketing and Inspection, Government of India, and the Directorate of Economics and statistics, Ministry of Food and Agriculture, Government of India are some of the government agencies which disseminate the collected market information through their regular publications and broadcasts on All India Radio.

f) *Price bulletins:* These are issued daily, weekly, or every month. The important bulletins through which price information is disseminated are: Bulletin of Agricultural Prices (Weekly), Agricultural Situation in India (Monthly), Agricultural Prices in India (Annual), and Bulletin on Food Statistics (Annual). The monthly situation and outlook ports are published by the Directorate of Marketing and Inspection, Government of India.

g) *Radio and television:* The information on the market situation in respect of prices and arrivals of commodities in major markets are regularly telecasted. Almost all channels now have the slot for market information. Several State Governments and National Information Centres of the

Government of India have initiated interlinking the markets with NIC-NET with view to ensure the quick flow and accessibility of market information on prices and arrivals. The information on this is also available on internet.

h) *Through internet:* Internet has become a main source of market information. All the world major markets' grade-wise prices and arrivals of various commodities on different days are available. Even the origin wise and variety-wise information is also available through internet. Directorate of Marketing and Information (DMI) has been pioneering in this aspect.

i) Krishi channel: Recently a new Television Channel dedicated to agriculture has been proposed. The channel will cover production and marketing including international trade issues. The farmers have high hopes from it. This will also extend the marketing information in future.

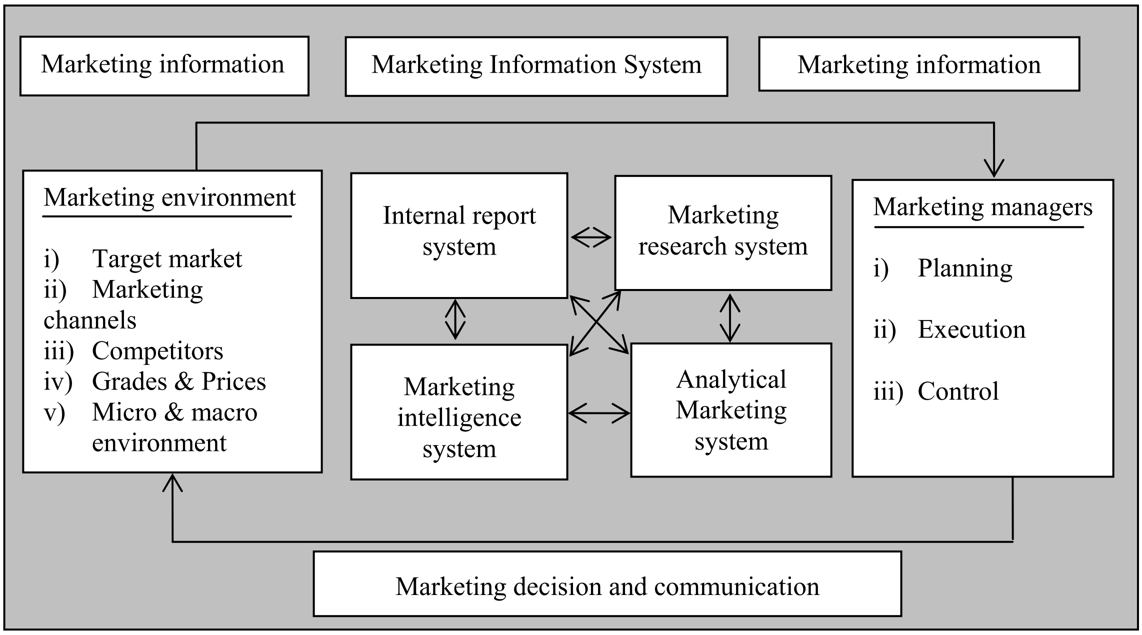
j) Kisan call centres: Kisan Call Centres will be spread throughout the country in various states/zones. These will have direct link with experts on various agricultural aspects including agricultural marketing, in State Agricultural Universities/ Research Institutes or a panel of experts at these centres only. Any farmer can seek information/ ask any question related to agriculture at any time by dialling 1551, a toll free number. The solution to his problem will be suggested on line or with in 24 hrs depending upon question and experts availability.

11.6 COMPONENTS OF MARKETING INFORMATION SYSTEM

Instead of a plethora of unrelated data on market information one needs pin pointed information which farmers/traders/firms combines various inputs with internal information and presents integrated report for him. Thus every farmer or trader must organize a rich flow of information or they must search for relevant information. Conceptually in a competitive world they must study the information need and design marketing information system to meet its demand. The various components of marketing environment are

- Target market
- Marketing channels
- Competitors
- Publics
- Microenvironment forces and
- Macro environment forces.

They must collect and monitor marketing environment and market trend information and analyze through four subsystems making up the Marketing Information System. These subsystems are presented in the following diagram.



Let us take a closer look at above four subsystems.

i) *Internal report system:* Every farm/firm manager produce internal report showing their current production, sales, cost, inventory, profit and capabilities. They plan the information need and design to collect it.

ii) *Market intelligence system:* This system provides the farm/firm/coy with happenings data in the commercial environment. The farm manager get the information through reading newspaper, reports, internet, telephone/ mobiles, telegraph, suppliers, distributors, specialist, panel of experts, even purchase the intelligent from outside, or keep their own staff to get information. Farmers normally need the information of standard/grades, prices, transport, channels, strategies, legal system, institutions and competitiveness.

iii) *Marketing research system:* It is the systematic design, collection, analysis and reporting of data and finding relevant information specific to situation facing the firm. The managers either get the data analyzed or study the specific situation himself. They measure market potential based on various marketing components and analyze it to take decision.

iv) *Analytical marketing system:* It consists of advanced techniques for analyzing marketing data and problems. The data is available in the farm records/firms data bank. Farm/firm manager try to find out major variables (and their significance) which affect the sales potential. They thus find the potential markets and the segment of the markets through analytical system. Then they plan for marketing of produce. They choose the mode of transport, distributor and channels.

Based on analysis of market information they can plan and execute the plan, monitor and keep control over the business.

11.6.1 Steps Involved in Designing MIS

- Identifying the broad information requirement of the organization.
- Classifying the information requirement and identifying whether it is for planning purposes or control purpose.

- Evaluating the cost of collecting and processing the information.
- Comparing the cost verses benefits.
- Decoding the frequency and timing of collection of information.
- Identifying the sources of information.
- Designing the mechanism/procedure for gathering, processing, storing and retrieval of information.
- Analyzing and interpreting the information and disseminating it to the right persons at the right time and in the right manner.
- Monitoring, maintaining, reviewing and improving the system.

11.6.2 Marketing Information Benefits

Various benefits that flow from marketing information are listed below:

- It helps marketing planning by making available reliable information on the external environment and the internal realities of the company.
- It helps effective tapping of marketing opportunities and provides effective defence against emerging marketing threats.
- It helps early spotting of changing trends; it provides market intelligence to the firm.
- It facilitates the development of action programmes for achieving goals.
- It helps the farmer/trader adjust their products and services to the needs and tastes of customers.
- It helps the farmer/trader control their marketing activities.

The quality of marketing decisions are decided to a great extent by the quality of marketing information available to the decision maker.

11.6.3 Criteria for Evaluating Market Information

For maximum benefits, the market information must meet a number of criteria. Some of those are described below:

1. *Comprehensive information:* The information must cover all agricultural commodities and markets including international markets. A reasonable and comprehensive information includes prices, price trends, production, supply movements, stocks, and demand conditions at each level of the market for a product. Providing such a mass of information, especially under the constantly changing conditions is a formidable and expensive task.

2. *Accuracy and trustworthiness:* Information must be accurate and trustworthy. However by nature, market information can never be 100 per cent accurate, but it must be an honest market appraisal in order to earn the trust of information users. Constant efforts are made to improve the accuracy of market information and news services.

3. *Usability:* Information also must be relevant and in usable form. It is not enough to simply collect a number of reports. Information must be collected, packaged, and disseminated with the user's interests in mind.

Much market information goes unused because it is not in usable form. In such case the efforts made in collecting the information go waste.

4. *Confidentiality:* The information should be confidential to whom it is collected. The information revealed under this situation of confidentiality will be more correct and may assist in drawing policy implications. The names of firms, to whom the market information is collected, should not be leaked out.

5. *Timeliness:* Market information must be timely, in the sense of being relevant to current decisions, and must be speedily transmitted to users. Much market information is unusable. Futures market traders require minute-to-minute market information.

6. *Accessibility:* Each interested party like farmers, consumers, government officials and marketing agencies should have equal access to all the information relevant to the bargaining and marketing processes.

7. *Relevance and clarity:* Market information must be relevant and clear.

8. *Objectivity:* It should convey objective message.

9. *Strategic value:* It should be conceived and used as a marketing decision support system.

10. *Economic:* It must be economical. In other words it should be cost effective

11.7 LACUNAE IN MARKET INFORMATION

Although sellers need pin pointed marketing information. However, such information is normally highly subjective. The major lacunae in existing market information are as follow:

- Lack of information of the right kind. Sometimes right kind of information is not available and is very difficult to under stand by the illiterate farmers in India. The market reports are also incomplete and bulky many times and do not serve any purpose.
- The available information are not in desired form. Most of the information pertains to wholesale marketing. One also needs information of prices at retail level or quality or pack size.
- Lack in timely dissemination of market information. Most of the time, the news reported is so late that it is of no use. Inadequacies of information especially on phyto-sanitary aspects under changing global scenario prevents wider access to international market by Indian Exporters.
- Reliability of the information is very poor. The biasly collected and disseminated information further adds to woe.

11.8 HOW MARKETING INFORMATION CAN BE IMPROVED

Following are some of the suggestions for improvement in the existing market information system, so that the marketing system for agricultural commodities becomes orderly, efficient and effective in helping the agencies involved in marketing:

- Uniform units should be quoted. A standardized system of quoting the prices of the different varieties, grades and weight of the commodity should be followed instead of many time quoted in the local units, so that the prices may be compared over time and space.

- The prices announced on FM/AM/ local AIR should cover more local markets rather than important secondary and terminal markets located in far off areas. The frequency of, and time allotted for the announcement should be increased so that the farmers may benefit from the information. The broadcast time should be such that the farmers can listen to the announcement and take decisions about consignment of the produce to the market.

- Prices should be displayed on notice boards at important public places like hospitals, schools, panchayat ghars, etc.

- The staff posted for the collection of market news should be knowledgeable and trained. There must be thorough and frequent check to ensure that guess work, manipulation and bias are excluded.

- Market news should have no place for rumours: Rumours are harmful for the cultivators.

- Market news provided should be as fresh as possible so that it may create confidence and trust among the users.

- A correct and intelligent interpretation of market information should be made and announced. This is very important, for farmers may not be able to interpret correctly.

- There must be proper-coordination between market intelligence and policy making departments so that the later may better understand the problem and can make such adjustments in the information as may be called for.

- In many markets, a price range is reported instead of a single price. This is so because of the variation in quality and the large number of transactions taking place in the market. The range is very wide, and may not serve the purpose of the users. Therefore, the price range should not be very wide or ambiguous.

- The users of market information should be trained from time to time as the development takes place. This will help them to take the best advantage of market information.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. a) Define a market information system.

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

b) Explain its role in increasing the income of the farmers and exporters.

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

11.9 LET US SUM UP

Marketing information is extremely important in commercial agriculture. Its importance has further increased as a result of opening of WTO chapter in the history. The farmers/ Traders in India increase income and employment by strategic planning for domestic marketing. Their income will increase through external trade especially in commodities in which it has comparative advantage. Small farmers can take a collective venture for their benefit through the group action or through co-operatives. Thus, marketing information is a powerful tool for enhancing the income of producers, processor, traders or any other firm.

11.10 KEY WORDS

Market information (MI)	:	is the information/data on various marketing aspects that is necessary for taking decision for profitable selling of the products.
Marketing information system (MIS)	:	Marketing information system is system of collecting and analysing information related to marketing of goods and services.
Directorate of marketing and inspection (DMI)	:	An organisation of Government of India under ministry of agriculture that looks after various aspects of agricultural marketing.
APMC (Agricultural produce marketing committees)	:	It is committee that looks after functioning and facilities in the defined marketing area (normally a whole sale market area).
Agmarknet	:	It is a market information network which has linked large no. of agricultural markets in India.
Market intelligence	:	Marketing intelligence furnishes information on changes in market conditions, changes in customers' requirement, emerging strategies of competitors and emerging opportunities in the business that helps in furtherance of seller's objective.
KCC (Krishi call centres)	:	These are specially created centres which provide information on calling them.
Components of MIS	:	Components are the sub-systems of MIS which collect and analyse the market information that helps in sellers decisions to plan, execute and control.
Lacunae of MIS	:	Shortcomings of MIS.
Price bulletins	:	These are special publications giving information on prices of various commodities prevailing in various markets.
Micro environment	:	Marketing environment relates to individual market/commodity such as existing traders, practices, standards, grades, rules and regulation etc.
Macro environment	:	Macro environment will include legal aspects, phyto-sanitary aspects, grades, preference and practices in a state markets /country markets.

11.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. a) Your answer should include MIS definition.

   b) Your answer should include how Marketing Information is able to increase income of the farmers (both for domestic and international marketing) as well as exporters by taking right decision based on objective judgement.

2. a) Your answer should include news paper, telephone, posts, magazines, bulletins, display boards, internet as agencies/sources of marketing information.

   b) Answer to question of best agency/sources will be based on your own judgement but you should explain why the agency or source suggested by you is best.

3. a) Answer to this question should include; what information is required, what sources of information are available, mechanism to collect, analyse, process and interpret collected information, sources-wise costs comparison, evaluation of adopted MIS.

   b) While answering benefits of MIS you should explain how it helps in planning, tapping opportunities, meeting trend of preferences of consumers, catching to needs for goods and services controlling of marketing activities and increasing the income of farmers/ intermediaries and the welfare of the consumers.

4. a) Your answer should include the points; inadequacy of information, lack of right information, unavailability of information in desired form, authenticity of marketing information.

   b) Your answer should includes suggestion on uniformity in quoting and displaying prices, quality, grade and variety wise prices in local markets, recruiting knowledgeable staff, reliability of information and proper co-ordination.

5. a) Components of marketing environment will include target market, marketing channels, competitors, grades & prices and other micro and macro environment.

   b) Your answer should include internal reporting system, marketing research system, marketing intelligence system and analytical marketing system including their functions.

6. a) Your answer should include usefulness of MIS to various marketing functionaries including farmers and exporters.

b) Your answer should include evaluation in terms of fulfilment of required information, timeliness, relevance, clarity, accuracy, trustworthiness, strategic value and cost effectiveness.

3. Laudon Kenneth, C. and Jane Price, Laudon (1996) Management Information System. Prentice Hall Publication. N.J., USA.
4. Parsad, Jagdish and Prasad, Arvind (1995) Indian Agricultural Marketing: Emerging Trend and Prospects: Mitall Publication, New Delhi.
5. Ramaswamy, V.S. and Namakumari, S. (1999) Marketing Management Planning, Implementation and Control. MACMILLAN India Limited, Delhi.
6. Saxena, Ranjan (1997) Marketing Management. Tata McGraw Hill Publication. New Delhi.

UNIT 12 MINIMAL PROCESSING

Structure

12.0 OBJECTIVES

After reading this unit, you should be able to understand:

- consumer and market trends in the market that have favoured minimal processing, its advantages;
- key requirements of minimal processing; and
- quality maintenance in Minimal processing.

12.1 INTRODUCTION

The present day food processing industry is moving with a fast pace. The food market today is more competitive, consumer driven and technologically advanced. Compared with the market place of 25 years ago, it has more processed fruit and vegetable products and more innovative packaging. New development in scientific research, consumer demands, taste preferences and technological advances in food processing are some important factors affecting the food industry and new product development**.** Progress in scientific research and food biotechnology also has played a tremendous impact. The present day consumer is more health and quality conscious and more averse to traditional chemical preservatives. The way he perceives the food is also changing. This has had a dramatic impact on food processing technologies. Food processors are exploring new processing and preservation technologies to suit the changing needs of consumers. This has left processors with less flexibility in choosing preservatives and preservation methods. Newer methods of processing and packaging material are being tried to suit to the changing needs of consumers. Minimal processing is one such technology that has arisen because of the changing needs and need for fresh and quality products. Minimal processing (MP) in layman's language are precut fruits and vegetables which are packed in suitable packaging material that permits suitable shelf-life and fresh like characters. Before we see what is minimal processing, let us see its background and examine some factors that have changed the consumers and in turn the food industry.

Background of minimal processing

Need for minimal processing in the present day can be traced back to factors like changed life styles, demographic patterns and more working women and more income. Let us se them in detail.

Changing life styles and demographic patterns

The present day families are nuclear and more fragmented compared to then the families of earlier days. The joint family system has broken apart and nowadays more nuclear families are seen. Smaller families have different needs then joint families. The concept of unitized packaging instead of bulk packaging has arisen due to this change in family structure. This is in turn putting more demands on food processing industry. Smaller families can easily opt for ready to meals then joint or big families. Have you observed that the demand for bakery segment foods has been rising because consumers are asking for more take away meals and snacks rather than traditionally home-cooked set meals. Pizzas, burgers, patties and other confectionary items have put bakeries as major business sectors. These items are becoming increasingly popular among youngsters and college going students.

Apart from this there are changes in life styles and populations too. There are more working women in cities. They have less time for kitchen. Thus more demand for convenient food items. Also we have more older people in population. This group has different food requirements then the younger population.

More working women and more incomes

Since both men and women are working and there are dual incomes in the families. This is probably the reason for more eating out habits seen nowadays. This has also made the present consumer more adventurous who likes to try more different types of product. Consumer in metropolitan cities has developed taste for Chinese, Mexican, Italian, apart from our traditional south Indian and Gujrati foods. The present day scenario was very different from market place twenty years ago.

Need for convenience and quality

Convenience and Quality are the buzz words in the market place. You will ask me what is 'Convenience', and how does it relate to processing of food. Observe some common examples around you. Pizzas, burgers, patties are some examples of convenient bakery take away foods in the market. They are convenient because you don't have to cook them simply buy them and eat them. Lets see more examples from fruits and vegetables. Have you observed that your subjiwala who sells green leafy vegetables such as palak, mustard and fenugreek now also keeps a small machine to cut them? Earlier this was never seen. Our mothers and grandmothers would spent hours together in cleaning and cutting such leafy vegetables. He now delivers convenience to you by cutting the leafy vegetables at this end. In cities, majority of women are working. She has less time for food preparation, and thus prefer to have precut vegetables. Why only working women even housewives like to have precut vegetables since it saves time and labour. Let us observe some more examples. Have you observed peeled and sliced pineapple rings and fleshy axils of pomegranate being sold in the busy market place? They are the most appropriate examples of convenience. You would often such things around busy office complexes. It is easier to eat an apple fruit than a pineapple which needs to be peeled, cored and sliced. What if the fruit is sold in form of sliced rings. It becomes more convenient to eat. Similar is the case with pomegranate, which needs to be peeled and fleshy arils, be removed from white placental tissue. Such convenience has become essential because of busy part and parcel of the urban lifestyle. Precut fruits and vegetables fulfil convenience and provides fresh like characters. With this background in mind, it will be easy for you to understand what minimal processing is. Now let us come to our main topic minimal processing.

Consumer and market trends

1. More health conscious
2. More working women in cities, less kitchen time, more eating out habits
3. More ageing and diverse population
4. Low fat, sodium and reduced calorie requirement
5. High requirement of Vitamin/mineral fortified food

Industry response to consumer trends

1. Increase in products with low fat and calories e.g. low fat butter, cheese spreads
2. Increase in availability of low calorie sweetner (asparatame, acesulfame) and diet colas
3. Introduction of foods with added health benefits (margarines, sport bar, fortified drinks) Choices in many categories such as dairy salad dress, frozen meals, snacks)
4. Increased availability of convenient foods breakfast bar, meal kits and ready to eat to meals, yoghurt cups, sprouted cereals and pulses, drinkable soup and frozen dinners.
5. Exploring newer methods of processing e.g. microwave and aseptic processing

Let us group these changes and see their consequences in a graphic form

Changes		Consequences
	→ Convenience →	More snacking, portability food service, relaxation foods, less cooking skill
More obesity, older consumers, health awareness (food/fitlink), safety concerns, alternative health solutions	→ Health →	More functional foods, natural/organic less junk foods
More older consumers, balanced health approach income polarization, change in leisure time	→ Indulgence →	More large portion sizes snacks, sweetness in flavouring, premium brands
More travel, immigration, media fragmentation, segment fragmentation, sophisticated consumers	→ Novelty →	More brand switching, fun foods, ethnic and brand foods

12.2 ADVANTAGES OF MINIMAL PROCESSING (MP)

In scientific language, MP is defined as these procedures such as washing, sorting, trimming, peeling, slicing or chopping that does not affect the freshness of the product. The result of such operations is a convenient fresh product that can be prepared and consumed in less time. Minimal processing is also called Light Processing. It may be defined in another form. Any fruit or vegetable or combination thereof that has been physically altered from its original form but remain in a fresh state. Since it includes pre-processing unit operations such as cutting, slicing and dicing, it is also called as 'Light Processing'.

Why has there been demand for such type of processing? What are its advantages over the other methods:

1. Consumers are increasingly demanding convenient, ready to use and ready to eat fruit and vegetables with a fresh like quality and containing only natural ingredients. They can easily go for meal preparation.

2. Delivers fresh like characteristics. Peeled, cut/shredded fruits and vegetables if delivered in time, offer fresh like characters.

3. Not only general consumers, the catering industry also wants to purchase fruits and vegetables that are sliced, grated or shredded. This is primarily for the reasons of expense, labour and hygiene.

4. Pre-packaging allows for more efficient portion control.

5. Solid waste disposal problems are reduced.

6. Demand on limited refrigerated storage spaces are reduced.

7. Supply of a variety of ready-to-eat items that exhibit excellent uniformity of quality and identity is available over many weeks.

Minimal processing is different from conventional processing

Conventional processing is different from minimal processing. While conventional food processing methods extend shelf-life of fruits and vegetables, minimal processing renders products highly perishable, requiring chilled storage to ensure a reasonable shelf-life. Preparation steps such as cutting, peeling renders them susceptible to wilting and desiccation. In conventional processing such as canning and freezing, many of these problems are prevented or controlled by heat inactivation or freezing or use of protective packaging materials or through application of food additives. Several chemicals are used for this purpose. Another important point of difference is that since no heat is applied to maintain fresh like characters, use of preservatives becomes mandatory here.

12.3 PERISHABILITY OF MP

MP produce are highly perishable. They deteriorate fast because of physiological ageing, bio-chemical changes and microbial spoilage, which may result in the degradation of the colour, texture and flavour of the produce. Major deterioration factors are enzymes, ethylene and increased respiratory activity.

Enzymes

During peeling and grating operations, many cells are ruptured and intracellular products such as oxidizing enzymes are liberated. These enzymes are responsible for deterioration. The most important enzyme with regard to MP is polyphenol oxidase (PPO), which causes browning. Enzymatic browning requires presence of different components: oxygen, an oxidizing enzyme and a suitable substrate. To prevent browning, at-least one of these components must be removed from the system. Another important enzyme is lipo-oxidase which causes the formation of numerous bad smelling aldehydes and ketones.

Ethylene Production

Ethylene is a gas which is produced when fruits and vegetables respire. This gas is also called as the ripening harmone, and plays an important role in ripening of fruits. Cutting and peeling both release ethylene. It may be partially responsible for bringing about physiological changes in sliced fruit, such as softening.

Increase in respiration activity

Depending upon the produce and cutting grade and temperature, respiration activity of minimally processed increases 1.2-7.0 fold or even more. Increased respiration leads to anaerobic conditions and increased rate of spoilage.

12.4 FACTORS AFFECTING QUALITY

The main factors affecting the quality of minimally processed produce are harvesting operations, raw material, preparation procedures (trimming, cutting, peeling, shredding, processing conditions and Good manufacturing practices) In fact you can also study them under major unit operations of minimally processed produce.

Harvesting

Harvesting is a fundamental unit operation required for the production of minimally processed produce. Most of the raw material for fresh cut produce is cultivated under contracts that specify the cultivars and cultivation techniques in western countries (including sowing time, pesticide, fertilizer applications, and harvest conditions). Following points should also be borne in mind with regard to harvesting.

- Harvesting should be done preferably in the morning hours because of the cooler temperature.
- Pre-cooling to 1^{o}C, as soon as possible to extend potential shelf-life.
- Processing within 2 days of harvesting.

Raw material

Not all types of vegetables may be suitable for MP. Say, for example, onions, carrots and cabbage may be highly suitable for MP. Vegetables that can be washed and peeled easily are more suitable. Vegetables like tomato, calocasia and okra may not be best suited. Again, it is important to understand that not all varieties of a particular vegetable may be used for preparation. The correct choice of variety is particularly important in case of carrot, potato and onions. For example, carrot varieties that give the most juicy grated product cannot be used in the production of grated products that need to have a shelf-life of several day. Poor colour, flavour and microorganisms can create become problems if the selection of the variety is not proper. Main criteria in assessing suitability of cultivars to minimal processing are:

1. Processing yield (30-50%).
2. Low sensitivity to physiological disorders and microbial diseases.
3. Mechanical resistance to damage
4. Resistance to elevated carbon dioxide and/or low oxygen.
5. High sugar content because sugar may be responsible for energy stress.
6. Low respiration rate

Trimming

Trimming is an important unit operation sought after in vegetables especially in salad mixes. All unwanted parts of plants including outer green leaves are removed manually. This can be done using stainless steel knives, or ceramic blades. Cutting or bruising plant tissues with browning capability results in a brown discoloration. Using very sharp blades and chill storage can reduce browning.

Peeling, cutting and shredding

Some vegetables or fruits such as potatoes, carrots or apple require peeling. Peeling should be as gentle as possible. There are several methods of peeling, for example, hand peeling, steam, or lye peeling or industrial peeling using rotating carborundum drums. The ideal method is hand peeling using sharp knife. Peeling increases the respiration rate. Cutting and shredding must be performed with knives or blades that are as sharp as possible, these being made from stainless steel. Sharp blades are always better than blunt and dull blades. Blunt blades and knives impair the retention of quality because these rupture cells and release tissue fluid to a great extent. Mats and blades that are used in slicing operations can be disinfected with 1% hypochlorite solution. Cutting of vegetables should be preferably done under water. Because the internal liquid of injured cell is removed by water flow, browning is markedly compared to any commercial cutting technique.

Cleaning/washing/drying

Fruits and vegetables, after harvesting are covered with soil, mud or sand, they should be carefully cleaned before processing. Usually, a second washing is performed after peeling and/or cutting. For example, cabbage must be washed after shredding, however, carrot must be washed before grating. Washing after peeling and/or cutting removes microorganisms and tissue fluids, thus, reducing microbial growth and enzymatic oxidation during subsequent storage. Washing is done in ice-cold water (< 5^{o}C). Washing the produce in flowing or air-bubbling water is preferable to simplify dipping it in water. Both the microbiological and the sensory qualities of washing water must be good and its temperature is low, preferably < 5^{o}C. The recommended quantity of water that should be used is 5-10 l/kg of product before peeling and/or cutting and 3 l/kg after peeling and/or cutting. Preservatives can be used in the washing water to reduce microbial numbers and retard enzymatic activity, thereby improving both the shelf-life and sensory quality of the product. Chlorine is the most common preservative that is used in MP. Chlorine or citric acid (100-200 mg/l) is effective in the washing water before or after peeling to extend shelf-life. The effectiveness of chlorine can be enhanced by using a low pH, high temperature, pure water and correct contact time. The optimum chlorine concentration is 100 mg/l at a contact time of 12-13 seconds. Use of chlorine is banned in some European countries such as Belgium, Germany and Holland. The last step of washing operation is rinsing with tap water containing less than 0.5 ppm active chlorine. This step is used when chlorine is used at a concentration of higher than 1 ppm. Careful washing with water containing 100 mg chlorine/litre and subsequent rinsing improved the sensory shelf-life of minimally processed vegetables by several days, up to 7-8 days. Excessive free water on leaf surface leads to rapid bacterial spoilage.

Draining

Washing water should be gently removed from the product. Centrifugation seems to be the best method. It is important to choose the centrifugation time and rate carefully.

Dipping in anti-browning agents: Browning inhibition

Browning is the main quality problem in pre-peeled or cut fruits and vegetables. What happens to the apple slices and peeled potato, if you leave them open in air. You will find that after sometimes, the outer tissues start getting brown. This browning is basically a type of enzymatic browning, caused due to action of enzyme known as polyphenol oxidase (PPO). Oxidation of phenols in the presence of PPO causes these tissues to brown. Dipping the tissues in water or in salt water can reduce browning to some extent but cannot totally eliminate browning. The traditional preservative used to prevent browning are sulphites. Potassium metabisulphite is the most common preservative that has been used to control browning, however, its uses has some disadvantages. Recently, there have been reports regarding their harmful side effects for people with asthma. It is for this reason the US Food and Drug Administration (FDA) has partly restricted the use of sulphites in 1990, and since then there is increasing interest in substitutes for sulphites. In India, however, they continued to be used. Citric acid (CA) combined with ascorbic acid (AA) alone or in combination with potassium sorbate in case of potato, or Hexyl-resorcinol in the case of apple, seem to be promising alternatives for sulphites, particularly when hand peeling is used. Potatoes when heated for 5-20 min in a solution containing 1% ascorbic acid and 2% citric acid at 45-55^oC, cooled and then dipped for 5 min in a browning inhibitor solution containing 4% ascorbic acid. The combined treatment inhibits potato discolouration for 14 days at 4^oC, compared with 3-6 days with the browning inhibitor treatment alone.

12.5 PACKAGING AND STORAGE OF MINIMAL PROCESSED FRUITS AND VEGETABLES

12.5.1 Modified-Atmosphere Packaging and Edible Coatings

Packaging and storage is the last operation in the production of minimally processed fruits and vegetables. The most appropriate packaging method for precut raw fruit and vegetable is modified-atmosphere packaging (MAP). The basic principle in MAP is to create a modified atmosphere either passively or by using permeable packaging materials and by using a specified gas mixture with permeable packaging. The main purpose is to create an optimal gas balance inside the package, where the respiration activity of a product is as low as possible, but the levels of oxygen and carbon dioxide are not detrimental to the product. In general, the aim is to have a gas composition of 2-5% CO_2, 2-5% O_2 and the rest nitrogen. However, Optimal O_2-CO_2 atmosphere cannot be maintained by use of most of the films, especially when the produce has a very high level of respiration. One solution to this problem is to make microholes of a defined size and defined number in the matter to avoid anaerobiosis.

MAP is being used commercially for minimally processed lettuce, carrots and cabbage although current design is not sufficient to prevent the onset of fermentation under normal marketing conditions. In these cases, fermentation alters the flavour and quality of the product. This approach will not work for products such as broccoli that produce offensive off-flavour.

Packaging films such as combinations of ethylene vinyl acetate with oriented polypropylene and low density polyethylene have proved useful as these combinations have significantly high gas permeability. The shelf-life of shredded cabbage and grated carrots packed in these composites is 7-8 days at 5^oC. This is 2 days higher than oriented polypropylene which is generally used in the vegetable industry.

Edible coatings are another possible packaging method for extending the post-harvest storage life of minimally processed foods. Use of edible coatings is made from lipid resins, polysaccharides and proteins. In addition, plasticizers such as polyhydrin, alcohol, waxes and oils are added to improve flexibility and elongation of polymeric substances. Can you cite an example of edible coatings in your daily routine? The medicine capsules that you take when you fall sick, is a good example of an edible coating. Coatings serve dual functions. They serve as carrier of antimicrobial agents and retard loss of desirable flavour, volatiles and water vapour and restricts exchange of CO_2 and O_2 creating a modified atmosphere.

The packing room must be clean and refrigerated at 1-2^oC and must be separated from the washing section. Most of MP are packed in bags of polypropylene (25-40 um thick). Oriented polypropylene (OPP) is preferred to polyethylene mostly for its brightness, crispness and suitability for machine packing. The permanence of this film is suitable for packaging fresh cut endive and lettuce provided that distribution temperature does not exceed 10^oC. This film generates a modified atmosphere within bag that prevents necrosis of salad leaves. Salads (including lettuce), that are highly sensitive to oxidation are flushed with nitrogen so that residual oxygen within package range from 1-3%.

Temperature management after packaging is very essential, for minimizing the damaging effects of mechanical injury. Low temperature storage reduces metabolic reactions. It has a tremendous effect on respiration rates, and affects permeability of gases through packaging films and also slows down microbial growth. To ensure high quality products it is recommended that fresh cut products be kept at temperatures just above freezing. Usually 4-6^oC temperature is recommended for storage of fresh precut produce.

12.5.2 Some General Processing Conditions, GMP's and Key Requirements of MP

Have you noticed that there was no mention of heating step in MP. It is for this reason that they must be handled and stored at refrigerated temperature at < 5°C to achieve a sufficient shelf-life and ensure microbiological safety. Shelf-life of minimally processed fruits and vegetables strictly depends upon maintenance of low temperature during storage. However, there are certain microorganisms which can also grow under low temperature conditions. Can you name any of such microorganisms? Pathogens such as *Listeria, Monocytogenes, Yersinia enterocolilica* and *Salmonella* can survive and even proliferate at low temperature. Such microorganisms are known as Psychrotrophic. So maintenance of hygienic conditions throughout the processing chain is the crux of MP. This becomes all the more important since no thermal heat processing is used. Following hygienic codes of practices or GMPs (Good manufacturing practices) are key requirements for MP and the best way to eliminate or keep away microorganisms.Lets see some points

The key requirements in the minimal processing of fruit and vegetables.

- Good quality raw materials (correct variety, correct cultivation, harvesting and storage conditions.
- Strict hygiene and good manufacturing practices, use of hazard analysis and critical control point principles.
- Low temperatures during processing.
- Careful cleaning and/or washing before and after peeling.
- Good quality water (sensory, microbiology, pH) for washing.
- Use of mild additives in washing water for disinfect ion for the prevention of browning.
- Gentle spin drying following washing.
- Gentle peeling.
- Gentle cutting, slicing and/or shredding.
- Correct packaging materials and packaging methods.
- Correct temperature and humidity during distribution and retailing.

We have seen that MP are extremely perishable. In order to extend their shelf-life we should follow certain guidelines which are aimed at reducing biological, physical and chemical hazards. Guidelines propose conditions under which raw materials are grown as well as processing and distribution guidelines. Let us see some of these guidelines.

Forward only movement

Generally raw material is considered to be unclean product. I think by this time you know why is this so? Raw material is unclean because it may be loaded with surface microorganisms which if not cleaned can cause contamination. Keeping this in mind, raw material should be separated from the clean finished product. This requires that there should be no crossing over in the processing line between the raw material and clean products.

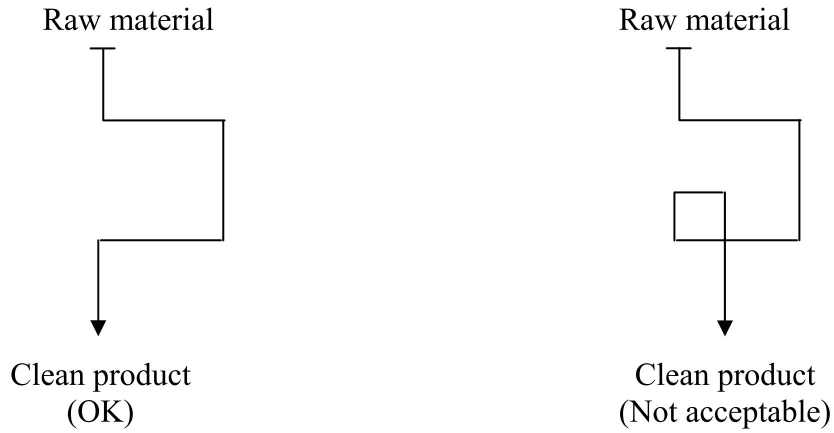

Figure 12.1: Principle of forward-only movement

Separation of the trimming room, washing room and the packing room

In order to prevent cross contamination, the different processing rooms must be delimited by walls in order to progressively increase cleanliness from the trimming room to the packaging section

Trimming room →	Washing disinfecting rinsing →	Packaging

Figure 12.2: Segmentation of processing line

Temperature control

Fresh-packed products must be immediately stored at 4°C and maintained at 0-4°C until delivered to consumers.

Air flow	→	→	Positive Pressure	
	12°C	WASHING	4°C	
Raw material	Trimming pre-washing		Packing	Carton expedition

Figure 12.3: Temperature gradient and air flow in the processing unit

The following are therefore recommended:

1. Limit exposure to temperatures above 10°C

2. Refrigerate the product at 0-2^{o}C before packing in order to be at the right temperature during the operation.
3. Maintain this temperature during storage.

The temperature gradient and flow of products run counter-currently. Temperature in the trimming and disinfecting rooms must not exceed 12^{o}C and must not exceed 4^{o}C in the packing room and ware house.

Air Flow

Ventilation systems are designed to maintain the required temperature and prevent both condensation and circulation of dust. The air current must flow from the packing to the trimming room.

Wastes

Waste materials are evacuated from the facility to avoid any cross-contamination (Figure 12.4). The equipment and machinery used for non-edible material and waste must be clearly identified and never used for edible product. Moreover, they should be easy to wash and sanitized.

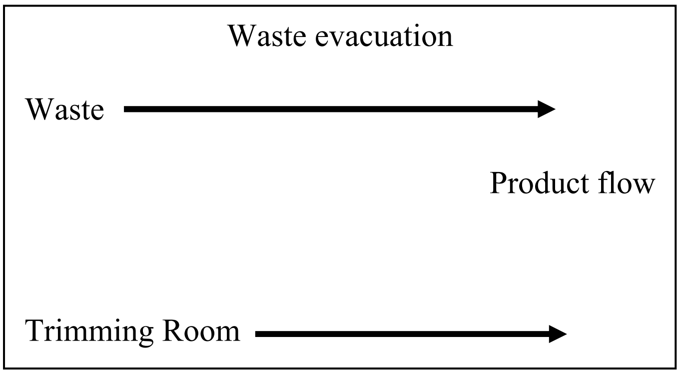

Figure 12.4: Waste disposal

Cleaning, equipment, material and utensil

Washing should be performed by any method of combination of methods involving mechanical action (scrubbing, brushing, water, jet spraying) or chemical cleaning (acidic or alkali detergent). A detergent or disinfecting detergent should be applied so as to permit the elimination of dirt and bacterial biofilms. Efficient rinsing with potable water should eliminate the detached particles and detergent residues.

Sanitation

Product safety is the very critical sanitation issue of the minimal processing plant. Processing of the product and employee practices are some of the factors influencing the plant sanitation. These include, sanitary layout of processing facility, processing rooms with positive airflow and sanitary design of processing equipment. Washing the premises and machines with steam or chemicals. Good manufacturing practices (GMP's) and hygiene are pre-requisites to ensuring quality in minimally processed foods.

Hygenic procedures for operators

Personnel should know the hygienic procedure (International Code of Practices, general principles of food hygiene) and wear protective clothing and foot-wear specific to the area.

Quality assurance programs

An effective quality assurance system throughout the handling steps between harvest and retail display is required to provide a consistent good quality supply of fresh-cut fruits and vegetables to the consumers and to protect the reputation of a given marketing label. Quality assurance starts in the field with selection of proper time to harvest for maximum quality. Exposure of commodity to temperatures, relative humidities, and/or concentration of oxygen and ethylene outside its optimum ranges accelerates loss of quality. The loss of flavour and nutritional quality occurs at the faster rate then appearance factors. That's why quality assurance programs should be based on quality attributes and not on appearance factor as is often the case.

Following is a list of handling steps and associated quality assurance functions:

1. Training workers on proper maturity and quality selection, careful handling, and produce protection from sun exposure during harvesting operations

2. Checking product maturity, quality, and temperature upon arrival at the processing plant

3. Implementing an effective sanitation program to reduce microbial load

4. Checking packaging materials and shipping containers to ensure they meet specifications

5. Training workers on proper processing and packaging operations

6. Inspecting a random sample of the packed product to ensure that it meets grade specification

7. Monitoring product temperature to assure completion of the cooling process before shipment

8. Inspecting all transport vehicles before loading for functionality and cleanliness

9. Training workers on proper loading and placement of temperature-recording devices in each load

10. Keeping records of all shipments as part of the "trace-back" system

11. Checking product quality upon receipt and moving it quickly to the appropriate storage area

12. Shipping product from distribution centre to retain markets without delay and on a first-in/first-out basis unless its condition necessitates a different order

12.6 LET US SUM UP

A characteristics feature of minimal processing is an integrated approach where raw materials is an integrated approach, where raw materials, handling, processing, packaging and distribution must all be properly considered to make shelf-life extension possible. New cultivars need to be selected and created or hybrids adapted to meet the specific requirements of minimal processing**.** The equipment used in unit operations, such as peeling, and shredding, needs further developments so it can process produce more gently. Further for maintaining quality in minimal processing requires anti-browning agents such as acidulants (citric acid), reducing agents like ascorbic acid. All these combined with proper packaging material and low temperature will result into a shelf stable product.

12.7 KEY WORDS

Minimal processing : is defined as these procedures such as washing, sorting, trimming, peeling, slicing or chopping that does not affect the freshness of the product.

Good manufacturing practices : refers to hygienic code of practice which are to be followed to maintain quality in food processing unit.

Modified atmosphere packaging : It involves modifying the atmosphere around the food product inside the wrapper. This allows chemical, enzymatic or microbiological reactions to be controlled and therefore reduces or eliminates the main processes of deterioration in the product

12.8 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - Availability of more processed fruits and vegetables.
   - Innovative packaging.
   - Consumer demands (demand for convenient and quality products, dual incomes).
   - Taste preferences.
   - Technological advances in food processing.

2. Your answer should include the following points:

   - Demand for convenient and high quality processed products.
   - More working women in cities and less time for kitchen

3. Your answer should include the following points:

   - Bakery goods, pizzas, burgers, French fries, confectionary items.
   - Fruit and vegetable juices tetra packs take away colas, instant juice concentrates.
   - Frozen foods, frozen vegetables, peas, beans, cauliflowers etc.
   - Sauces ketchups, concentrate purees, yoghurts, curds etc.

4. Your answer should include the following points:

   - Pre-cut salads and fruit slices.
   - Sprouted pulses.
     Shelled peas.

5. Minimal processing is defined as procedures such as washing, sorting, trimming, peeling, slicing/chopping that does not affect the freshness of product.

6. MP is also known as

   - Light processing
   - Precut produce

7. Need for fresh like characters.

   - Need for convenience.
   - Need for quality.
     Fresh produce gives health

8. MP is different from conventional processing in following manner:

   - No heat used.
   - Product has limited shelf life (4-21 days).
   - Chilled/refrigerated storage is must during transportation & retailing.
   - Produce is more close to fresh ones.

Check Your Progress Exercise 2

1. MP are perishable because

   - Cutting/shredding renders produce susceptible to desiccation/wilting, biochemical and microbial spoilage.
   - Fast degradation of colour, flavour and texture because of ethylene liberation, increased respiratory activity and enzymatic changes.

2. Main enzymes responsible for colour and flavour changes are:

   - Polyphenol oxidase causes browning.
   - Lipo-oxidase causes bad smelling odours

3. Your answer should include the following points:

   Key requirements for minimal processing

   - Good quality raw material.
   - Strict hygiene and use of GMPs.
   - Low temperature during processing.
   - Good quality water.
   - Gentle spin drying.
   - Gentle peeling, slicing and shredding.
   - Correct packaging material and packaging methods.

4. Low temperature lowers down metabolic activities and helps to extend shelf-life.

   - Delays microbial spoilage.
   - Name some microorganisms.
   - Salmonella sp.
   - Listeria sp.
   - Monocytogenes sp.
   - Yersinea sp.

5. The optimum chlorine concentration is 100 mg/l at a contact time of 12-13 seconds.

6. Your answer should include the following points:

   Second washing is performed after peeling/cutting/shredding/dicing. It is done in ice-cold water (> 5^{o}C). It is important because it:

   - Removes tissue fluids and microorganisms.
   - Reduces enzymatic oxidation.
   - Low temperature seals the cut/damaged surfaces.
   - Washing before peeling and after cutting/shredding/dicing.

- Second washing in ice-cold water (> 5°C).
- Use of preservatives in washing water containing 100 mg chlorine/l.
- Rinsing with tap water after washing.

7. Your answer should include the following points:

- Washing before peeling and after cutting/shredding/dicing.
- Second washing in ice-cold water (> 5°C).
- Use of preservatives in washing water containing 100 mg chlorine/l.
- Rinsing with tap water after washing.

8. Your answer should include the following points:

- Oriented polypropylene.
- LDP – Low density polyethylene.
- Ethylene vinyl acetate.

9. Main Micro-organisms are:

- L. monocytogenes.
- Acromonas hydrophila

10. Your answer should include the following points:

Main criteria in assessing suitability of cultivars to MP.

- Processing yield (30-50%).
- Mechanical resistance to damage.
- Resistance to elevated CO_2 or low oxygen.
- Low respiration rate.

11. Your answer should include the following points:

- Onions
- Carrots
- Cabbage

12. Your answer should include the following points:

- Low pH
- High temperature
- Correct contact

13. Your answer should include the following points:

- Gentle rather than harsh peeling
- Peeling with sharp knives
- Disinfection with 1% hypochlorite solution
- Cutting or peeling done under water

14. Your answer should include the following points:

- Placing the tissues in water immediately after cutting
- Use of potassium metasulphite
- Citric acid combined with ascorbic acid alone or in combination with potassium sorbate.

15. Your answer should include the following points:

    MAP is not recommended for:

    - Broccoli
    - Cauliflower
    - Onions

    Because they emanate offensive odours during storage.

Check Your Progress Exercise 3

1. *Forward only movement*

   Forward only movement refers to complete separation of raw material from clean finished product. This requires that there is no crossing over in the processing line between raw material and clean products.

2. Your answer should include the following points:

   - Sodium chloride
   - 4-Hexyl resorcinol
   - Ascorbic acid
   - Sporix and cyclodextrins.

UNIT 13 PROCESSING BY HEAT APPLICATION

Structure

13.0 OBJECTIVES

After reading this unit, you should be able to:

- define types of heat applications;
- describe the role of heat application during processing and product preparation;
- state the effect of heat application on quality of food, microorganisms and enzymes; and
- discuss the effect of heat in combination with time, temperature, pH or acidity.

13.1 INTRODUCTION

Fruits and vegetables are living entities and highly perishable horticulture produce. Enzymes and microorganisms can easily spoil these commodities. In order to keep fruits and vegetables for a longer period, they are protected by several means. Heat application is one of the most important methods of preservation of fruits and vegetables. The main purpose of processing of fruits and vegetables by application of heat is to inactivate enzymes and killing of microorganisms. Heat can be applied in different forms such as blanching, pasteurization and sterilization. Heat application influences the texture and composition of fruits and vegetables, and microorganisms and enzymes. Heat application plays a great role during various unit operations of processing of fruits and vegetables viz., peeling, preparation of juice and pulp; syrup and brine, during blanching, exhausting, pasteurization or sterilization. There are certain factors like time, temperature; pH and acidity in combination with heat application will affect the quality of the processed products. There are several types of processed products, generally preserved by heat application such as jam, jelly, juices, sauces, candies, canned and bottled products etc. Heat processing has advantages such as to improve eating quality and availability of some nutrients and a simple control of processing conditions.

13.2 EFFECT OF HEAT ON TEXTURE AND COMPOSITION

Carbohydrates, proteins, fats, vitamins, minerals and fibre are the major dietary constituents of fresh vegetables in addition to a large quantity of water. Fruits are held in high public regard as sources of wholesome food and are valued for their taste, aroma and texture. Fresh fruits appeal virtually to all the senses, smell, taste, touch, sight and even sound as when one bites into crunchy apple. Vitamins and minerals are the major contributions of fruits to the human diet. Although some fruits are also considered good energy sources and some may contribute notable amount of fat (e.g. Avocados and nuts), sugar (e.g. Dates and figs) and proteins (e.g. tucuma). Fruits may play an important role in the diet by supplying fibre.

Heat processing is one of the most important methods for extending the storage life of fruit and vegetable products. Because of this extended life, the processed products are made available throughout the year. This has increased the availability of nutrients to the consumer. However, heat processing also has a detrimental effect on nutrients since there is thermal degradation of nutrients. Therefore, heat processing makes it possible to extend and increase availability of a food product to the consumer, but the food product may have a lower nutrient content compared to the fresh food product. This is a great challenge to the food processing industry is to minimize the loss of nutrients during thermal processing.

Heat processes are used in terms of blanching, pasteurization and sterilization. The primary objective of heat processing is to increase the palatability of the food and to increase the storage life of food product besides minimizing food-borne diseases. For example, the cooking, which includes roasting, boiling, frying etc. The heat processes viz. blanching, pasteurization and sterilization has already dealt in Para 2.5 and 2.6 in a greater details, here we are discussing their effect on texture and composition of fruits and vegetables.

Heat processing generally includes the terms blanching, pasteurization and sterilization and their principal purpose is given here.

Blanching is a heat process frequently applied to fruit and vegetables prior to freezing, drying or canning. The objective of the blanching process depends on the subsequent treatment of the foodstuffs. The adequacy of the blanching operation is enzyme inactivation. Generally, if enzymes are inactivated, the heat treatment was sufficient to accomplish the objectives of blanching prior to canning.

Pasteurization is a heat process meant to inactivate part, but not all, of the vegetative microorganisms present in the food product. Since the food is not sterile, the pasteurization must also be used in conjunction with other preservation techniques like fermentation, refrigeration, and maintenance of anaerobic conditions.

Sterile is a term, which used to a condition in which no viable microorganisms are present. A viable organism being one that is able to reproduce under conditions optimum for its growth. Sterilization is a term used to apply to a heat process that produces a sterile condition in food product. Some microorganisms and their spores are extremely heat resistant and cannot be destroyed completely. Severe heat treatment can only make the food sterile, but it will influence the organoleptic and nutritive value of food. Therefore, the sterilization process is also used in conjunction with other preservation techniques, such as packaging and control of storage temperature. Thus, the remaining dormant microorganisms or their spores will not grow in the environment of the food under the storage. Foods that have been thermally processed and meet this requirement are said to be "commercially sterile".

Heat processing may change not only the chemical composition of the food but also its structure by softening tissues, releasing or tying up moisture, destroying or forming colloidal suspensions, gels or emulsions. Protein may become denatured and therefore more available to some organisms than it was in the native state. Starch or protein may become gelated, releasing moisture and becoming more easily decomposed. For the same reasons, cooked food usually is more easily decomposed than the original fresh food.

Preservation is a convenient method of storing fruit for use in periods when the fresh products are not available. The characteristics of fruit are usually altered to such an extent during processing that the processed products do not necessarily resemble the fresh products. If processed and stored properly, the nutritive value of these processed fruit is comparable to that of the fresh products.

The thermal processes viz. blanching, pasteurization and commercial sterilization have to be optimized for nutrient retention, given in the box below:

Process	**Method of optimization**
Blanching	Thermal losses, leaching losses, oxidative degradation, damage to product
Pasteurization	HTST if heat resistant enzymes are not present
Commercial	Convection – heating foods and aseptic processing.
Sterilization	HTST until heat-resistant enzymes become important
Conduction	heating foods; not necessarily HTST; difficult but not impossible calculation.

Effect of blanching on nutrients

The effect of blanching on food nutrients is generally considered based on thermal, leaching and oxidative losses. Blanching is done either by dipping in hot water or exposing to steam. In water blanching the loss of water –soluble vitamins increases with contact time, and fat – soluble vitamins are relatively unaffected. Steam Blanching results in greater retention of water – soluble nutrients than water blanching. There is a slight improvement in ascorbic acid retention with IQB (individual quick blanch) as compared to conventional steam blanching. In conclusion, blanching can significantly reduce the nutrient content of foods. The extent of losses of nutrient is dependent on the blanching method and the product.

Effect of pasteurization on nutrients

The foods having a low pH (mostly below 4.5) are generally pasteurized. Some food products, which receive pasteurization, are summarized in the box given below:

Food Products preserved by Pasteurization treatments

Sl. No.	**Product Pasteurized**	**Temperature (^oC)**
1.	Carbonated Beverages	60-65
2.	Non Alcoholic fruit drinks	65-70
3.	Dill Pickles, Carbonated fruit juices	70-75
4.	Apple juice (Holding process) grape juice, raspberries, strawberries in syrups in cans or jars	75-80
5.	Processed and pickled vegetables, wine (U.S.), desiccated coconut	80-85
6.	Apple juice (flash process), canned olives, citrus juices, peeled tomatoes (pH 4.1)	85-90
7.	Tomato puree, citrus juices (flash process) tomato juice, peeled tomatoes (pH 4.5), Jam	90-95
8.	Wine (flash process), fruit puree, fruit juices, canned fruits (internal can temp.)	95-100

Source: Shapton et al. (1971)

Since most of the heat – labile nutrients are relatively stable in acid conditions; nutrients losses in those products are relatively minor. Although thermal losses during pasteurization may be small, oxidative losses can be high.

We have already discussed that HT ST (High Temperature Short Time) process results in greater nutrients retention for those nutrients affected by the pasteurization process. They are primarily thiamin, vitamin C and vitamin B 12. The nutrients that are more sensitive to high temperature are generally the same ones that are of concern during storage. It would be reasonable that the lower the storage temperature, the slower the rate of nutrient degradation.

Effect of commercial sterilization

The destruction of nutrients the thermal process is dependent on i) time-temperature treatment used as the basis of the process and ii) rate of heat transfer into the product. The commercial developments have focused primarily on increasing the rate of heat transfer into the product. Hence, agitated retorts such as the orbitort, steritort, flame sterilizer and hydrostatic cooker have been developed.

In addition to increasing the rate of heat transfer, however, there also has been a gradual shift to higher processing temperature. This results in adaptation of HTST process for greater nutrient retention in those products heating primarily by convection. It has been observed (Ammerman 1957) that retention of vitamin C in tomato juice is improved when processing is conducted at a HTST condition.

The HTST process is particularly adaptable to aseptic processing. In this system, processing temperatures in excess of 149^{o}C are used for very short periods i.e. order of seconds. Under these conditions nutrient retention may be greatly enhanced. HTST aseptic canning also results in a significant improvement in organoleptic qualities i.e. colour, taste and aroma. In an evaluation of HTST aseptic processing, it was found that thiamin retention was significantly greater in HTST products than in conventionally canned and retorted products. Based on existing literature available, nutrient losses range from 0 to 91 percent, depending on the nutrient and product.

It is a misconception to think that commercially sterile products remain unchanged during storage. This is not the truth. Organoleptic and nutrient changes do occur during storage, the extent of the changes being dependent on the time and temperature of storage. It has been observed that low temperature storage results in an improvement in nutrient retention.

In conclusion, it is evident that there is a significant loss of nutrients during canning and that these losses increase during storage. Altering heat processing and storage conditions to maximize nutrient retention is an important and necessary consideration for the fruit and vegetable processing industry.

13.3 EFFECT OF HEAT ON MICROORGANISMS AND ENZYMES

Generally the food spoilage takes place at any temperature between –5^{o} and 70^{o}C. Since microorganisms differ so widely in their optimal, minimal and maximal temperature for growth, it is obvious that the temperature at which a food is held will have a great influence on the kind, rate and amount of microbial induced change that will take place. Even a small change in temperature may favour an entirely different kind of organism and result in different type of spoilage. For example, moulds and yeasts generally do not grow well above 35 to 37°C, hence not important in foods held at high temperatures. But moulds and yeasts grow well at ordinary room temperatures and many of them grow fairly well at low temperatures. Most bacteria grow best at ordinary temperatures. Some (thermopiles) grow well at high temperatures and others (psychrotopes) at chilling temperatures. The heat, which kills microorganisms and inactivate enzymes is supposed to be denaturation of the proteins. The heat treatment varies depending upon the different factors such as kind of organism, its state and the environment during heating. Depending upon the heat treatment employed, only part of the vegetative cells, most or all of them may be killed. There are known certain terms of heat treatment given below:

Heat Processing – Use of high temperature to destroy enzymes and microorganisms that could reduce quality and /or safety of food.

UHT – A very severe heat treatment, very short in time.

Pasteurization – A mild heat treatment used primarily to destroy pathogenic organisms but it also destroys enzymes and reduces microbial load. Requires an addition preservation method to extend shelf life (for example – refrigeration, drying).

Commercial sterilization – A severe heat treatment that destroys pathogenic and many microorganisms that could spoil food. Extends shelf life, room temperature stable.

Sterilization – A very severe heat treatment that destroys all microorganisms.

Details of these heat treatments can be seen in other Para of this unit.

Factors affecting heat resistance

There are certain factors, which are known to affect the heat resistance of cells or spores of microorganisms. This point must be kept in mind when microorganisms are compared and when heat treatments for destruction of an organism are considered. The main known factors are listed below:

1. The temperature – time relationship – The time for killing cells or spores under a given environment decreases as the temperature is increased.

2. Initial Concentration of Spores – the more the spores present, the greater is the heat treatment required to kill all of them.

3. Environment of Vegetative spores –

   i) *Medium of growth:* Nutrients in the growth medium influences the heat resistance. The better the medium for growth, the more resistant the spores cell.

   ii) *Temperature of incubation*: In general, resistance increases as the incubation temperature is raised toward the optimum for the organisms.

   iii) *State of growth and age:* Very young immature spores are less resistant than mature ones.

   iv) *Desiccation:* Certain spores are harder to kill by heat than those kept moist.

4. Composition of substrate also influences the thermal death time of the microorganisms.

   i) Moist heat is a much more effective killing agent than dry heat.

   ii) *pH:* In general microbial cells or spores are most heat – resistant in a substrate near neutrality. (See more details in 2.7 Para)

   iii) *Other constituents:* Common salt and sugar also protect some organisms or spores. The colloidal materials, especially proteins and fats, are protective against heat.

Heat resistance of microorganisms

The heat resistance of microorganisms usually is expresses in terms of their thermal death time. The thermal death time (TDT), which is defined as the time it takes at a certain temperature to kill a stated number of organisms (or spores) under specified conditions.

Most of the yeasts, moulds and their spores are killed by moist heat at 60°C, but some species are considerably more heat resistance, but may not survive 100°C. The bacterial vegetative cells are easily killed at 80-90°C. But resistance of bacterial spores at 100°C may vary from less than 1 minute to over 20 Hours.

Heat resistance of enzymes

The most food enzymes are destroyed at 80°C, some may with stand higher temperatures, especially if high temperature – short –time heating is employed. Generally the effect of heat is intended for preservations of food i.e. to kill bacteria and inactivate enzymes. For example, the pasteurization of milk, fruit juice and beverages and the sterilization of canned foods. The main aim is to deliver the required microbial kill with as little damage to the structure and consumption of the food products as possible.

13.4 ROLE OF HEAT APPLICATION – PEELING, JUICE PROCESSING, SYRUP/BRINE PREPARATION & FILLING

13.4.1 Use of Heat in Peeling of Fruits and Vegetables

Generally fruits and vegetables are peeled by hand, mechanical means, use of heat and lye solution. Heat in various forms is applied in last two methods of peeling. Heat is generally used in the form of boiling water, steam, roasting by a direct gas flame and heating in steam under pressure.

Peaches, tomatoes, beetroots are either immersed in boiling water or exposed to live steam until it loosen skin or cracked or peel is separated from the flesh easily, and then cool by spraying or immersion in cold water. The loose/ cracked or separated skin is easily slipped from the fruit by hand or by spraying water.

Sweet potatoes are steamed under pressure to soften the skin and are peeled by hand. Sometimes peeling of carrots, beets, potatoes and apples and some other vegetables can be done by heating under pressure to a very high temperature for a few seconds then releasing the pressure. This method of peeling can be a continuous or batch type process.

Pimientos and onions are flame-peeled in a continuous natural gas-heated chamber at very high temperature (1568°C). Then they are washed in sprays of water. Uniform size of the produce gives better results.

Heat is also used during lye peeling. It makes the lye solution more effective than cold lye. Lye is a solution of alkali such as sodium hydroxide. Its strength and time of immersion of the commodities depends upon type and nature of fruits and vegetables and thickness of their skin. Lye peeling is used on peaches, sweet potatoes, apricots and carrots. Sometimes the sodium carbonate-sodium hydroxide mixture is also used, is called canners alkali. The lye solution having 1.5 to 2 percent sodium hydroxide is used for peeling of fruits. For vegetables 10 to 15 percent sodium hydroxide solution is used. The time of immersion in lye solution for fruits varies from ½ to 2 minutes and 6-8 minutes for vegetables. The boiling dilute lye solution causes the separation of the outer skin of the fruits from the flesh. In case of sweet potatoes the action of lye solution is upon the cutin.

13.4.2 Use of Heat in Juice and Pulp Processing

Use of heat application helps in clarification and preservation of fruit juices and beverages. Fruit juices after pasteurization will become clear during storage. The length of storage required depends upon the type of juice and other conditions. For example the pomegranate juice will become clear within twenty four hours, after pasteurization where as grape juice requires several months for setting solids and it can be enhanced by refrigerated low temperatures.

The heat treatment is used to pasteurize the fruit juices and it means the destruction of all microorganisms capable of increasing in the juice of causing spoilage. It doesn't kill the spore forming bacteria such as *Bacillus subtilis* and *Bacillus mesentericus* but these spore bearing bacteria cannot grow in acid fruit juices. However, pasteurization should be done at such a temperature and for such a time that yeast and moulds are destroyed. For example yeast is killed in a few minutes by heating juice at 60-66°C. But resistant mould spores require a temperature of 80^{0}C for 20 minutes; however, carbonated juices can be pasteurized safely at 66°C. Thus, we can conclude that the fruit juices must be pasteurized at lower temperature (71-74°C).

The presence of carbon dioxide generally does not reduce the death temperature of fruit juice microorganisms such as yeast, mould spores, and bacteria. But it prevents the growth of surviving mould spores. However, it has been observed that carbonated and heavily inoculated fruit juice heated for 30 minutes at 65°C, which prevents subsequent development of mould spores.

The bulk juices are pasteurized either as continuous or batch type process. The continuous pasteurization is done in a tubular or plate type heat exchangers. Hot water or steam is used as heating medium. The batch type pasteurization is done in steam-jacketed kettle or in a tank equipped with steam coils. In these vessels, the juice is placed and heated to the desired temperature. This system has some disadvantages such as the small portion of juice may be over heated or exposed to air and cause oxidation during pasteurization and injury to colour and flavour on prolong heating.

Heating can also be done by electricity. The fruit juices are passed between carbon electrodes. The juice is heated instantaneously to the desired temperature when ordinary alternating current (110 Volts 60cycle) is passed in the electrodes. Heat is generated by passage of current against the resistance of juice, without heating the electrodes.

The fruit juices are also preserved by flash pasteurization and cooling. The prolong heating results in considerable injury to the flavour and colour of the products. Hence, the fruit juices are heated at higher temperatures and rapidly cooled and then under aseptic conditions filled into sterile containers such as bottles and sealing by sterile cork or caps. Great care must be taken to avoid the infecting juice with mould or yeast. For example the juice is heated to about 82 to 90°C for a few seconds only, the juice suffers very less injury to colour or flavour. In some instances the citrus, apple or tomato juice is flash pasteurized momentarily at 116°C or higher, but cooled to 98°C (tomato juice) and 88°C to other juices before filling into the container. This treatment will inactivate enzymes also. Now a day's pasteurization is generally done by "hot-fill-hold-cool" method. In this method the hot sterile bottles or cans usually filled hot directly from bulk or continuous pasteurizer, sealed and given no further heating but cooled in the air and water, respectively.

Heat should also be used to sterilize bottles, cans, and bottle caps otherwise they may cause infection in bottled beverages.

13.4.3 Syrup/Brine Preparation and Filling

The syrups are added to fruits and brines are added to vegetables during canning. These additives improve the flavour; fill the spaces between the pieces of canned fruits and vegetables and aid in the transfer of heat during the processing.

For making syrup, cane sugar, liquid glucose or invert sugar is used but usually cane sugar is employed. The sugar is dissolved in small quantity of water to yield heavy syrup (60-65^{0}Brix). The cane sugar and water are heated together until a clear syrup is obtained. Heat treatment is provided through steam. Tanks with steam heated coils or steam jacketed kettle is used for the preparation of the syrup. Sugar syrup is clarified by passing through cloth. Then it is diluted to the desired degree Brix depending on the nature and grades of the fruit. Here the heating helps in dissolving sugar in the water and quick filtration before it is cooled. Hot syrup is filled into cans containing fruit pieces, which helps in reducing time of exhausting.

Dilute brines of 1 to 2 percent common salt are used during canning of vegetables. Salt used for canning should be at least 99 % sodium chloride ($NaCl$) and lower purity less than 98 % should not be used. Salt is dissolved in water by heating, after proper filtration is filled into the cans containing prepared vegetables before exhausting. Hot brine is used for filling into the cans.

13.5 BLANCHING AND EXHAUSTING

13.5.1 Blanching

Blanching is a unit operation applied to fruits and vegetables prior to canning, drying or freezing. Blanching is a mild type of heat processing. It involves heating food to preset temperature for preset time. It is usually done in water or steam at a temperature less than 100°C. Prepared fruits and vegetables is kept in hot water or exposed to steam and then cool rapidly to ambient temperature.

Blanching is used to destroy microorganism and enzymatic activity in fruits and vegetables. Blanching caused inactivation of enzymes in canning, freezing and dehydration, because freezing and dehydration are insufficient to inactivate enzymes. Sometimes canning process may allow sufficient time for enzymatic activity. And under blanching may increase the enzymatic activity. There are four types of enzymes such as lipoxygenase, polyphenololase, polygalacturonase and chlorophyllase, which causes loss of quality in fruits and vegetables, must be inactivated. The enzymes such as catalase and peroxidase are heat resistant, which need appropriate time and temperature to inactivate them.

Blanching also reduces the number of microorganisms. Blanching of fruits and vegetables in steam has the advantages such as less loss of water-soluble constituents, less volume of waste, easy to clean and sterilize. But it has some disadvantages i.e. higher capital costs, uneven blanching, and low efficiency. Generally hot water blanchers are used because of lower capital costs and better energy efficiency. But it has some disadvantages like loss of water-soluble constituents, risk of contamination and higher cost of water and disposal of effluent than steam blanchers.

Blanching of green leafy vegetables especially spinach at boiling point causes loss of green colour but lower temperature (77°C), it retains the natural green colour, even when heated at higher temperature (121°C) during sterilization. At lower temperature time the enzyme chlorophyllage remains active for little time and convert chlorophyll to a phyllin, which retain green colour.

13.5.2 Exhausting

Exhausting is a mild type of heat processing. It is one of the unit operations involved during canning of foods. Exhausting, generally remove air and gases from cans. It can be done either by application of heat. In this method, the cans are passed through a tank of hot water or exhaust box under steam. The temperature of water is generally ranged between 82^0C to 100^0C and the center of the can should reach a temperature of about 79^0C. The time of exhausting varies from 6 to 10 minutes, depending upon the nature of the commodities. Generally, exhausting of the cans is preferred at lower temperature for a longer time to ensure to uniform heating of the contents, without softening of the produce. Exhausting at high temperature should be avoided, otherwise it will be formed more volume of water vapour, which may produce greater vacuum in the can.

Exhausting help in avoiding the corrosion of the tin plate and pin holing during storage, minimizing discolouration by preventing oxidation, better retention of vitamin C, prevents bulging of cans when stored at high altitude. It also helps in reducing chemical reaction between containers and food and prevents development of expressive pressure and strain during sterilization of cans.

13.6 PASTEURISATION AND STERILISATION

13.6.1 Pasteurization

Pasteurization is a mild type of heat processing. In this method, the heat treatment is performed below 100°C, which kills some selective but not all of the microorganisms present. Heating is done in form of hot water, steam, dry heat or electric currents. The food products are cooled rapidly to ambient temperature after heat treatment.

The main function of pasteurization is to inactivate enzymes, kill non-spore forming bacteria, yeasts and moulds. Pasteurisation is used in combination of other preservation methods such as fermentation (pickles), refrigeration and anaerobic conditions as the food products are not sterile. Pasteurization is generally used in fruit juices, where the environment is not suited for the growth of spoilage causing microorganisms.

The severity of pasteurisation depends on pH of the food products. In low acid ($pH>4.5$) foods, the destruction of pathogenic bacteria, whereas in high acid foods ($pH<4.5$), the destruction of spoilage microorganisms and inactivation of enzymes are essentially the requirement.

Heating to 100°C mostly preserves the fruit juices or slightly below for a sufficient time to kill spoilage microorganisms are called pasteurization. Generally, the fruit juice is hermetically sealed in cans or glass bottles before being pasteurized. The juice would not spoil as long as the cans or bottles remain sealed against the entry of spoilage microorganisms from outside. Some spores and spore forming bacteria like *Bacillus subtilis* and *Bacillus mesentericus* can survive the process. But these organisms are highly sensitive to acid products and cannot grow in acid fruit juices and beverages. Generally, the fruit juices are pasteurized at about 85^{0}C for 25 to 30 minutes depending upon the nature of the juice and the size of the containers. In this process most of the bacteria, mould, spores and yeasts are readily killed.

Fruit juices are pasteurized by two methods. First by heating the juice at a low temperature for a long period, and secondly by heating the juice at high temperature for a short time (HTST). Pasteurisation is governed by the temperature and its types & methodology. For example under 'Holding' pasteurisation also called Bottle method, the prepared and finished juice is filled into glass bottles leaving proper head space. The bottles are then sealed airtight and pasteurized. The headspace is left in the bottle for the expansion of the juice during heating. In over-flow method of pasteurization, the fruit juice is heated to a temperature about 2.5^{0}C higher than the pasteurisation temperature. The hot juice is filled into hot sterilized bottles upto brim and sealed by crown corking. A care is taken that the temperature of the juice does not fall below pasteurisation temperature during filling and sealing.

In flash pasteurization the juice is heated rapidly to a temperature of 5.5^{0}C higher than pasteurisation temperature for one minute and filled into bottles and canes, sealed air-tight under cover of steam and then cooled. The steam will sterilize the seal. The flash pasteurisation has some advantages, that it helps in minimizing loss in flavour, retention of vitamins, it effects economy in time and space, keep the juice uniformly cloudy, heats the juice uniformly, which reduces to a minimum any cooked taste of the juice. Flash pasteurisation is a type of higher temperature and short time (HTST) heating system.

Some liquid foods are pasteurized after packaging. Food packaged in glass containers is generally pasteurized with hot water. The unpackaged foods such as fruit juices and beverages of low viscosity are pasteurized in continuous operation using plate heat exchangers.

13.6.2 Sterilization

Sterilization is a process of heat application above 100°C, which is employed to deprive microorganisms of their ability to multiply. We can obtain this sterilization temperature by using steam under pressure. The boiling point of water can be raised if the water and steam are enclosed in a strong retort (autoclave). In this retort, temperature increases with increase in steam pressure. The temperature at sea level is 100°C without pressure but at 0.7kg/cm2 steam pressure the temperature of 121°C or above may be easily obtained. At these high temperatures the spores of the heat resistant bacteria are quickly killed. The longer is the heat treatment time at lethal temperatures, the larger is the number of killed microorganisms. At higher temperature, the shorter is the time required to kill microorganisms and lower is heat-included damage to food products.

Theoretically, absolute sterility does not exist. In commercial practice not all cans of food are sterile. However, they usually do not spoil because conditions in the container are not favourable for the growth of concerned microorganisms. The pH may be too low or absence of oxygen. Therefore, the term processing is highly suitable than the term 'sterilization' applied to canned foods.

The foods products low in acid and often high in protein and contain spore-forming bacteria are difficult to sterilize. The acidity of fruits and tomatoes greatly lower the death or sterilizing temperature, which usually explains why acid fruits are easily sterilized.

The purpose of sterilization is the destruction of all pathogenic, spoilage causing organisms and non-pathogenic microorganisms. This process will make the treated product safely preserved at room temperature. Thus, the food products with safe preservation at room temperature are generally defined as commercially sterile.

13.7 COMBINATION OF TIME, TEMPERATURE, pH/ ACIDITY

13.7.1 Time and Temperature

The food is generally decomposed by the presence of microorganisms and can be prevented by killing them. The heat preservation is one of the most important methods of killing / inactivation of microorganism as well as enzymes which are already present in the food. Heat application kills the microorganisms because of denaturation of proteins. Different microorganisms have different heat resistance. This can be shown by their thermal death time (TDT) at a particular temperature. For example the TDT of *Lactobacillus bulgaricus* is 30 min. at 71°C; *Escherichia coli* is 20-30 min. at 57.3°C and *Streptococcus thermophylus* is 15 min. at 70-75°C. Thus it is the combination of time and temperature required to kill the specified microorganisms. In a set of given conditions, with increase of temperature the time required to kill cells or spores decreases.

The canning is one of the major methods of food preservation based on destruction of microorganisms by heat treatment and prevention of recontamination. The heat treatment in respect of time and temperature is governed by the nature of food product and size of the container. Thus we can enlist below certain factors, which affect the heat resistance of cells or spores.

i) Initial concentration of spores
ii) The time-temperature relationship
iii) The type and nature of microorganisms
iv) Composition of substrates such as moisture content, pH or acidity, fat, protein, pectin, etc.

The heat treatment based on temperature can be grouped as

i) Pasteurization (heating below 100°C)
ii) Blanching (heating at about 100°C)
iii) Sterilization (heating above 100°C)

You can find more details in Para 13.5 and 13.6.

We can see a time and temperature combination during canning process. The canned food is most sterile when packed; hence the filled cans are exposed to temperature-time profile sufficient to give a safe product. In this process the heat is applied externally which will be the cause of product to lag the surface and bulk product temperatures. Therefore it is essential to estimate the temperature at the slowest heating point. It will also ensure that a product is not over processed. For example canned low acid foods having the pH greater than 4.5 is generally processed at a reference temperature of 121.1°C for 3 minutes at its slowest heating point. Thus, we can consider this thermal process of canned food as safe. If the temperature of thermal process varies, then time will also vary and it can be seen, from the literature. The time – temperature profile as follows: 1.2 min at 125°C; 3.9 min at 120°C; 12.2 min at 115°C; 38.7 min at 110°C; 122.2 min at 105°C and 386.5 min at 100°C.

13.7.2 pH or Acidity

The processing temperature is generally governed by the pH or acidity of food product. The food having a lower pH than 4.6 or higher acidity is generally given low temperature heat treatment. While, food having a higher pH than 4.6 or lower acidity is given high temperature heat treatment.

Food product can be classified based on pH or acidity as follows:

1. *Low acid, pH 5.0 and higher:* This class includes mostly non-acid vegetables and some fruits such as peas, beans, corn, asparagus and bael

fruit, papaya etc. All types of microorganisms including Clostridium botulinum can spoil these products.

2. *Medium acid, pH 5.0-4.5:* Vegetable mixtures, soups, which has partially acidic ingredients. All types of microorganisms also spoil these. The flat sour producing microbes is of importance.

3. *Acid, pH 4.5-3.7:* This group includes tomatoes, pears, pineapple, figs etc. These products can be spoiled by non-spoiling aciduric types, butyric anaerobic and thermophilic anaerobic.

4. *High acid, pH 3.7 and below:* This class includes citrus juices, grape fruits, rhubarb, berries, pickles and sauerkraut.

The bacterial spores are easily destroyed in fruits at pH 3.0 than in vegetables at pH 5.0 and above. These microbial spores do not grow at pH below 4.5. Hence, pH 4.5 has been considered as dividing line between acid and non-acid foods. It is usually practice in canning process. A canned food product, having a pH below 4.5, can be processed at boiling water (100°C). But the food having pH above 4.5 is processed under pressure 0.7 to 1.0 kg/cm^2 to raise the temperature more than 100°C.

The heat inactivation of enzymes in food products is generally governed by time of heat application as well as by pH. Lowering of pH by addition of acids, control enzymatic browning. Acids, which are naturally found in plant tissues such as citric, malic, and ascorbic acids help in reducing enzymatic browning.

13.8 ROLE OF HEAT APPLICATION DURING PRODUCT PREPARATION

Preparation of jam, jelly, juices, sauces, candies etc require a substantial amount of heating. This heat treatment is essential for safe preservation of these products, is being discussed below.

13.8.1 Use of Heat in Jam and Jelly Production

Let us **define** the jam and jelly, marmalade and preserves, and then we will discuss how heat is essential during their preparation.

Jam: Jam is prepared by boiling whole fruit pulp with cane sugar (sucrose) to a moderately thick consistency without retaining the shape of the fruit. As per FPO specification 45 parts of fruit to each 55 parts of sugar, is used for preparation of jam.

Jelly: Jelly is prepared by boiling fruit with water, expressing as water (pectin) extract), adding sugar, and concentrating to such consistency that gelatinization takes place on cooling. The best jelly is clear, sparkling, transparent and of attractive colour. It should retain the shape when removed from container or glass bottle.

Marmalade: Marmalade is a clear jelly in which shreds of peel are suspended. It is generally prepared from citrus fruits.

Preserves: cooking prepared fruit in sugar syrup until the concentration of sugar reaches 55 to 70 percent makes Fruit preserves. In this product, fruits retain its shape and are crisp rather than soft. Here also 45 parts of fruit for each 55 parts of sugar is employed.

Heat in Jam and Jelly Production

Jams

Jams may be made from all varieties of fruits. Good, fully matured fruits are selected, washed, peeled. Thin skinned fruits do not require peeling such as Apricots, plums etc but stone can be removed by machine. Fruits should be boiled in a small quantity of water and steamed and passed through pulper and finisher to get the desired texture pulp. Hence, heating is required to boiling or cooking the fruit to make into pulp. Cane sugar or sucrose is added to the pulp in equal ratio for most of the fruits. But for sweet fruits of low acidity such as ripe peaches, sweet prunes and grapes less than equal weight and sugar is required.

Boiling is an important heat treatment in the preparation of jam, jelly, marmalade and fruit preserves. Boiling or cooking is desirable, it causes intimate mixing of the fruit pulp and sugar. It partially concentrates the product by evaporation of excess moisture. Boiling is again dependent upon the firmness of fruits. Soft fruits in small lots can be concentrated to desired consistency as rapidly as possible. Other hard fruits are more resistant to heat application, may be boiled more slowly. Steam-jacketed stainless steal kettles are commonly used in commercial practice. Vacuum pan is also used to minimize heat damage to the product. Most jam should be concentrated to boiling temperature of 103 to 105^{0}C. The end points of jams boiling vary with fruit varieties, amount of sugar and some other factors. However, the finished jam should show 65 to 68 percent soluble solids as determined by refractometer.

Jelly

The pectin, acid and sugar are essential to the preparation of a normal fruit jelly, out of which pectin is the most important. To make a jelly of excellent consistency, pectin, acid, sugar and water must be in the proper portion. If the fruit is deficient in any one of the constituents, which can be added from outside source. However, we should take proper care in selection of fruits. Fruits rich in pectin, acid and sugars and fully ripe are selected to impart good flavour and texture to the finish product.

The pectin is precipitated as a hydrated colloid that forms a network of fibrils throughout the mass, binding the sugar into the gel. The concentration of sugar makes the texture stiffer. Acid causes the jelly to be the firmer by toughening the fibrils. This is the reason that these constituents must be in the right proportion viz. pectin 1%, sugar 60 to 65%, fruit acid 1% and water 33 to 38%.

Washed fruits are cut into slices or crushed. Very juicy fruits like berries, do not require water, simply they crushed and heated to the boiling point for 2 to 3 minutes and juice or pectin extracted pressed out. Firmer the fruits like apple, guava, oranges are cut or crushed and water is added half to equal volume of the fruits. They are required to be heated to 20 min. Citrus fruits require two to three volume of water for each volume of fruits and require to be heated for 30 to 60 min.

After addition of water, the fruit is boiled and then slowly put on simmering fire for the sufficient time (as mentioned above) to extract pectin, acid and sugars. A clear fruit extract is filtered and tested for pectin content by alcoholic test. The equal amount of juice and alcohol is taken in a centrifuge tube, mixed well, centrifuging, and reading the volume of the sediment. The viscosity of the juice varies with the pectin content hence, the viscosity test by any standard method may be used as a guide for pectin content.

Then fruit extract, sugar, acid are taken in an appropriate proportion. The whole mass is boiled to the end point.

Boiling is one of the important steps in jelly preparation. The boiling dissolve sugar, causes mixing of sugar, acid and pectin to form jelly. During heat treatment certain organic compounds coagulates, which can be skimmed from the surface and their removal make jelly clearer. The principal purpose of boiling is to increase the concentration of sugar to the point where jellying will occur. End point can be measured accurately by use of a thermometer. The thermometer is inserted in the boiling juice. If the juice contains the proper portion of sugar, acid and pectin, the boiling point of the liquid will be a few degrees higher above the boiling point. At sea level the boiling point will be 104 to 105^{0}C and corresponding to a concentration of 65 to 68 percent total solids in the jelly after cooling. This can be also measured by refractometer.

Marmalade

Marmalade preparation is similar to jelly with the difference that it contains pieces of fruit peel suspended there in. The principles of jelly making, apply also to the preparation of marmalade.

Preserves

Fruit preserves should retain the form of original fruit, either whole or cut fruit in clear sugar syrup of higher concentration. Fruit should not be overcooked or caramelized.

Preserves are processed by three different methods viz. open-kettle one-period process, the slow open-kettle process and by vacuum cooking of preserves. Heat treatment is the essential part of these cooking and it influences the quality of the finished products. These three methods are briefly discussed below:

Open kettle one period process: This is a simple method of preserve making and usually employed by housewives. In this process fruit is boiled in steam-jacketed kettles with sugar or in syrup until fruit is impregnated with thick or heavy density syrup. Soft fruits and berries should be boiled for short time. But the firm fruits like peach, pears, aonla require a long period to impregnated them with the syrup. Here, the end point can easily be determined by refractometer at 68 percent soluble solids or by a thermometer, which shows the boiling point about 104 to 105°C at sea level. It is a rapid method with low cost operation, but may result in serious injury to flavour and colour of the finished product.

The slow open-kettle process: In this process the fruit is heated for short time on successive days in sugar syrup of progressively increasing sugar concentration. This will avoid undue injury, to the colour and flavour of the preserves. Initially fruit is boiled enough in syrup containing about 40 percent sugar. Then the mixture kept aside for 24 hours and then further boiled for 3-4 minutes with the addition of 10 percent more sugar. This step is repeated until the product has the desired consistency and then placed in the final containers and sterilized.

Vacuum cooking of preserves: The vacuum cooked preserves are of superior quality in respect of flavour and colour then the preserves made in an open cooker.

The fruit preserves filled into glass jars or can at 88 to 96^{0}C and in commercial practice are generally pasteurized.

Candies: Candied fruits or candies are prepared essentially of slowly impregnating the fruit with sugar syrup until the sugar concentration in fruit is so high enough to prevent spoiling. Repeated boiling and storage in syrups of progressively increasing concentration of sugar generally accomplish this. The fruit is washed and dried to remove excessive sugar from surface. Then it is coated with glaze of sugar and glucose syrup, called glazed or candies. We have learned that heat treatment is essential part of the preparation these products.

13.8.2 Use of Heat in Ketchup and Sauce Production

Tomato ketchup:– Tomato ketchup (catsup, catchup) can be defined that it is a clean, sound product made from strained tomato juice, with spices, sugar, salt, vinegar, onion and garlic etc. It should contain not less than 12 percent tomato solids and 28 percent total solids.

Sauce: It can be defined that the sauce is a clean, sound product made from properly prepared fruits/ tomatoes / peppers with spices, salt, sugar, ginger, onion, garlic etc. It should contain total solids from 12 to 25 per cent.

For preparation of tomato ketchup the first step to prepare tomato juice or pulp for which fully ripe, red coloured fruits are taken. Heat application plays an important role in juice extraction from tomatoes particularly in hot break method. Tomatoes are cut or sliced and immediately heated to boil in their own juice for 3 to 5 minutes to facilitate juicing or pulping. The heat treatments help in the following ways:

1. The pectin present in the skin and seeds can be incorporated into the juice otherwise juice may separate into liquid and pulp.

2. Heat treatment inactivates/destroy the pectate enzymes otherwise hydrolyse the natural pectin present in tomatoes and resulting the thin juice.

3. Boiling tomatoes release the pectin and it thickens the pulp.

4. Boiling sterilizes the tomato juice partly, thereby controlling to some extent the growth of microorganisms, which may cause fermentation etc in the juice.

5. It also inactivates some oxidative enzymes, resulting better retention of vitamin C.

6. The cooking also releases the red colour present in the tomato skin.

7. Heat treatment yield higher juice recovery than cold method.

The tomato ketchup can be made from tomato juice or its concentrate or paste. Here we can say that for preparation of juice concentrate, paste or ketchup the original tomato juice has to be concentrated by application of heat. Thus, heat treatment evaporates water resulting in concentration of juice. The concentration of tomato juice is carried in two ways i.e. by open cooking and cooking under vacuum.

In the **open cooking** – the tomato juice is cooked or boiled in aluminium vessel (Patila), at smaller scale. In large scale, the juice is heated mostly in stainless steel steam jacket – kettle to the desired consistency, which can be measured either by refractometer or specific gravity hydrometer. The open cooking is generally employed, but it has some disadvantages. During cooking the product is exposed to the oxygen in the air, which may destroy vitamin C and makes the juice brown. Sometimes edible oil is added to prevent foaming, boiling, over sticking or burning. It also helps in lessening oxidation.

In **vacuum cooking** – All the above defects are removed in vacuum cooking. In this method the juice is placed in vacuum pan and heated. Under vacuum, boiling takes at reduced temperature of 71°C. This method results in the superior quality of finished product with better retention of vitamin C and colour than open cooking. In the end vacuum is broken and the juice is sterilized by heating to 100°C for about 10 minutes.

Sauce can be made from Soyabean, mushroom, apple and mixtures of various other fruits. Thin sauce is mainly consists of vinegar extract of various flavouring materials like spices and herbs for example Soya sauce, Worcestershire sauce. Thick sauce is highly viscous and contains fruit pulp and more sugar. Their cooking is similar to tomato ketchup.

Similarly fruit juices such as apple juice, pineapple juice, orange juice etc. are also concentrated which can be seen in other blocks and all needed heat treatment.

13.9 LET US SUM UP

Fruits and vegetables are generally preserved by heat application. Heat treatments are in terms of blanching, pasteurization and sterilization, which also affect the fruit and vegetable compositions, microorganisms and enzyme activity. Heat treatment protects the processed food products from spoilage causing bacteria, moulds and yeasts as well as enzymatic changes.

Heat treatment also made processed food palatable but reduces some of the nutrients. If appropriate time – temperature used and storage at low temperature helps in reducing the nutrient losses. It also enhances their storage life.

Appropriateness of the factors such as salt, sugar, fat, and protein, besides time – temperature and storage temperature also influences the quality and nutrients retention in the processed products.

Heat treatment in various forms is employed during canning process, for peeling, blanching, syrup or brine preparation, filling, exhausting, sterilization etc.

Heat is also applied during product preparation so that jam, jelly, and marmalade etc are set properly. Heat application is also employed in processing of juice and beverage.

Thus appropriate time – temperature depending upon the product and presence of microorganisms and enzymes can manufacture processed products of good quality with proper retention of nutrients.

13.10 KEY WORDS

Pasteurization : process of heating food product to a specific temperature for a specific time to kill the most heat resistant vegetative pathogen.

Sterilization : A process to heat food product to a specific temperature for a specific time to kill the most heat resistant spore-forming organism.

D-value : It is also called "decimal reduction time" or "thermal death rate" and defined as time (in minutes) at a particular temperature (°C) required to kill 90 percent of a microbial population.

Canning : It is defined as preservation of foods in sealed containers and usually implies heat treatment as the principal factor in the prevention of spoilage.

HTST : High temperature short time.

13.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - Constituents include carbohydrate, proteins, fats, vitamins, minerals, fibre, water, flavouring compounds

2. Your answer should include the following points:

   - Palatability
   - Storage life
   - Food borne diseases

3. Your answer should include the following points:

   - Blanching - Leaching, thermal oxidation, product damage
   - Pasteurization - Enzymes
   - Commercial - Heating food enzymes
   - Sterilization

4. Your answer should include the following points:

   - Different heat treatment terms are:

UHT, Pasteurization, sterilization, commercial sterilization.

5. Your answer should include the following points:

   - Temperature – time relationship
   - Environment (Nutrients, incubation temperature, state of growth and age, desiccation
   - Substrate composition (moisture, pH, other constituents)

Check Your Progress Exercise 2

1. Your answer should include the following points:

   - Blanching
   - Pasteurization
   - Commercial sterilization

2. Your answer should include the following points:

   - Degree of heat application / HTST
   - Time of heat treatment
   - Better nutrition, flavour
   - Minimum cooked taste if any

3. Your answer should include the following points:

   - Heating at higher temperature
   - Complete elimination of microorganisms
   - Destruction of pathogenic, spoilage causing organism

Check Your Progress Exercise 3

1. Your answer should include the following points:

   - Types of peeling
   - Heating medium – boiling water, steam, roasting, steam under pressure
   - Softening, cracking, loosening of skin

2. Your answer should include the following points:

   - Heat application – in clarification and preservation of juice
   - Destruction of yeasts and moulds but not killing the spore forming bacteria
   - Time and temperature

3. Your answer should include the following points:

   - Food classification based on pH and acidity

4. Your answer should include the following points:

   - Mixing of fruit and sugar
   - Preparation of pectin or water extract for jelly making
   - Cooking point
   - Temperature of fruit and sugar mixtures

UNIT 14 DRYING AND DEHYDRATION OF FRUITS AND VEGETABLES

Structure

14.0 OBJECTIVES

After reading this unit, you should be able to:

- know the importance of drying/ dehydration of fruits and vegetables;
- know the drying and rehydration ratio and factors affecting the drying rate of fruits and vegetables; and
- describe the theories and methods of drying and dehydration of fruits and vegetables.

14.1 INTRODUCTION

Drying or dehydration is accomplished by the removal of water from the fruits and vegetables below a certain level at which enzyme activity and growth of microorganisms is affected adversely. The dried or concentrated fruits and vegetable products are called as high sugar high acid foods or high value low volume foods. These dried or concentrated products save energy, money and space in shipping, packaging storing and transportation. Dehydration or drying process usually involves heating, in which water is removed from solid or near solid substances. Both term drying and dehydration mean the removal of water. The term **drying** is generally used for drying of the produce under the influence of non-conventional energy sources like sun and wind. **Dehydration** on the other hand refers to the process of removal of moisture by the application of artificial heat under controlled conditions of temperature, relative humidity and air flow. The sun drying is dependent upon the elements which are beyond the strict control. It is a slow process and thus, not suitable for many high quality products. Generally, it will not lower the moisture contents below about 15% which is too high for storage stability of numerous products. Removal of water from foods provides microbiological stability and assists in reducing transportation and storage costs. Fruit juice is concentrated by evaporating of water and most of the aromatic juice should be heated for short time as possible and cooled rapidly. This minimizes the effect on flavour, aroma, and sugar compounds.

14.2 THEORIES OF DRYING AND DEHYDRATION

There are two steps involved in drying & dehydration.

1. **Heat transfer theory**

   Transfer of heat therefore, consists of transferring some of this molecular or atomic motion from one region to another. There are three broad mechanisms by which such transfer can occur, conduction, convection, and radiation. In conduction, the energy is transmitted from particle to particle by a process of direct contact or random Collin with no bulk movement of material. Transfer of heat by convection involves bulk mixing of fluids of different temperatures. Radiation is the transfer of energy from a radiating source through space which may or may not be occupied by matter. It is by radiation that we receive all our energy from the sun.

2. **Mass transfer theories**

   The removal of moisture from a food product involves simultaneous heat and mass transfer. Heat transfer occurs within the product structure and is related to the temperature gradient between the product surface and the water surface at some location within the product. As sufficient thermal energy is added to the water to cause evaporation, the vapours are transported from the water surface within the product to the product surface. The gradient causing moisture – vapour diffusion is vapour pressure at the liquid water surface, as compared with the vapor presser of air at the product surface. The heat and the mass transfer within the product structure occurs at the molecular level, with heat transfer being limited by thermal conductivity of the product structure, while mass transfer is proportional to the molecular diffusion of water vapour in air. The rate of moisture diffusion can be estimated by the expression for molecular diffusion. The mass flux for moisture movement is a function of the vapour pressure gradient as well as the mass diffusion for water vapour in air, the distance for water vapour movement within the product structure and temperature. The transport of vapour from the product surface to the air and the transfer of heat from the air to the product surface is a function of the existing vapour pressure and temperature gradients, respectively, and the magnitude of the convective coefficient at the product surface.

14.3 ADVANTAGES OF DEHYDRATED FRUITS AND VEGETABLES

Fruits and vegetables that are properly dehydrated, particularly to a low moisture level (below 5%) have the following advantages:

1. Dehydration hardly affects the main calorie – providing constituents of fruit. It leaves the mineral content virtually unchanged. Therefore, the process is helpful in preserving the nutritive content of the final product. Vitamin losses are no grater with dehydration than with other preservation methods.

2. Dried fruits and vegetables have an almost unchanged shelf-life under proper storage conditions and there is no grater degree of bacteria, enzymatic changes, and mould actions.

3. Transportation, handling and storage costs are substantially lowered, and need of costly refrigeration during transportation and storage is eliminated Due to their reduction in average weight of $1/7^{th}$ to $1/9^{th}$ of the raw material shipping and handling weight is therefore reduced by approximately 90%.

4. They provide consistent product, an important modern marketing requirement. Seasonal variation in product quality is either absent or at a minimum with low –moisture fruits and vegetables.

5. They provide opportunities for maximum convenience, flexibility, and economics in production because they can be sized, shaped, formed, etc, to fit almost any requirement. With low moisture disposal and pollution problems.

6. They utilize the most economical and disposable from of packaging. The two major considerations in packaging dried fruits and vegetables are the exclusion of moisture and oxygen. Metal cans, plastic bags, and laminated bags and boxes effectively limit the passage of moisture and oxygen.

7. They offer many distinctive conventional as snack products.

14.4 MERITS OF DEHYDRATION OVER SUN DRYING

Dehydration is rapidly increasing importance over the sun drying because of its following characteristics:

1. **Drying conditions**

   Dehydration implies control over climatic conditions within a chamber, or micro environment control. Sun drying is at the mercy of the elements. Dehydration can be carried out throughout the year, irrespective of the prevailing climatic conditions of that region and require less land for drying activities. Sun drying of fruits and vegetables however, can be carried out in limited regions and time during which there is plenty of sun shine and practically little or no rain during the drying season, and require more land for drying activities.

2. **Sanitary conditions**

   In dehydration plant the sanitary conditions are controlled, and dehydration of fruits & vegetables is done under very hygienic conditions whereas in open field's contamination from dust, insect, birds and rodents are major problems.

3. **Relative cost**

   Dehydration has usually somewhat more costly than sun drying but undoubtedly the superior cooking quality of the dehydrated products will cause them to command a sufficiently higher price. For the small orchardist the cost of sun-drying trays is usually less than that of dehydrator, but for the large operator the cost of the dehydrator in some cases be no more than that of sun drying trays.

4. **Colour**

   During sun-drying green or slightly immature cut fruits such as peaches, and apricots, acquires the colour of its fully mature fruits. In dehydration the fruit retains the colour possessed at the time of cutting. Fruit of green, colour retaining this colour after dehydration, therefore, it is essential that fruit used for dehydration be fully mature. If the cut fruit is exposed to the sun for a few hrs before dehydration, the green colour disappear.

5. **Cooking quality**

   Dehydrated fruits, when cooked, more nearly resemble the cooked fresh fruits in flavour and colour than do cooked sun dried fruits. Comparison should be made of the refreshed and cooked fruits rather than the dried fruits. In coking quality, dehydrated foods are usually superior to sun dried counterparts.

6. **Relative yields**

   Dehydration usually gives a somewhat higher yield of dried product (calculated to a common moisture content) than is obtained by sun drying, even under ideal sun drying conditions. This difference is due probably to loss of sugar in sun drying through respiration or fermentation. During cloudy or raining weather loss of sugar in sun drying through fermentation becomes excessive.

14.5 FACTORS AFFECTING DRYING

Food dehydration involves two steps (i) to get heat into the product and (ii) to get moisture out of the product. The above two steps are not always favoured by same operating conditions. For example food may be pressed between two heated plates. This would give close contact and improve heat transfer into the food through top and bottom, but the close contact of the plates would interfere with the escape of free moisture. Thus it might be better to use one bottom hot plate to get heat in and a free surface on top of the food to let moisture out. The following factors discussed below are playing very important role in affecting the drying rate.

Temperature

The rate of heat transfer into the food which provides the driving force for moisture removal. is affected by the temperature difference between the heating medium and the food. Greater the difference, greater will be the heat transfer and moisture removal. When the heating medium is air, temperature plays a second important role also of carrying away the water driven from the food in the form of water vapour. But the moisture will create a saturated atmosphere at the food's surface which will slow down the rate of subsequent water removal.

Surface area

The heat and mass transfer is affected by surface area and higher surface area result into increased rate of drying. Therefore, the food to be dehydrated is sub divided into small pieces or thin layers which speeds drying for two reasons. First larger surface area provides more surface in contact with the heating medium and thus, more surface area from which moisture can escape. Second smaller particles or thinner layers reduce the distance through which heat must travel to the centre of the food and reduce the distance through which moisture in the centre of the food must travel to reach the surface and escape.

Air velocity

High velocity air, in addition to taking up moisture will sweep it away from the drying foods surface, preventing the moisture from making a saturated atmosphere which would slow down subsequent moisture removal.

Dryness of the air

When the food dried in air, then food will dried rapidly due to more absorption and more holding capacity of moisture by dry air than the moist air . Moist air is closer to saturation and so can absorb and hold less additional moisture,

The extent of dryness of the air also determines how a low moisture content food product can be dried to low moisture content. Dehydrated food is hygroscopic and each food has own its equilibrium relative humidity. Equilibrium relative humidity (ERH) is the humidity at a given temperature where the food will neither lose moisture to the atmosphere nor pick up moisture from the atmosphere.

14.6 PRE-TREATMENTS FOR DRYING OF FRUITS AND VEGETABLES

To obtain excellent quality of a dried product the raw produce needs to be harvested and handled properly. For better quality of dried products following pre-treatments required to be undergo.

Harvesting

To obtain high quality dried fruits and vegetables, the raw product must be harvested at optimum maturity and processed as carefully and rapidly as possible, for example pear is a fruit that is held after picking, because the best quality product is obtained when they are picked green and allowed to ripen in storage.

Washing

Fruits and vegetables are usually rinsed in cold water. To remove surface dust particle and pesticides spray residues, a residual chlorine content of 10-20 ppm of water is recommended to decrease the initial count of raw material to minimum.

Peeling and slicing

Root vegetables, apple and some times cling-stone peaches are peeled prior to drying. This is accomplished by various means: refractory, lye, hot brine peeles, high pressure steam for root crops, mechanical knife peelers for apples and dilute lye for cling-stone peaches. Prunes, grapes, berries and cherries are dried as whole, although latter may be pitted. Apricots, nectarines and peaches are halved and pitted, pears are halved and apples are peeled, cored and either sliced or sectioned.

Pricking

Many pre-treatments given to food before drying are aimed at making the structure more porous to facilitate mass transfer and speedup drying rate. Many pre-treatments are given before drying. Peas, carrots and aonla are pricked to increase the drying rate. Pricking can be done by a hand operated pricking machine. In preserve making the whole fruits, vegetables or their slices are uniformly pricked with stainless steel prickers or forks. Pricking is also useful while preserving fruits and vegetables by osmotic dehydration.

Soaking

The fruits and vegetables slices after pricking are soaked in plan water, lime water, brine or alum solution for few hrs to few days before blanching and cooking.

Curing

Curing is practiced in onion and garlic. It dehydrates raw material by sun drying or by hot air drying at a temperature of 30°C. In garlic it is carried out until the segments can be easily separated.

Alkaline dip

Alkaline dip is used primarily for fruits that are dried as whole especially prunes and grapes. Dipping facilitates drying by forming fine cracks in the skin. A sodium carbonate or lye solution (0.5% or less) is used at a temperature ranging from 93-100°C.

In Australia and some Mediterranean countries cold dip solution such as carbonate or lye with olive or commercial solution are used. The main active ingredients of commercial solution are oleate esters. These dips accelerates moisture loss by causing the wax plates on the grape skin to dissociate thus, facilitating water diffusion.

Acid dip

Before sulphuring use of an acid pre-dip provides better colour stability to a product. A dip of 1% ascorbic acid and 0.25% malic acid has been used to retard enzymatic browning in peaches. Steeping of mushrooms in 0.5% to 1.0% citric acid for 16 hrs results into better quality dried products in respect of colour, appearance, rehydration properties and keeping quality. .

Blanching

Blanching is a partial pre-cooking treatment in which vegetables/ fruits are usually heated in water or in live steam to inactivate the enzymes before processing.

Purpose of blanching

- Reduces drying time
- Removes inter- cellular air from the tissues
- Causes softening of texture
- Retards the development of objectionable odour and flavour during storage by enzyme inactivation
- Retain carotene and ascorbic acid during storage
- Removes pungency (onion)
- Impart desired translucent appearance to the product.

Sulphuring

The whole fruits, slices or pieces are exposed to the fumes of burning sulphur inside a closed chamber known as sulphur box for 30-60 minutes.

Purpose of sulphuring

- Prevent oxidation and darkening
- Act as preservative/ antimicrobial agents
- Check the growth of moulds
- Prevent cut fruits from fermentation
- Prevent the vitamin losses

Sulphiting

Sulphitation is a process in which the product is dipped in a SO_2 in water.

Purpose of sulphiting

- Maintains an attractive colour
- Prevents spoilage
- Preserves certain nutritive attributes until marketing
- Act as antioxidants and protect the carotene and ascorbic acid content of dried fruits.

Post drying treatments

The practices as post drying treatments which are followed after drying are described as follow:

Sweating

Sweating is a practice of storage of dried product in bins or boxes for equalization of moisture or re-addition of moisture to a desired level. It is used primarily with some dried fruits and some nuts (almonds and walnuts).

Packaging

Most product are packaged after drying for protection against moisture, contamination with micro-organisms, and infestation with insect , although some dried foods (e.g. fruits and nuts) may be held as long as a year before packaging.

In-package desiccant

In package desiccant means the packaging of the dried product with a material like calcium oxide or silica' gel that will continue to absorb the remaining moisture during storage. Silica gel @ 1 to 2% in powdered foods, prevent moisture picking after seal of the package and brought down the moisture from 3% to 1% n case of orange juice powder without a significant loss of vitamins at 21.1 to 67.8°C for 6 months and thereby, eliminating caking.

Pasteurization

It is usually limited to dry fruits to kills any pathogens that might be present as well as destroys spoilage organisms. The fruits usually pasteurized in the package and the treatment varying with the fruits is from 30-70 min at 100% relative humidity at 65.6 to 85°C.

14.7 DRYING RATE

The initial removal of moisture occurs as the product and the water within the product start evaporation due to slight increases in temperature and followed the initial stages of drying . A significant reduction in moisture content then will occur at a constant rate and at a constant product temperature. The constant-rate drying period occurs within the product at the wet bulb temperature of the air. While the most situations, the constant rate drying period will continue until the moisture content is reduced to the critical moisture content. At moisture content below the critical moisture content, the rate of moisture removal decreases and followed the falling rate drying period.

14.8 DRYING AND RECONSTITUTION RATIO

Drying ratio

Drying ratio is always vary with the type of variety, growing conditions, time of harvest, grade of raw material and loss in preparation. In this connection, dehydration ratio should not express on the basis of moisture percent in the material, but it should be expressed on a dry basis i.e. as the ratio of water content to dry matter. The weight of dry matter going into the dryer will be the same as that taken out. The amount of water changes, but the dry matter does not.

Knowing the water content of the fresh material entering the dryer and of the product leaving the dryer, the drying ratio, or its reciprocal drying yield, can be calculated as follows.

$$\text{Drying ratio} = \frac{\text{Weight entering dryer}}{\text{Weight leaving dryer}} = \frac{100 - \text{M1}}{100 - \text{M0}} = \frac{\text{TO} + 1}{\text{T1} + 1}$$

Where M0 = is the percent moisture of the material entering the dryer,
M1 = percent moisture of the product leaving the dryer
T0 = lb of water per lb of bone-dry material entering the dryer
T1 = lb of water per lb bone-dry material leaving the dryer.

For example, potatoes, prepared and ready for the dryer, have about 78 percent moisture, when properly dried they have about 7 percent moisture. Then

M0 = 78, M1 = 7, T0= 78/22 = 3.55, T1 = 7/93 =0.075

$$\text{Drying ratio} = \frac{100 - 7}{100 - 78} = \frac{3.55 + 1}{0.075 + 1} = 4.23 = 4.23:1$$

$$\text{Drying yield} = \frac{100 - 78}{100 - 7} = \frac{0.075 + 1}{3.55 + 1} = 0.236 \text{ or } 23.6 \text{ percent}$$

It should be noted that the over all ratio between weight of raw material entering the plant and weight of finished product leaving it must take into consideration losses incurred during preparation and final inspection.

Reconstitution ratio

Rehydration means the quantity of water absorbed by dehydrated foods.

Calculation can be made to express the results in terms of rehydration ratio" "coefficient of rehydration" and "percent of water in the rehydrated material"

Examples of such calculations are as follows:

Rehydration ratio

Suppose the weight of the dehydrated sample used for the test is 10 g (W_D) and the drained weight of rehydrated sample is 60 g (W_R).

Then $= \frac{W_R}{W_D} = \frac{60}{10} = \frac{6}{1}$, the rehydration ratio is 6 to 1 = 6:1.

Coefficient of rehydration

The drained weight of the rehydrated sample is 60 g (W_R), the weight of the dehydrated sample is 10 g (W_D) and contain 5 per cent moisture (W_M), and the original material before dehydration contained 87 percent moisture (A). Then

$$\frac{W_R}{\frac{(W_D - W_m)100}{100 - A}} = \frac{60 \times (100 - 78)}{10 - (10 \times 0.05)} = \frac{780}{9.5} = 82\% \text{ or } 0.82$$

Percent of water in rehydrated material

Knowing the drained weight of the rehydrated sample, the percent of water in the rehydrated material can be calculated;

$$\frac{60 - 9.5}{60} \times 100 = \frac{5050}{60} = 84.1\%$$

Note: For better rehydration it is suggested that the following conditions be met.

1. Detrmine the time of soaking and boiling that is compatable with optimum quality of the product.
2. Start the test with at least enough water to submerge the pieces , but do not use so much water that excess amount are present at the end of the test.
3. Shake or stir if necessary to insure wetting of all pieces during the test.
4. Control the rate of heating so as to prevent rapid and variable losses of water while boiling.

14.9 ROLE OF WATER ACTIVITY AND ITS IMPORTANCE IN DRIED PRODUCTS

Water activity (a_w) is defined as the ratio of the vapour on the aqueous solution to that of pure water at the same temperature i.e.

$$a_w = \text{Vapour pressure of solution at T°C}$$

Vapours pressure of pure water at T°C.

Water activity is also equal to the equilibrium relative humidity (ERH);

$$a_w = \frac{\text{Equilibrium relative humidity}}{100}$$

The a_w has a major role to play on microbiological spoilage and chemical changes produced in the food. The principles of water and microorganisms relation includes:

i) water activity, rather than water content determines the lower limit of available water for microbial growth. Most bacteria do not grow below a_w 0.91 and most moulds cease to grow at water activity of 0.80. Some xerphylic fungi have been reported to grow at water activities of o .65, but the range of 0.70 – 75 is generally considered their lower limit.

ii) Environmental factors affect the level of water activity required for microbial growth. The less favourable the other environmental factors (nutritional adequacy, pH, oxygen pressure, temperature) the higher becomes the minimum a_w at which microorganisms can grow.

iii) Some adaptation to low water activities occurs, particularly when a_w is depressed by addition of water soluble substances (principle of IMF), rather than by water crystallization (frozen foods) or water removal (dehydrated foods).

iv) When water activity is depressed by solutes. The solutes themselves may have effects which complicate the effect of a_w per se. For instance, at a given a_W microbial growth is less effectively depressed by glycerol than by sodium chloride. More recent (IMF) have resulted in the following additional findings.

a) Water activity modifies sensitivity of microorganisms to heat, light and chemicals. In general organisms are most sensitive at high water activities (i.e. in dilute solution) and minimum sensitivity occur in an intermediate moisture. Minimum water activities for production of toxins are often higher than those for microbial growth. The phenomenon may represent an important safety factor in the distribution of dehydrated and intermediate moisture foods.

b) The effect of water on chemical reactions in foods are more complicated than are its effect on microbial growth. It plays one or more of the following roles; a) as a solvent for reactant and for products, b) as a reactant (e.g. in hydrolysis reactions) c) as a product of reactions and d) as a modifier of the catalystic or inhibiting activities of other substances (e.g. water in activities some metallic catalysts of lipid per oxidation).

14.10 COMMON TYPES OF DRIERS USED FOR DRYING OF FRUITS AND VEGETABLES

A) Solar driers

These are suitable for drying of onion flakes. The matrix type solar air heater consists of an iron scrap as an absorber. The upper surface of this matrix is painted dull black. Air is made to flow through the matrix in the upwards direction. Similarly in rock type solar air heater is connected with the cubic shaped dehydration chamber, through an air duct of appropriate dimension. Dehydration chamber has provision for holding trays and thermometer a glass door and a chimney. Solar driers are different types like tent type drier, walk-through drier, air flow inside indirect drier cabinet, indirect chimney driers etc.

B) Air convention driers

Air convection driers have some sort of insulated enclosure, a means of circulating air through the enclosure and a means of heating this air. They also have various means of product support and special devices for collecting dried product, some have air driers for lower drying air humidity. Movement of generally is controlled by fans, blower and baffles. The air may be heated by direct or indirect methods. In direct heating the air is in direct contact with a flame or combustion gases. In indirect heating the air is in contact with a hot surface such as pipes or fins heated by steam, flame or electrically.

1. Kiln driers

This is the one of the simplest kind of air convention drier. In this dryer a furnace or burner on the lower floor generated heat and warm air rises through a slotted floor to the upper storey. Food such as apple slices spread out on the slotted floor of drier and turned-over periodically. This type of drier generally will not reduce moisture to below 10%. A rotary kiln drier dries the product in a rotating drum using a burner to blow hot air into the drum along with the product. Because of higher temperatures of drying, this method has some limitations with respect of limited nutrient levels and off- colour of the finished product.

2. *Cabinet tray and pan dryers*

Cabinet drier are suitable for small scale operations. Fresh air is drawn by the fan through the heater coils, filtered by screened to remove dust, and than blown across the materials on trays to an exhaust system. The air may pass across and between the trays or may be directed up through the perforated trays. Cabinet tray and pan driers are comparatively inexpensive and easy to set in forms of drying conditions. These may run up to 25 trays high and will operate with air temperature of about 93°C (200°F) dry bulb and air velocities of about 2.5-5 m/s across the trays. They are commonly used to dry fruit and vegetable pieces and depending upon the food and the desired final moisture, drying time may be of the order of 10-20 hrs.

3. *Tunnel and continuous belt driers*

The main construction feature by which tunnel driers differ is the direction of air flow relative to tray movement. When the direction of air flow and that of tray movement is opposite, then it is counter-flow or counter current principle. Its significant is that the air ,when it is the hottest and dries, contacts the nearly dry product, whereas the initial drying of entering carts get cooler, most air that has cooled and picked up moisture going through the tunnel. Since the initial product temperature and moisture gradients will not be great, the product is less likely to undergo case hardening or other surface shrinkage leaving wet centres. Further, lower final moisture can be reached since the dried product encounters the driest air. In contrast, there are also co-current flow, tunnels with the incoming trays and dry-hot air travelling in the same direction. In this case, rapid initial drying and slow final drying cause case hardening, internal splits and porosity as centres finally dry, which sometimes is desirable in special properties.

The common features of the dryer include uniform automatic feeding of product to the belt in a controlled thin layer, zone heat and air flow control in different sections, tumbling over the product onto a second strand of belt, automatic collection of dried product and of course continuous operation.

4. *Belt trough driers*

A special kind of air convection belt driers is the belt trough drier in which the belt from a trough and belt is usually made up of metal mesh and heated air blown up through the mesh. The belt moves continuously keeping the food pieces in the trough in constant motion to continuously expose new surface. This speeds-up drying with air of about 135°C (272°F) vegetable pieces dried to 7 to 5% moisture range in about 1 hr. High operating temperatures result in high drying rates without causing appreciable heat damage to vegetable pieces because the constant agitation keeps individual piece from being exposed to the very hot dry air for more than a movement. Then, each piece is surrounded by air at much lower temperature for a longer time before again moving into the zone of intense drying,. Onion slices dried in this way tend to separate and become entangled. Fruit pieces that exude sugar on drying tend to stick together and clump with the rumbling motion.

5. *Air lift drier*

Several types of pneumatic conveyer dryers go a step beyond tem being to exposure more surface area of food products. These dryers tem being to finish dry materials that have been partially dried by other methods, usually to about 25% moisture or at least sufficiently low. So that the material becomes granular rather than having a tendency to clump and mat. A product from drum drier having 25% moisture can be brought to about 6% moisture more efficiency in a heated air steam than on the drum. This is because it is more difficult to remove moisture in this falling rate of dehydration. The suspended particles when dry are separated from the air and collected in a cyclone type separator.

6. *Fluidized bed drier*

Another type of pneumatic conveyor drier is the fluidized bed drier. In fluidized bed drying heated air is blown up through the food particles with just enough force to suspend the particles in a gentle boiling motion. Semi dry particles such as potato granules gradually migrate through the apparatus until they are discharged dry. Heated air is introduced through a plate that supports the bed of granules. The moist air is exhausted at the top. This process is continuous and the duration of time that the particles remain in the drier can be regulated by the depth of the bed. This type of drier can be used to dehydrate peas and other particles. Fluidized bed drying has numerous advantages such as a) high drying intensity, b) uniform and closely controllable temperature throughout, c) high thermal efficiencies, d) time duration of the material in the drier may be chosen arbitrarily, e) elapsed drying time is usually less than in other types of drier, f) equipment operation and maintenance are relatively simple, g) the process can be automated without difficulty, h) fluidized drier are compact and relatively small, i) several process may be combined in a fluidized bed drier.

7. *Spray drier*

By far the most important kind of air convection drier is the spray drier which is used widely for dehydrating liquid food products. It is limited to foods that can be atomized (liquid and low viscosity passes or purees). Automization into minute droplets results in drying in a matter of seconds with common inlet air temperatures of about 204^{o}C. The liquid product to be dried is automized into a chamber, where it is put in contact with a stream of hot air and rapidly dried. The dry particles suspended in air stream, flow into separation equipment where they are removed from the air, collected and packaged or subjected to further treatment, such as instantizing. A wide range of products like banana, potatoes, proteins from various plants sources, soy isolates, citrus juices, tomato puree corn hydrolysates etc. have been successfully drying by this dryer.

8. Bin dryer

Bin drier are used, particularly for pieces from of vegetable products to complete the drying operation. Usually it is a finishing step after truck apron or tunnel drying during which most of the moisture has been removed. Typically, a bin drier reduces the moisture content of a particularly dried products (10-15% moisture) cut vegetable to 3-6% or even lower in the case of onion slices and possibly cabbage shreds. Win dryer consists of a metal or wooden box equipped with an air inlet at the bottom and a wire mesh deck or false bottom with an air supply duct below it so arranged that warm dry air can be passed through the nearly dry product piled on the deck.

C) Roller drier

Roller drier consists of one or two hollow drums which are fitted so that a heating medium, usually steam but occasionally water or a special high temperature, heat transfer liquid can be directed through them. The drums are mounted to rotate about the symmetrical axis and are customarily driven with a variable speed mechanism, feeding device applies a thin, uniform, layer of the material to be dried on the hot drum surface. A knife or doctor blade is fitted to the drum at an appropriate location. The material is dried as the heated drum rotates towards the doctor blade which scrapes the thin layer of dry material from the drum surface.

1. Drum drier

In drum drying liquid foods, purees, pastes, and mashes are applied in a thin layer onto the surface of a revolving heated drum. The drum generally is heated from within by steam. Driers may have a single drum or a pair of drums. The food may be applied between the nip where two drums comes together, and then the clearance between the drums determines the thickness of the applied food layer. Drum drying has some inherent limitations which restrict the kinds of foods to which it is applicable. To effect rapid drying drum surface temperature must be high generally above 121°C. This give product, a more cooked flavour and colour than when they are dried at a lower temperature. Another limitation is the difficulty of providing zoned temperature control needed to vary the drying temperature profile. With a modified atmospheric double drum drier and with appropriate separating conditions, fruit and vegetables flakes are produced with commercial success. The vapour which evolved during drying are exhausted through hoods over and under the drums. The product collection zones are maintained at about 10-20% RH. Drum drying process are used successfully in the production of powdered cranberries, tomato cocktail, pea and bean soups, apple, flakes, potato flour, tomato juice flakes, mashed flakes and sweet potato flakes.

2. Foam-mat drier

Foam-mat driers are used primarily for liquids which are pre-foamed by whipping, adding a few level of an edible whipping agent-to liquids that do not whip readily. Foaming a liquid exposes enormous surface areas for quick moisture removal which also permits use of lower drying temperatures. Foam is deposited in a uniform layers of many foods can be dried to about 2-3% moisture in approximately 12 min.

D) Vacuum dryers

In vacuum drying the temperature of the food and the rate of water removal are controlled by regulating the degree of vacuum and the intensity of heat input. Heat transfer to the food takes place largely by conduction and radiation. Vacuum drying methods usually can be controlled with a higher degree of accuracy than the n method which depends upon air convection heating. All vacuum drying system have four especial elements: a vacuum chamber of heavy construction to with stand outside air pressure that may exceed internal pressure by as much as 9800 kg/m^2 a heat supply, a device for producing and maintaining the vacuum, and components to collect water vapour as it is evaporated from the food.

1. *Vacuum puff drier*

   Vacuum puff drier refers to the dehydration of liquid materials in vacuum by evaporating water under pressure in excess of 1 mm of Hg, so that the products puff during drying and form expanded honey combed structures. This process is distinguished from freeze drying in that latter is done under extremely low pressure, always well below 1 mm and sometimes as low as 5 µm, with the materials in a frozen state.

   In puff drying of juice, a porous structure is obtained by applying vacuum to a viscous juice concentrate when bubbles of water vapour and entrapped air formed expand throughout the material. Vacuum temperature and velocity of the concentrate are controlled so that the puffed material has about 20 times the volume of the liquid concentrate. In certain juice such as tomato, which have low soluble solids content and a high insoluble solids or pulp content, puffing is not satisfactory unless air or another gas is incorporated into the concentrate.

2. *Vacuum shelf puff driers*

   One of the simplest kinds of vacuum driers is the batch type vacuum shelf drier. If liquids such as concentrated fruit juices are dried above 5 mm Hg, the juice boils and splatters, but in the range of about 3 mm Hg and below, the concentrated juice puffs as it losses water vapour. The dehydrated juice then retains the puffed spongy structure. High vacuum dehydrator operates at fractions of a millimetre of mercury. At 2 inch or 50 mm of mercury pure water boils at 38°C. Since temperatures well below 38°C (101° F) can be used, in addition to quick solubility there is minimum flavour change or other kinds of the heat damage. It is also suitable for the dehydration of food piece.

3. *Continuous vacuum belt puff drier*

   The drier consists of a horizontal tank like chamber measuring about 17m length and 3.7 m in diameter. The chamber is connected to a vacuum producing moisture condensing system. Two revolving hollow drums are mounted within the chamber and a stainless steel belt is connected around the drums which move in a counter clockwise direction. The drums on right as heated with steam confined within it. The drum heat the belt passing over it by conduction. As the belt moves it is further heated by infrared radiant elements. The drum to the left is cooled with cold water circulated within it and cools the belt passing over it. The liquid food in the form of a concentrate is pumped into a feed pan under the lower belt strand. An applicator roller dipping into the feed continuously applies a thin coating of the food onto the lower surface of the moving belt. The food is dried in a vacuum equivalent to 2 mm Hg. When the food reaches the cooling drum it is dried to about 2% moisture. At the bottom of cooling drum is a doctor blade which scrapes the cooled, product, into collection vessel. It is used commercially to dehydrate high quality citrus juice crystals and other delicate liquid foods. Products dried with this equipment have a slightly puffed structure.

E) Freeze driers

Freeze dryers are used to produce dehydrated foods of exceptional quality. In freeze dryers the material such as fruit juice concentrate, is first frozen on trays in the lower chamber of a freeze driers and the frozen material dried in the upper chamber under high vacuum. The material dries directly by sublimation of ice with out passing through the intermediates liquid stage. The dried product by this method is highly hygrospic. It reconstitutes readily. Mango pulp, orange juice concentrate and guava pulp have been found to give freeze dried powders of excellent quality in regard to taste, flavour, reconstitution properties etc.

F) Slush driers

Slush driers are used to obtained the benefit over the freeze dryer and air or vacuum drying without the drawback of drying from a partially frozen state where in 20-70% of water present is frozen with remainder being liquid. The high dissolved solid contents of the liquid portion of the mixture aids volatiles relation and the need for maintaining the ultra low temperature requirement for freeze drying is avoided.

14.11 IDEAL CONDITION FOR PACKAGING AND STORAGE OF DRIED PRODUCTS

Packaging is an integral part of processing. It provides a barrier between the food and the environment. It controls light transmission, transfer of heat, moisture and gas, and movement of microorganisms or insects. The shelf life of a dehydrated product is influenced to a large extent by the packaging. So package must confirm the following special criteria:

a) Protection of the dehydrated product against moisture, light, air, dust, micro flora, foreign odour rodent etc.

b) Strength and stability to maintain original container properties through storage, handling and marketing.

c) Size, shape, appearance to promote stability of the product.

d) Composition of the container must be approved for use in contact with foods.

e) Cost of the package should not be more than the cost of content packed inside of the package.

Dried fruits and vegetable should be quite dry and should be packed in moisture proof container such as tin container. If care is not taken to guard against entry of excessive moisture the contents inside the package become mouldy. Wooden boxes or cardboard containers are not generally moisture proof and insect proof unless special methods are adopted to line them. Proper packaging of dehydrated fruit and vegetable products prevents, deterioration and spoilage during storage under ordinary conditions, as well as under extra ordinary conditions. With the recent introduction of a variety of plastic packaging materials and film, a great deal of research work has been carried out in many parts of the world to develop suitable packaging. In the case of fruit juices powders, some spice products etc their packaging becomes highly critical and decisive. Packages based on cheap indigenous materials such as brown casing paper (60 gauge) aluminium foil (0.0mm) polyethene (150 gauge) pouches with a 2 ply corrugated liner wax ed carton, etc have been developed to ensure a minimum shelf life of one year under field conditions.

Dried and dehydrated foods should be stored in a dark, dry, cool, place, and lower the temperature of storage, longer the life of the product. Storage practices for dried fruits are variable, but a temperature of 40°F is commonly used with little attempt humidity control. The best storage for most dried fruits is 32°F and 55 percent relative humidity. Some fruits such as dried apples, apricots and peaches, do not seem to be harmed by 80 percent relative humidity at 32°F. Other particulars raisins and figs gain moisture, and sugar to a harmful extent at this humidity.

14.12 DRYING PROCESS FOR FRUITS AND VEGETABLES

The process used for drying of individual fruit and vegetable is described as follows:

Fruits

Grapes: Raisins prepared from grapes are the most important dried fruit product. Muscat and wine varieties are dipped in boiling solution of 0.5% caustic soda followed by rinsing and sulphuring for 1 hr and then, drying at 55-60°C in a dehydrator or sun drying. Ripe bunches of grapes are hung inside the dark rooms known as Kishmish khanas till berries acquire a greenish or light amber tint colour. Monucca or raisins is prepared from large seeded Haitha grapes which are lye dipped prior to sun drying. In California, the Sultana or Thompson seedless grapes are dried.

Banana: Washing, peeling, cutting, into halves lengthwise or crosswise (12 mm thickness), sulphuring for 30 min followed by drying at 55-60°C in a mechanical or solar drier.

Prunes: Washing, cleaning, pitting perforation and drying.

Apricot: Washing, cutting, into halves, destoning, sulphuring for 30 min. followed by drying at 50-60°C in a mechanical or solar drier.

Mango: Washing, peeling , cutting into 12 mm thick slices, sulphuring for 2 hrs followed by drying at 45-50°C in a mechanical or solar drier. Ripe mangoes are taken and juicy squeezed by hand and dried as Aam pappad.

Date: Washing, dipping in boiling solution of 0.5% caustic soda followed by rinsing and drying in a dehydrator at 45-50°C.

Fig: Washing, sulphuring for 1 hr followed by drying at 55 to 60°C in a mechanical or solar drier.

Aonla: Washing, grating followed by addition of salt @ 40 g/kg to the grated material and then, drying in mechanical or solar drier.

Apple: Washing, peeling, coring, trimming and slicing into 5 mm thickness, followed by sulphuring for 30 min or immersion in 1-2 % KMS solution for 30 min. This follows the drying at 60-65°C in a mechanical or solar drier.

Papaya: Washing, peeling, removal of seeds, cutting into 6 mm thick slices, sulphuring for 2 hrs followed by drying at 60-65°C in a mechanical or solar drier.

Pear: Washing, peeling, cutting into halves, holding in 1-2% salt solution, sulphuring for 30 min. or immersion for 20 min in 1-2%KMS solution followed by drying at 60-65°C in a mechanical or solar drier.

Peach: Washing, stone, peaches like july Elberta cultivars is used for drying. The drying process includes washing, removal of pits, cutting into halves, sulphuring for 30 min followed by drying at 60-65°C in a mechanical or solar drier.

Other Fruits: Pomegranate seeds are dried into Anardana, cherries and berries are also dried.

Varieties of the common fruits suitable for drying

Apples	Baldwin, Bellflower, Delicious, Gravenstein, Hoover, Jonathan, king, Yellow Newtown, Permain, Rhode Island greening, Rome Beauty, Wagener, Winesap
Apricot	Blenheim, Royal, Tilton
Figs	Adriatic, Black Mission, Calimyrna, Kadota
Nectarins	Hardwick, Newboy, Quetta, Stanwick
Peaches	California midsummer varieties and Phillips cling
Peaches (freestone)	Elberta, Lovell, Muir
Pears	Bartlett
Prunes	French, Imperial, Sugar, Robe de Sergeant
Raisins 9Golden bleached) dehydrated	Thompson Seedless
Currants (Zante)	Black Corinth

Vegetables

Onion and *garlic* make excellent dehydrated product: onion is dried in the form of flakes and powder whereas; garlic is dried as cubes and powder. Their use in the dry form has great scope particularly for export point of view.

Beans: Washing, peeling and cutting into 10 mm thick slices, steam blanching for 10 min. followed by drying at 60-65°C in mechanical or solar drier.

Beet: Washing, peeling and cutting into 10 mm thick slices, steam blanching for 10 min. and drying at 60-65°C in mechanical or solar drier.

Bitter gourd: Washing, removal of both ends cutting into 10 mm thick slices, blanching for 7-8 min. and drying at 65-75°C in mechanical or solar drier.

Brinjal: Washing, cutting lengthwise into 10 mm thick slices, blanching for 4-5 min and then, immersion for 1 hr in 1% KMS solution followed by drying at 50-52°C in mechanical or solar drier.

Cabbage: Washing, removal of outer leaves and cutting into fine shreds, blanching for 5-6 min, immersion for 10 min in 0.5% KMS solution and draining by drying at 55-60°C in mechanical or solar drier.

Cauliflower: Washing, removal of stalks, covering leavers and steams, breaking of curd suitable size pieces, blanching for 4-5 min. immersion for 1 hr in 1% KMS solution and draining followed by drying at 55-60°C in mechanical or solar drier.

Carrot: Washing, scrapping, stalks and tips, cutting into 10 mm thick slices blanching for 2-4 min. in boiling solution of 2% salt followed by drying at 60-65°C in mechanical or solar drier.

Chilies (red): Mature dark red pods are tied to a string and hanged in sun or dried at 50-55°C in a dehydrator.

Green peas: Washing removal of shell, blanching grains in boiling water or steam for 3-4 min. immersed in 0.5% KMS solution and draining followed by drying at 60-65°C in mechanical and solar drier.

Palak, methi and other leafy green vegetables: Sorting, washing, trimming-off rough stems and stalks and shred making followed by blanching for 2 min in boiling water or steam and then drying at 60-65°C in mechanical or solar drier.

Potato: washing, peeling, and cutting into 10 mm thick slices, blanching in boiling water or steam for 3-4 min. and immersion in 0.5% KMS solution followed by drying at 60-65°C in mechanical or solar drier.

Tomato: washing, blanching for 30-60°C, peeling and slicing into 1 cm thick slices followed by drying at 60-65°C in mechanical or solar drier.

Turnip: Washing, removal of stalk, peel, cutting into 5 mm thick slices, blanching for 2-4 min. in boiling water then immersion for 1-2 hr in 1%KMS solution, followed by drying at 50-55°C in mechanical or solar drier.

Mushroom slices: mushrooms are one of the most important vegetable prepared by dehydration. Steps include trimming, blanching with SO_2 @ 500-1000 ppm for 5-10 min. slicing followed by drying in mechanical or solar drier.

Ginger: trimming, washing, cutting or slicing and drying in mechanical or solar drier.

Drying schedule for fruits

Fruits	Preparation	Pretreatments (in boiling lye solution 0.2% NaOH)	Time of sulphuring (min)
Apple	Peel, core and cut in 5 mm thick slices	-	15-30
Apricot	Wash halves destine	-	20-25
Peach	Halves peel, destine	-	20-25
Grape	Wash	2-5 sec.	10-15
Banana	Wash peel, cut into thick slices	-	2 hrs
Mango	-do-	-	2 hrs
Papaya	Wash peel, cut into 5 mm thick slices	-	2 hrs
Pine apple	-do-	-	2 hrs

Drying schedule for vegetables

Vegetables	Preparation	Blanching in boiling water	Sulphitation in 0.5% KMS
Potato	Peel cut into 3mm thick slices	3-4 min	30 min
Carrot	-do-	4-5 min	30 min
Okra	Remove both ends and cut into 6mm thick slices	5-6 min	30 min
Cabbage	Remove outer leaves and cut into 4-8 mm thick shreds	5-6 min	30 min
Cauliflower	Remove stalks leaves and stem cut into 10 mm thick slices	5-6 min	30 min
Peas	Shelled peas	3-4 min in boiling water containing 0.5% KMS,0.1% Sodium bicarbonate and 0.1% magnesium oxide	30 min
Spinach	Short, wash thoroughly in water and cut into 10 mm portion	-do-	Nil

Fenugreek	Short, remove stalks and stem and wash leaves thoroughly	Blanch above for 2-3 min	Nil
Onion	Remove tops and tails, peel and cut into 4-8 mm thick shreds	Nil	Nil
Garlic	Peel and cloves cut into 6 mm thick shreds	Nil	Nil
Bitter Guard	Remove both end and cut into 6mm thick slices	Blanch in boiling water	30 min
Pumpkin	Peel remove seeds, and cut soft portions into 6mm thick slices	2 min	30 min

14.13 LET US SUM UP

Dehydration or drying is an important and oldest preservation method in food processing. Water removal from food is primarily done to lower the water activity (a_w) so that microbial growth is inhibited. It also saves energy, moisture and space in shipping, packaging, storage and transportation of dried fruit and vegetable products. These are known as high value low volume food or high acid high sugar foods. Prolong heat processing of fruits and vegetables affect their delicious flavour, nutritional quality and acceptability. In recent years, the achievements in the drying / dehydration of fruits and vegetables have led to the development of more improved methods and techniques of drying including water removal at low or ambient temperature. These techniques include osmotic dehydration, foam-mat drying (especially micro flake process), modified drum drying, explosion puffing, slush drying, vacuum drying, freeze drying etc. Various treatment have been developed for treating fruits and vegetables to increase the rate of drying or decrease the drying time to reduce the production of brown pigment. So by using these techniques, the overall quality of the dried products including sensory and nutritional value, has been improved.

14.14 KEY WORDS

Water activity	:	Water activity (a_w) is the ratio of vapour pressure of food (P) and pure water (p_o) and expressed by aw = p/p_o.
Dehydration	:	Removal of moisture under control conditions of temperature, air flow and humidity.
Drying	:	Drying of the product under the sun.
Conduction	:	Transfer of heat with contact particle to particle.
Blanching	:	Partial pre-treatment in which vegetables are heated in water or live steam to inactivate enzyme before processing.
Sulphuring	:	Exposing the of fruits to the fumes of burning sulphure inside a closed chamber.
In-package desiccant	:	Packaging of the dried products with a material like calcium oxide or slica gel.
Sorption isotherms	:	water sorption isotherms is a graphical presentation of data which shows the water relationship of food.
Concentration	:	Removal of water from foods mostly by heat application and concentration of soluble solids or solutes.

Preservation	:	Methods to hold food for a longer period than generally kept at ambient conditions. Food is safe, nutrients and free from and microbial infection.
ERH	:	Equilibrium Relative Humidity.
Osmotic dehydration	:	Removal of water through a membrane from higher concentration to lower concentration.
Unit operation	:	It is a step in the complete process or a physical change in form or place, for example, peeling, cutting, grading, etc.
Drying ratio	:	Drying ratio is the reciprocal of fresh material to dried material.
Spoilage	:	The food which has been damaged or injured which make the food undesirable for human use.
Rehydration ratio	:	Reconstitution ratio is the quantity of water absorbed by dehydrated foods.
Reverse osmosis	:	Reverse osmosis means movement of water through the membrane by applying pressure on the solute side of the membrane in excesses of the osmotic pressure.

14.15 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - Drying of commodity in the sun with non conventional sources of energy like sun and wind.
   - Drying the commodity under controlled conditions like temperature, relative humidity and air flow.

2. Your answer should include the following points:

   - To reduce the weight and bulk
   - To reduce the water activity

3. Your answer should include the following points:

   - Transfer of heat through conduction
   - Transfer of heat through convection
   - Transfer of heat through radiation

4. Your answer should include the following points:

   - Transfer of vapour from product surface to the air
   - Transfer of heat from air to the product surface

5. Your answer should include the following points:

   - By addition of thermal energy to the product
   - By transfer the heat to the product and water surface

Check Your Progress Exercise 2

1. Your answer should include the following points:

   - Transport cost less
   - Storage cost less
   - Shipping cost less

2. Your answer should include the following points:

   - Bette quality of finished product
   - Carry out through out the year
   - High yield of the product

3. Your answer should include the following points:

   - They can fit into any size
   - They can fit into any shape
   - They can fit into any forms
   - Low disposal and pollution

Check Your Progress Exercise 3

1. Your answer should include the following points:

   - Temperature and RH
   - Product size and surface area
   - Air velocity and dryness of the air

2. Your answer should include the following points:

   - To get heat in
   - To let out mass out

3. Your answer should include the following points:

   - Provides the driving force for moisture removal
   - Carry away the water driven in the form of water vapour

4. Your answer should include the following points:

   - Provide more surface in contact with heating medium
   - Provide moisture surface for moisture removal

5. Your answer should include the following points:
   - To reduces the travelling distance through which moisture is travel from the centre of the product.
   - To reduces the travel distance through which heat transfer from the surface to the centre.
6. Your answer should include the following points:
   - To facilitate mass transfer
   - To speedup drying rate
7. Your answer should include the following points:
   - To form fine cracks in the skin
   - To facilitate drying
8. Your answer should include the following points:
   - To inactivate enzyme
   - To reduce the drying time

Check Your Progress Exercise 4

1. Your answer should include the following points:
   - T constant rate the moisture same as critical moisture
   - At falling rate the moisture is below the critical moisture
2. Your answer should include the following points:
   - Drying means as drying the produce under the influence of conventional energy source like sun and wind, below a certain level of moisture, at which enzymes activity is nil.
   - Reconstitution ratio is expressed on a dry basis i.e. ratio of water content to dry mater.
3. Your answer should include the following points:
   - Optimum ratio of dried material and water/sugar solution
   - Time and temperature of the water/sugar solution
   - Shaking if necessary

Check Your Progress Exercise 5

1. Your answer should include the following points:
   - Water activity (a_w) is defined as the vapour on the aqueous solution to that of pure water at the same temperature.
2. Your answer should include the following points:
   - Uniform automatic feeding
   - Zone heat collection of dried product
   - Continuous operation
3. Your answer should include the following points:
   - High drying intensity
   - Uniform and closely controllable temperature
   - Operation and maintenance simple

4. Your answer should include the following points:
   - Regulating degree of vacuum intensity
   - Regulating heat input intensity

Check Your Progress Exercise 6

1. Your answer should include the following points:
   - Provide a barrier between food and environment
   - Control light transmission
   - Control transfer of heat and gas
   - Control the movement of microorganisms and insect.
2. Your answer should include the following points:
   - The optimum temperature 32°C
   - The optimum RH 55%.

UNIT 15 FREEZING

Structure

15.0 OBJECTIVES

After reading this unit, you should be able to:

- basic principle of freezing preservation;
- importance of freezing;
- methods of freezing, packaging and storage; and
- maintaining quality in frozen foods.

15.1 INTRODUCTION

In the present chapter we will study about a technology that uses low temperature to preserve food products. You might have noticed that in majority of the preservation methods heat is often used to kill or inactivate microorganisms to extend the shelf life of foods. Subjecting the food materials to low temperature is yet another alternate method to preserve foods. Raw plant material is normally considered to unclean. This is because any raw plant or animal food may be assumed to contain a variety of bacteria, yeasts and moulds. These microorganisms constitute the surface microflora and they need optimum conditions to bring about undesirable changes in the food. Each microorganism present has an optimal, or best, temperature for growth and minimal temperature below, which it cannot multiply. As the temperature drops below this optimal temperature towards the minimal, the rate of growth of the organisms decreases and is slowest at the minimal temperature. The enzymatic reactions in foods also take place at optimum temperatures. If you lower the temperature the enzymatic reactions are also lowered and foods can be prevented from spoilage. This is the basic principle behind freezing preservation of foods.

Do you know what are basic principles of food preservation. I am sure you must have gone through them in other chapters. Let me refresh your memory. Basically there are three methods of preservation. Their main aim is to control the activities of microorganisms. In short you can also refer to them as 3K's. They are 1) Keep them away 2) Kill them 3) Keep them away from growing

The first K refers to use of asepsis methods to keep the microorganism away. The second K refers to killing pathogenic microorganisms to prevent spoilage. Finally the third K employs methods that create conditions which prevent or retard the growth of nonpathogenic type of microorganisms. The Freezing technology is based on the third principle of preservation. Low temperature retards the biochemical reactions occurring in foods and prevents biochemical reactions in food. Microorganisms also get inactivated at low temperature.

15.2 THE FREEZING POINT OF FOODS

Living cells contain much water, often two-thirds of more of their weight. In this medium there are organic and inorganic substances, including salts and sugars and acids in aqueous solutions, and more complex organic molecules, such as proteins which are colloidal suspension. Thus more the salt, sugar, minerals and proteins in a solution. The lower its freezing point (depression of freezing point) and the longer it will take to freeze when put in freezing chamber. If water and fruit juice for example are placed in a freezer, the water will freeze first. Further unless the temperature is considerably below freezing point of pure water, the juice will never freeze completely but rather will become icy and slushy. That is why most of the foods freeze at temperatures between 0-3°C. The temperature of the food undergoing freezing remains relatively constant until the food is mostly frozen, after which time the temperature approaches that of freezing medium. The freezing process is thus a process of lowering of the product temperature from its original value to the storage temperature. From each point, the heat must be removed by conduction to the surface of food. The surface heat is then removed to the refrigeration medium. The freezing time depends upon number of factors such as dimensions, shape of product, thermal properties, temperature of refrigerant medium.

Frozen foods have an excellent safety records and freezing has never been reported to be cause of food poisoning. The great advantage is that microorganisms do not grow in foods when the temperature is –10°C or colder. Foods preserved by means of other preservation methods (chilling, drying, canning) have been more or less directly involved in food safety problems because these foods are stored at temperatures that allow microbial growth.

Freezing has long been established as an excellent method of preserving high quality in food products. Generally freezing preserves taste, texture and nutritional value of foods better than any other preservation method. When done, properly it is the most satisfactory method of preserving many fruits and vegetables. More over the original flavour, colour, texture, and nutritive value is usually retained during freezing in comparison to other methods of freezing. Freezing, however does not, add anything to the original qualities of fresh fruits and vegetables. Therefore, for the highest quality frozen foods, they must be of highest quality in their fresh state, and well-tested ways of preparing them for freezing must be carefully followed. Frozen foods are considered as healthy. Recently, U.S. Food and Drug Administration's (FDA) petition on March 25, 1998 approved an American frozen food industry petition to allow frozen produce to be labelled as "healthy," The nutrient profiles of selected raw fruits and vegetables and frozen, of the same fruits and vegetables revealed relatively equivalent nutrient profiles. In fact, some data showed that the nutrient content level for certain nutrients was higher in the frozen version of the food than in the raw version of the food. In fact most fruits and vegetables during transportation or during retail storage undergo severe depletion of nutrients and essential vitamins. These losses can be prevented if they are frozen soon after they are harvested.

Before actually we see freezing let us understand the meaning of some terms which are often used while describing aspects of low temperature storage and are often are loosely defined. The common terms are Cool Storage, Refrigeration and Freezing. Let us see what is the difference between each other.

Difference between cool storage, refrigeration and freezing

	Cool storage	**Refrigeration**	**Freezing**	**Freezer storage**
Temperature	16 to –2°C	4.5-7°C	-2°C to lower	–18°C
Microorganism	Spoilage microorganisms can grow rapidly at temp. >10°C. Some grow below 0°C if water is unfrozen.	Pathogenic microorganisms grow slowly. Psychotrophic microorganisms grew.	No significant growth of spoilage or pathogenic microorganism. However, multiplication of microorganisms can take place if food is thawed.	

Frozen foods offer various advantages and disadvantages. Let us now see what are they.

15.3 ADVANTAGES OF FROZEN FRUITS AND VEGETABLES

1. The fresh vegetables and fruits closely resemble their frozen counterparts in freshness, since the metabolic activities are arrested to such an extent that all the enzymes are inactivated and microorganisms are under control.

2. The taste, flavour and colour of fruits and vegetables are preserved to a maximum.
3. They have high nutritive value since the retention of nutrients is maximum.
4. Since frozen vegetables have already been subjected to a heat treatment they require less time for cooking thus saves considerable time in kitchen and also saves fuel.
5. Greater convenience in handling and preparation.
6. Freezing is a suitable choice for preserving fruit juices containing anthocyanin and carotenoid pigments since the retention of pigments is maximum.
7. They offer more hygienic food
8. Cent percent edible portion of food of food in each package
9. Since the degradative effect of heat treatment is bypassed in this, the method of freezing can retain the pigment of such fruit juices and concentrates in its best form
10. Freezing can also serve as an intermittent technology for preserving commodities in bulk and supplying in a different form when demand arises eg peas can be frozen in bulk quantities and during demand defrosted put in a brine solution packed in flexible pouches and circulated in market whenever required.
11. Value for money especially off-season
12. No pollution problem in consuming areas
13. The waste collected during freezing can be utilized for production of value added products.

Limitations

1. Some water soluble nutrients may be lost during freezing as the process involves blanching in boiling water.
2. Users of quick frozen foods need to invest on freezers to maintain the quality of the product till used. This adds to the cost of the product.
3. Proper freezing transport facilities have to be developed for each product.
4. Quick freezing can be handled at the industrial level because it involves specialized freezing equipment, technological know-how, strict quality control which would not be feasible on a small scale.
5. Sales markets have to be established in all markets with refrigerated display cabinets.

15.4 QUICK AND SLOW FREEZING

During freezing process the product temperature is lowered and most water is transferred into ice crystals. With decreasing temperature the liquid phase becomes more and more concentrated. As the volume of ice is about 10% larger than volume of water, internal pressure of food may rise to 10 bar or more. This pressure is sufficiently high to cause undesirable textural changes in foods but not as high as necessary to inactivate microorganisms. The size of ice crystal may vary with method of freezing i.e. quick freezing or slow freezing. Quick freezing is defined as the process where the temperature of the food passes through the zone of ice crystal formation in 10 minutes or less. The process removes quick removal of water and small ice crystals are formed in it. Whereas slow freezing involves slow removal of water and process may take 3-72 hours. This also involves ice crystal formation which have more damaging effect on the texture. The advantages of quick freezing over slow freezing are that 1) smaller ice crystal are formed hence there is less mechanical destruction of intact cells of the food; 2) there is shorter period of solidfication and therefore less time for diffusion of soluble materials and for separation of ice; 3) there is more prompt prevention of microbial growth; 4) there is more rapid slowing down of enzyme action. Quick frozen foods therefore are supposed to thaw to a condition more like that of the original food than slow-frozen foods.

15.5 PRE-TREATMENTS PRIOR TO FREEZING

Fruit and vegetable pieces which need to be frozen must preserve their natural colour, flavour and texture and be free from antioxidants or other additives. This is especially required for high moisture product ingredients such as fruit salads or ice-creams. Apart from maintaining sensory properties they should also retain nutritive properties. Chemical and physical action of freezing are highly detrimental to fruit and vegetables, since their texture is mainly ensured by turgor pressure or turgescence (the ability to retain water inside the cells). Rupture of cell wall due to growth of ice crystals and/or enzymatic action during freezing causes loss of shape and prevents its return to the initial state. Loss of shape causes increased drip loss during thawing and a less defined texture. Water is an important molecule involved in deterioration reaction, during freezing and freezing storage. Water within food, migrates towards cold outer surface and then evaporates re-crystallizing as ice. Food surface becomes dry and colour fades. Water may also participate directly in deterioration reactions which involve changes in colour due to enzymatic or non-enzymatic reaction on pigments and production of off-flavour. To minimize such changes in food products, it is important to use certain pre-freeze treatments prior to freezing. These treatments reduce detrimental changes by inactivating the deterioration reactions and by reducing the water content in the material. Common pre-treatments used prior to freezing include washing, blanching, soaking and packaging. Let us now study these pre-treatments one by one.

15.5.1 Blanching

Blanching is a common heat pre-treatment commonly used for most vegetables that are to be frozen and ultimately cooked before use. The aim of blanching is to inactivate enzymes responsible for deterioration in food. Inactivation is achieved by denaturing the proteins that would otherwise take part in reactions leading to deterioration. However, there are also certain disadvantages of blanching:

1. Cellular tissues are affected by high temperature.
2. Loss of texture and an increased risk of microbial contamination due to removal of foods natural microbial flora.

This can however be overcome by using improved blanching treatments employing high temperature short time (HTST) exposure rather than low temperature long time (LTLT).

Lets us now see what are different blanching methods:

1. Immersion
2. Steaming

Immersion

Immersion blanching refers to blanching by directly immersing the food particles in boiling water. This treatment has number of advantages and disadvantages. Sometimes certain additives may be used in blanching water to complement blanching. For instances, addition of citric acid (0.5%) to immersion bath decreases pH. Addition of bisulfite (0.5%) prevents mushroom browning and yellowing of cauliflower. Blanching is quickly followed by a cooling stage. This is done by cooling the product under cool water to bring down its temperature. Rapid cooling avoids microbial growth on the exposed surfaces.

Steaming

Blanching by steaming has the advantage of minimizing the leaching out of soluble materials. However, at the same operating temperature, steam blanching takes 20-40% longer than immersion blanching because of poor thermal exchange.

15.5.2 Dehydro-Freezing

Sometimes depending upon the type of food, and its final use of product, some moisture is removed from the food. This is partial dehydration. Partial dehydration is generally achieved by air drying. The process is also called dehydro-freezing i.e. dehydration prior to freezing. It offers many advantages over conventional freezing:

1. Saves energy
2. Better quality and stability

For partial air drying, selection of food ingredient is very important. The food ingredient selected should be of high water activity (aw > 0.98), since water removal is limited to 50-60% of the original content. To avoid browning, blanching or other treatments such as dipping in antioxidant solution (ascorbic or citric acid, sulphur dioxide) can be used. The air dehydration step usually produces a weight loss up to 50%.

Apple, pear, peach and strawberry are commonly dried by air drying. Partial water removal from the food leads to the concentration of cytoplasmic components within the cells, and to the depression of the freezing point. However, there are certain disadvantages associated with such drying:

1. Free flow of the product is hindered due to particle agglomeration
2. Colour is affected.

For example, kiwi and strawberry fruits are susceptible to heat modifications. For such fruits, air drying must be replaced by osmotic dehydration, which is more effective even at room temperature and which operates away from oxygen.

15.5.3 Osmotic Dehydration

Conventional air-drying can be substituted by or combined with osmotic dehydration as a pre-freezer treatment. The process involves placing the solid food (whole or in pieces) into solutions of high sugar or salt concentration. Usually sucrose, corn starch syrup have been used as osmotic solutions. The principle behind osmotic dehydration is the same as that of osmosis. Placing the food pieces in high osmotic solution leads to ex-osmosis and concentration of the cytoplasmic content.

15.6 FREEZING TECHNOLOGY

After pre-treatments the material is subjected to the freezing step. Fruits and vegetables (F&V) can be frozen by various methods.

15.6.1 Air or Still Freezing

Air freezing is the oldest of the freezing methods. The equipment is the simplest. The food is simply placed in an insulated cold room at a temperature maintained in the range of –23°C to 30°C. This method is different from the air-blast freezing, which employs air velocities. Although there is some air movement by natural convection, in some cases gentle air movement is promoted by placing circulating fans in the room. This method is also referred as *still air freezing* or *sharp freezing*. It is similar to the freezing conditions that exist in home freezers except that temperatures are low i.e. –18 to –30°C.

15.6.2 Air-Blast Freezing

These freezers operate at temperatures of –30 to –45°C, with forced air velocities of 10-15 m/sec. Food is frozen as batch to tunnels through which carts or belts may be moved continuously. Particulate unpackaged foods, such as loose vegetables are fed onto the moving belt when speed is adjustable according to the required freezing time. In other designs, food moves on trays, in a vertical direction. Trays of particulate products such as peas or beans automatically move upward through a cold air blast.

Today, along with foods frozen as a single block in package, vegetables and other particulate items are frozen individually. This technology is called individually quick frozen or IQF. The freezing process allows the formation of small crystals of ice inside the cell of the product, in order to avoid cellular damage. Therefore when the product unfreezes, there is no spill out of the cellular fluids, warranting the nutritive value, texture and flavour of the product. The particulate items are frozen individually, so they can be poured from a bag for greater convenience. Since, there is some tendency for such particulates to stick together during freezing, product is mechanically dislodged from trays and passed through a beaker device to disaggregate to large clusters. Its major advantage is that you need not unfreeze all the product, only the required quantity be taken out and thawed. Did you know that Safal peas marketed by NDDB are IQF.

The air flow is normally counter-current air flow to bring the coldest air into contact with the already frozen product, and there is no tendency for product to rise in temperature and partially thaw through the freezing process. Normally, in concurrent system, coldest air enters the unfrozen products and tends to rise in temperature through the tunnel as product gives up heat and freezes. Whenever unwrapped food is placed in a cold zone, there is tendency for the food to lose moisture, after the food is frozen.

In freezer, this can have two consequences: 1) Frosting over of refrigerated coils or plates, necessitating frequent defrosting to maintain heat exchanger efficiency, and 2) Drying out of food at surface resulting in defect called **freeze burn**. The food shows brownish colouration at surface and nutrient losses are high. Rates of freeze burn is high in accelerated blast freezers where air is moving at high velocity. To minimize freeze burns, 2 techniques are employed:

1. Pre-chilling food with air of high RH at about –4°C. Because of high humidity, there is a minimum moisture loss. The food then moves into second colder zone when it is quickly frozen. This rapid finish-freezing provides minimum time for the already cold product to lose more moisture, which also decreases the defrosting requirement on freezer coils.

2. Second technique is to wet the unpackaged food pieces in pre-chilling zone so to freeze a thin ice glaze around each food piece.

15.6.3 Fluidized Bed Freezing

In various air-type freezers, cold air is blown up through a wire mesh belt that supports and conveys the product. This imparts a slight vibratory motion to food particles, which accelerates freezing rate. When the air velocity is increased to the point where it exceeds the velocity of free-fall of the particle, fluidization occurs; this is called *fluidized-bed freezing*. This motion not only subdivides the product and provides intimate contacts of each particle with cold air, but keeps clusters from freezing together.

15.6.4 Continuous Type Fluidized-Bed Freezer

Particulate foods are fed by a shaker onto a porous trough. The food is pre-chilled and high velocity refrigerated air fluidizes the product, freezes it and moves it in continuous flow for collection and packaging.

An interesting feature of this unit is continuous and automatic defrosting. Air is blown via fan through cooling coils and up through the porous food trough. Cold air tends to condense its moisture onto cooling coils. A spray of propylene glycol antifreeze is maintained over cooling coils to melt ice as it would be formed. In this way, cooling coils are maintained at maximum operating efficiency.

15.6.5 Indirect Contact Freezing

Indirect contact freezing is based on the principle of placing the food on plates, trays, belts or cold walls so that it is in indirect contact with the cold wall. The food, usually as flat packages, is placed between shelves and there is provision after loading for applying pressure to squeeze the shelves into more intimate contact with the top and bottom of the packages for faster freezing. All is enclosed within an insulated cabinet. The efficiency of freezing depends on the extent of contact between the plates and the food. For this reason, packages should be well filled or slightly over-filled to make good pressure contact with the plates.

15.6.6 Immersion Freezing

Immersing the food directly in a refrigerant other than cold air is called immersion-freezing. It has the following advantages:

1. There is intimate contact between the food or package and the refrigerant, therefore, resistance to heat transfer is minimized.

2. Although loose food pieces can be frozen individually by immersion freezing and air freezing, immersion freezing minimizes their contact with air during freezing, which can be desirable for foods sensitive to oxidation.

For direct immersion freezing, the refrigerant used must have the following properties:

1. It should be Non-toxic.
2. It should be Clean.
3. Free from frozen tastes, odour/bleaching agents.

There are two types of refrigerants for immersion freezing:

1. Low-freezing point liquids: They are chilled by indirect contact with another refrigerant e.g., solutions of sugars, sodium chloride and glycerol.

2. Cryogenic liquids such as compressed liquefied nitrogen, which owe their cooling effects to their own evaporation.

15.6.7 Immersion Chilling and Freezing (ICF) in a Concentrated Aqueous Solution

A third technique ICF is quite similar to osmotic dehydration, in that both involve direct contact between food pieces and a concentrated solution. However, ICF is carried at low temperature ranging from –20°C to 0°C, whereas in case of osmotic dehydration, the temperatures range from +30°C to 80°C. The characteristics of the dissolved solutes determine the extent in temperature to which the solution remains in the liquid state.

Advantages

1. Rapid heat transfer.
2. Individualized freezing.
3. Lower operating and investment costs.

Because of low operating temperatures, and the freezing process occurring inside the food during ICF, mass transfer rates are much lower than in osmotic dehydration ranging from 1 to 7% water loss and 0.5 to 1% solute gain.

However, in spite of its potentialities, ICF process has been developed little on an industrial scale, because of an inadequate control of mass transfer (water and solutes) between the product and the refrigerating solution. The freezing time depends upon (1) Dimension and shape of product, (2) thermal properties, (3) initial and final temperature, and (4) temperature of the refrigeration medium.

15.6.8 Immersion Freezing with Cryogenic Liquids

Cryogenic liquids are liquefied gases of extremely low boiling point such as liquid nitrogen and liquid carbon dioxide, with boiling point of –196°C and

–79°C respectively. Although liquid nitrogen is capable of freezing food down to –196°C, this is virtually never done, because it entails unnecessary cost and could even be damaging to some foods. The food is seldom frozen to a temperature below –45°C and quality results largely from the speed at which the temperature is reached. In most of the cases of fruits, vegetables, meat and fish items, it may take 1-3 minutes. Major advantages of liquid nitrogen freezing are as follows:

1. It undergoes slow boiling at –196°C, this provides great driving force for heat transfer.

2. Liquid nitrogen, like other immersion fluids, intimately contacts all portions of irregularly shaped foods, thus, minimizing resistance to heat transfer.

3. No primary refrigerant is required to cool this medium, since low temperature results from the evaporation of liquid nitrogen.

4. Liquid nitrogen is non-toxic and that to food constituents. Moreover, it can displace air from food and thus minimize oxidative changes during freezing and through packaged storage.

High quality frozen foods are produced because of high speed of liquid-nitrogen freezing. High cost of liquid nitrogen remains to be its major limitation. Liquid nitrogen is manufactured by comprising air and simultaneously removing the heat of compression. The cooled compressed air is then allowed to expand through specially designed valves. This expansion causes further chilling.

15.7 PACKAGING AND STORAGE

A wide variety of materials have been used for packaging of frozen foods including plastics, metals and paperboards. Polyethylene (PE), low density Polyethylene(LDPE) and High density Polyethylene (HDPE) are commonly used for packaging of IQF foods i.e. fruits, vegetables and fish. Materials are easy to seal and can be easily printed. LDPE is also easily available and cheap. HDPE can tolerate temperature in excess to 100°C. Both HDPE and LDPE however provide relatively poor barrier protection from oxygen. Polyester tetraphthalate (PET) is another common material used. The trays of the material are suitable for reheating in conventional and microwave oven with stability at temperature in excess of 250°C. However the materials are expensive and can become brittle at freezer temperature. Polystrene (PS) is also general plastic material used for frozen food applications. Commercial storage of frozen storage of frozen products is usually done in deep freezers at –18 to –20°C.

15.8 QUALITY AND PHYSICAL CHANGES IN FROZEN FOODS

When the food is frozen it undergoes number of quality and physical changes. Lets us see what they are.

15.8.1 Concentration Effects

We have already seen that during freezing concentration of solutes take place. Damage due to concentration results in

1. Gritty, sandy texture of food due to precipitation of solutes out of solution.
2. Salting out at proteins effect due to solutes remaining in concentrated solution.
3. Drop in pH drop causing proteins to coagulate.
4. Gases in solution are also concentrated. This can cause super-saturation of gases and ultimately force them out of solution. Frozen beer or soda pop may have such a defect.

15.8.2 Ice Formation: Nucleation and Crystallization

The freezing process includes 2 main stages first is the formation of ice crystals which is termed as nucleation and subsequently crystallization or increase in crystal size. Nucleation is nothing but combining of molecules into an ordered particle of sufficient size to serve as a site for further crystal growth. It is important for freezing to initiate. When the temperature falls below 0°C, viscosity increases and nucleation stops. Now crystals start growing. Before we understand how ice-crystals are formed, it is important to understand the type of fluids in the cells. There are 2 types of fluids viz., Extra-cellular fluid (EF) and Intracellular fluid (IF). The concentration of salts and other soluble products is higher within the cells than outside. The cell membrane acts as osmotic barrier and maintains the difference in concentration. When the product is frozen, the first ice-crystals are formed outside the cells, since the freezing point is higher. The cells lose water by diffusion through the membrane and the water will crystallize to ice on the surface of the crystals already formed in the extra-cellular space. As the cells lose water, the remaining solution within the cell becomes more concentrated and their volumes shrink causing the cell wall to collapse. The large ice-crystals formed outside the cell wall occupy a larger volume than the corresponding amount of water and therefore, will execute a physical pressure on the cell wall. When the pressure becomes high, it can damage the cell wall and lead to release of intracellular fluid (Drip loss). If the freezing rate is high, ice-crystals are formed outside the cells. Only at a very high freezing rates, small crystals are formed uniformly throughout the tissue, both externally and internally with regard to the cells.

15.8.3 Freeze Cracking

Generally, light freezing rates lead to small ice crystals and to better quality food systems. However, some products may crack when submitted to high freezing rates as in cryogenic fluids. This is particularly seen in mango slices frozen by liquid nitrogen. Pre-cooling prevents freeze cracking.

15.8.4 Moisture Loss

Moisture loss, or ice crystals evaporating from the surface area of a product, produces freezer burn. We have already discussed what freezer burn is. This surface freeze-dried area is very likely to develop off flavours. Packaging in heavyweight, moisture-proof packaging material will prevent freezer burn.

15.8.5 Drip Loss

Formation of ice crystals causes a physical pressure on the cell wall. When the pressure becomes high, it can damage the cell wall and lead to release of intracellular fluid. This is called drip loss.

15.8.6 Rancid Flavour

Another group of chemical changes that can take place in frozen products is the development of rancid oxidative flavours through contact of the frozen product with air. This problem can be controlled by using a wrapping material which does not permit air to pass into the product. It is also advisable to remove as much air as possible from the freezer bag or container to reduce the amount of air in contact with the product.

The winning strategy of frozen good industry is to continually improve quality.

Here is a list of some tips to produce quality frozen products:

1. High quality raw material containing high level of vitamins (especially water-soluble ones, like vitamin C) and minerals to ensure that after pretreatments such as blanching the nutritional value remains high. Colour, flavour and texture are yet other factors affecting quality. Peas is an good example of the cultivar affect and harvesting period on the quality of frozen product. Consumers and the frozen industry prefer sweet and tender varieties with small seeds which are completely different from what is required by the canning industry and the fresh market.

   When peas are ripening, their sweetness is due to the sugars (about 6%) and to the low starch content (1%). Immediately after harvesting there is a rapid reaction conversion of sugar into starch which can exceed 4%. This reaction determines a gradual reduction of sweetness, an increase infirmness and sensation in mealiness.

2. Interval between harvesting and freezing Fruits and vegetables undergo fast changes in chemical composition, sensory attributes and nutritional value. The product should be processed as quickly as possible e.g., peas and spinach have intense metabolism (high respiration rate after processing) which means severe decrease in quality if the time between harvesting and processing is too long. By using quick refrigeration, these negative phenomena can be stopped.

15.9 STORAGE AND TRANSPORTATION OF FROZEN PRODUCE

To preserve quality and safety in frozen foods, strict temperature requirements are must during storage, handling, distribution, retail display and consumer storage. It is recommended that food temperatures are maintained at –18°C or colder, although exceptions for brief periods are allowed during transportation or local distribution when –15°C is permitted. Also, retail display cabinets should be at –18°C, to an extent consistent with good storage practice, but not warmer than–12°C. The transport and distribution sections of the chill chain are particularly important to control in order to ensure both safety and quality. It is important to check temperature of foods at each point within the chill chain from storage and transportation.

15.10 FUTURE TRENDS IN FROZEN FOODS

Demand for frozen foods will grow

Growth of corporate cultures, dual incomes, western life styles and need for convenience are likely to lead to growth of this sector. Changing life styles are increasing both the consumption of convenient food products and eating out habits. In the food service sector and fast food chains, reliance on frozen food is greater because they offer the ability to control supply with variable demands. The frozen food consumption is bound to increase in India too. Consumers today view adoption of western life styles as index of progress. In near future, we should not therefore be surprised to see increased consumption of western style convenience foods as the amount of time available to women has been substantially decreasing. Certainly, we are already seeing the major food multi-functional giants, such as MAC Donalds', Pizza Hut, Dominos investing in these future markets.

Frozen foods will be more nutritious

The frozen food industry is in best position to deliver healthy products to the consumers. Careful selection of ingredients, superior genotypes, good formulation and processing and a well controlled frozen food chain have the ability to deliver products much closer to their original nutritional content than can possibly be achieved through the chilled chain wherever rapid deterioration is inevitable.

Anti-freeze proteins

An area of research that has caused great excitement in the scientific community and increasingly in the frozen food industry is the field of antifreeze proteins (AFP). These proteins were first discovered in Antarctic and Arctic fish species. The freezing point of sea water is –2°C. The freezing point of fish serum is –1°C. These proteins allow fish to survive below their melting point without freezing. AFP's have been extracted and identified in grasses such as polar fish, winter rye, in carrots and in a number of insects. These proteins can affect freezing by lowering freezing temperature and retarding recrystallization. Claims for AFP have been made from many food plant materials including carrots and brussel sprouts. Such discoveries have begun to show a possible future for AFP in food industry. We can see the potential of transforming plants (transgenic which can express AFP and therefore expected to have a greater resistance to re-crystallization damage during distribution with the resultant effect of increased textural quality and retention of nutrients on thawing.

15.11 LET US SUM UP

Among processing methods freezing is the best method as it results in quality product with high retention of nutrients. Quality of frozen foods can be constantly improved and maintained by selecting the right kind of fruit or vegetable, its right cultivar, pre-freezing treatment and technology. Storage at low temperature is important to maintain quality.

15.12 KEY WORDS

Freezing point	:	Temperature at which the liquid congeals into the solid state at a given pressure and temperature.
Refrigerated storage	:	Refers to storage temperatures above freezing point of water i.e. about 16 to –2°C.
Quick freezing	:	Quick freezing is defined as the process where the temperature of the food passes through the zone of ice crystal formation in 10 minutes or less. The process removes quick removal of water and small ice crystals are formed in the process.
Slow freezing	:	Slow freezing involves slow removal of water and process may take 3-72 hours.
Fluidized bed freezing	:	A method of freezing used for particulate items such as peas, diced carrots, corn and berries. The freezer employs a bed with a perforated bottom through which refrigerated air is blown vertically upwards.
Blanching	:	Blanching is a common heat pre-treatment commonly used before processing most vegetables. The main aim is to inactivate enzymes responsible for deterioration in food.
Sublimation	:	The change of state from ice to water vapour or water vapour to ice. Unpackaged frozen material changes to gaseous form e.g. dry ice(frozen carbon dioxide)when exposed to extreme cold air.
Dehydro freezing	:	Is pre-treatment given prior to freezing, involving partial removal of water
Individual quick freezing	:	Is the latest advanced technology for freezing particulate vegetable items. The product is frozen individually and helps in
Freeze burn	:	It refers to a defect which develops during frozen storage. Moisture loss due to sublimation from surface leads to discolouration in form of patches of light coloured tissues. This can be controlled by humidification or lowering of storage temperature or better packaging.
Antifreeze	:	Chemical substances that added to a liquid to lower its freezing point. These chemicals prevent freezing and are commonly used in coolants for aeroplanes and automobiles.

15.13 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   Freezing is considered best method of preservation because,

   - It preserves colour, taste, texture and nutritional value of foods better than any other preservation method.
   - Frozen foods have an excellent safety record and freezing has never been reported to be cause of food poisoning.

2. Your answer should include the following points:

   Have nutrient profiles higher or equal to raw food, e.g., freshly harvested fruit and vegetables may loose considerable amount of nutrients during transportation and retail outlet, but freshly harvested frozen foods retain most of nutrients

3. Your answer should include the following points:

   Refrigerated storage refers to storage temperature above freezing. Generally the temperature is maintained at 16 to -2°C. Commercial and household refrigerators operate at 4.5 to 7°C. Frozen storage however refers to storage temperature below –18°C.

4. Your answer should include the following points:

   At 0°C, water will freeze first than fruit juice because water is a pure fluid, whereas, juice has many dissolved organic or inorganic substances including salts, sugar and acids in the aqueous solution. Apart from this there are also proteins and colloidal suspensions. They cause a depression of freezing point, thus, to freeze juice, lower than 0°C temperature is employed.

5. Your answer should include the following points:

   Quick freezing: It is defined as the process where the food passes through the zone of maximum ice crystal formation in 10 minutes or less, whereas, in slow freezing the process may take 3-72 hrs depending upon the commodity.

6. Your answer should include the following points:

   Main differences between quick and slow freezing are:

Quick freezing	**Slow freezing**
The process involves quick removal of water, may take 10 min.	The process involves slow removal of water, may take 3-72 hrs.
Small ice-crystals are formed which maintain the textural integrity of cell.	Large ice-crystals are formed which seriously affect the cell texture.
Prompt prevention of microbial growth.	Slow prevention of microbial growth.
After thawing the food resembles like that of original food.	After thawing the food is soft and mushy.

Check Your Progress Exercise 2

1. Your answer should include the following points:

   Pre-freeze treatments prior to freezing is mainly given to reduce the water content of cells which thereby

   - Prevents rupture of cells and maintains cell texture
   - Avoids increased drip loss
   - Also avoids changes in colour of food due to enzymatic and non-enzymatic reactions.

2. Your answer should include the following points

   Blanching: It is a common heat pre-treatment used prior to processing (drying, freezing and dehydration). It is necessary to blanch fruits and vegetables prior to freezing in order to inactivate enzymes responsible for deterioration in quality of frozen foods.

3. Your answer should include the following points:

   Advantages of osmotic dehydration over air drying:

   1. Retains better colour.
   2. Prevents particle agglomeration.
   3. Prevents oxidation.
   4. Effective at room temperature.

   Highly suited for fruits such as kiwi and strawberry which are susceptible to heat modification.

Check Your Progress Exercise 3

1. Your answer should include the following points:

   Some factors affecting rate of freezing are:

   - Shape of the product.
   - Kind of the product.
   - Thermal properties of the product.
   - Temperature of the refrigerant medium.

2. Your answer should include the following points:

   Some important commercial freezing methods are:

   1. Air or still freezing.
   2. Air blast freezing.
   3. Fluidized bed freezing.
   4. Continuous type fluidized bed freezer.
   5. Immersion freezing.
   6. Immersion freezing with cryogenic liquid IQF (individual quick freezing is being used for freezing peas.

3. Your answer should include the following points:

   Cryogenic freezing is a freezing process involving liquid nitrogen (–196°C) as the refrigerant medium, is termed as cryogenic freezing. The quality of the food frozen by liquid nitrogen is best because:

   1. Food is quick frozen and takes 1-3 minutes.
   2. It is non-toxic to food constituents and can displace air from food, thus, minimizing oxidative changes during freezing.

4. Your answer should include the following points:

   Difference between still air freezing and air blast freezing:

Still air freezing	**Air blast freezing**
Temperature is maintained at –23 to –30°C.	Temperature is maintained at –30 to –45°C.
Air movement by natural convection.	Air movement with forced air velocity of 10-15 sec.

5. Your answer should include the following points:

   IQF is individual quick freezing. It is the latest technology for freezing particulate food items.

   Advantages:

   1. The particulate items are frozen individually.
   2. Small ice-crystals are formed. Thus, when the product unfreezes, there is no spill out.
   3. High nutritive retention and sensory quality.
   4. Allow greater convenience because only required quantity can be separated from the large cluster and thawed.

6. Your answer should include the following points:

   Drying and discolouration of the food at surface is termed as freeze burn. The food shows brownish discoloration at surface and nutrient losses subsequent to thawing. Frozen fish is most susceptible to freeze burn. The defect can be minimized by

   1. Pre-chilling the food with air of high RH at about –4°C.
   2. Wet the unpackaged food pieces in pre-chilling zone so as to freeze a thin ice glaze around each piece.

Check Your Progress Exercise 4

1. Your answer should include the following points:

   Antifreeze proteins are proteins that when added to a liquid to lower its freezing point. These proteins have been identified and isolated from many cold-tolerant insects and plants. These proteins are of great importance in improving the quality of frozen products.

2. Your answer should include the following points:

   A wide variety of materials have been used for packaging of frozen foods including plastics, metals and paperboards. Polyethylene (PE), low density Polyethylene (LDPE) and High density Polyethylene (HDPE) are commonly used for packaging of frozen foods.

UNIT 16 CHEMICAL ADDITIVES

Structure

16.0 OBJECTIVES

After reading this unit, you should be able to:

- explain the meaning of a food additive;
- understand the role of additives in food preservation;
- discuss the different permitted preservatives in food industry and their concentrations;
- discuss the various applications of food additives; and
- know the simple low cost, low energy intensive preservation technologies.

16.1 INTRODUCTION

Fruits and vegetables are a major source of important vitamins and minerals. Owing to its vast agro-climatic conditions, India produces almost all types of fruits and vegetables. Being highly perishable, fruits and vegetables have to be preserved and processed for later use. India processes 1.8 per cent of the total fruit and vegetable produce. Chemical preservation of perishable commodities by various food additives forms a major part of the preservation industry which is used in conjunction with other forms of preservation like canning, freezing, dehydration etc.

Food additives as chemical preservatives have been used for centuries to extend shelf life of the variety of food products. Smoke, alcohol, vinegar, oils and spices were used more than 10,000 years ago to preserve foods. They have been used since man first learned to preserve food products from one harvest season to the next to preserve and conserve the food and its nutritional value. The use of salt and smoke for preservation dates back to thousands of years. The Egyptians used colours and flavourings to enhance the appeal of certain foods, while the Romans used saltpeter, spices and colours for preservation and quality improvement. In the past 40 years, developments in food science and technology as well as changes in consumer demand have led to a substantial increase in the use of food additives. This has given consumers a variety of foodstuffs of high and uniform quality at reasonable prices. They play a vital role in today's bountiful and nutritious food supply.

Social changes in this century have caused a rapid evolution of the food supply throughout the world. While a shrinking percentage of the population is engaged in primary food production, we demand more variety than ever before in the food we eat. With a growing percentage of both two-wage and single-parent families, the demand for convenience foods has never been greater. Meeting consumer demands for variety taste and convenience with food products that are at the same time wholesome, safe and affordable, can be achieved using modern food processing technologies including a variety of food additives proven useful and safe through long use and rigorous testing.

16.2 DEFINITION OF CHEMICAL ADDITIVES (FOOD ADDITIVES)

Additive means any substance which is not a normal constituent of the food material and is purposeful addition which is aimed for technological, organoleptic and nutritional reasons. According to the WHO, a food additive is defined as a substance or mixture of substances other than the basic foodstuff, which is present in food as a result of any aspect of production, processing, storage and packaging. The term does not include chance contaminants. Food additives have also been defined by the National Academy of Sciences as those chemicals that may be incorporated in foodstuffs, either directly or indirectly during growing, storage or processing of foods.

The Prevention of Food Adulteration Act (PFA) specifies any substance as additive which is not normally consumed as a food itself but used as a typical ingredient of food whether or not it has nutritive value, the intentional addition of which to food for technological reasons including organoleptic purpose during manufacturing, processing, preparation, treatment, packaging, transport or holding of such food results or may be reasonably expected to result in it or its by-products. PFA rules therefore encompass all food and food products in the country and aim at ensuring the consumers get food and food products of satisfactory composition by laying down mandatory quality standards.

16.3 FUNCTIONS OF FOOD ADDITIVES

- To enhance the consumer acceptability.
- To help in maintaining or improving the nutritional quality.
- They should be non-toxic, non-allergic, safe and effective.
- To enhance stability or keeping quality by acting as antimicrobial agents with the resulting reduction in waste and prevention of chemical and biological deterioration.
- To make food more attractive and provide sufficient aids in the food products for improving texture, colour and flavour.

- To check spoilage by inactivating microorganisms and maintain safety of foods.
- To facilitate preparation.
- To improve palatability of the product.

16.4 PERMITTED FOOD ADDITIVES AS PRESERVATIVES

Preservatives are substances when added to food to retard, inhibit or arrest the activity of microorganisms such as fermentation, acidification and decomposition.

16.4.1 Classes of Preservatives

CLASS I

Common salt, sugar, dextrose, spices, vinegar or acetic acid, honey. They are mainly natural products which are used comparatively in higher concentrations than class II preservatives.

CLASS II

They are generally synthetic chemicals used in small quantities. Benzoic acid and its salts, sulphur dioxide and the salts of sulphurous acid, nitrites and nitrates, sorbic acid and its salts, propionic acid and its salts, lactic acid and its salts are used. Potassium metabisulphite is generally used in non-coloured products whereas in coloured products containing anthocyanin pigment, sodium benzoate is used.

16.4.2 Legitimate Uses in Food Processing

Food additives have a legitimate use in the food processing and distribution systems in promoting the utilization of available foods. The use of food additives may be technologically justified when it serves the following purposes:

1. The maintenance of the nutritional quality of a food.
2. The enhancement of keeping quality or stability with resulting reduction in food losses.
3. Making foods attractive to the consumer in a manner which does not lead to deception.
4. Providing essential aids in food processing.

Safety in using an additive is an all important consideration. While it is impossible to establish absolute proof of the non-toxicity of a specified use of an additive for all human beings under all conditions, critically designed animal tests of the physiological, pharmacological and biochemical behaviour of a proposed additive ca provide a reasonable basis for evaluating the safety of use of a food additive at a specified level of intake.

The Food and Drug Administration of the Department of Health, Education and Welfare administers the Federal Food, Drug and Cosmetic Act, in the United States. The federal Food, Drug and Cosmetic Act controls the addition of all additives to food. Chemicals may be incorporated legally in the fabrication of many foods, and many chemicals indeed serve to improve the quality of many foods.

16.5 TYPES OF FOOD ADDITIVES

Of the variety of ways food additive have been classified, most involve functional groupings. Chemical groupings are convenient since they place molecules of similar structure and physical-chemical properties in comparable categories. Toxicological and metabolic studies also may be correlated with chemical groupings. However, compounds of a single chemical family perform different functions in the food industry. Moreover, since chemical structure does impart physical-chemical characteristics, many function classes follow responsible chemical lines; i.e., the enzymes are major classes in either system. The consumer viewpoint is less restricted than is the legal, governmental or scientific; without knowing hows or whys, he wants an attractive product which provides assurance of health. A functional classification is given to place in perspective the specific types. The classification presented in detail below is comparable to, but provides an overall view less well than, this simplified system of user.

16.5.1 Intentional Food Additives

- Nutritive
- Freshness maintenance
- Sensory
- Processing aids

16.5.2 Incidental Food Additives

Many of the 2-3000 chemicals added to food occur in nature. They may be isolated from rich source material and used at will. Some, i.e., enzymes, will never be commercially available from synthetic sources. However, it is more efficient to make most of them in the laboratory. Thus, although some more efficient to make most of them in the laboratory. Thus although some are isolated in relatively pure form from natural sources, most are man made.

Table 16.1: Range of concentration of chemical preservatives permitted in various processed foods are given below:

Preservative	Concentration (ppm)	Food
Sulphur dioxide or salts of sulphurous acid	49-3000	Squashes, fruit pulp, crushes, jams, syrups, beer, pickles, beverages etc.
Propionic acid and its salts	5000	Bread
Benzoic acid and its salts	50-600	Syrups, squashes, jams, jellies, RTS beverages, pickles, chutneys
Sorbic acid	200-3000	Beverages, cakes and icings, cheese, cider, dried fruits, salad dressings, wine, margarine
Nisin	1000	Cheese
Nitrites	200	Cooked pickled meat
Nitrates	500	Cooked pickled meat

Table 16.2: Uses of various food additives

Additive	Use
Preservatives	• Sorbates are used as mould and yeast inhibitor in processed cheese and spreads, salad dressings, dried fruits, yogurt, fermented milks, soft drinks, soup concentrates, wine, cider and cakes. • Propionates are used as mould and rope inhibitors in bread, baked goods and dairy products. • Benzoates are used in beverages, fruit juice, pickles, jams, beer, dessert sauces, marinated fish, coffee essence. • Parabens are used in low acid foods (pH > 5.0) e.g. meat products, fruit juices, pickles, jams, beer, dessert sauces, marinated fish, coffee essence. • Sulfur dioxide and sulfite salts are used in dried fruits, soft drinks, purees, fruit juices, fermentation industry, dessicated coconut, tinned crabmeat, powdered garlic, frozen mushrooms, sausage meat.
Antioxidants	Wine, beer, cider, fruit juices, dried fruits, milk.
Colouring Agents	Confectionery, cake and drinks industries and in dairy sector.
Flavours	Soft drinks, sugar, confectionary, ice cream, soups and jams, biscuit and cake industry.
Texture modifiers	Margarine, salad cream, chocolate, processed milk, ice-cream, jelly and sauces.
Sweeteners	Confectionery, bakery products, soft drinks, jam, jellies, and ice-cream.
Antifoaming agents	Bakery products, meat products, confections, dairy products, beverages, jams and jellies.
Firming agents	Canned vegetables, canned apples, frozen apples and cheese.
Acidulants	Baked goods, beverages, confections and gelatin desserts, dairy products, fruit and vegetable processing and processed meats.
Nitrite	Various meats and cheeses.

16.6 NUTRITIONAL ADDITIVES

The term nutritional additives can be used to mean the addition of vitamins, minerals, amino acids, fatty acids, as well as other pure chemical compounds to food in order to improve or maintain the nutritional quality of foods. However, manufacturers soon discovered that along with an improvement in nutritional qualities, nutritional additives often provide functional qualities.

Nutritional additives can be used to restore nutrients to levels found in the food before storage, packaging, handling, and processing. An early example of this is the enrichment of grain products, corn meal, and rice. Another use of nutritional additives is to improve the nutritional status or corrected nutritional inferiority in a food that replaces a more traditional nutritional food, an example would be fortification of breakfast drink substitutes with folacin and vitamin C. With the advent of nutritional levelling and increased public interest in nutritional properties of food, the food industry rapidly recognized that the addition of nutritional additives can be a selling point.

Although it is often thought that the major reason to add nutritional additives to a food supply is to provide nutrients and improve dietary status, nutrients are also added for a variety of other purposes. For example, vitamin C and E may be used for antioxidant properties; beta carotene may be used to provide colour. In these cases consumers obtain both functional and nutrient advantage.

Like all additives, nutritional additives are commercially available in an array of forms such as powders, encapsulated in gelatin, emulsified in oil. The form used depends upon the type of application. Nutrition additives are often protected by protective additives such as antioxidants. Two critical factors in the selection of the form of the additive are stability of the vitamin preparation and its miscibility with the intended food matrix.

16.7 THE POTENTIAL USE OF PROBIOTICS

Almost a hundred years have passed since the introduction of theories on the prolongation of life by modulation of intestinal ecosystem. The scientific basis for use of probiotic organisms has only recently been firmly established and some sound clinical studies have been published. The physiological and nutritional properties of selected bacterial strains are well characterized, and it is possible to verify that some strains are “probiotic” with document effects of maintaining and promoting the health of the host when used as part of the daily diet.

Few well-documented probiotic dairy strains are available at present. The most important are listed in Table 16.3. Specific effects of probiotics include, for example, modulation of diarrhea from various causes, relief of lactose intolerance, and constipation. More recent claims with some strains include enhancement of immune functions, vaccine adjuvant effects, reduction of serum cholesterol levels, and changes in colour cancer-related parameters. The immune enhancing effects have been reported in several studies for two strains, *Lactobacillus acidophilus* LCI and *Lactobacillus* GG, which appear to act as immunoadjuvants. Effects on cholesterol levels remain to be verified since so many confounding factors have contributing to varying extents in different population groups. At the moment, no firm proof on any of the probiotic strains of lactic acid bacteria is available, and more well defined clinical work is needed.

The future of research on probiotic bacteria will focus on selecting new, more specific strains for the well being of the host. Different regions of the gastrointestinal tract may be benefiting from different probiotic bacteria and maybe the time has come for disease specific strains. This is particularly true with conditions such as rotavirus diarrhoea and gastritis caused by *Helicobacter pylori*. However, the requirement for good clinical studies will become ever more important. Carefully controlled studies on selected strains could result in the development of probiotic bacteria targeted for specific diseases and their prevention. Mixtures of such organisms may be of general therapeutic value as additives in clinical foods.

Table 16.3: Current probiotic bacteria and their reported effects

Sl. No.	Strain	Reported effects in clinical studies
1.	Lactobacillus acidophilus La-5	Immune enhancer, adjuvant, protection against traveller's diarrhoea; balance intestinal microflora.
2.	Lactobacciullus acidophilus NCFB 1748	Lowering of fecal enzymes, decreasing fecal mutagenicity, prevention of radiotherapy-related diarrhoea.
3.	Streptococcus boulardii	Prevention of antibiotic-associated diarrhoea; treatment of Clostridium difficile diarrhoea.
4.	Lactobacillus johnsonii LA1	Adherence to intestinal cells; balances intestinal microflora; immune enhancement; adjuvant in H. pylori treatment
5.	Lactobacillus casei Shirota	Prevention of intestinal disturbances, balancing intestinal bacteria, lowering fecal enzyme activities, positive effects on superficial bladder cancer.
6.	Streptococcus thermophilus; Lactobacillus bulgaricus	No effect on rotavirus diarrhoea; no immune enhancing effect during rotavirus diarrhoea; no effect on fecal enzymes; strain-dependent improvement of lactose introlerance symptoms.
7.	Bifidobacterium lactis Bb-12	Treatment of viral including rotavirus diarrhoea; balancing intestinal microflora; alleviation of food allergy symptoms.
8.	Lactobacillus reuteri	Shortening of rotavirus diarrhoea; colonizing the intestinal tract.

16.8 BASIS FOR CONCERN

Concern is directed toward synthetic rather than naturally occurring additives. In-home interviews found concern about additives was related to a general fear of chemicals and diseases, specially cancer (Sloan et al, 1986). Consumers believe chemicals present hidden and unknown dangers, which people are powerless to predict (McNutt et al, 1986). Consumer association with chemicals may relate to environmental concerns such as acid rain and toxic waste dumps. Over half of consumers indicated they think there is a connection between chemical spills and their feelings about chemicals in food. Almost 20% of the consumers believe that chemicals are never good for people and over 80% believe that chemicals cause cancer.

Consumers indicated a lack of trust in regulators and regulatory procedures. Both men and women believed that expert opinion was influenced by who paid their salary. Concern was believed justified since some approved additives were later withdrawn later on.

Food allergies may also trigger about additives. In the early 1980s, 26% of U.S. consumers said that they feared an allergic reaction to artificial ingredients, and 22% avoided particular food fearing the food may contain an allergen and avoided such foods. Similarly in Australia, the main concern given for food additives was allergies.

Consumer response to additives may also berelated quality. Over 75% of consumers indicated that artificial flavours give food a poorer taste than natural flavours. Their descriptions of artificial flavouring range from "too salt" to "too sweet" and from "strong tasting" to "flat tasting". Almost 70% of consumers attributed better quality to natural flavours.

Consumers appear unaware of potential benefits from additives. More than 80% of Canadian consumers surveyed in 1978 thought that food colours were unnecessary. They believed that additives made food are less safe. Sloan and co-authors believe that consumers will accept a product if benefits outweigh disadvantages and possible risks are small.

16.9 STEEPING PRESERVATION

Fruits and vegetables can be preserved safely in a chemical solution that checks enzymatic, oxidative and microbial spoilage in the preserved material. The chemical solution makes use of various food additives such as organic acids (glacial acetic acid, citric acid, lactic acid), chemical preservatives (potassium metabisulphite, sodium benzoate) along with salt, sugar, spices etc. in water, which are quite cheap and easily available in the market. Any container (glass, porcelain or glazed earthenware jars) can be used for storing the steeped material. Flow sheet of steeping preservation of fruits and vegetables is as shown below:

Select raw vegetables such as cauliflower, ginger,
lotus stem, carrot, radish and raw mango slices

↓

Prepare the raw material by peeling, cutting and washing

↓

Fill the prepared material in clean glass jars

↓

Prepare chemical solution in potable water using 3%salt, 8% glacial acetic acid
and 0.2% metabisulphite
Fill the chemical solution up to the brim in glass jars
containing fruits and vegetables

↓

Maintain the ratio of material to solution 1:1.5. Close the

↓

jars tightly and store them in a cool and dry place
Wash vegetables thoroughly before use for culinary purpose.
For pickle, *pakora* and chutney preparations, material
can be used straight away after taking out from the solution

Advantages of Steeped Preserved Products

The steeped preserved products have many advantages:

- The method of preservation is very simple and cheap.
- Compared to canning or bottling where heat sterilization is essential, the vegetable or fruit in this method does not suffer much loss of texture even if it is blanched.
- Sulphur dioxide present in potassium metabisulphite (if added in the solution) helps to retain vitamin C content of the preserved material.
- The method can be used on a commercial scale, at the production centres by using large sized wooden vats coated with wax or wax coated cement tanks, which can be properly sealed.
- This low cost technology can be used for bulk packing in glut season for retail-off season sale in the market.
- Preserved material can be stored for 6-8 months at an ambient temperature and beyond one year, at a low temperature.
- Steeping preservation is used either for preserving the material for packing various products or for curing them for lactic fermentation for the preparation of fermented processed products.

16.10 PRESERVATION OF PULP, JUICES, SAUCES, CHUTNEYS, PUREES AND PASTES

Preservation of Pulps and Juices

Fruit pulps and juices can be preserved by adding 1g KMS and 10g citric acid per kilogram or pulp/juice. There is no need to add citric acid in acidic fruits such as lemon. The citric acid and KMS should be dissolved separately in little amount of water and then added in fruit juices. In coloured fruit juice, i.e. coloured grapes, phalsa and plums etc., sodium benzoate is added instead KMS as the latter bleaches the colour of the product. Preserved pulps and juices can be stored for 6-8 months at room temperature and beyond one year at low temperature. In this method, pulps and juices to be sterlized by heat initially, cool it and then use there preservatives. Similarly, the container used for packing should be reasonably impermeable to air and water vapour.

Preservation of Sauces, Chutneys, Purees and Pastes

Preservatives added for the preparation of pulp, juices, sauces, chutneys, purees and pastes are important constituents of these products. Vinegar, salt and sugar are common preservatives used for preservation of these products. The chemical preservatives such as sodium benzoate and potassium metabisulphite used in commercial scale preparations ensure long term storage by retarding the growth of microorganisms without interfering with the other physico-chemical and sensory characteristics of the preparation. Following are the consideration for the selection of a chemical to be used as a preservative in various food preparation.

- Type of organism to be controlled
- Length and conditions of product storage
- Physical and chemical characteristics of the food

16.11 USE OF CHEMICALS DURING CURING OF PICKLES

Fermented foods have many advantages such as prolonged shelf life, extended seasonal life, less time for cooking and sometimes increased acceptability and digestibility. They also act as laxatives. Vegetables can be preserved by simple lactic acid fermentation which enhances the organoleptic and nutritional quality of the product.

Commercial preservation of many pickle relies upon conversion of carbohydrates to organic acids during bulk storage and/or the addition of sufficient amount of sugar, vinegar and other ingredients to the fully cured and packed products to preclude any microbial growth. Organic acids, oils, salt and spices have antimicrobial properties at suitable concentration. Pickles in brine as such or after fermentation however, need some amount of preservative or pasteurization to prevent the spoilage.

Spices such as garlic, cloves, chillies, mustard seeds, dill herbs etc., have antimicrobial effect. Antibacterial and antifungal properties of mustard seeds are due to allylthiocyanate, a volatile aromatic compound which inhibits the growth of *Saccharomyces cerevisiae.* Mustard seeds promote growth of lactic acid bacteria and inhibit scum yeasts which can break down lactic acid. Essential spice oils such as thyme, sage, lemon and dill inhibit the growth of different yeasts in fermentation of olives, thereby, prolong in the effectiveness of lactic acid fermentation. Chemical preservatives such as sorbic acid inhibit fungi, yeasts and bacteria without interfering with the development of lactic flora.

16.12 PRESERVATION OF WHOLE TOMATO CONCENTRATE

Tomato is considered a necessary adjunct of almost all vegetable curries throughout the country. It adds to their taste, lends colour and supplements the nutritional quality of the vegetable preparations. Tomato crush is a distinct type of product which contains the whole of tomato inclusive of skin and seeds and thus differs from tomato puree and paste.

The tomato crush is prepared by boiling the tomatoes, blending and continuing to boil till a thick consistency. Preservatives are added to it prolong its shelf life. For every kilogram of the thick paste, 5ml of glacial acetic acid is added followed by boiling for 8-10 minutes. Then to the hot one kilogram of tomato crush, 0.4g potassium metabisulphite and 0.2 g sodium benzoate are added after dissolving in a small quantity of water. This mixture of two preservatives retains better red colour (lycopene) in tomato crush.

16.13 LET US SUM UP

In this unit on chemical additives we have examined the role of food additives in the food industry. This has included the study of the classes of different food additives, their role and mode of action, nutritional additives, the permitted preservatives and their applications.

We have also studied the simple, low cost, low energy processing technologies which are needed to keep the processed and preserved products within the reach of a much wider section of the population. These methods of chemical preservation and fermentation are easy to follow, economical and cater to the indigenous need, save losses of fruits and vegetables as well as their valuable nutrients, utilize market surplus, promote horticulture and give boost to the preservation industry, benefit the consumers and provide better returns to growers.

The chemicals, which are intentionally added to our food, constitute a small but important part of the many chemicals which man is adding to his environment. These chemicals are needed to efficiently produce an abundance of high quality food. The global and the scientific view still include unintentional and generally recognized additives as safe materials. Unintentional additives may have been incorporated into the food during its production, processing, storage or marketing. Intentional food additives include chemicals, which are used for nutritional purposes, consumer acceptance, preservation of quality and processing. The changing food industry allows the homemaker of today to spend only 90 minutes per day in the kitchen compared with the 5 hours used by her mother. Her convenience foods, which save time, effort and sometimes money, contain many of the direct additives.

16.14 KEY WORDS

Food additive : A substance or a mixture of substances other than the basic food stuff, which is present in food as a result of any aspect of production, processing, storage and packaging and does not include chance contaminants.

GRAS : Additives which are Generally Recognised As Safe.

Preservative : Substances which when added to food retard, inhibit or arrest the activity of microorganisms such as fermentation, acidification and decomposition.

Steeping preservation : Preservation in a chemical solution that contains various food additives such as organic acids (glacial acetic acid, citric acid, lactic acid), chemical preservatives (potassium metabisulphite, sodium benzoate) along with salt, sugar, spices etc. in water, and checks enzymatic, oxidative and microbial spoilage in the preserved material.

Whole tomato crush : Tomato product which contains the whole of tomato inclusive of skin and seeds.

16.15 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answer should include the following points:

1. Food additives help to improve the quality of food we eat. They enhance the consumer acceptability, help to maintain the nutritional quality, stability of the food, check spoilage by inactivating microorganisms, facilitate preparation of food and improve palatability e.g.: Preservatives, antioxidants, colouring agents, texture modifiers, antifoaming agents, acidulants, flavours etc.

2. Class I preservatives are natural products e.g.: salt, sugar, dextrose, spices, vinegar, honey etc which can be used at a higher concentration to preserve foods. Class II preservatives are synthetic chemicals such as benzoic acid, sulfurous acid, propionic acid, nitrites, nitrates etc. which are used in small concentrations to preserve food.

3. Your answer should include the following points.

   - Additive means any substance which is not a normal constituent of the food material and is purposeful addition which is aimed for technological, organoleptic and nutritional reasons.
   - According to the WHO, a food additive is defined as a substance or mixture of substances other than the basic foodstuff, which is present in food as a result of any aspect of production, processing, storage and packaging. The term does not include chance contaminants.
   - Food additives have also been defined by the National Academy of Sciences as those chemicals that may be incorporated in foodstuffs, either directly or indirectly during growing, storage or processing of foods.

Check Your Progress Exercise 2

Your answer should include the following points:

1. Steeping Preservation implies preservation in a chemical solution that contains various food additives such as organic acids (glacial acetic acid, citric acid, lactic acid), chemical preservatives (potassium metabisulphite, sodium benzoate) along with salt, sugar, spices etc. in water, and checks enzymatic, oxidative and microbial spoilage in the preserved material. It helps to preserve foods for more than a year.

2. Fermentation implies decomposition of carbohydrates and carbohydrate like substances under aerobic and anaerobic conditions. It helps to break complex material to easily digestible form and make it easily digestible. Fermented food have prolonged shelf life, require less time for cooking and increased digestibility and acceptability.

EXPERIMENT 1 ASSESSMENT OF POST HARVEST LOSSES AT DIFFERENT LEVELS (FROM FIELD TO CONSUMERS)

Structure

1.1 INTRODUCTION

Assessment of Post Harvest losses from field to consumers is extremely important from the point of post harvest management. Saving all these losses indirectly means increase in availability of the commodity and finally helping the society. Estimating losses at different levels such as farm, wholesale and retail can accomplish the loss assessment by adopting appropriate sampling procedure at each stage. You should understand that a modest improvement in reducing wastage per unit handled at each level when multiplied by millions of unit at each stage in post harvest system could significantly increase the availability of fruits and vegetable.

Objectives

After studying and performing this experiment, you should be able to:

- determine pre-harvest loss of fruits & vegetables at field level due to insect, pest and disease incidence as well as the harvesting damage; and
- determine post-harvest loss of fruits & vegetables due to poor marketing efficiency including faulty packaging, inefficient transport, and inadequate storage facility at traders level.

1.2 EXPERIMENT

1.2.1 Principle

Pre and post harvest care of fruits and vegetables in India is by and large very poor which lead to high losses. The poor marketing efficiency including faulty packaging, inefficient transport, and inadequate storage facility is indirectly reflected in high loss. It is important to know the magnitude of post harvest losses at different stages of marketing as well as at farm. More attention to be given where losses are more and immediate corrective measures should be taken to reduce such losses.

1.2.2 Requirements

- Physical Balance/weighing scale.
- Quality assessment instruments viz. Refractometer, Pressure tester etc.
- Questioner/check list (To obtain data on losses at different level, from farmer, traders etc during survey).

1.2.3 Procedure

- Collect the loss assessment data by interviewing the farmers and traders on fresh, affected/ decayed/damaged/diseased quantity produced and handled respectively.
- Best way would be to draw a sample from the harvested produce of each commodity at farm level and a sample for each commodity at traders level taken randomly to assess the losses.
- At each stage segregate the sample into fresh/marketable and affected/unmarketable produce.

1.2.4 Observations

The sample of the fruits and vegetable collected is initially sorted into fresh (marketable) and unmarketable (decayed, diseased, damaged etc). The unmarketable ones are partly sold or processed (deformed, over/under size but free from spoilage) and partly rejected (diseased or decayed). The percentage of fresh (marketable) and affected (unmarketable) parts of the sample of fruits and vegetables at each level can be worked out easily.

1.2.5 Calculations

$$\%\ \text{loss} = \frac{\text{Q2 affected/unmarketable produce}}{\text{Q total quantity of sample}} \times 100$$

$$\%\ \text{fresh} = \frac{\text{Q1 fresh/marketable produce}}{\text{Q total quantity of sample}} \times 100$$

Q = total quantity of sample (Q1+ Q2)

Q1= fresh/marketable

Q2= affected/unmarketable

1.2.6 Result

Loss assessment is expressed = Percent (w/w)

1.3 PRECAUTIONS

- Prepare questionnaire for the interview of farmers and traders well in advance.
- Questions to be asked in a friendly manner in order to extract the maximum facts.
- Samples to be drawn at farmers and traders level with utter care so that it gives representative sample.

EXPERIMENT 2 DEMONSTRATION OF VALUE-ADDITION — BY POST HARVEST HANDLING AND PACKAGING

Structure

2.1 INTRODUCTION

Horticultural produce, in general, and fruits and vegetables, in particular, if they are properly handled i.e. sorted, graded, waxed, pre-cooled and unit packed can produce value added products. Unfortunately, in our country most of the fruit and vegetables immediately after harvest are sent to the market as a result a huge quantity of unwanted materials are also sent but if they are timely eliminated before marketing and gainfully utilized can not only add indirect value to the product but also reduce garbage in the metro cities. Ideally fruits and vegetables after harvest should be sorted, graded, waxed, pre-cooled and unit packed at packing stations situated at appropriate points in every district. This process will reduce the transportation and handling cost of inedible parts and help the consumer by providing a convenience food that can fetch higher price.

Objectives

After studying and performing this experiment, you should be able to:

- determine the importance of sorting, grading, waxing, pre-cooling and packaging, and how it can directly add value to the harvested produce; and
- determine the amount of fresh/marketable materials from the harvested lot and how to add value to the cull fruits and vegetables by making processed product.

2.2 EXPERIMENT

2.2.1 Principle

Sorting removes unwanted materials that are obviously unsuitable for sale, such as fruits and vegetables with severe mechanical injury, decay and under or over size that are unsuitable for fresh marketing. While grading groups commodity based on size, shape, colour etc. and is necessary to get suitable returns with respect to the quality attributes of the commodity. Acceptability depends on the size, attractiveness and organoleptic quality of the particular commodity. Therefore sorted and graded produce will add value. Waxing is an extra discontinuous layer applied manually or mechanically for the purpose of replacement of natural wax. This reduces water loss, gives cosmetic appearance and provides better shelf life. Prompt pre cooling reduces water loss and physiological activity, limits the growth of decay organisms, maintain quality and increase the shelf life. Ideal packaging reduces undue damage during handling and transportation, while unit packaging provides convenience and thereby increases the value of the commodity.

2.2.2 Requirements

- Sorting and grading – plastic crates and stainless steel/aluminium top tables, stools and weighing scale.
- Waxing – wax emulsion, perforated trays and electric fans.
- Precooling – ice, bucket and thermometer probe type.
- Unit packaging – stretch / cling film, small pulp/plastic tray and small baskets.

2.2.3 Procedure

Sorting and grading

- Sorting and grading may be done manually or mechanically.
- In absence of a mechanical sorter and grader an experienced person can undertake both these operations efficiently.
- After collecting the sample of the fruits and vegetable, sort out the fresh/marketable and unmarketable/decayed/diseased/damaged ones.
- After sorting out fresh/marketable fruits and vegetable, grade them according to soundness, firmness, cleanliness, size, shape, weight, colour and maturity.
- But the most prevalent practice is size grading.

Waxing

- Wax the fruits by dipping them in wax emulsion for 30-60 seconds or give a spray of wax.
- Remove excess wax by allowing them dripping.
- Dry with the help of an electric fan.

Pre-cooling

- Collect the sorted and graded fruits and dip them in a bucket containing ice water.
- This is known as hydro cooling you follow this practice in fruits but not in all horticultural commodities.
- In the case waxed fruits one should follow air-cooling.

Packaging

- Ideally after sorting, grading and waxing the fruits and vegetables are packed in CFB (Corrugated fibre board boxes).
- Unit packaging of fruits and vegetables can be done conveniently with the help of stretch/cling film.
- This film has the property that under tension it stretches and when tension is released it comes back to its original forms.
- This property helps in unit packaging for retail sale.
- Take a few fruits on a tray or basket or individually and wrap them with stretch/cling film.
- The whole operation can be carried out without heat application.

The cull fruits and vegetables free from microbial infection should be processed into value added products.

2.2.4 Observations

After rejecting the unmarketable fruits and vegetables, from the harvested lot, one can easily find out the percentage of fruits and vegetables ideal for fresh market. Sorted, graded, waxed, and unit packed fruits and vegetables can fetch higher price because of better quality (appearance), reduction in transportation and handling cost and in addition it provides convenience to the consumer.

You can easily find out the effect of waxing and unit packaging by comparing the differences in terms of quality (appearance) and weight loss with that of un-waxed unpacked ones. Conducting sensory evaluation can assess the quality.

The pulp prepared and preserved from the cull fruits can be gainfully utilized for making various processed product as when required.

2.2.5 Calculations

$$\text{Idea for fresh market \%} = \frac{\text{Weight of Marketable fresh produce}}{\text{Total quantity of harvest lot}} \times 100$$

$$\text{Weight loss (\%)} = \frac{\text{Initial weight} - \text{weight at the end of storage}}{\text{Initial weight}} \times 100$$

Sensory evaluation = Experienced assessors randomly selected should evaluate overall acceptability, colour, texture and flavour/odour. Attributers are to score on five point hedonic scale of excellent, 1; good 2; fair 3; poor, 4; and very poor, 5.

2.2.6 Result

Weight loss and spoilage is expressed = Percent (w/w).

Freshness = Visual observations.

Sensory evaluation = overall score.

2.3 PRECAUTIONS

- Select only freshly harvested produce, which has not undergone any segregation or selection.
- If freshly harvested produce is not available collect representative sample from the bulk arrival in wholesale market.
- Packaging should only be done with the sorted and graded fruits and vegetables.
- Avoid rough handling of the material
- Sorted fruit and vegetables unfit for fresh marketing due to under size, oversize, deformed, physically damaged but free from microbial spoilage should be kept carefully for processing into a value added product.

EXPERIMENT 3 ON FARM STORAGE — PUSA ZERO ENERGY COOL CHAMBER

Structure

3.1 INTRODUCTION

In a tropical country like India, a tremendous amount of quality deterioration of horticultural produce takes place immediately after harvest due to lack of on-farm storage facilities. Refrigerated cool storage is considered to be the best method of storing fruits and vegetables. However, this method is not only highly energy intensive but also involves huge capital investment. The present trend world over is to develop a simple low cost cooling system for storage of fruits and vegetables. In order to overcome the problem of on farm storage, low cost environment friendly Pusa zero energy cool chambers have been developed. The greatest importance of this low cost cooling technology lies in the fact that it does not require any electricity or power to operate and all the materials required to make the cool chamber are available locally, easily and cheaply. Even an unskilled person can install it at any site, as it does not require any specialized skill. Most of the raw material used in cool chamber is also re-usable. The cool chamber can reduce the temperature by 10-18^{o}C of ambient temperature and maintain high relative humidity of above 90% throughout the year that can increase the shelf life and retain the quality of fresh horticultural produce.

Objectives

After studying and performing this experiment, you should be able to:

- construct the Pusa zero energy cool chamber even in remote area and learn how to maintain the temperature and humidity in side the chamber; and
- demonstrate the performance of Pusa zero energy cool chamber in increasing the shelf life of fresh fruits and vegetables.

3.2 EXPERIMENT

3.2.1 Principle

Based on the principles of direct evaporative cooling, the Pusa zero energy cool chamber works. Considerable cooling effect can be obtained by evaporation of water and faster the evaporation, greater is the cooling. Evaporative cooling occurs when air that is not already saturated with water vapour is blown across any wet surface. Theoretically the lowest temperature that can be reached by the evaporation of water is the wet bulb temperature. The materials primarily used in constructing these chambers i.e. bricks and sand fortunately both has great capacity to absorb and/or retain water which evaporates slowly and steadily depending on the atmospheric temperature and humidity resulting in cooling.

3.2.2 Requirements

- Construction materials: bricks, sand, bamboo etc.
- Top cover: khas khas fixed in a bamboo-frame.
- Watering of the chambers: watering can or bucket and mug, water tank, drip system etc.
- Plastic crates for storage and plastic sheet for cover.
- Temperature and relative humidity: Maximum minimum and wet and dry bulb thermometer or digital thermo-hygrometer with extension cord.
- Hand sprayer (small) for spraying of insecticides/fungicides.

3.2.3 Procedure

For construction of Pusa zero energy cool chamber select an-upland having a nearby source of water supply.

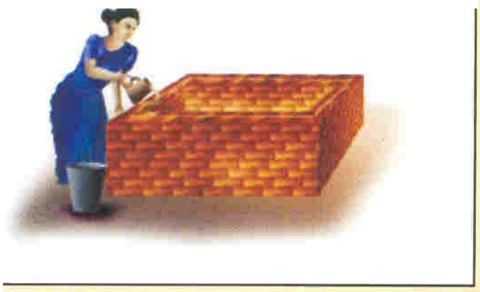
- Make floor of the chamber with the help of bricks size 165 cm × 115 cm.
- Erect the double bricks wall on the above floor to a height of 67.5 cm leaving a cavity of 7.5 cm.
- Drench the chamber with water and soak the fine riverbed sand with water. Fill the cavity between the double brick wall with this wet sand.
- Make a frame of top cover with bamboo (165 cm × 115 cm) frame and 'sirki' straw or dry grass.
- Make a thatch/tin/asbestos shed over the chamber in order to protect it from direct sun or rain or snow.
- After construction following operation instructions are to be followed. Keep the sand, bricks and top cover of the chamber wet with water.
- In order to achieve desired temperature and relative humidity, water twice daily (morning and evening). Alternatively, fix a drip system for watering with plastic pipes and micro tubes connected to an overhead water source.
- Store the fruits and vegetables in this chamber by keeping in perforated plastic crates. Cover these crates with a thin polyethylene sheet.
- The cool chamber should be reinstalled once in 3 years with new bricks utilizing the old bricks for other purposes.

DIAGRAM FOR CONSTRUCTION OF PUSA ZECC

1. Making floor of chamber

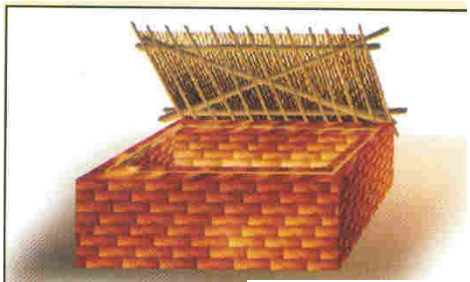
2. Erecting double wall with cavity

3. Watering the chamber



4. Filling wet sand

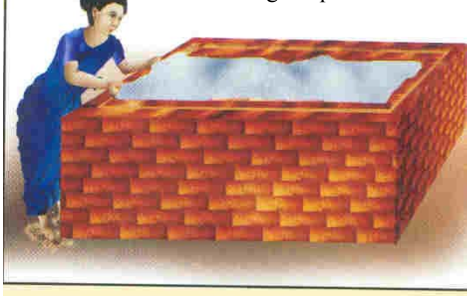
5. Making top cover



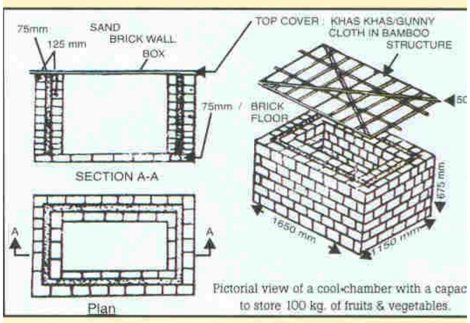
6. Cool chamber

7. Storing in plastic crates/baskets

8. Covering the plastic sheet



9. Cool Chamber under shed



3.2.4 Observations

Once the Pusa zero energy cool chambers is constructed, regular observations to be taken regarding the performance of cool chamber in terms of temperature and relative humidity as well as the shelf life increase of fruits and vegetables.

Temperature and Relative Humidity can be recorded with the help of Max. Min. Thermometer and Dry & Wet bulb Thermometer, otherwise it can be done with the help of digital thermo-hygrometer for display of temperature and relative humidity.

The shelf life increase of fruits and vegetables is recorded regularly by taking the weight, incidence of spoilage/diseases and assessing the quality (sensory evaluation).

3.2.5 Calculations

$$\text{Weight loss (\%)} = \frac{\text{Initial weight} - \text{weight at the end of storage}}{\text{Initial weight}} \times 100$$

$$\text{Spoilage (\%)} = \frac{\text{Weight of spoilt material}}{\text{Initial weight}} \times 100$$

Sensory evaluation = Experienced assessors randomly selected should evaluate overall acceptability, colour, texture and flavor/odour.

Attributers are to score on five point hedonic scale of excellent, 1; good 2; fair 3; poor, 4; and very poor, 5.

3.2.6 Result

Weight loss expressed as Percent (w/w).

Spoilage expressed as Percent (w/w).

Freshness expressed as Visual observations.

Sensory evaluation expressed as overall score.

3.3 PRECAUTIONS

- The site should be selected where breezes blow and should be build in an elevated place to avoid water logging.
- Only clean, unbroken bricks with good porosity must be used sand should be clean and free from organic matters, clay etc.
- The bricks and sand should be kept saturated with water. The chamber should not be exposed to sun, rain or snow.
- Only plastic crates should be used for storage and avoid bamboo baskets, wooden/fibre board / boxes, gunny bags.
- Efforts should be made to prevent water drops coming in contact with stored material.
- The chamber should be kept clean and disinfect the chamber periodically with permitted insecticide/ fungicide/ chemical, to protect from fungus, insect / pests, reptiles, etc.

EXPERIMENT 4 SOLAR DRYING OF FRUITS AND VEGETABLES

Structure

4.1 INTRODUCTION

Preservation of food by drying is perhaps the oldest method. Large quantities of fruits and vegetables are dried in the sun in different parts of the world. Sun drying or solar drying of fruits and vegetables is practiced widely in tropical and sub-tropical regions where there is plenty of sunshine and practically little or no rain during the drying season. Only small capital investment is required with this simple procedure. Advantages of dehydrated fruits and vegetables are more viz. mineral content remain unchanged, hardly affects the main calories-providing constituents of food, long shelf life if packed and stored properly, transportation, handling and storage costs are substantially reduced and finally the consumer uses all that he buys thus no waste disposal and pollution problems. However, there are some disadvantages, since sun drying depends on uncontrolled factors, production of uniform and high quality product is not expected. Some over drying and contamination by dust, dirt, and insect infestation of the finished products is usually tolerated. It is a slow process, unsuitable for producing high quality products. If the ancient sun-drying technique is improved by creating ideal system of solar drying then quality of the dried product also be improved.

Objectives

After studying and performing this experiment, you should be able to:

- demonstrate the techniques of pre-drying treatments required for fruits and vegetables to produce a quality-dried product; and
- display the Improved Solar Drier / Black Polyethylene Cover drier by actually drying some fruit or vegetable following ideal conditions of packaging and storage of solar dried fruits and vegetables.

4.2 EXPERIMENT

4.2.1 Principle

The major purpose of drying or removal of water/moisture from fruits and vegetables is to protect them against deterioration. Microbes cannot grow and multiply in absence of sufficient water in the environment. Many of the enzymatic reactions are hydrolytic in nature and require water as one of the reactants. Chemical reactions in food materials are also slowed down in absence of an adequate water. Therefore, by removing water from the fruits and vegetables, it should be possible to preserve them by checking the spoilage causing agents. This principle forms the basis for preservation of fruits and vegetables by drying. Employing blanching, sulphuring or sulphitation can improve the quality of sun-dried fruit and vegetable products. The retention of green colour and β-carotene (provitamin A) can be improved by indirect solar drying. The quality of the dried fruits and vegetables can be retained successfully if they are ideally packed in moisture proof pack and stored in cool dry place.

4.2.2 Requirements

- Preparation table having stainless steel sheet or aluminum top
- Stainless steel peeling, coring and pitting knives
- Blanching tank/aluminum vessel
- Gas burner/heating arrangement
- Cooling tank
- Sulphitation/ SS tank or aluminum pan
- Sulfuring/Sulfur box
- Perforated aluminum trays
- Solar drier/facility for sun drying
- Black polyethylene sheet
- LDP/HDP pouches, Pouch sealing machine. Tin container with airtight closure.

4.2.3 Procedure

- Select fruits and vegetables very carefully for drying.
- Wash the fruits and vegetables thoroughly to remove any dirt and other extraneous matter.
- Prepare the fruits and vegetables by peeling and cutting into suitable sizes on the day of harvest itself.
- In the case of fruits, sulphuring is done as pretreatment to maintain their colour and also to avoid spoilage by microorganisms.
- Prepared fruits are then exposed to sulpher fumes by burning sulphur in a sulpher box.
- Blanching is used as pretreatment for vegetables, this is done by rapidly boiling the vegetables in water for known time to inactivate the enzymes and partially killing the microorganism.
- Immediately after blanching the vegetables are dipped in cold water to avoid over cooking.
- The blanched vegetables are sulphited by placing them in 0.5% solution of potassium metabisulphite for requisite time.

- The fruits and vegetables are then spread on perforated tray, dried in direct sun or in shade preferably in a well - ventilated room away from direct sunlight. Provision of a ceiling fan in the room will hasten the process of drying.
- Solar drying can be improved considerably by using black polyethylene structure.
- It should be made in such a way that it could hold trays containing fruits and vegetables for drying with the provision of entry of dry air from the bottom and exit of moist air from the top of the structure.
- The samples should be turned every 4-6 hours for uniform drying.
- Dried fruits and vegetables are highly susceptible to contamination and therefore, should be packed in polyethylene (plastic) bags/pouches as soon as they are cooled after drying is over.
- In order to prevent rodent attack, the plastic bags are placed in metal containers and closing the lid firmly.

4.2.4 Observations

During sun/ solar drying, it is necessary to observe that there is plenty of sunshine and practically little or no rain during the drying season. Weigh the trays at regular interval to determine the drying the rate. The vegetables should preferably be dried to a moisture level of about 5%, i.e. till the vegetables become crisp/brittle. In case of fruits higher moisture can be retained because of the presence of sugar. Observations are to be made on the aspect viz. drying rate, and ratio, final moisture content of the material and re-hydration ratio. Finally the quality has to be determined.

4.2.5 Calculations

The dehydration ratio can be worked out by taking the initial weight of the fruit or vegetable and final weight of the dried product.

$$\text{Dehydration ratio} = \frac{\text{Initial weight of the fruit or vegetables}}{\text{Final weight of the dried product}}$$

$$\text{Rehydration ratio} = \frac{\text{Weight of the dried fruit or vegetable}}{\text{Final weight of the soaked dried product after draining water}}$$

$$\text{Moisture (\%)} = \frac{\text{Initial weight} - \text{weight after drying}}{\text{Initial weight}} \times 100$$

Organoleptic quality / Sensory evaluation = Experienced assessors randomly selected should evaluate overall acceptability, colour, texture and flavour/odour. Attributers are to score on five point hedonic scale of excellent, 1; good 2; fair 3; poor, 4; and very poor, 5.

4.2.6 Result

Yield of dried product and moisture is expressed as Percent (w/w).

Drying and rehydration as Ratio.

4.3 PRECAUTIONS

- For the purpose of drying select fruits and vegetables in prime condition of eating and cooking.
- Recommended pre-treatments and drying process should be strictly followed.
- Care must be taken to see that the dried products are packed at the right time and do not pick up moisture
- Rodent attack on the plastic pouches must be prevented.

EXPERIMENT 5 PRIMARY AND MINIMAL PROCESSING

Structure

5.1 INTRODUCTION

In India, perishable fresh fruit and vegetables are marketed immediately after harvesting without primary processing and adequate packaging. On the other hand, in the developed countries, most of the fruits and vegetables after harvesting are transported to packing stations for primary processing. They are then trimmed, sorted, graded, unit packed and marketed. In our country, because of the absence of primary processing, a lot of inedible material is transported to the market and finally to the homes of consumers where they end up in the garbage bin. Primary processing is therefore, necessary to streamline the marketing of fresh horticultural produce to urban markets. The solid wastes originating from horticultural crops in metro cities can create drainage problems and cause water logging, as well as invite stray animals near garbage dumps. These bio wastes also deteriorate very rapidly causing unhygienic conditions and increasing atmospheric pollution and provide a breeding ground for insects, pests and rodents. Minimally processed fruits and vegetables are cleaned, peeled, cut, sliced, packaged and/or lightly processed. These foods are in great demand because of their convenience. All fruits and vegetables need not be minimally processed. It is very often not convenient for the consumer with a small family to purchase commodities like pineapple, jackfruit, watermelon, pumpkin, ashgourd, yam, etc. Therefore if it is suitably sliced, peeled and packed consumer will be more inclined to buy it. In metro cities minimally processed vegetables like primary processing can solve one of the greatest problems of garbage disposal.

All fruits and vegetables need not be minimally processed. It is very often not convenient for the consumer with a small family to purchase commodities like pineapple, jackfruit, watermelon, pumpkin, ashgourd, yam, etc. If the vegetables are available in ready to cook form a large number of workingwomen in metro cities will be greatly benefited.

Objectives

After studying and performing this experiment, you should be able to:

- demonstrate the techniques of primary processing of fruits and vegetables and show how the solid wastes originating from fruits and vegetables can be utilized in the farmers field thereby reducing cost of transport and the city garbage; and

- explain with practical demonstration of techniques of minimally processed fruits and vegetables and highlight its advantages.

5.2 EXPERIMENT

5.2.1 Principle

There is little difference in principle between primary and minimal processing. Primary processing is applicable in some fruits and vegetables, which carries lots of inedible/unmarketable part from the field to the market. Therefore, the main principle of primary processing is to eliminate the inedible parts without inflicting any damage to the main edible part. While minimally processed fruits and vegetables are cleaned, peeled, cut, sliced, packaged and/or lightly processed. One should keep in mind that while supplying minimally processed vegetable the maintenance of quality and hygiene must be of topmost priority.

5.2.2 Requirements

- Preparation table having stainless steel sheet or aluminum top.
- Stainless steel peeling, coring and pitting knives.
- Stainless steel washing tanks, constant supply of potable water.
- Electric fan / blower / drying arrangement.
- Packaging in polyethylene pouches, small plastic crates, CFB boxes.
- Pouch sealing machine.
- Shrink wrap/cling films, small cardboard tray/bamboo basket/perforated plastic container.
- Refrigerated storage/ walking coolers.
- Stainless steel pretreatment tanks.
- Laboratory facilities.

5.2.3 Procedure

Both the primary processing and minimal processing can be explained properly by giving example of a particular fruit or vegetables.

Primary processing

Cauliflower

- Procure cauliflower immediately after harvest
- Remove the inedible outer leaves and stems by cutting them with sharp knife without inflicting any damage to the edible curd
- The curds can be either wrapped in plastic film or kept as such in plastic crates for shipment in the market.
- The leaf and stem portions eliminated can be used as cattle feed or any other value added products.

Banana

- Harvest mature banana bunches carefully without causing any damage to banana fingers.
- Separate the banana hands from the bunch with help of a sharp knife.
- If facilities available wash the hands wax and dry them.
- Put the banana hands individually in plastic bag and place them in the crates for shipment.
- The banana stems left out can be used as value added product.

Minimal processing

- Select good quality fruits and vegetables for this purpose.
- Peel the fruits and vegetables and cut them into convenient pieces.
- Place them into appropriate containers or pouches for marketing.
- Some pre-treatments are recommended varies from commodity to commodity should be followed strictly.
- Transport and store the minimally processed under refrigerated condition.

5.2.4 Observations

It is advisable to maintain strict hygienic condition of the place and equipment. Strict vigil on the quality of primary and minimally processed fruits and vegetables are to be carried out. Yield of primary and minimally processed fruits and vegetable is to be recorded.

Shelf life or marketable life can be observed by determining the quality both in terms of microbial and organoleptic quality.

5.2.5 Calculations

The yield of the finished product and weight loss during storage should be determined.

$$\text{Primary processed produce}\,\% = \frac{\text{Weight of primary processed produce}}{\text{Weight of the original fresh produce}} \times 100$$

$$\text{Minimally processed produce}\,\% = \frac{\text{Weight of minimally processed produce}}{\text{Weight of the original fresh produce}} \times 100$$

$$\text{Waste}\,\% = \frac{\text{Weight of waste}}{\text{Weight of the original fresh produce}} \times 100$$

Sensory evaluation = Experienced assessors randomly selected should evaluate overall acceptability, colour, texture and flavour/odour. Attributers are to score on five point hedonic scale of excellent, 1; good 2; fair 3; poor, 4; and very poor, 5.

5.2.6 Result

Yield and wastage expressed as Percent (w/w).

Quality assessment is reported on Hedonic scale.

5.3 PRECAUTIONS

- Handle only freshly harvested horticultural produce for this purpose.
- Care must be taken to see that surface moisture from the finally prepared material before packaging should be removed.
- Once the primary/minimally processed fruits and vegetables are prepared and packed it should straight away go to refrigerated store.
- Keep rejects such as peel, seeds/stones or any other vegetable parts carefully for processing into a value added products and not thrown as garbage.

EXPERIMENT 6 EXTRACTION AND PRESERVATION OF PULPS AND JUICES

Structure

6.1 INTRODUCTION

The demand of fresh juices and pulp are increasing very rapidly. They are rich in essential minerals, vitamins and other nutritive factors. Freshly extracted fruit juices and pulp are the most palatable. It is desirable that juices and pulp should retain quality characters satisfactorily to the maximum extent while extraction. One should keep in mind that extraction of fruit juices and pulp are of utmost importance. There is no guidelines or specification that particular equipment is dedicated to extraction of juice or pulp of a particular fruit. It entirely depends on the equipment that gives the best juice or pulp of high quality. Generally, crushing and pressing extract juice from fresh fruits. In one case it is done continuously in one operation where as in the other the fruits are either crushed or cut into small pieces/halves and subsequently juice is pressed out. There are various types of equipment used in extraction of fruit juices and pulp.

Freshly extracted juices and pulps are highly attractive in colour and excellent in flavor, but deteriorate very rapidly if they are not preserved immediately, various factors influence and/or accelerate the loss of quality both internally and externally. The internal factors viz. water content, chemical composition; enzyme system etc. and the external influences such as temperature, hygiene or presence of contaminants play a significant role in retaining the quality of juices and pulp. There are various ways for the preparation of fruit juices and pulps, but preservation of pulp and juices by chemical preservatives, heat processing and freezing are very popular.

Objectives

After studying and performing this experiment, you should be able to:

- learn different methods and equipment to be used for extraction of juices and pulp that depends upon the structure of fruit, location and character of the tissues in which the juice is located;
- learn how to avoid destruction of vitamin C and undesirable oxidative changes in colour and flavour that occur during extraction and subsequent processing;

- conduct experiment/practical on how pulp and juices can be preserved by heat processing; and
- demonstrate preservation of pulp and juices by chemical preservatives.

6.2 EXPERIMENT

6.2.1 Principle

The method of extraction of pulp and juices depends upon the structure of fruit, location and character of the tissues in which the juice is located. In fruits like aonla, apple, grapes etc the juice is located throughout the fruit and is readily recovered by crushing and pressing. While in case fruits like apricot, peaches, plum, mango, tomato etc. the raw or cooked fruits are passed through a pulper or similar machine. In case of citrus fruits the juice is embedded in a sac and it requires entirely different machine such as halving and burring machine halving and burring machine. One must remember that undue aeration must be avoided during the extraction of juices/pulp from fruits that have not been heated to destroy enzymes, since destruction of vitamin C and undesirable oxidative changes in colour and flavour takes place. It is necessary to remember that the metal equipment should not contain traces of iron and /or copper that deteriorate the quality.

Fruit juices and pulp are generally preserved by application of heat, addition of chemicals and by freezing. Both the microbial and enzymatic spoilage can be well checked by application of heat. Preservation of pulps and juices by application of heat is known as pasteurization, in this process the pulps and juices are heated below 100° C but above 88° C to kill spore-forming bacteria, mould and inactivate enzymes. Acid fruit juices and pulp require lower temperature and less time for pasteurization than the less acid ones. Chemical preservatives are substances capable of inhibiting, retarding or arresting the process of fermentation, acidification or other decomposition of fruit juices and pulps. The permitted preservatives used in this country are sodium benzoate and potassium metabisulphite where the active agents are benzoic acid and sulphur dioxide respectively. Generally beverages like squashes, cordial etc. are preserved by chemicals as well as bulk preservation of pulps and juices.

6.2.2 Requirements

Requirements for extraction and preservation of pulps and juices are as follows:

Extraction

- Pulpers
- Screw type juice extractor
- Citrus juice extractor/ Rosing machine
- Citrus halving machines
- Fruit mill/fruit grater
- Basket press/hydraulic press/rack and cloth press,
- Crown corking/pp cap sealing machine
- Gas burner/heating arrangement
- Double seamer / crown corker

- Processing & cooling tank
- Stain less steel storage tanks
- Sterilization equipment
- Thermometer
- Aluminum pan
- Wooden laddle
- Mixing tank

Preservation

- Sodium benzoate
- Potassium metabisulfite (KMS)
- Citric acid
- Bottle filling machines
- Beer bottles, Jerry cans, Glass containers and closures

6.2.3 Procedure

Extraction

In general you can extract juices/pulp from fresh fruits and vegetables by crushing and pressing, but the method of extraction and equipment used varies. It would be more clear once it is explained with examples as follows:

Mango, tomato, papaya etc.

- These are all pulpy fruits therefore a pulper can extract the juice/pulp easily.
- Peel and cut the fruits in general before placing in the pulper.
- These are then crushed and pressed by the paddles against the cylindrical sieve.
- The juice/pulp flows out through the sieve into jacket and collect the juice/pulp by placing in a container below the pulper.
- The coarse residue, stone etc, passes out at the lower end of the sieve.

Citrus fruits

- Cut the citrus fruits in to two halves by revolving or stationery knife.
- Hold or press the cut half against the revolving burr or rose of extracting machine.
- Collect the reamed juice in a container placed below.

Apple, aonla, grape, pineapple, jamun, carrot etc.

- In order to extract the juice from the above-mentioned fruits and vegetables you have to grate or crush them in a grater or crusher.
- Then place the grated or crushed mass in a filter cloth tie it properly but loosely.

- Carefully put the filter cloth containing grated or crushed mass inside the basket.
- Put the load/wooden disc on the filter cloth containing grated or crushed mass and press the juice out by hand operated or hydraulic type press.

All the three types extraction methods are explained above however it is necessary to mention that the Screw type juice extractors can be used universally for extracting juices/pulp from all types of fruit pieces including citrus segments.

Preservation

The following two methods of preservation are to be conducted.

Heat processing

- Preservation of juices and pulps by heat processing are most popular and desirable method.
- Heat the juice or pulp to about 100o C for sufficient time to kill the microorganisms causing spoilage.
- Fill the almost boiling hot juice in preheated glass bottles without giving any head space and crown cork immediately.
- Keep the bottles in a horizontal position and cool them in air.
- Preserve the fruit and vegetable pulp by heat processing in open top can or in wide mouth bottles having closures, which can be sealed hermetically.

Chemical preservatives

- You know two permitted preservatives viz. i) sodium benzoate and ii) Potassium metabisulphite (KMS) used in preservation of fruit and vegetable juices and pulps.
- Benzoic acid is an effective agent but it is sparingly soluble in water however, its sodium salt is water-soluble therefore sodium benzoate is used.
- Addition of 0.06 to 0.1 percent sodium benzoate is sufficient in juice having a pH of 3.5 to 4.0.
- Potassium metabisulphite is soluble in water and used as a stable source of sulphur dioxide, which is an effective agent.
- Addition of 0.15–0.2 percent potassium metabisulphite is sufficient in juice/pulp having a pH of 3.5 to 4.0.
- Weigh exact amount of preservative and dissolve in small quantity of freshly boiled and cooled water before adding to heated and cooled pulp/juice.
- Fill in the container (glass jar, jerry can etc) and close it securely so that sulphur dioxide does not escape.

6.2.4 Observations

The main observations to be taken are selection of fruits, % of juice, % of pomace/rag, % of peels, % of stone, % of unknown loss, % of acidity and degree Brix or % of total soluble solids (TSS).

6.2.5 Calculations

$$\text{Juice (\%)} = \frac{\text{Weight of juice extracted}}{\text{Initial weight of the fruit}} \times 100$$

$$\text{Pomace/rag (\%)} = \frac{\text{Weight of residue after extraction}}{\text{Initial weight of the fruit}} \times 100$$

$$\text{Stone (\%)} = \frac{\text{Weight of stone removed}}{\text{Initial weight of the fruit}} \times 100$$

Calculation for acidity and degree Brix or total soluble solids (TSS), you should consult the practical manual viz BPVI-003 and BPVI-007.

6.2.6 Result

- Yield of juice is reported as Percentage
- Yield of pomace is reported as Percentage
- Yield of peel is reported as Percentage
- Yield of seed is reported as Percentage
- Acidity is reported as Percentage
- Total soluble solids (TSS) = % or ^{o}Brix

6.3 PRECAUTIONS

- Avoid overripe and microbiologically spoiled fruits for making juice and pulp.
- Wash the extractors and other equipment with hot water to reduce the chance of infection.
- Preserve the juice and pulp immediately after extraction in order to avoid quality deterioration and incidence soilage.
- Dry the pomace immediately in order to avoid spoilage and use it for the production of value added products.

EXPERIMENT 7 PREPARATION OF WHOLE TOMATO CONCENTRATE

Structure

7.1 INTRODUCTION

Tomato is one of the few nutritious vegetables, which has a great demand both in the fresh and processed form. During the season of abundance when there is a glut in the market and tomatoes are sold at through away prices and the growers do not get the remunerative price. It is an item of daily use and also an important ingredient in our culinary system. Unlike other ingredients such as onion, garlic, ginger etc. which are peeled/scaled before using, tomato is added whole without eliminating seeds or peel portion while cooking either in vegetarian or non-vegetarian food. Therefore, there is a great scope of preserving the whole tomato in the concentrated form along with its seeds and peel.

Objectives

After studying and performing this experiment, you should be able to:

- determine the importance of preserved tomatoes in the form of whole tomato concentrate to be used in off- season or when they are very costly in the market; and
- determine the importance of low cost processing of tomato in value addition and retention of quality attributes particularly the colour i.e. Lycopene known for its anti-oxidant property and as precursor of vitamin A.

7.2 EXPERIMENT

7.2.1 Principle

Whole tomato including peel and seeds are crushed, concentrated and preserved by combination of heat and chemical preservatives. This can be used for cooking purpose when prices are more for fresh tomato. It is a complete substitute for fresh tomatoes. By this way of low cost preservation, a huge quantity of post harvest loss of tomato can be prevented.

7.2.2 Requirements

- Preparation table having stainless steel sheet or aluminum top.
- Stainless steel knives.
- Gas burner/heating arrangement.
- Aluminum pan / stainless steel pan.
- Wooden ladle.
- Wide mouth glass or plastic bottles with closures.
- Chemicals – Acetic acid, potassium meta bisulphate (KMS) and sodium benzoate.

7.2.3 Procedure

- Select fully ripe and red tomatoes, wash them and cut into pieces after removing the green portions.
- Boil them in a stainless steel or aluminium vessel while crushing constantly with the help of a wooden ladle to get a homogenous mass including seed and peel.
- The whole tomato pulp should be concentrated to approximately one third (3 kg of fresh tomato will yield 1Kg of tomato concentrate) of its original weight when it forms a thick paste.
- Towards the end, boil the tomato concentrate for a couple of minutes by adding 0.5% glacial acetic acid.
- Cool the tomato concentrate to room temperature and add a mixture of 200ppm each of sulpher dioxide and sodium benzoate i.e. 0.4 g KMS and 0.2 g sodium benzoate per kg of concentrate after dissolving them in a small quantity of water.
- The mixture of two preservatives help in retention of red colour apart from helping in preservation of pulp.
- Fill the whole tomato concentrate in a clean dry glass/bottle and close it properly.
- Store the bottles in cool dry place and use as and when required.

7.2.4 Observations

Careful observation to be made that the green portions are totally eliminated(trimmed) tomatoes otherwise it will hamper the colour of the end product.

To avoid charring the product should be constantly stirred. The weight of the final product should be I/3 rd of the original weight.

7.2.5 Calculations

$$\text{Trimming (\%)} = \frac{\text{Weight of trimming}}{\text{Initial weight of the fruit}} \times 100$$

$$\text{Tomato concentrate (\%)} = \frac{\text{Weight of concentrate}}{\text{Initial weight of tomato}} \times 100$$

7.2.6 Result

Waste (trimmings) = %

Tomato concentrate = %

7.3 PRECAUTIONS

- Select fully ripe red tomatoes for making tomato concentrate reject the infected ones.
- Avoid over-boiling after addition of acetic acid.
- Add chemical preservatives towards end when the material is cooled to room temperature.
- Pack immediately in glass bottles or plastic pouches after addition of preservatives.

EXPERIMENT 8 UTILIZATION OF WASTE GENERATED DURING FRESH HANDLING AND PROCESSING

Structure

8.1 INTRODUCTION

One of the reasons for the food processing industries based on horticultural produce not being economically viable in our country is non-utilization of the valuable waste accumulated during handling and processing. The huge quantity of fruit and vegetable waste generated in the packhouse and fruit processing units can also be gainfully utilized for making value added products, thereby reducing the price of processed products. By doing so the processed food products of daily use of the common man will be well within their budget and food processing will become a more popular industry. In addition by utilizing the waste at the right time the problem of disposal of solid waste from the food factory can be solved to a great extent.

Objectives

After studying and performing this experiment, you should be able to:

- determine the extent of waste generated in a packing station and processing factory using fruits and vegetables; and
- explain the technique of utilization of fruits and vegetable waste material into a value added product.

8.2 EXPERIMENT

8.2.1 Principle

The waste generated both in fruit and vegetable packhouse and processing units in terms of cull fruits, peel, stone, cores, pits, seeds, trimmings, stems, pods are highly perishable. All these waste materials should be processed immediately into durable products, utilizing various techniques of preservation such as heat application, dehydration, addition of chemicals etc. otherwise they will convert into garbage. Various types of by products can be produced from the waste including both as feed material for the animal and food for human. The most common by products are pectin, citric acid, oils, vinegar, and alcohol. A large number of other materials like colour, essential oil, and nutrients can also be produced apart from processed food items like juices, jams, pickle, candies etc.

8.2.2 Requirements

- Preparation table having stainless steel sheet or aluminum top.
- Stainless steel peeling, coring and pitting knives.
- Blanching tank/aluminum vessel.
- Gas burner/heating arrangement.
- Solar drier/facility for sun drying.
- Pulpers.
- Fruit mill/fruit grater.
- Basket press/hydraulic press.
- Crown corking/pp cap sealing machine.
- Mixing tank, Beer bottles, Jerry cans for storage.

8.2.3 Procedure

As already mentioned waste generated both in fruit and vegetable pack house and processing units can be utilized for production of various types of value added products including human food and animal feed. It is not possible to describe the procedure of all these items. Therefore we have selected three items of waste, which can be gainfully utilized.

Fruit pulp from culled fruits – Fruits that are rejected both by the packing station and processing factories can be gainfully converted into pulp

- Collect the fruits (apple) and wash them thoroughly after rejecting the spoilt ones.
- Cut the apples into four to six pieces depending on the size. Remove the core portion containing seed.
- Separate the seeds and sundry them which can be sold to the nurseries
- The fruit pieces are then cooked/ boiled in requisite amount of water with constant stirring to soften them
- Pass the hot mass through a pulper or stainless sieve and collect the apple pulp.
- Adjust the acidity of the apple pulp to 0.5% with citric acid and preserve the apple pulp in a jerry can by addition of 2g of KMS (preservatives) per kg of pulp.
- The apple pulp can be used as such and you can be prepare various types of products viz. fruit slab, nectar/fruit drink, fruit toffee etc as and when required.

Cauliflower waste in packing station

Cauliflower produces about 60% leafy part and 40% edible curd. Utilize the leafy part as a value-added product both for human food and feed for cattle.

- Cauliflower produces about 60% leafy part and 40% edible curd. Utilize the leafy part as a value-added product both for human food and feed for cattle.
- Remove the thick midrib (stem) from the leafy portion and keep them separately.
- Cut both the leafy portion and the stem into small pieces and wash them thoroughly in running water.
- Blanch them separately in boiling water for 2 minutes before drying.
- Dry them separately preferably under polyethylene cover till they are crisp dry.
- Pack them in polyethylene bags and them securely in a tin container.
- Finally convert the dried leaves into cauliflower leaf powder, this is a rich source of β-carotene (pro-vitamin A) and is a potential source of fortification that could solve the acute problem of vitamin-A deficiency.
- Similarly stems cut into pieces blanched and dried could be used as animal feed in time of shortage or fodder crisis.

Candied citrus peel in a juice factory

- Collect the citrus peels after extraction of juice then remove the seeds and rags from inside the cup.
- Place the peel in 2.0 % common salt solution. Increase the strength of the solution by 2% every 24 hours until the strength reaches 8.0%. This takes about 4 days.
- On the fifth day wash the peels thoroughly and place them in freshly prepared 8.0% common salt solution. Containing about 0.2% potassium metabisuphite and 1.0 calcium chloride and store. Calcium chloride helps in keeping the peels firm.
- As and when required they are washed thoroughly in running cold potable water and then boil in order to soften them.
- After this put the peels in a vessel and cover them with cold syrup of 30° Brix and leave them for 48 hours.
- On the third day the brix will come down much below 30° it is then raised by 10 degrees, and the peels are boiled with syrup for about 5 minutes. The process is repeated until the brix is reaches 60 degrees.
- At this stage citric acid is added @ 1 g per Kg of peel. The strength of the syrup is raised to 75 degrees brix, 5 degree every day.
- The peels are then left in the syrup for 2-3 weeks. Finally they are dried on a stainless steel wire tray at room temperature till they are no longer sticky.

8.2.4 Observations

Note the amount of waste generated from a particular commodity during handling in the packing station and also while processing. Keep a record of the different types of waste and their quantity. You can add value to these waste by processing into some useful products, this will have an economic gain on the final product. This way the impact of value addition on the pricing of the original processed product can easily determined.

8.2.5 Calculations

Find out the percentage of total waste and also the percentage of different types of (leaf, stem, peel, seed/stone, core etc) waste generated from a particular commodity.

$$\text{Waste (\%)} = \frac{\text{Weight of the waste}}{\text{Weight of the commodity}} \times 100$$

Determination of economic gain, this can be done by actually calculating in terms of rupees as follows:

Price/value of the original processed product with out waste utilization = X

Price/value obtained from the waste material utilized by processing = Y

Price/value reduction of the original product X - Y = Z

Economic gain = X - Z

8.2.6 Result

Amount of waste is reported as %.

Economic gain is reported in rupees (or can also be expressed as %).

8.3 PRECAUTIONS

- Segregate the waste material like leafy portion, inedible/unmarketable parts in a packing station and seed, stone, peel and pomace in a processing industry.
- In order to avoid decomposition and stabilize the waste, dry the high moisture materials like pomace, peel etc for future use.
- Do not throw waste as it create environment pollution.

UNIT 1 AN OVERVIEW OF FOOD CHEMISTRY

Structure

1.0 OBJECTIVES

After reading this unit, you should be able to:

- explain what is food chemistry;
- state the historical developments in food chemistry; and
- discuss the different roles played by food chemistry.

1.1 INTRODUCTION

All of us need food for our survival and well being. We derive our food from the plant kingdom (like cereals, pulses, oilseeds, fruits, vegetables, root crops, etc.) and animal kingdom (like meat, fish, poultry, cow and buffalo, etc.). Do we know what are the constituents (nutrients) of the foods we eat? Do all foods contain the same constituents and in the same proportions or do they differ? Food chemistry has answers for all these. Today we have a fairly good knowledge of nutrient composition of all the common food materials and products so that we are able to plan a nutritionally balanced diet.

You have learnt the importance and methods of food preservation. Though we eat some foods in the raw form like fruits and vegetables, many others are stored for various length of time and consumed after cooking or converting them to some other forms as processed products like different types of wheat breads; various rice preparations, milk and meat products like cheese, yoghurt, sausages; fruit products like juices, jams, preserves; or dried and dehydrated products like mushroom powder. What changes take place in them after the food raw materials are harvested, processed and stored? Food chemistry deals with these.

Now we see numerous new ready to eat products on the grocer's shelf. They were not there 20 years ago. Steadily the numbers are increasing. How nutritious are these foods? We have become very familiar with the term 'food adulteration' but how to know whether a particular food is adulterated and if so with what it is adulterated? Yes, a food analyst can find it out.

A general overview of these aspects is given in this unit. You will be learning more details of them in the subsequent units.

1.2 WHAT IS FOOD CHEMISTRY?

Food Science deals with the physical, chemical and biological properties of foods as they relate to stability, quality, processing, safety, nutritive value, wholesomeness, convenience and cost. Food Science is an inter-disciplinary subject involving primarily bacteriology, chemistry, biology and engineering. Food chemistry, a major aspect of food science deals with the composition and properties of food and chemical changes it undergoes during handling, processing and storage. Food Chemistry is intimately related to chemistry and biological sciences like biochemistry, botany, zoology and molecular biology. The primary interests of biological scientists include reproduction, growth and physiological and biochemical (morphological) changes that biological substances undergo under environmental conditions that are compatible with life. On the contrary, food chemists are concerned primarily with biological substances that are dead or dying (post harvest physiology of plants and post-mortem physiology of muscle) and changes they undergo when exposed to very wide range of environmental conditions. That is why a food chemist is concerned with conditions suitable for sustaining the residual life processes (post harvest physiology) for example fresh fruits and vegetables during their marketing.

Both in home scale food preparation and commercial food processing, food raw material are converted into convenient forms by pounding or milling of food grains, pulses, etc., oil extraction, extraction of fruit juices, etc. Food chemists are concerned with the chemical properties of these disrupted food tissues. In other words, food chemists have much in common with biological scientists, yet they also have interests that are distinctly different and are of utmost importance to human kinds.

1.3 HISTORY OF FOOD CHEMISTRY

The origin of food chemistry is as old as human civilization and shrouded in obscurity. Until the 20th Century food chemistry did not have a clear identity and its early developments were associated with agricultural chemistry. During the period 1780-1850 many famous scientists made important discoveries, which laid the foundation of food chemistry.

Carl Wilhelm Scheele (1742-1786) is considered as one of the greatest chemist of all time who has done pioneering work in food chemistry. He isolated and studied the properties of lactose from milk, malic acid from apples and citric acid from lemon juice. He also tested a number of fruits for the presence of citric, malic and tartaric acids as well as various new chemical compounds. Antoine Laurent Lavoisier (1743-1794) also investigated the organic acid content a large number of fruits. He was perhaps the first to show that the process of fermentation could be expressed as a balanced equation. Theodore de Saussure (1767-1845) studied the CO_2 and O_2 exchange during plant respiration and determined the mineral contents of plants by ashing. Joseph Louis Gay-Lussac (1778-1850) and Louis-Jacques Thenard (1777-1857) devised the first method to determine the percentages of carbon, hydrogen and nitrogen in vegetables. Sir Humphrey Davy (1778-1829) who isolated the elements K, Na, Ba, Sr, Ca and Mg wrote books on agricultural chemistry. In his book elements of Agriculture Chemistry (1813) he stated "the most essential vegetable substances consist of hydrogen, carbon and oxygen in different proportion, generally alone, but in some few cases combined with azote (nitrogen).

Jons Jacob Berzelius (1779-1848) determined the elemental composition of about 2000 compounds there by verifying the law of definite proportions.Justus von Liebig (1803-1873) classified foods as either nitrogenous (vegetable fibrin, albumin, casein, and animal flesh and blood) or nonnitrogenous (fats, carbohydrates, and alcoholic beverages). He is also credited for perfecting methods for the quantitative analysis of organic substances by combustion. His book "Researches on the Chemistry of Food" is considered by many as the first book on food chemistry.

By the first half of the twentieth century, most of the essential dietary substances, namely carbohydrates, proteins, lipids, vitamins, minerals etc. were discovered and characterised.

1.4 FUNCTIONS OF FOOD CHEMISTRY

Food chemistry, along with the other discipline of food science and nutrition play a vital role in ensuring nutritious and safe food to the human being. It is needless to state that to accomplish these roles, a thorough knowledge of the detailed chemical (nutritional) composition of foods is of prime importance.

1.4.1 Chemical Composition of Foods

As already mentioned, food chemistry has enabled us to know the nutrient composition of most of the common foods. This knowledge on their nutritional role and importance also accumulated. Nutrition studies showed that the human system require certain nutrients like carbohydrates, proteins and fats in large quantities and some others like vitamins and minerals in much smaller quantities. Therefore, the former group of nutrients were termed "major nutrients" and the latter 'minor nutrients'. Depending on the composition of foods, they were classified as 'carbohydrate rich (starchy) foods (e.g. Cereals, root crops), protein rich foods (e.g. meat, poultry and marine foods, legumes), fatty foods (oil seeds, fatty meat and fish) etc, Fruits and vegetables, in general are good sources of the minor nutrients viz. vitamins and minerals which have protective roles against certain deficiency diseases. Therefore, fruits and vegetables were classified as protective foods.

Knowledge on food composition and nutrition has also enabled planning and designing balanced foods suitable for different age groups, sex, convalescing, etc. Balanced food is a food formulation, which will provide all the nutrients in required quantities. Wherever, a food formulation is still deficient in certain nutrients, this knowledge enabled fortification to supplement them.

Today's nutrition literate consumers are demanding information on the nutrient content of the foods they consume. This has resulted in nutrition labelling of food products, which has become mandatory in some countries. Nutrition label provides information on the nutrient content of a particular food product and also what percentage of the Recommended Dietary Allowance of the nutrient is present in one normal serving of the product. The serving size is expressed in millilitres or grams. It is needless to state that nutrition labelling requires precise chemical analysis of the products.

In addition to the major and minor nutrients mentioned already, a number of bioactive compounds have been isolated from foods especially from fruits, vegetables and herbs. They are collectively termed 'Nutraceuticals' or 'Phytonutrients'. Some of them include: carotenoids, flavonoids, sulphides and thiols and phenolic cyclic compounds. Several of them have been shown to have antioxidative protection of the human body, suppression of cancer growth, improvement of vascular health, retardation of osteoporosis and control of cataracts. These developments have revived the old concept of 'Food as Medicine'.

The knowledge of the chemistry of food constituents has also enabled in modification of foods and food constituents. Production of fermented foods is an example of food modification. A large number of traditional fermented foods have been produced in different countries. Improvements in their processing steps and ensuring consistent quality have been possible due to the knowledge in the chemical (biochemical) reactions. You will be learning more on this in subsequent units. Production of glucose syrup and high fructose syrup from starch, protein hydrolysates from proteins are examples of modification of food constituents.

1.4.2 Quality Changes in Foods

Quality of a food is a complex combination of several sensory and hidden (intrinsic) attributes. You are familiar with some of the sensory qualities like colour and appearance, firmness, mouth feel, flavour, taste etc. Alterations in these qualities of a food material, like for example, fruits results in value reduction and even rejection by the buyer. All these sensory quality changes are caused by chemical (or biochemical) reactions. For example, loss of the green colour of spinach on storage or cooking is due to degradation of chlorophyll. Similarly, browning of cut apples is initiated due to enzymatic oxidation of phenolic substances. Softening of fruits for example is due to the breakdown of pectins or toughening of meat is due to post mortem chemical changes resulting in pH reduction and tissue hardening. Flavour changes are also due to chemical reactions. For example, flavour change in fatty foods called rancidity is due to oxidation of unsaturated fatty acids. You will be learning more on these in subsequent units. The important point to be understood is that once you know the chemical cause of quality deterioration, it is possible to devise methods to control it.

The hidden quality factors of food are the nutrients content, and absence of adulterants and toxicants. Hidden quality cannot be perceived by sensory means. They have to be assessed by chemical means only. Among the hidden quality characteristics, nutritional quality changes are more important in storage and processing of foods. Among the nutrients, some of the vitamins are sensitive to processing conditions. For example, vitamin C (ascorbic acid) is very heat labile. Knowledge on the chemical kinetics of the reactions has enabled development of High Temperature Short Time processing technique and also non-thermal methods of processing. Breakdown of thiamine (vitamin B1) is well known. Therefore, sulphites are avoided for preservation of foods rich in thiamine. Nutritional evaluation of processed foods has been the subject of intense studies in recent times.

The quality changes in foods during processing and storage are due to two major factors namely product factors and environmental factors. Product factors include the chemical composition of a particular food, its pH, and available water content. Environmental factors of importance are temperature and time, light, access to microbial and insect attack and gas composition of the storage atmosphere. Altering the composition of food products to control quality changes is not easily possible except removal of water (drying) even though in a few cases it has been done. For example, to prevent browning of egg powder, glucose is removed from egg by enzymatically oxidising it.

Temperature effect on quality is to a great extent controlled by storage at low temperatures. One of the major functions of packaging is to prevent or reduce the effect of light on food quality. The effect of gas atmosphere on quality is equally important. When a food product is exposed to the atmosphere (containing about 79% N2 and 21% O2) several oxidative reactions take place. Examples are oxidation of fatty acids, oxidation of ascorbic acid, oxidative changes in flavour and browning reactions. In order to prevent the effect of oxygen in canned foods, the cans are exhausted (steam heating of cans filled with the product before sealing) to expel air, fruit juices are deaerated, antoxidants are added to fatty foods etc. You will be learning these techniques in other units. Another method is to alter the gas atmosphere, especially to eliminate or reduce oxygen content in the gas atmosphere inside a package. You must have seen pillow packs (bloating pouches) of potato chips. They are filled with nitrogen to prevent browning and also to avoid physical damage to the chips. In the case of fresh fruits and vegetables, complete exclusion of oxygen is harmful. Knowledge of the biochemistry of plant respiration shows that reducing the oxygen concentration and increasing the carbon dioxide concentration can extend the storage life of these commodities. This has led to the development of Modified Atmosphere Packaging (MAP) and Controlled Atmosphere (CA) Storage of fresh fruits and vegetables. In MAP, mostly the gas composition is modified by the respiring commodities while in CA storage, the gas composition is modified physically by introducing or removing the respective gases.

Food adulterants and toxicants in foods have to be monitored to ensure food safety. This is a growing challenge to the food chemist.

1.4.3 Safety Evaluation of Foods

Most scientific developments have both benefits and harmful effects. Food chemistry is no exception. The new knowledge gave ample opportunity to unscrupulous purveyors for food adulteration. Practically all foods are liable for adulteration. A few examples of food adulterants are given below.

Food products	Common adulterants
Milk	Cane sugar, starch, water
Spices and condiments	Sand, colouring matter, paddy husk, lead chromate, saw dust, argemone seed
Oils and fat	Mineral oil, argemone oil, tri-ortho-cresyl phosphate (TOCP), animal fat (tallow) in vegetable fat
Cereals and cereal products	Kesari dhal, colouring matter, talc, inorganic pigments
Beverages	Artificial sweeteners, unpermitted colouring matter, excessive preservatives
Coffee and tea	Cashew nut endocarp, date seed, tamarind seed/ powder, saw dust, added colour
Ice cream	Artificial sweeteners, unpermitted colours like metanil yellow
Synthetic vinegar	Mineral acids
Alcoholic drinks	Methanol, chloral hydrate

In addition to the intentional addition of harmful substance to the food (Adulteration), food contaminants coming into foods like agricultural chemicals (pesticide residues), heavy metals, etc. also need to be monitored.

As a consequence of this public health hazard, a new branch of food chemistry called analytical food chemistry developed essentially to detect adulteration and contaminants. Along side, new legislations to make adulteration unlawful also emerged which greatly expanded efforts by chemists to learn about the native properties of foods, the chemicals commonly used as adulterants and the means of detecting them. You will be learning more on these in subsequent units.

1.4.4 Waste Management

Food processing industries produce huge quantities of wastes – solid and liquid. The liquid wastes (effluents) are loaded with high concentration of sugars and other organic substances. They are quite often discharged into nearby streams. Environmentalists cry foul for justifiable reasons. The Environment Protection Act (EPA) has stipulated various parameters for safe discharge of effluents. This means that the effluent has to be treated suitably to degrade the constituents of the effluents to the safe limits. Therefore, knowledge of the chemical composition of the effluent is vital for designing the effluent treatment protocols.

About 10 to 50 per cent solid wastes are generated while processing food raw materials. They can be in the form of fruit and vegetable peel and pomace, rice husk and bran, milling wastes of other grains and legumes, slaughterhouse wastes and fish processing wastes. The easiest way to dispose them off is to dump them in the nearest land, compost or use them as fuel. A clear knowledge on the chemical composition of the wastes has enabled isolation of by products from them, some of them more valuable than the main product. For example, more than twenty by products are recovered from the peel and pomace of citrus fruits, which brings in more returns to the industry than the citrus juice concentrate, which is the main product. Some of the by products produced are pectin, peel oil, seed meal and oil, candied juice sacks etc. You will be learning more about by product utilization in another unit.

Microbial (also biochemical) conversion of the organic compounds in the wastes to biogas (mostly methane) is another possibility to utilise the food processing wastes. Biogas can be used as fuel.

1.4.5 Societal Roles

As the time progressed, food chemists had to assume greater responsibilities, the most important being involvement in social issues. As already mentioned the developments in food chemistry have created the monster called 'Food Adulteration'. It is the responsibility of the food chemist to contain it. The food chemistry knowledge has also opened up the possibility of using numerous chemicals called food additives to modify or improve the functional properties of foods. Some of them include: antioxidants, emulsifying, stabilizing and anticking agents, and colouring and flavouring agents. Many of the new food products will not have their functional properties without the addition of some of these additives. Their number is continuously increasing. There is considerable fear, often out of ignorance on their use. Food chemists can play the role of educating and advising the public on their usage. Today food chemists are playing a very complimentary role along with the physiologists, microbiologists, nutritionists, food scientists and technologists in providing safe foods to people in the form and place where they wish to have them.

1.5 LET US SUM UP

Food chemistry plays a number of important functions in food and nutrition. Some of them include:

- Understanding the chemical nature of food constituents has enabled planning of food formulations suitable for different categories of people.
- Knowledge on the chemical reactions these compounds undergo has helped to control quality changes by developing suitable methods and techniques.
- Food chemistry knowledge assists in food modifications like food fermentations, modified products etc.
- Detects and identifies food adulterants there by ensure food safety.
- Enables proper and profitable management of food processing wastes.
- Advises on judicious use of food additives.

1.6 KEY WORDS

Food chemistry	:	Study of food constituents, their properties and changes during handling, processing and storage of foods.
Major nutrients	:	Carbohydrates, proteins and lipids.
Minor nutrients	:	Vitamins and minerals.
Nutrition labelling	:	Label of a packaged food product showing the content of its different nutrients per serving.

Nutraceuticals	:	Bioactive compounds like carotenoids, flavonoids, thiols present in some foods.
Hidden quality	:	Quality attributes like nutrient content, freedom from adulterants, toxicants that cannot be perceived by the human senses.
EPA	:	Environment protection act.
Enzymatic changes	:	Enzyme catalysed chemical reactions.
Biogas	:	Gas, mostly methane produced by anaerobic fermentation of organic wastes.

1.7 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - Chemical composition, properties;
   - Chemical changes during storage, processing

2. Your answer should include the following points:

   - Scheele, Lavoisier, Liebig, Thenard

Check Your Progress Exercise 2

1. Your answer should include the following points:

   - Nutrient requirement of human system
   - Nutrient content of different foods
   - Mixing in suitable proportions

2. Your answer should include the following points:

   - Food formulation containing nutrients in required proportion.

3. Your answer should include the following points:

   - Nutrient content per serving

4. Your answer should include the following points:

   - Bioactive compounds
   - Carotenoids
   - Flavonoids
   - Thiols

Check Your Progress Exercise 3

1. Your answer should include the following points:

   - Chlorophyll degradation in spinach and green colour change
   - Pectin degradation and fruit softening

2. Your answer should include the following points:

   - Product factors
   - Environmental factors

3. Your answer should include the following points:

   - Exhausting
   - Nitrogen packing
   - Modified Atmosphere Packaging
   - Controlled Atmosphere storage

Check Your Progress Exercise 4

1. Your answer should include the following points:

   - Starch, sugar, water in milk
   - Paddy husk, saw dust in spices
   - Dates seed, tamarind seed in coffee and tea
   - Mineral acid in vinegar

2. Your answer should include the following points:

   - Pectin, peel oil
   - Biogas

3. Your answer should include the following points:

   - Educating and advising the public on the safe use of food additives.

1.8 SOME USEFUL BOOKS

1. Braverman, J.B.S. (1963) Introduction to the Biochemistry of foods, Elsevier Publishing Company, Amsterdam, London, New York.

2. Meyer L.H. (1969) Food Chemistry, Van Nostrand Reinhold Company, New York, Cincinnati, Toronto, London, Melbourne.

3. Owen R. Fennema (1976) Principles of food science, Part I-Food Chemistry, Marcel Decker Inc.; New York.

UNIT 2 AN OVERVIEW OF FOOD PHYSIOLOGY

Structure

2.0 OBJECTIVES

After going through this unit, you should be able to:

- know the different stages of growth in the life of fruit;
- understand the physiological changes in fruits and vegetables that take place after harvest;
- tell how senescence can be delayed; and
- mention the structural and compositional changes that take place after harvest.

2.1 INTRODUCTION

Fruits and vegetables are living tissues and remain alive even after harvest. They undergo considerable morphological and bio-chemical changes during growth and following harvest. The visual changes in colour are most prominent indicator of ripening. Many of the quality parameters of harvested produce are affected by pre-harvest factors starting from planting, planting density, irrigation and hormonal treatment. To obtain a produce with good quality all these factors must be controlled.

2.2 MORPHOLOGICAL CHARACTERISTICS

The life of fruit and vegetable crops can be divided into three major physiological stages following germination- growth, maturation and senescence. Growth involves cell division and subsequent cell enlargement, which accounts for final size of the commodity. Maturation usually commences before growth ceases. Growth and maturation are often collectively referred to as development phase. Senescence is defined as the period when anabolic (synthetic) bio-chemical processes give way to catabolic (degradative) processes, leading to ageing and finally death of the tissue. Ripening is considered to begin during the later stages of maturation and to be the first stage of senescence. Development and maturation of fruit are completed only when it is attached to the plant, but ripening and senescence may proceed on or off the plant. But in many plants, a growth after harvest has been observed which is considered undesirable. Elongation and toughening in asparagus, toughening in beans, sprouting in potato and onions are the examples of such growth that occurs after harvest.

Growth and Development

Many tiny individual cells make up the plant body. Each cell consists of living system [protoplasm] and usually a cell wall. The protoplasm is the most significant part of the plant. It is in fact a factory, which manufactures the products of the plant, including the walls of the cell themselves. It is composed of water, salts, sugars, proteins, fats, enzymes, vitamins, growth regulators and a complex of other materials. All of this is organised, through a special portion of the protoplasm [nucleus], into a living unit. As the plants grow and develop, individual cells divide and differentiate into particular kinds of cells and groups of cells, called tissues and organs performing special functions. This addition of cells and the increase in biomass is called growth. An essential organ of a plant is fruit, which develops from another organ of the plant called flower.

Development of fruit and seed

The flower is a group of specialized leaves concerned with the development of structures, which lead to sexual production. A flower consists of four parts:

i) an outer whorl of sepals, usually green, collectively known as the calyx;
ii) petals, usually coloured, which together are called the corolla;
iii) stamens, which produce the pollen grains and male germ cells; and
iv) the pistil, which consists of one or more sections [carpels] bearing the female germ cell and later the seed.

The flower parts are mounted on a portion of the stem known as receptacle. During the formation and development of flowers of any part of the plant, growth regulators play an important role.

A fruit develops from the ovary of pistil. It may consist of a single carpel, as in cherry or of several carpels, as in tomato. Also other parts of the plant may be associated with the fruit, as the enlarged receptacle of the strawberry, the sepals of mulberry and the stem of the pineapple. Attached to the inner edges of the carpel and enclosed within them are the parts (ovules), which develop into seeds.

Initiation of fruit development

Male cells [gametes] from the pollen grains are transferred to the tip (stigma) of the pistil and grow down (through the style) to fertilize the female cells, which are formed in the ovules enclosed in the ovary. The process by which the pollen grains are transferred to the stigma of pistil is called pollination and the process of the fusion of male and female cells (gametes) is called fertilization. The fertilized cell called zygote further grows, divides, differentiates and develops into a new plant (embryo) enclosed in the seed coats. Later, the ovary develops into a fruit. Therefore, the fruit is a matured or ripened ovary. All these processes are carried through the influence of certain growth regulatory compounds called plant-hormones.

Physiology of growth and development

Carbohydrates, which are essential to both plant and animal life are produced in the leaves in a process known as photosynthesis, in which the green colour pigment of the plant (chlorophyll) utilizes light energy to form simple carbohydrate materials (as sugars) from water and carbon dioxide of the atmosphere.

$$6\ CO_2 + 6\ H_2O + 673{,}000\ Cal \leftrightarrow C_6H_{12}O_6 + 6\ O_2$$

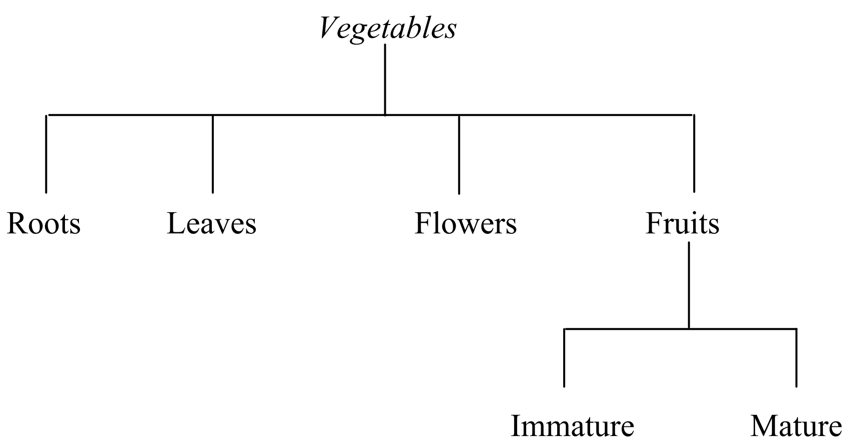
Carbohydrates are moved from the leaves to other parts of the plant. The most important tissues involved in translocation are the xylem and phloem. It is believed that the carbohydrates travel through phloem, while water and minerals travel mainly through xylem.

Food may be stored in various storage organs, such as roots, tubers, rhyzomes, bulbs, corms, fruits and seeds. Storage may occur at different seasons of the year and may in some plants be controlled by the length of the day, the length of the night period and the day & night temperatures. In many plants that live for more than one season (perennials), accumulation in the underground storage organs takes place at a rapid rate in the fall of the year.

Fruits and Vegetables

Fresh fruits, as well as fresh vegetables are essential components of human diet. Both contain a number of nutritionally important compounds, such as vitamins, which cannot be synthesized by the human body; vitamin C is the most important essential nutritive substance found mainly in fruits and vegetables.

The fruits are used as a table commodity whereas the vegetables are usually cooked and then used as food. Some of the vegetables are "fruit-vegetables" and most of the vegetables are the other vegetative organs of the plant that include root, stem, flower, shoot, leaves and associated parts. On the basis of the parts of plants used as food, the vegetables are classified in the following groups:



Similarly, depending on the parts of the ovary wall [pericarp-epicarp, mesocarp and endocarp] developing into flesy and succulent organs of the fruits are classified as under:

Fruits

Drupe Berry Pepo Hesperidum Pome Aggregate type

2.3 POST-HARVEST PHYSIOLOGY OF FRUITS AND VEGETABLES

Fruits and vegetables are highly perishable commodities with active metabolism during the post-harvest period. Proper handling plays an important role in increasing food availability. On removal from the parent plant, vegetative parts, such as fruits, roots, stems etc are deprived of their normal supply of minerals, water, and also in some instances, simple organic molecules [e.g. sugars, hormones] that normally would be translocated from other parts of the plant. Innumerable physiological and bio-chemical processes are initiated and continued in the edible plant tissues at the time of harvest. Although the photosynthetic activity is negligible, most tissues remain capable of transforming many of the constituents already present in them. The diversity of metabolic shifts, which are specific to a given commodity [and often variety] are manifest in events such as 'rotting', 'ripening', 'sprouting', 'scald', 'brown core', 'hard core', 'toughening', and 'yellowing'.

The kind and intensity of physiological activity in detached plants determines their storage longevity. Some plant parts, such as seeds, fleshy roots, tubers, bulbs are morphologically and physiologically adapted to maintain the tissue in a dormant state until environmental conditions are favourable for germination or growth. Metabolic activity, though depressed, is not completely halted in such tissues. Fleshy fruits are unusual in that maturation is followed by a ripening process, which is associated with the development of optimal eating quality.

The diversified visible physiological changes, like sprouting, browning, toughening etc are desirable in some commodities and undesirable in others in relation to the eating quality. Almost all such changes are observed during a most important physiological process called ripening.

Physiology of Ripening

The term "ripening" is generally referred to the physical and bio-chemical changes taking place in the fruits after the cessation of growth till the onset of senescence and decay. The ripening process is dependent upon maturity, since a given stage of development must be attained before ripening proceeds. The process of ripening continues while the fruit is on the tree, but the damage caused by the birds, insects etc makes it uneconomical to allow the fruits to ripen on the tree. Hence, the fruits are usually harvested at the horticulturally mature stage. Fruits being living entities continue to carry on the normal physiological processes resulting in the ripening and finally decay or death of the fruit even after they are separated from the parent plant/tree. Most of the fruits show the ripening changes after harvest with a few exceptions like grapes, which are to be ripened only on the vine, as they do not ripen well after harvest. Since the changes taking place in a fruit during ripening greatly influence the eating quality and the monetary value of the commodity depends on it, a detailed knowledge of the physiology and biochemistry of ripening is desirable for the successful storage and marketability of fruits.

Changes during Ripening of Fruits

Important changes occurring in the fruits during ripening include – 1) Respiration, 2) Transpiration, 3) Carbohydrates, 4) Texture, 5) Flavour, 6) Pigments, 7) Organic acids, 8) Nitrogenous compounds, 9) Tannins, and 10) Enzyme activity.

1. Respiration

Fruits and vegetables of different species differ as to the nature and the rate of the changes taking place but most of them share a respiratory pattern known as "the climacteric". In some fruits, it has been observed that the respiration rate increases with the ripening to a maximum level called as 'Climacteric' peak which is followed by a steady decline in respiration rate, often called senescence. The fruit attains the eating ripe stage at the climacteric peak or sometime after the peak, depending on the species and to some extent temperature and composition of the atmosphere in which the commodity is stored. All other fruits showing no such respiratory pattern are called non-climacteric. In citrus fruits [oranges and lemons], the maturation and ripening progress slowly and the respiratory activity tends to decline following harvesting of commercially mature fruits.

Another important criterion for distinguishing a 'Climacteric fruit' from a 'non-climacteric fruit' is the response to ethylene application. It is well known that ethylene has an enhancing effect on fruit respiration. Biole (1954) showed that a non-climacteric fruit would react to ethylene treatment at any stage of its preharvest or postharvest life, whereas a climacteric fruit will exhibit a respiratory response only if ethylene is available during the pre-climacteric stage, and becomes insensitive to ethylene treatment after the onset of the climacteric rise.

There is a fairly consistent relationship between storage type of fleshy plant tissues and respiration, e.g. peas with a high respiration rate [50 mg CO_2/kg/hr] have a short storage life [1 week at 5°C], while turnips with low respiration rate [6 mg CO_2/kg/hr] have a long storage life [16-20 weeks at 5°C]. The shelf life of a given commodity can be greatly extended by placing it in an environment, which retards the rate of respiration. In other words, the environment modification by refrigeration and carbon dioxide/oxygen (CO_2/O_2) conc. controlled atmosphere will provide a direct effect on the determination of shelf life of the commodities.

Respiratory quotient

From measurements of CO_2 and O_2, it is possible to evaluate the nature of respiratory process. The ratio of CO_2 to O_2 is termed the respiratory quotient [RQ]. This is useful in deducing the nature of the substrate used in respiration, completeness of the respiratory reaction and degree of anaerobic or aerobic process.

2. *Transpiration*

When the fruit is picked and severed from the plant, water no longer flows into the fruit, although the loss of water continues. This process of loss of water in vapour form is known as transpiration. By the time the fruit loses 5% of its original weight, it appears shriveled enough to lose its eye appeal as well as the eating quality. The fruit becomes unattractive because of wrinkled appearance. Hence, this loss of water due to transpiration should be checked in order to maintain its marketability. Judicious application of wax emulsion or other skin coating or pre-packaging with thin paper or cling films could successfully reduce such water losses. On the other hand, in some fruits during ripening, the water content of the pulp increases and the peel decreases, as in the case of banana, which makes the fruit better in eating quality.

2.4 STRUCTURAL CHANGES DURING GROWTH AND RIPENING

A number of changes occur in fruits during ripening. Softening of tissue during ripening is attributed to the changes in cell wall thickness, permeability of plasmalemma, and amount of intercellular spaces. The change in colour of ripened fruit is due to transformation of chloroplast to chromoplast. Although the structure of mitochondria is maintained during growth and ripening, it may degrade in overripe stage. Cuticle deposition increases continuously during ripening but the epidermal hairs either reduce in number or disappear completely.

2.5 COMPOSITIONAL CHANGES DURING GROWTH AND RIPENING

Carbohydrate

Sugars are important for pleasing fruit flavour (sugar acid ratio), attractive colour and texture. As the ripening starts these sugars undergo metabolic transformation both quantitatively and qualitatively. Most of the soluble carbohydrates are metabolized completely as the fruit ripens. Pectic substances and cellulose are the reserve carbohydrates that also serve as potential sources of acids, sugars and other respiratory substances during ripening.

In the process of ripening many changes occur in the carbohydrates fraction of fruit during the climacteric and senescence. Green or raw fruit usually contains starch in abundance, but is short in soluble sugars that provides sweetness to it. During ripening, the starch is enzymatically [hydrolysis by alpha- and beta-amylases] converted into sugars. Thus, the major bulk of carbohydrate fraction of a fully ripened fruit consists of sugars. The sugars commonly found in fruits are glucose and fructose [invert sugars] and sucrose.

Organic Acids

The organic acids are among the major cellular constituent undergoing changes during ripening. In most of the fruits there is a considerable decrease in the acidity of fruits during ripening.

The sourness of fruits is due to the presence of organic acids like citric, malic, succinic, tartaric, oxalic etc. These acids usually decide the quality of fruits as the blending of sugar and acids render the fruits tasty, besides flavour. Though these organic acids are present in varying amounts in raw or unripe fruits, but the concentration considerably changes as the fruits ripen. In fruits like oranges, the acids are converted enzymatically into sugars rendering them sweet as they ripen, whereas there is no change in lemons. So they remain sour till they start decaying. But, in some fruits like mangoes, there is a considerable decrease in acidity when the fruits fully ripen. This is probably due to the utilization of these acids in respiration through Kreb's Cycle. Generally, in fruits the total acidity shows a decrease with the increase in ripeness of the fruits.

Amino Acids and Proteins

A major turnover of amino acids in mango takes place during ripening, whereas in carombola it continuously declines. Small increases in protein content were also observed in mango, tomato and avocado.

The nitrogen content of fruit is due to proteins forming insoluble fraction and the soluble fraction comprised of amino acids. The total nitrogen content of fruits at the early stages is high, but with the advancement in growth, shows gradual decrease. This is probably due to the increase in other constituents like water, starch, sugar, organic acids etc. During ripening, the total nitrogen may show a further decrease in some cases.

Lipids

Phospholipids occur in the cytoplasm and in many structural units of plant tissues. They are physiologically more important than neutral lipids in storage organs. Considerable increases in the level of total lipids and fatty acids have been observed in ripening mango in contrast to many fruits and vegetables. However in fatty fruits of avocado the oil composition during maturation remains more or less constant.

Chlorophyll

Disappearance of green colour marks the initiation of ripening in most of the fruits. Chlorophyll content of ripening fruit decreases universally.

Carotenoids

A dramatic synthesis of carotenoids occur during the last step of ripening. It has been reported that the levels of carotenes, free geraniol, mevalonic acid, all precursors of carotene biosynthesis increases progressively during ripening.

Other Pigments

The colour imparted to raw or ripe fruits and vegetables are due to presence of various pigments. The pigments of different tissues are the chlorophyls (green), anthocyanin [reddish to purple], flavonoids [yellow], leucoanthocyanins [colorless], tannins [colorless to yellow or brown], betalains [red], quinones and xanthones [yellowish] and carotenoids [yellow and red].

During storage some of these pigments undergo considerable changes. Carotenoids formation and destruction may be affected by the storage conditions. In certain instances, these reactions are stimulated by O_2, inhibited by light and high temperature. Carotenoids include lycopone, Beta, Gamma carotenes and are synthesized enzymatically in the fruits. Anthocyanin synthesis is stimulated by light and is often affected by temperature. Purple colour of red cabbage intensifies when stored below 10^o C. Chlorophyll degradation is accompanied by synthesis of other pigments as the fruits ripen. Chlorophyll metabolism is markedly influenced by environmental parameters, such as light, temperature and humidity and the effects of these factors are specific for the tissues. For example, light accelerates degradation of chlorophyll in ripening tomatoes and promotes formation of the chlorophyll pigment in cold stored potatoes.

Tannins

The tannins and other polyphenolic constituents are present in abundant quantities in immature, raw or developing fruits. As the maturity and ripening progresses the total polyphenolic content reduces gradually.

Pectic Substances

The most obvious changes during ripening of fruit are the alteration in texture. The plant cell wall is made up of cellulose fibrils embedded in a matrix consisting largely of pectic substances, hemicellulose, proteins, lignins etc and water. Cell wall and middle lamella components increase during development of fruits, but as the fruit ripens the content of soluble pectates and pectinates increase, while total pectic substances decrease.

The cell walls are surrounded by parenchymatous cells, which will absorb water and generate hydrostatic pressure within the living cells. This is called turgor pressure that gives the desirable property of crispness to the commodity. During storage, the loss of moisture due to transpiration and respiration results in the loss of crispness or the turgidity of the commodity. In addition, the changes in the pectic substances – [which form a component of the cell walls of the fruit] – account for the firmness of the fruits. During ripening, the protopectin, which is insoluble and forms, the middle lamella of the cell wall, decreases in quantity and the soluble pectin content rises, thereby making the flesh less firm or soft. A decrease in the chain length and loss of methyl groups of proto-pectin probably occurs during ripening, accounting for the rise in soluble pectin. This is brought about enzymatically mainly by the enzymes pectinase and pectin methyle sterase.

Volatile Products

Each fruit has specific aroma which ripened fruit emanates. Although different fruits vary in nature of volatile compounds, they are emitted in noticeable amount only when the fruit starts ripening. Although the degree of maturity is the main physiological factor affecting aroma production, the aroma composition is also affected by environmental conditions during maturation. In overripe fruits mostly alcohol and esters are formed when fermentation develops.

One of the marked differences between an unripe and ripe fruit is the intensity of flavour of the fruit. The flavour of fruits or vegetables are considered to originate by the presence of basic constituents, such as carbohydrates (particularly mono- and disaccharides], proteins [particularly free amino acids] and fats [triglycerides or their derivatives], as well as vitamins and minerals. These constituents are produced through photosynthetic and related metabolic activities occurring in the commodities. Some volatile compounds may exist in the tissues as such but in some it may be formed enzymatically upon rupture of cells or by microorganisms. Besides ethylene, a number of other volatile odorous constituents like amyl esters of formic, acetic, valeric and caprylic acids have also been identified. These organic emanations produced during ripening of fruits contribute to the aroma of fruits and hence are of considerable importance from the standpoint of fruit quality.

Enzymes

Enzyme action is responsible for many chemical and physical effects during ripening. Softening of fruits, conversion of starch to sugar or vice versa, changes in amino acid content, and enzymes bring changes in color.

Most of the bio-chemical changes occurring in fruits during ripening can be attributed to enzyme reactions. The change from starch to sugar, sucrose to invert sugar or protopectin to pectinic acid are all due to enzymic reactions.

Oxidative enzymes like catalase and peroxidase were shown to have increased to a considerable extent in 'Alphonso' and 'Neelam' varieties of mangoes during ripening as indicated by the higher rate of respiration. Similarly, glycolytic and hydrolytic enzyme activity were also found to increase in ripening mangoes, particularly during climacteric and post-climacteric stages. Transminase activity also increased in mangoes, resulting in the increased amounts of amino acids. Chlorophyllase activity followed the climacteric pattern in bananas, but suggested that the ensuing chlorophyll degradation may not be relevant to ripening. Other enzyme that increases in activity during ripening and following respiratory climacteric is fatty acid synthatase in Avocado fruit.

2.6 LET US SUM UP

The quality of fresh produce depends on many factors during growth and after harvest. The cultural practices followed before harvest has marked effect on fruit quality. A number of physiological and bio-chemical changes take place during growth of the produce that continues after harvest also. Therefore it is important to follow good pre and post harvest practices to extend the shelf life and maintain the quality of horticulture produce.

2.7 KEY WORDS

Morphological changes : Visible changes on the outer surface of the product.

Chemical changes : Changes in composition of the product.

Ripening : The advance stage in the development at which fruit and vegetable are suitable for consumption/ utilization.

Growth : Gradual development towards maturity (increase in size, weight, etc.).

Maturation : Becoming full grown or fully developed.

Senescence : Beginning of final phase in the life of plant.

Cultural practices : A set of operations used for raising a crop in the field.

Planting density : Number of plants per unit area.

Pruning : To cut away or remove unnecessary plant parts.

Thinning : Reduction of population of plants.

2.8 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answers should include following points:

   - Growth
   - Maturation
   - Senescence

2. Your answers should include following points:

   - Cell wall thickness
   - Plasmalemma
   - Intercellular spaces

3. Your answers should include following points:

   - Chloroplast
   - chromoplast

4. Your answers should include following points:

   - Anabolic
   - Catabolic
   - Aging
   - Death

Check Your Progress Exercise 2

UNIT 3 FOOD CONSTITUENTS – CARBOHYDRATES AND LIPIDS

Structure

3.0 OBJECTIVES

The aim of this unit is to introduce you to the chemistry of two major constituents of foods viz. carbohydrates and lipids. After reading this unit you will become familiar with the following aspects:

- *carbohydrates:* Monosaccharides, disaccharides, oligosaccharides and polysaccharides; their occurrence in foods, structure, properties and uses in food industry; and
- *lipids:* Occurrence, chemical properties, fatty acids and their properties and their changes during processing and storage of foods.

3.1 INTRODUCTION

Carbohydrates along with lipids are the primary source of energy for the human system. Carbohydrates are widely distributed in plants and to a limited extent in animals. They under go various changes during processing of foods. Lipids are present both in plant and animal foods. They also undergo physical and chemical changes during processing and storage of foods. Therefore, an understanding of the chemical nature of these substances is very important for preserving foods. In this unit you will be learning the chemical aspects of carbohydrates and lipids.

3.2 CARBOHYDRATES

The first products of photosynthesis in plants are carbohydrates. These compounds, in one form or another, constitute more than one half of the organic matter on earth. The major part of plants is built of carbohydrates while the animal world contains rather limited amounts of them.

3.2.1 Occurrence

Carbohydrates occur in plant and animal tissues as well as in microorganisms in different forms and quantities. They along with oils and fats are the primary source of energy for the human system. In plants, a wide variety of monosaccharides and oligosaccharides occur. Starch is the main storage carbohydrate in root crops and cereals. Similarly, the 'building bricks' or structural carbohydrates of plants are cellulose, hemicellulose and pectin. Some plants, as well as seaweeds and microorganisms produce different types of gums, which are a different group of polysaccharides. Fruits contain predominantly the monosaccharides, glucose and fructose, and the disaccharide sucrose as well as other mono and oligosaccharides in smaller concentrations. Animal foods have mainly glucose and the storage carbohydrate is glycogen. In milk it is almost exclusively the disaccharide lactose. Another group of polysaccharides called dietary fibre (pectin, hemicelluloses, pentosans, etc.) are gaining considerable health importance. Table 3.1 gives an idea of different types of carbohydrates present in different types of foods.

Table 3.1: Average carbohydrate composition and Water content of some foods

Carbohydrate	Cereals		Legumes		Fruits		Vegetables

Water	14.0	13.0	11.0	2.0	84.0	86.0	79.0	93.0

3.2.2 Nomenclature

Carbohydrates were first named according to their natural sources eg. cane sugar, beet sugar, malt sugar, grape sugar etc. Subsequently they got trivial names often from a prefix related to the source followed by the suffix '-ose'. Examples are: fructose (fruit sugar), maltose (malt sugar), lactose (milk sugar), xylose (wood sugar) etc. Though these names do not provide any information on their chemical structure they are still being used widely.

3.2.3 Classification

Carbohydrates are classified into monosaccharides, oligosaccharides and polysaccharides.

Monosaccharides

The simple carbohydrates, the monosaccharides, are neutral, crystallisable substances, which are readily soluble in water. Most of them are sweet covering a wide range of sweetness. Monosaccharides may be divided chemically into polyhydroxy aldehydes (aldoses) and poly hydroxy ketones (ketoses). Depending on the number of constituent formaldehydes (CH2O), these sugars are classified as:

Bioses (CH2O)2;	C2H4O2 (example: glycol aldehyde)
Trioses(CH2O)3;	C3H6O3 (example: glyceraldehyde)
Tetroses (CH2O)4;	C4H8O4 (examples: Erythrose, threose)
Pentoses (CH2O)5;	C5H10O5 (examples: Ribose, rafinose,)
Hexoses (CH2O)6;	C6H12O6 (examples: glucose, mannose, gulose, galactose, fructose, sorbose)

The monosaccharides, which are of primary importance in foods, are hexoses and pentoses.

Hexoses: Five hexoses, three of them aldoses (glucose, mannose and galactose) and two ketoses (fructose and sorbose) are found in the free state in plants. The simple open chain formula of these hexoses (propounded by Fisher) are shown in Figure 3.1.

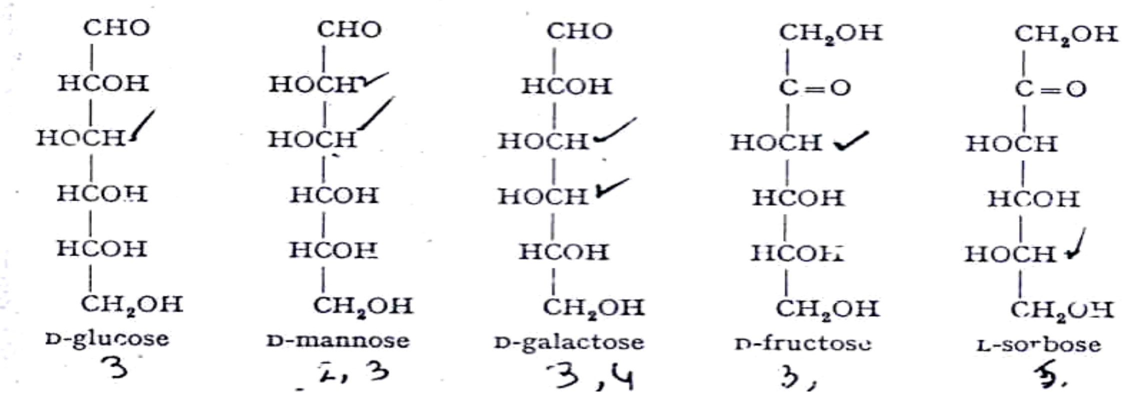

Figure 3.1: Open chain formulae of some hexoses

You will notice that the differences in the structures of these hexoses are in the orientation of the hydroxyl (-OH) groups. Mannose is different from glucose in its configuration at carbon atom 2. Sorbose differs from fructose in its configuration at carbon atom 5. The above formulae of glucose and other sugars show the free carbonyl group and four optically active (asymmetric) secondary hydroxyls. This results in stereoisomerism in sugars. Sugars are designated as D or L. The designation of D or L refers to the two series of sugars, in the D series, the highest number asymmetric carbon has the OH group directed to the right and in the L series this hydroxyl points to the left. The following structures (Figure 3.2) of the simplest sugars, D and L glyceraldehydes explains the series.

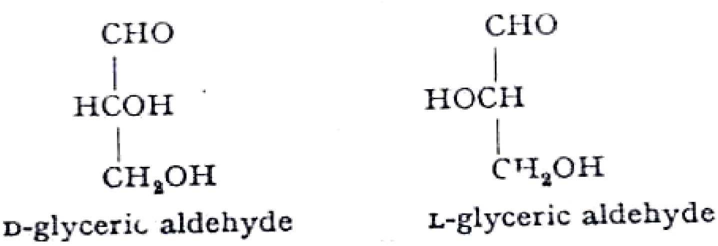

Figure 3.2: D and L glyceraldehydes

Most natural sugars are members of the D series. The open chain formulae of sugars do not explain all the chemical properties. Therefore, various ring structures have been introduced. For example glucose has been assigned a pyranose (6 membered ring) structure and fructose a furanose (5 membered ring) structure.

The simple sugars exhibit a property called optical rotation. You will be learning more on this aspect under polarimetry. In simple terms, optical rotation refers to the property of a substance in solution to rotate plain polarised light to right (dextro rotatory designated by (+)) or to the left (levo rotatory designated by (-)) for example glucose is dextro rotatory and fructose is levo rotatory. A sugar, for example glucose when dissolved in water exist in tautomeric equilibrium between two anomeric forms, each having different degree of optical rotatory power. They are designated as α and β as indicated below (Figure 3.3).

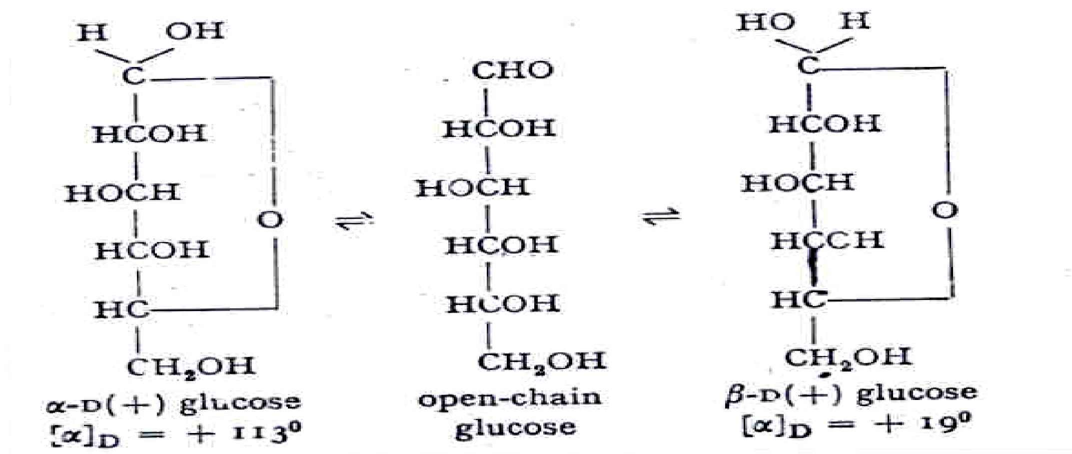

Figure 3.3: α-D and β-D glucose structures

Sugar related compounds present in nature

Amino sugars: Amino sugars usually contain D-glucosamine (2-deoxy-2-amino glucose). They occur as components of high molecular weight compounds such as the chintins of crustaceans and molluscs as well as in certain mushrooms and combined with the ovomucin of egg white.

Glycosides: Glycosides are sugars combined with an alkyl or aryl group. Glycosides are hydrolysed by acid or enzyme to the corresponding sugar and aglicone. Amygdalin is an example of a cyanogenic glycoside, which is present in bitter almonds. Complete hydrolysis of amygdalin yields glucose, benzaldehyde and hydrocyanic acid. Other important glycosides are flavonone glycosides like the citrus bitter principles hesparidin and naringin. Deoxy sugars occur as components of nucleotides like 2-deoxy ribose, which constitute part of deoxy ribo nucleic acid (DNA).

Sugar alcohols: Sugar alcohols occur in some fruits and are produced industrially by reduction of sugars. Reduction of glucose yields sorbitol. Xylitol is a five carbon sugar alcohol. These sugar alcohols are sweet as sugar but are only slowly absorbed in the body and hence are used in diabetic foods. The structure of sorbitol and xylitol are given below (Figure 3.4).

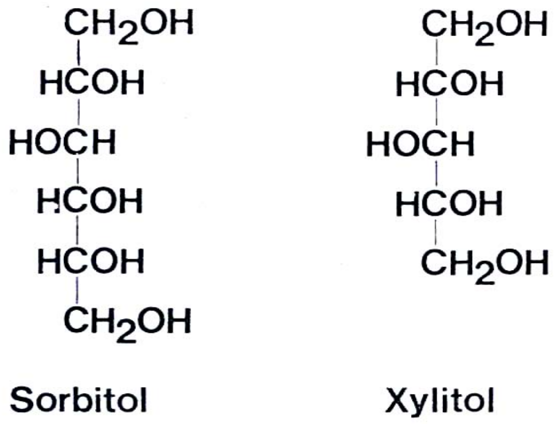

Figure 3.4: Sorbitol and Xylitol

Oligosaccharides

Oligosaccharides are water-soluble polymers of a few condensed monosaccharides. Those most commonly found in foods are homopolymers of D-glucose (e.g. maltose) or heteropolymers of D-glucose condensed with D-fructose (e.g. Sucrose) or D-glucose with D-galactose (e.g. lactose). The above oligosaccharides are di-saccharides. Raffinose a trisaccharide is found in sugar beet. It is a polymer of D-glucose, D-fructose and D-galactose.

Sugars and sweeteners: Sucrose is the most widely used natural sweetener. Of all the sugars, D-fructose is known to be the sweetest. It is customary to compare the degree of sweetness of different sweeteners to sucrose to which the number 100 has been assigned. Fructose has sweetness value of 173.3 and glucose 74.3. Therefore, the hydrolysis product of sucrose (invert sugar containing glucose and fructose) has sweetness value of 173.3+74.3/2 = 123.8. The relative sweetness of various sweeteners is given in Table 3.2.

Table 3.2: Degree of sweetness of various sweeteners

Sweetener	Degree of Sweetness
Sucrose	100
Fructose	173.3
Glucose	74.3
Corn Syrup	30.0
Honey	97.0
Saccharin	30,000 – 50,000
Dulcin	20,000

Corn sweeteners: Cornstarch can be hydrolysed by acid or acid-enzyme process to yield smaller and smaller fragments and ultimately glucose (dextrose). The degree of depolymerisation is expressed as dextrose equivalent (D.E.) which is defined as the amount of total reducing sugars expressed as dextrose and calculated as a percentage of the total dry matter.

Glucose syrup is a concentrated solution of sugars obtained by hydrolysis of starch and having D.E. of 20 or more. When a product has a D.E. of less than 20, it is called maltodextrins. Glucose can be isomerised to fructose by an enzyme called isomerase. As fructose is sweeter than glucose, High Fructose

Syrup (HFS) which is sweeter than glucose syrup is prepared using the enzyme.

Polysaccharides

Polysaccharides are polymers of the simple mannoses, hexoses or pentoses, which occur in nature in different forms. Unlike the sugars they are not sweet and are mostly insoluble in water. Examples of polysaccharides found in nature are cellulose, starch, pectin and chitin.

Cellulose: The structural materials of the entire plant world consist largely of cellulose. Cotton is essentially pure cellulose. On hydrolysis cellulose yields glucose meaning that it is a polymer of glucose. Celluloses from different sources have molecular weight ranging from 100,000 to 2,000,000.

Cellulose is insoluble in water and most solvents and is relatively resistant to hydrolysis by dilute acids. Man and carnivorous animals are unable to digest cellulose, since they lack the necessary enzymes for its breakdown in their intestines. However, many microorganisms and protozoa are able to break it down. Ruminants are able to digest cellulose because of the presence of these microorganisms in their intestines. Though cellulose has only indirect food value (cellulose feed is converted to meat by animals) it has many other uses like in the manufacture of paper, textiles, explosives, paint, etc.

Starches: Starch is the most important polysaccharide and is distributed widely in nature as a reserve material in plants. It contributes more calories to the normal human diet than any other single nutrient.

Starch from different sources consists of granules of different shapes and sizes. Generally all starches contain two types of molecular structures namely amylose and amylopectin.

Amylose is a long straight chain of glucose units, which reacts with iodine to give blue colour. Amylopectin is a branched molecule consisting of a number of amyloses, which reacts with iodine to give reddish brown colour.

Amylose and amylopectin content of starches from different sources vary. In the most common starches such as corn, rice and potato, amylose is the minor component and represents about 17 to 30% of the total. Some varieties of pea and corn starch may have as much as 75% of amylose.

Starch granules naturally present in plants are completely insoluble in cold water and upon heating they will start to swell and the gelatinisation temperature. Continuation of heating above this temperature results in further swelling of the granule and the mixture becomes viscous and translucent. When such a paste is agitated, the swollen starch granule structure breaks down and the viscosity greatly reduces. When a cooked starch paste is cooled, it may form a gel or under conditions of slow cooling, the linear compound may form a precipitate. This phenomenon called retrogradation. The staling of bread is ascribed to retrogradation of starch. The rate of staling is temperature dependent. Retrogradation is faster at low temperature and hence bread stales more quickly in the refrigerator than at room temperature. Freezing, however, prevents staling and retrogradation of starch.

The functional properties of starches such as its cooked paste viscosity play an important role in their food applications. Cereal starches (corn, wheat, rice and sorghum) form viscous short bodied pastes which set to opaque gels on cooling. Root and tuber starches (potato, cassava or tapioca) form highly viscous paste, which are clear but on cooling become weak gels. Waxy starches (waxy corn and rice) form heavy bodied springy pastes. These pastes are clear and have a low tendency for gel formation. High amylose starch requires high temperature for gelatinisation and gives short bodied paste which form very firm opaque gels on cooling. These are suitable for film formation, which find application in coating of fruits as edible coats. In order to impart the desired functioning properties, starches can be modified by certain chemical or enzymes treatments. Such starches are called 'modified starches'.

Pectic substances: Pectic substances occur as constituents of cell walls. In the native form, they are bound to cellulose as protopectin. Mild acid hydrolysis of protopectin yields pectin or pectinic acid. Pectinic acids are collidal, galacturonic acids containing more than negligible proportion of methyl ester groups. Pectins are water dispersable pectinic acids having varying methyl ester contents that are capable of forming gels with sugar and acid under suitable conditions. Pectic acids are composed mostly of colloidal polygalacturonic acids and are essentially free from methyl ester groups.

A linear chain of anhydro-D-galacturonic acid units is the basic structure of pectic substances. In an earlier section you have studied the structure of galactose. When the –CH2OH of a hexose is replaced by –COOH it becomes an uronic acid. The chemical structures of some uronic acids are shown in Figure 3.5.

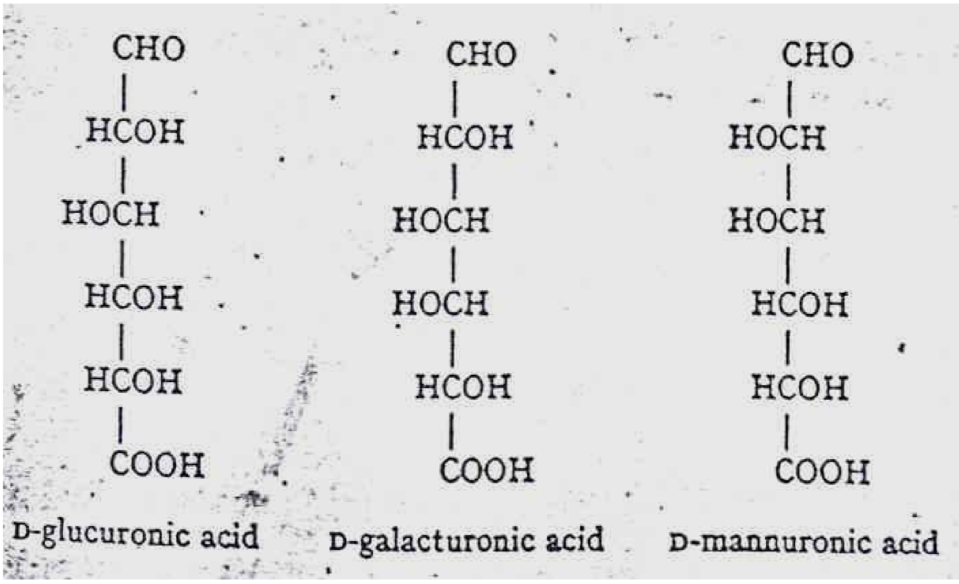

Figure 3.5: Uronic acids

A number of enzymes have been found to catalyse the various stages of pectin break down. You are familiar with softening of fruits during their ripening. It is due to the break down of pectin by the pectin degrading enzymes present in the fruits. There are two major types of pectin degrading enzymes. One is called pectin esterase (PE) or pectin methyl esterase (PME). This enzyme removes the methoxyl groups from the pectin molecules thereby reducing the viscosity of pectin solution and destroys its gelling property. The other enzyme is called polygalacturonase (PG), which breaks down pectinic acid chain into smaller fragments. For PG to act on pectin, the pectin molecule has to be initially demethylated to pectic acid by PME

Pectin as a jellifying agent: The most important use of pectin in food is based on its ability to form gels and it is therefore widely used in the manufacture of jams, jellies and marmalades. Depending on the degree (extent) of methylation (DM) of the carboxyl groups in pectin, they are classified into high and low methoxyl pectins (HMP and LMP). Generally, pectin having more than 50% methylated carboxyl groups (DM more than 50) are called high methoxyl pectin (HMP). HM pectins form gels with sugar and acid. For a good jelly, the sugar content should be in the range of 65–70% and pH 2.8 to 3.2. When the degree of methylation is below 50, the pectin is called low methoxyl pectin (LMP). Low methoxyl pectins form gels at a lower level of sugar but with divalent cations especially calcium. They can be gelled over a much wider pH range also. Therefore, LMP is used in preparing low sugar diabetic jams and jellies.

Citrus peel and pomace as well as apple pomace are good sources of pectin. Therefore, these raw materials are usually used for the manufacture of pectin.

Gums: The term gum has been applied to many substances, both hydrophilic (water attracting) and hydrophobic (water repelling) that has gummy characteristics. Sometimes hydrophobic gums are called resins. Gums are essentially polysaccharides and are of plant and microbial origin.

Plant gums: Plant gums can be classified as seed gums, plant exudate gums and seaweed gums. They find wide food applications as stabilisers, thickeners, foam stabilisers, clarifying agents, flavour fixing agents, etc. Table 3.3 gives details of some vegetable gums used as food additives.

Table 3.3: Properties and use of some vegetable gums

Name and Source	Properties
Seed gums	
Guar gum *(Cyamopsis tetra gonoloba)*	Non ionic, heat stable, hydrates in cold water
Locust bean gum *(Ceratonia siliqua)*	Like guar but heat required for maximum hydration and viscosity.
Plant exudate gums	
Gum Arabic *(Acacia senegal)*	Highly soluble, low viscosity, clear solution.
Seeweed extracts	
Agar *(Rhodophyceae)*	Forms strongest and most stable gel. Gels are transparent and reversible upon heating and cooling.
Carrageenans *(Rhodophyceae)*	Anionic, forms stable complexes with proteins and other gums.
Alginates *(Phaeophyceae)*	Anionic, widely variable viscosity properties in acid and salt, forms gels and films

Microbial gums: Polysaccharides produced by microorganisms are finding wide food applications today. Dextran gums are produced by the action of micro- organisms like *Leuconostoc mesenteroides* on sugar syrup. They are readily soluble in water and have typical characteristics of a hydrocolloid like plant gums. Xanthan gum is produced by the action of *Xanthomonas campestris* on sugar containing medium. This gum consists of condensed D-glucose, D-mannose and D-glucuronic acid groups.

3.2.3 Chemical Reactions of Carbohydrates

Several of the chemical reactions of carbohydrates affect the food quality. During food processing operations, especially heat processing like sterilisation, cooking and dehydration, carbohydrates undergo several changes. Part of the non reducing sugars (like oligosaccharides) and polysaccharides hydrolyse to form reducing sugars. The carbonyl groups of the reducing sugars combine with the basic amino groups of proteins, peptides and amino acids to form sugar – amine compounds which undergo a series of reactions called Maillard reactions to produce dark coloured compounds and sometimes off flavour. This reaction is also referred to as non-enzymatic browning reaction to distinguish the enzyme mediated browning we observe, for example in cut fruits like apple where it is oxidation of some phenolic compounds.

Sugars alone in the absence pf amino acids can also cause browning or blackening. At very high temperatures (above 100°C) reducing sugars condense with each other to form higher oligosaccharides and cyclic compounds. Such darkening reaction of sugars is called caramalisation.

3.3 LIPIDS

Of the three most important nutrients, carbohydrates, proteins and edible fats, the latter belongs to a large class of very diverse substances called lipids. They can be classified into three main groups, their common property being that all contain fatty acids.

3.3.1 Occurrence and Classification

a) Fats and oils: They consist of triglycerol esters of fatty acids (designated here as F1, F2, F3) of the following general formula (Figure 3.6), which easily undergo hydrolysis forming glycerol and fatty acids.

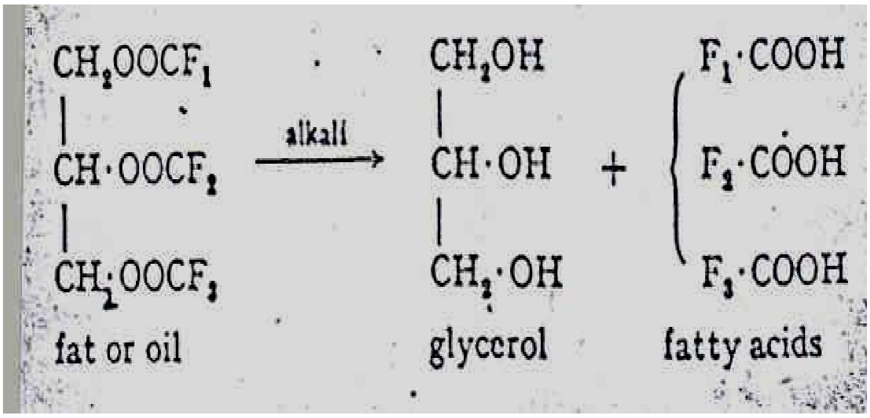

Figure 3.6: Alkali hydrolysis of fats and oils

Liquid fats are commonly referred to as oils.

b) *Waxes:* They consist of fatty acids esterified by monohydric long chain alcohols such as melyssil alcohol (C30H61OH) in bees wax.

c) *Phospholipids:* They are complex compounds in which glycerol or other alcohols are esterified partly by fatty acids and partly by phosphoric acid and by basic nitrogen compounds.

Lipids occur in all parts of plants and animal tissues. However, they are abundantly found in specific fat tissues, seeds and nuts (Table 3.4).

Table 3.4: Fat content of some foods

Food	Fat (%)
Cereals	
Maize	3.6
Rice	0.6
Wheat	1.5
Wheat germ	7.4
Pulses	
Bengal gram	5.3
Black gram	1.4
Green gram	1.3
Peas, dried	1.1

Poultry meat	0.6
Mutton	13.3
Egg (hen)	13.3
Dairy products	
Milk (cow)	3.6
Milk (buffalo)	8.8

3.3.2 Fatty Acids

Even number straight chain saturated and unsaturated fatty acids makeup the greatest portion of the fatty acids of the natural fats. The fatty acid composition of fats and oils has great bearing on human health.

Saturated fatty acids: These are straight chain acids with an even number of carbon atoms from C_2 to C_{26}. Their general formula is:

$$CH_2\,(CH_2)_n\,COOH$$

Where n is the number of – CH_2 groups.

The most widely distributed fatty acids in oils and fats are palmitic, lauric and stearic. It is customary to designate fatty acids by the number of carbon atoms they have. For example 16:0 refers to a fatty acid with 16 carbon atoms and zero refers to the number of double bonds (unsaturated carbon atoms). The chemical formulae of the three fatty acids are given below:

Lauric acid (12:0) : $CH_3.\,(CH_2)_{10}.COOH$
Palmitic acid (16:0) : $CH_3.(CH_2)_{14}.\ COOH$
Stearic acid (18:0) : $CH_3\ (CH_2)_{16.}\ COOH$

Unsaturated fatty acids: The most widely distributed unsaturated fatty acids in oils and fats are given below:

Oleic acid (18:1) : CH3.(CH2)7 CH=CH.(CH2)7. COOH
Linoleic acid (18:2) : CH3.(CH2)4 (CH:CH.CH2)2. (CH2) 6.COOH
Linolenic acid (18:3) : CH3.CH2. (CH: CH.CH2) 3. (CH2) 6.COOH
Archadonic acid (20:4) : CH3.(CH2)4. (CH: CH.CH2) 4. (CH2)2.COOH

3.3.3 Properties of Fats and Oils

Lipids are water insoluble but soluble in organic solvents such as petroleum ether, hexane, chloroform etc. Certain physical and chemical properties of fats and oils help in identifying them. Fats do not melt sharply but soften over a range of temperatures and therefore melting point is not a very reliable technique to identify a fat. However, it provides some information on its identity. Different oils and fats have refractive indices with narrow variations. Therefore, refractive index measurement helps in testing the purity. Their smoke point, flash point and fire point characterizes fats and oils. The smoke point is the temperature at which a fat or oil gives off a thin bluish flame. The flash point is the temperature at which the mixture of vapour with air will ignite and the fire point is the temperature at which the substance will sustain continued combustion.

Chemical properties: A number of chemical tests have been evolved to identify fats and oils and to detect adulteration. All oils and fats show some range of values and therefore sometimes more than one test is necessary.

Reichert–Meissl number: It is a measure of the amount of water soluble volatile fatty acids. It is defined as the millilitres of 0.1N alkali (such as potassium hydroxide) required to neutralise the volatile water soluble fatty acids in a 5g sample of fat. The common volatile water soluble fatty acids are butyric (C4) and caproic (C6) and caprylic (C8) acids. Reichert-Meissl number is particularly valuable in detecting adulteration in butter.

Saponifaction number: It is defined as the number of milligrams of potassium hydroxide required to saponify one gram of fat or oil. When potassium hydroxide reacts with a triglyceride, 3 moles of potassium hydroxide react with one molecule of fat. If the triglycerides contain low molecular weight fatty acids, the number of molecules present in 1 gram sample of fat will be greater than if the fatty acids have long carbon chains and higher molecular weights. The fats with the low molecular weight fatty acids will consequently have a higher saponifaction number. For example, butter with its unusually high percentage of butyric acid has the highest saponification number.

Iodine number: It is the number of grams of iodine absorbed by 100 g of fat. The double bonds found in the unsaturated fatty acid react readily with iodine or certain iodine compounds to form an addition compound even while the fatty acid is combined with glycerol in fat. The iodine number is therefore, a measure of the extent of unsaturation of the fatty acids in a fat.

Rancidity: We are familiar with the development of rancid smell in oils on storage. The process of auto oxidation and the resulting deterioration in flavour of fats and fatty acids are often described by the term ‘rancidity’. Temperature, moisture, the amount of air in contact with the oil or fat, light as well as the presence or absence of antioxidants influence rancidity development. Usually rancidity is referred to oxidative deterioration, but in many fats especially butter, rancidity refers usually to hydrolytic changes resulting from enzymatic activity. In general animal fats develop rancidity faster than vegetable or seed fats.

Oxidation of fats and oils is usually referred to as auto oxidation, because the rate of oxidation increases as the reaction proceeds. Fats and oils containing unsaturated fatty acids are generally susceptible for auto oxidation, though in practice deviations are possible due to the presence of natural antioxidants in them. The reaction products of auto oxidation of oils and fats are peroxides, hydroperoxides, aldehydes and short chain fatty acids which are responsible for the off flavour. **Peroxide value** of fats measures the extent of rancidity development. It is based on the amount of iodine released from potassium iodide by peroxides.

Lypolysis: Fats and oils also become rancid due to lypolysis. The ester linkages of lipids are subject to hydrolysis resulting from enzymes, heat, or chemical reactions. These reactions are collectively known as lypolysis, lypolytic rancidity or hydrolytic rancidity. The free fatty acids that develop during storage and processing of oil seeds and animal tissues must be removed by a refining process. The lower free fatty acids being volatile by steam can be removed by steam distillation under vacuum while the remaining fatty acids are converted by means of sodium or potassium hydroxides into soaps by settling or centrifugation.

Antioxidants: Antioxidants are nothing more than substance with preferential ability to oxidize namely certain compounds, which will oxidize prior to the substances that are being protected. They are both water soluble and fat soluble. For protecting fats, oils and fatty foods, fat-soluble antioxidants are required. Butylated hydroxy anisole (BHA), Butylated hydroxy toluene (BHT) and esters of gallic acid are common antioxidants for this category of foods. Many naturally occurring substances also function as antioxidants. Most prominent are tocopherols. Their presence in natural vegetable oils is the cause for stability of such oils.

Hydrogenation: The physical requirement of many fats used in foods is generally different from those of natural fats and oils. Hydrogenation, the direct addition of hydrogen to double bonds of fatty acids is used to modify vast quantities of fats and oils. Vanaspati is an example of hydrogenated fat. Close control of hydrogenation results in highly specific results. For example, salad and cooking oils can be improved by controlled hydrogenation. Hydrogenation of fats and oils is achieved by mixing them with hydrogen at elevated temperature in the presence of a suitable catalyst, the most common being nickel.

3.4 LET US SUM UP

Carbohydrates are widely distributed in nature. They are grossly classified into monosaccharides, oligosaccharides and polysaccharides. Simple sugars like glucose and fructose are monosaccharides. Sucrose (cane sugar) is the most important disaccharide.

Unlike monosaccharides and oligosaccharides, polysaccharides like cellulose and starches are insoluble in water. Both cellulose and starches are made up of glucose units, but differ in their number of glucose units and their nature of bonding.

Sugars undergo browning reactions during processing and storing. Nonenzymatic browning reactions (Maillard reactions) are initiated mainly due to the reaction between reducing sugars and their amino acids.

Plant gums are also a class of polysaccharides. They have many food and industrial applications.

Lipids are distributed widely in plant and animal foods. They are classified into oils and fats, waxes and phospholipids. Oils and fats on hydrolysis yield fatty acids and glycerol. Fatty acids can be saturated or unsaturated. There are different methods to find out the degree of unsaturation in fats and oils. Unsaturated fatty acids in fats and oils are responsible for rancidity development. Adding antioxidants to fats and oils and fatty foods can prevent development of rancidity.

3.5 KEY WORDS

Monosaccharides : Simple sugars or monoses, readily soluble in water and most of them are sweet to taste.

Hexoses : Six carbon sugars like glucose and fructose.

Oligosaccharides : Water soluble polymers of a few condensed monosaccharides.

Disaccharides : Polymers of two condensed monosaccharides like sucrose, maltose and lactose.

Degree of sweetness (DS) : Sweetness scale in which sweetness of sucrose is assigned the number 100. Fructose has DS of 173.3 and saccharin 30,000 to 50,000.

Polysaccharides	:	Polymers of simple sugars having high molecular weights. Examples are cellulose and starch.
Pectic acid	:	Unmethylated poly galacturonic acid.
High and low methoxyl pectins	:	Pectic acid in which more than 50% of the carboxyl groups are methylated and in which less than 50% carboxyl groups methylated are called high and low methoxyl pectins respectively.
Gums	:	Complex polysaccharides of plant and microbial origin having gummy characteristics.
Maillard reaction	:	Reaction between reducing sugars and amino acids leading to brown compounds.
Rancidity	:	Development of rancid odour in oils and fatty foods on storage.

3.6 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answers should include the following points:

1. Simple sugars, polymers of few monomers, water soluble, sweet. Polymers of simple sugars of large molecular weight.
2. Glucose, fructose, mannose, sorbose.
3. Rotation of plain polarised light.
4. Amygdaline, naringin.
5. Sucrose, maltose, lactose.
6. Sucrose hydrolysis, fructose sweeter than glucose.

Check Your Progress Exercise 2

Your answers should include the following points:

1. α and β linkages, degree of polymerisation.
2. Galacturonic acid
3. Degree of methylation of pectic acid.

Check Your Progress Exercise 3

Your answers should include the following points:

1. Guar gum, gum Arabic, carrageenans.
2. Xanthan, dextran.
3. Sugar – amino acid reaction.

Check Your Progress Exercise 4

Your answers should include the following points:

1. Avocado
2. Glycerol and fatty acids
3. Double bonds, palmitic, stearic, oleic, linolenic
4. Water soluble volatile fatty acids
5. Degree of unsaturation
6. Oxidation of unsaturated fatty acids

UNIT 4 FOOD CONSTITUENTS – PROTEINS, ENZYMES AND WATER

Structure

4.0 OBJECTIVES

After reading this unit, you will be able to answer:

- what are proteins and amino acids? How proteins are classified? Protein structure, their Denaturation and the role of protein and amino acids in non-enzymatic browning. Proteins of plant, seeds, marine and animal origin. Classification and properties of enzymes etc.; and
- you will also learn the importance of the state of water in foods in food preservation, freezing of water, water quality and standards and water analysis.

4.1 INTRODUCTION

Unlike the other two major nutrients viz., carbohydrates and lipids that are essentially energy sources, proteins constitute the main structure of the animal and human body. These constituents characterised by their nitrogen content are involved in many vital processes intricately associated with all living matter. Some proteins function as biocatalysts (enzymes). There are different types of enzymes in all living systems. They catalyse most of the biological reactions. As enzymes have high degree of specificity, mostly one enzyme can catalyse only one reaction. Several enzymes like amylase, invertase, glucose oxidase, Pectinases, proteases, find application in food processing.

Water is an essential constituent of foods. The state of water in foods has great bearing on food preservation. The physical, chemical and microbiological quality of water used in food processing operations should conform to certain minimum standards.

4.2 PROTEINS

Protein is one of the three major basic nutrients required for growth and development, the other two being carbohydrates and lipids. The word protein was coined from the Greek proteios, which means 'of the first rank'. Proteins are very complex organic substances, constitute the main structure of the animal and human body. These macromolecules, characterized by their nitrogen contents are involved in many vital processes intricately associated with all living matter. Some proteins function as biocatalysts (enzymes) and hormones to regulate chemical reactions within the body.

4.2.1 Amino Acids

Amino acids are the building blocks of proteins. Proteins are polymers of some 20 amino acids joined together in different proportions and sequences. Most amino acids have general chemical structure as given in Figure 4.1.

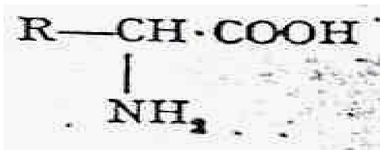

Figure 4.1: General chemical structure of amino acids where R= aliphatic, aromatic, heterocyclic etc. groups

They have both amino group and acidic carboxyl group. In proteins the amino acids are joined together by peptide bond (-CO-NH-) (Fig.2) i.e. The carboxyl group of one amino acid is linked with the amino group of the second amino acid with elimination of H_2O.

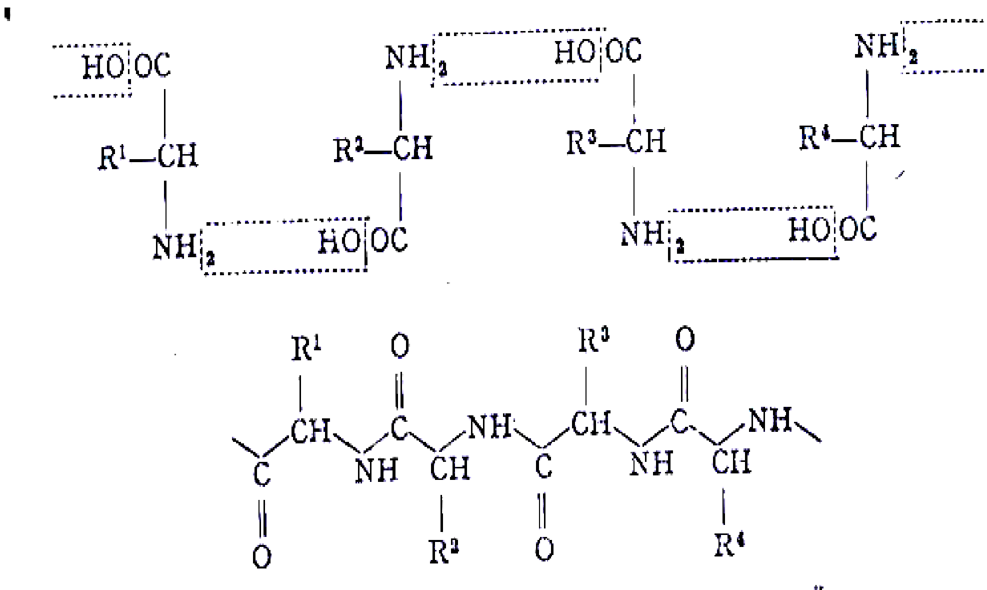

Figure 4.2: The peptide bond

Amino acids found in nature are classified into six groups: viz.,

1. Aliphatic mono amino mono carboxylic amino acids e.g. glycine, alanine, valine, leucine, isoleucine, serine and threonine.

2. Sulphur containing amino acids e.g. cysteine, cystine and methionine.

3. Aliphatic mono amino dicarboxylic amino acids, e.g. aspartic acid and glutamic acid.

4. Aliphatic basic amino acids, e.g. lysine, arginine and histidine.

5. Aromatic amino acids, e.g. phenylalanine and tyrosine.

6. Heterocyclic amino acids, e.g. triptophan and proline.

Of the above amino acids, eight for adults and ten for children are considered essential or indispensable for the human diet. They are: lysine, triptophan, phenylalanine, threonine, valine, methionine, leucine and isoleucine. The amount of these amino acids present in a protein and their availability determine the nutritional quality of the protein. In general animal proteins are of higher quality than plant proteins. However, plant proteins can be upgraded nutritionally by judicious blending. That is why, traditionally people consume a variety of pulses. Egg protein is one of the best quality proteins and is considered to have a biological value of 100. It is widely used as a standard and protein efficiency ratio (PER) values are sometimes based on egg white as a standard. Cereal proteins are generally deficient in lysine and threonine. Soya is a good source of lysine but deficient in methionine. Cottonseed protein is deficient in lysine and groundnut protein in methionine and lysine. The protein of potato although present in small quantity is of excellent quality and is equivalent to that of whole egg.

4.2.2 Protein Classification

Proteins are divided into two main groups namely simple and conjugated and derived proteins.

Simple Proteins

Simple proteins yield only amino acids on hydrolysis and include the following classes:

a) *Albumins:* They are soluble in neutral salt free water. Usually these are proteins of relatively low molecular weights. E.g. egg albumin, lactalbumin and serum albumin in the whey proteins of milk, leucosin of cereals, legumelin in legumes.

b) *Globulins:* They are soluble in salt solutions and almost insoluble in water. E.g. Serum globulins and β-lacto globulin in milk, myosin and actin in meat, glycinine in soybean.

c) *Glutelins:* Soluble in very dilute acids or bases, insoluble in neutral solvents. E.g. Wheat glutelin and oryzenin in rice.

d) *Prolamins:* Soluble in 50-80% ethanol and insoluble in water. E.g. Gliadin in wheat, zein in corn and hordein in barley.

e) *Scleroproteins:* Insoluble in water and neutral solvents and resistant to enzymatic hydrolysis. These are fibrous proteins serving structural and binding purposes. Gollagen of muscle tissue, elastin of tendens, creatin of hair and fibroin of silk are examples.

f) *Histones:* Basic proteins containing a large number of basic amino acids like lysine and arginine. Soluble in water and precipitated by ammonia.

g) *Protamins:* Strongly basic proteins of low molecular weights. They are rich in arginine. E.g. Cupein from herring, and scombrin from mackerel.

Conjugated Proteins

Conjugated proteins contain an amino acid part combined with a non protein material such as lipids, nucleic acid, carbohydrates and others. Some of the conjugated proteins are:

1. *Phospho proteins:* They constitute an important group including many major food proteins. This group includes casein of milk and the phosphoprotein of egg yolk.

2. *Lipoproteins:* These are combination of lipids with proteins and have excellent emulsifying capacity. Lipo protein occurs in milk and egg yolk.

3. *Nucleoproteins:* These are combination of nucleic acids with protein. They are found in cell nuclei.

4. *Glycoproteins:* These are combination of carbohydrates with protein. Ovomucine of egg white is an example.

5. *Chromo protein:* These are proteins with coloured prosthetic groups. Hemoglobin, myoglobin, chlorophyll and flavo proteins are examples.

4.2.3 Protein Structure

The Primary structure of proteins is related to the peptide bonds between the component amino acids and also to the amino acid sequence in the molecule. A peptide chain may become involved in hydrogen bonding between amide nitrogen and carbonyl oxygen. These bonds may be formed between different areas of the same polypeptide chain or between adjacent chains. Such bonds establish the secondary structure of proteins, which may be of helical or sheet form.

The tertiary structure of protein is established when the chain are folded into compact structures stabilized by hydrogen bonds, disulphide bridges, etc. Large molecules may form quaternary structures by association of sub units.

4.2.4 Protein Denaturation

Denaturation is a process of change in structure of proteins without breaking covalent bonds. The process is peculiar to proteins and affects different proteins to different degrees. Denaturation can be brought about by a variety of agents of which the most important are heat, pH, salts and surface effects. The destruction of enzyme activity by heat is one of the most important operations in food processing. You are familiar with the coagulation or hardening of egg white on heating it. It is due to denaturation of egg albumin. Freezing can also cause protein denaturation as in the case of fish, which becomes tough on freezing and thawing. Milk protein casein and gelatin are examples of proteins, which can be boiled with out apparent denaturation.

4.2.5 Non-Enzymatic Browning

Browning of several foods is familiar to all of us. Browning of potato chips, brown crust formation on bread and cakes, browning of evaporated milk, browning of jams, candies, fruit juice concentrates etc. are all examples of non-enzymatic browning. The browning reaction can be defined as the sequence of events, which begins with the reaction of the amino group of amino acids, peptides or proteins with a glycosidic hydroxyl group of sugars and terminates with the formation of brown nitrogenous polymers or melanoidins. While some browning reactions like brown crust formation on bread and cake are desirable, most others are undesirable and may accompany formation of off flavoured compounds.

Methods of preventing browning could consist of measures indented to slow the reaction rates such as control of moisture, temperature or pH or removal of an active intermediate. Generally it is easy to use an inhibitor. One of the most effective inhibitors of browning is sulphur dioxide. It is known that sulphur dioxide can combine with the carbonyl group of an aldose to give an addition compound thus blocking further transformations leading to formation of dark coloured compounds.

$$NaHSO_3 + R\text{-}CHO \rightarrow RCHOHSO_3Na$$

However, as sulphite can destroy the vitamin thiamine, it is not desirable to use it to inhibit browning in foods, which are good sources of this vitamin.

4.2.6 Protein from Different Sources

Human requirement of proteins is met from both animal and plant sources.

Proteins of Animal Origin

A typical adult mammalian muscle contains 18-20% protein. Muscle proteins are categorized on the basis of their origin and solubility as sarcoplasmic, myofibrillar and stroma proteins. Protein content of milk ranges from 3 to 4%. Buffalo milk has slightly higher level of protein. Milk proteins are grossly divided into casein and whey protein, the average ratio being 80:20. Egg contains on an average 11% shell, 31% yolk and 58% white. The yolk contains about 50% solids of which one third is protein and two third lipids. Egg white is essentially an aqueous solution containing about 12% protein.

Proteins of Marine Origin

Fish flesh contains on an average 10-21% protein. Fish muscle proteins, like those of mammalian muscle are generally classified as sarcoplasmic, myofibrillar and stroma proteins but their proportions differ.

Proteins of Plant Origin

The protein source of vegetarian diet is from cereals, pulses and oil seeds besides small quantities from vegetables.

Cereals like wheat and rice are important sources of protein because they are the staple foods of Indians. On an average wheat has 12-13% protein while rice has 7-9% protein. Gluten proteins are responsible for the unique bread making property of wheat. Wheat and rice proteins are generally deficient in the essential amino acid lysine.

Seed Proteins

Legumes (pulses) and oil seeds are major sources of vegetable proteins. The average protein content of the major pulses is given in Table 4.1.

Table 4.1: Protein content of major pulses

Legume	Protein (%)
Bengal gram dhal	20.8
Black gram dhal	24.6
Field bean, dry	24.9
Green gram dhal	24.5
Lentil (lens culinaris Medic)	25.1
Peas, dried	19.7

The average protein content of some of the oil seeds is given in Table 4.2.

Table 4.2: Protein content of some oil seeds

Oilseed	Protein (%)
Ground nut	26.7
Soybean	43.2
Sesame	18.3
Cotton seed	19.5
Sunflower seed	12.5

4.3 ENZYMES

Enzymes are called bio- catalysts. They are globular protein catalysts that accelerate several biological reactions. Enzymes are present in all biological systems both plant and animal. Enzymes show high degree of specificity. This property is very important in food processing where it is often desirable to modify only a single component in the process.

4.3.1 Nomenclature and Classification

Enzymes are classified into six major groups depending on the type of reactions they catalyze i.e. 1) oxido reductases, 2) transferases, 3) hydrolases, 4) lyases, 5) isomerases and 6) ligases

Over the years, thousands of enzymes have been isolated and identified. Quite often two or three enzymes differ only slightly from one another in their properties causing difficulty in naming them. Therefore, the International Union of Biochemistry on Nomenclature and Classification of Enzymes has assigned a code number of four numerals for each enzyme, which fully identifies an enzyme. However it is too cumbersome to follow this classification and therefore for routine purpose most of the enzymes have been given a trivial name, which is short and simple.

4.3.2 Properties of Enzymes

As already mentioned, all enzymes are proteins but all proteins are not enzymes. Some enzymes consist of protein only, but most enzymes contain additional non- protein components such as carbohydrates, lipids, metals, phosphates or some other organic moiety. The complete enzyme is called holoenzyme, the protein part apoenzyme and the non- protein part cofactor. The compound which is being converted in an enzyme reaction is called substrate, In an enzyme reaction the substrate combines with the holoenzyme and is released in a modified form as shown below.

$$\text{Enzyme} + \text{Substrate} \leftrightarrows \text{Complex} \leftrightarrows \text{Enzyme} + \text{Products}$$

Enzyme activity is affected by various factors like temperature, pH, chemicals etc. By far the most important is the requirement of optimum temperature and pH for their maximum activity. These properties serve both for obtaining maximum activity for an enzyme as well as for inhibiting the enzyme activity.

By far the largest group of enzymes important in food processing is the hydrolases. A few oxido reductases and isomerases are also encountered. Hydrolases catalyse the following general reaction.

$$AB + HOH \rightarrow HA + BOH$$

Typical examples of hydrolases are amylases, pectin esterase, poly galacturonase, proteases, lipases etc. Most of the enzymes used in industrial applications are now obtained from microorganisms. Table 4.3 gives examples of some of the important enzymes encountered in food processing.

Table 4.3: Some enzymes used in food processing

Enzyme	Food	Purpose/ action
Amylases	Baked products Brewing	Increase sugar content for yeast fermentation Conversion of starch to maltose for fermentation
Invertase	Artificial honey	Conversion of sucrose to glucose and fructose
Naringinase	Citrus juice	De-bittering of citrus juice
Pectinases	Fruit juice	Improve yield and clarity
Proteases	Brewing Meat and fish	Clarification, chill-proofing Tenderization
Lipases	Oils	Hydrolytic rancidity (deteriorative)
Glucose oxidase	Egg powder	Prevention of browning by removing glucose
Polyphenol oxidase	Fruits	Enzymatic browning (deteriorative)

4.3.3 Immobilized Enzymes

One of the most important recent developments in the use of enzymes in industrial food processing is the fixing of enzymes on water insoluble inert supports. The fixed enzymes retain their activity and can be easily added or removed from the reaction mixture. The use of immobilized enzymes permits continuous processing and repeated use of the enzyme. Another important use of immobilized enzymes is in analytical and medical fields.

4.4 WATER

Water is an essential constituent of most foods. It may occur as an inter cellular and/or extra cellular component in vegetables and animal products, as a dispersing medium or solvent in a variety of products, as the dispersed phase in some emulsified products such as butter or margarine and as a minor constituent in other cases. The presence of water influences deterioration of food, either chemical or microbiological. Thus an understanding of its properties and its behaviour in foods is of great importance.

4.4.1 State of Water in Foods

Water is present in foods in different forms. They are grossly characterised as bound water and free water. Bound water is the water, which is bound to other constituents of foods like proteins and remains unfrozen. This water is unavailable as a solvent. The state of water in food is described by the relationship between the moisture content of the product and the relative humidity of the air surrounding it. This ratio is called water activity, which is an important characteristic of the system. The relative humidity corresponding to each specific moisture content of the product called equilibrium relative humidity (ERH) and the following relationship applies.

$$a_w = p/p_o = ERH/100$$

where a_w = water activity
p = partial pressure of water in food
p_o = vapour pressure of water at the same temperature
ERH = Equilibrium Relative Humidity in %

At high moisture contents, when the amount of moisture exceeds that of solids, the activity of water is close to or equal to 1.0. When the moisture content is lower than this amount, water activity is lower than 1.0. Below moisture content of about 50% the water activity decreases rapidly and the relationship between water content and relative humidity is represented by the sorption isotherm. The adsorption and desorption processes are not fully reversible;

therefore, a distinction can be made between the adsorption and desorption isotherms according to whether a dry product is subjected to increasing moisture levels or whether the moist product is gradually equilibrated with lower moisture levels and the product is being dried. Figure 4.3 shows the adsorption desorption isotherms.

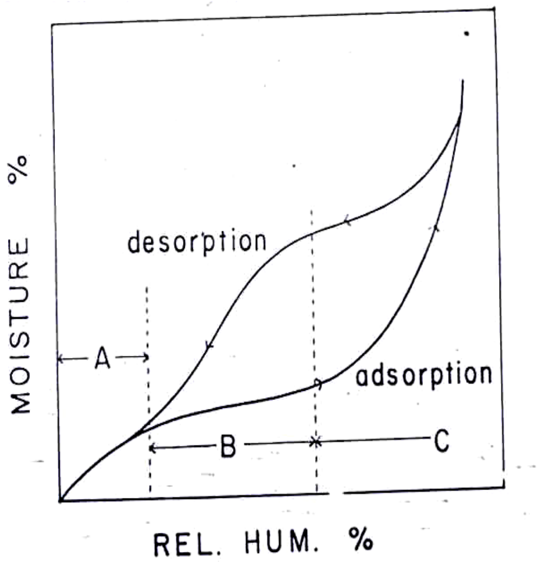

Figure 4.3: Adsorption desorption isotherms

Generally the isotherms are required for the observation of hygroscopic products and the desorption isotherms are useful for investigation of the process of drying. A steeply sloping curve indicates that the material is hygroscopic and a flat curve points to a product, which is not sensitive to moisture.

4.4.2 Water Activity and Food Spoilage

Moisture content and water activity are of major importance in affecting a progress of chemical and microbiological spoilage reactions in foods. Dried and dehydrated foods have very good microbiological stability though browning reactions take place. Such products have moisture content in the range of 5-15% and have low water activity. Intermediate moisture foods (IMF) have moisture content in the range of 20–40% and are fairly shelf stable. IMFs generally have water activity above 0.5. Adding/having soluble solids like sugar achieve this. Example of such products is jams, preserves, cakes, dry fruits, etc. Bacterial growth is practically nil below water activity of 0.90. Yeasts and moulds are usually inhibited between 0.88 and 0.80 water activity, although some osmophilic yeast can tolerate water activity as low as 0.65.

Most enzyme reactions are inhibited below water activity of 0.85. Non-enzymatic browning reactions are dependent on water activity showing maximum around 0.6–0.7. Since water activity is a major factor influencing the keeping quality of a number of foods, it is obvious that packaging can play an important role to maintain optimal conditions for long storage life. Packaging aspects will be dealt with in another section.

4.4.3 Freezing of Water

During freezing of water, the water molecules arrange themselves in a tetrahedral fashion. These results in a hexagonal crystal lattice which is loosely built and has relatively large hallow spaces resulting in high specific volume. This is the reason for increase in volume of water on freezing. You must have observed ice cubes floating on water. The density of ice at 0° C is only 0.9168.

Water can exist in three phases, viz., solid, liquid and gas. The conditions under which they exist are separated by three equilibrium lines (Figure 4.4).

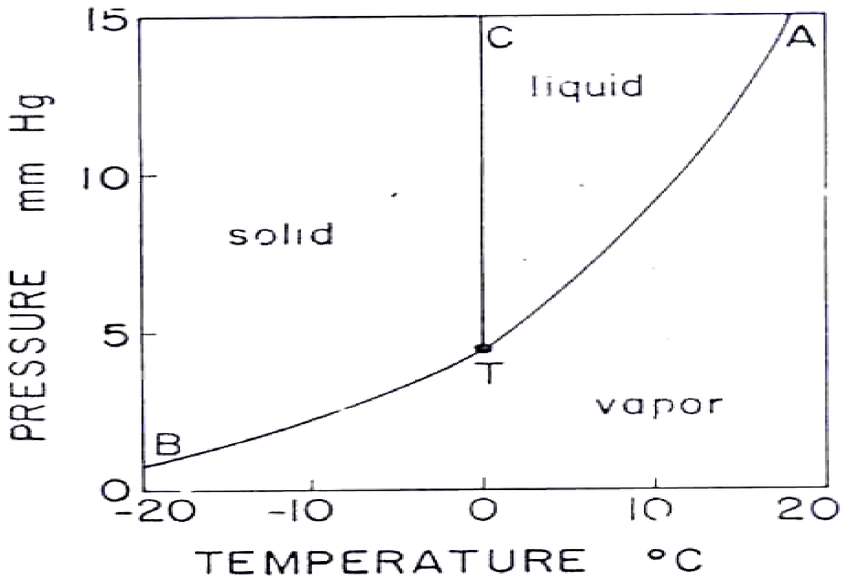

Figure 4.4: Phase diagram of water

The vapour pressure line TA, the melting pressure line TC and sublimation pressure line BT. They meet at the triple point T, where all three phases are in equilibrium. When ice is heated at pressures below 4.58 mm Hg it changes directly into vapour form (sublimation). This is the basis of freeze-drying.

Slow freezing will result in large ice crystal formation and rapid freezing in tiny ice crystal formation. Large ice crystals tend to damage the cell walls resulting in texture lose in frozen fruits, fish, meat, etc. During freezing of foods, water is transformed to ice with high degree of purity and solid concentration in the unfrozen liquid is gradually increased. This is accompanied by changes in pH, ionic strength, viscosity, osmotic pressure, vapour pressure and other properties. These changes along with the lower temperature are responsible for decrease in microbial activity and often on destruction of micro- organisms in frozen foods.

4.4.4 Water Quality and Standards

Water is used for different purposes in food processing. They include water used as ingredient in finished products, for generating steam, for cleaning raw materials, for cleaning plant and equipment, as heat exchange medium for heating and cooling etc. The water quality for different purposes varies.

In general, only potable water should be used in the preparation of food indented for human consumption. Potable water is that water which contains no bacteria capable of causing human intestinal diseases and is aesthetically satisfactory for drinking purposes, i.e. free from undesirable odours and flavours.

Potable water should have good clarity, colourless and free from objectionable odour and taste.

Hardness of Water

Calcium and magnesium salts cause hardness of water. Permanent hardness is due to chlorides and sulphates of calcium and magnesium and temporary hardness is due to bicarbonates of these ions. Hardness is expressed as ppm (parts per million i.e. mg per litre) of $CaCO_3$ (calcium carbonate) on which basis water is classified according to degree of hardness (Table 4.4).

Table 4.4: Classification of water based on hardness

ppm of $CaCO_3$	Condition
Less than 50	Soft
50 to 100	Slightly hard
100 to 200	Hard
Above 200	Very hard

Microbiological Quality

The bacteriological quality of water used throughout the plant should meet the standards required for drinking water. The fitness of water for drinking purposes with respect to bacterial content is determined by the presence or absence of the coliform group of bacteria including Escherichia and Aerobacter species which indicate the possibility of faecal contamination. Waters drawn from deep wells or those purified by artificial means seldom show the presence of E.coli in 100 ml.

The quality of water required varies for different process food industries. The essential microbiological parameters of the BIS standards for water meant for general purposes are given in Table 4.5.

Table 4.5: Bacteriological tolerances

Sl. No.	Characteristic	Tolerance
1.	Coliform bacteria, MPN index/100 ml.	Less than 1
2.	Standard plate count, per ml., Max.	50 (Note 1)
3.	Proteolytic and lipolytic organisms, combined count per ml. Max.	5 (Note 2)

4.4.5 Chlorination

As in the case of municipal water supply, chlorination of industrial water has become a common practice in food processing plants as a means of improving plant sanitation. Gaseous chlorine or calcium and sodium hypochlorites are used for chlorination of water.

Chlorine Demand of Water

When chlorine is added to water other than distilled water, a small amount, normally 0.25 to 0.75 ppm, reacts with impurities in the water. This quantity of chlorine is called the **chlorine demand** of the water. The impurities responsible for chlorine demand include compounds containing iron, manganese, nitrites and sulphides. The chlorine, which reacts with these compounds, has no germicidal properties and cannot be measured by the methods used for testing chlorine concentration.

Break Point Chlorination

When chlorine is added to water, initially it is used up to satisfy the chlorine demand of the water. As additional chlorine is added, a free residual chlorine appears. At the same time, some chlorine loosely combines with nitrogenous matter present in water to form chloro-nitrogen compounds. The residual chlorine gradually increases until it reaches a concentration depending on the physical and chemical nature of the water, at which an oxidation reaction occurs between the free chlorine and the chloro-nitrogen compounds. The free residual nitrogen is decreased by the amount necessary to completely oxidise the chloro-nitrogen compounds. Further addition of chlorine beyond this point will result in a second rise in free chlorine concentration, which increases in almost direct proportion to the rate of chlorine application (Figure 4.5). The point after the first rise in concentration at which the free residual chlorine reaches its lowest level is known as the break point. Break point chlorination is defined as chlorination to a degree where a persisting residual chlorine of 2-10 ppm occurs. The residual chlorine in water exists either as free chlorine or chlorine which has loosely combined with other elements. The rate at which bacteria exposed to chlorine are killed is proportional to the amount of chlorine present as hypochlorous acid.

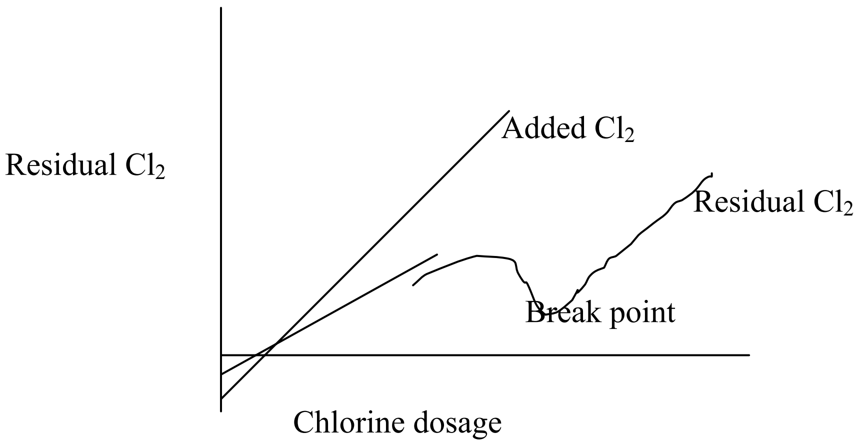

Figure 4.5: Break point chlorination of water

Chlorination of Water

In plant chlorination reduces bacterial count and clean up time and avoids odours. Chlorination of cooling water (for cooling canned products) prevents spoilage from recontamination. Residual chlorine of 5 ppm in the water is considered sufficient. Residual chlorine of 10-20 ppm is recommended for cleaning purposes. Chlorine concentration of 5 ppm has no effect on the flavour, odour or colour of canned products. For chlorination of water, hypochlorites are usually added in the form of stock solution containing 5000–10000 ppm of chlorine.

4.4.6 Packaged Drinking Water

As all of us know the quality of water supplied for drinking in many parts of our country is very poor and varies from place to place. Several diseases are spread through water. That is why today we find a booming packaged drinking water industry in the country. Water meant for producing packaged drinking water goes through a series of treatment and processes like filtration, reverse osmosis, ozonisation, etc., to obtain the required quality. PFA has laid down detailed specifications for packaged drinking water. The salient aspects of the specification are given in Table 4.6.

Table 4.6: Specifications for packaged drinking water

Sl. No.	Characteristics	Requirements
1.	Total soluble solids	Not more than 500 mg/litre
2.	PH	6.5–8.5
3.	Nitrates (as NO3)	Not more than 45 mg/litre
4.	Nitrites (as NO2)	Not more than 0.02 mg/litre
5.	Sulphide (as H2S)	Not more than 0.05 mg/litre
6.	Manganese (as Mn)	Not more than 0.1 mg/litre
7.	Copper (as Cu)	Not more than 0.05 mg/litre
8.	Zinc (as Zn)	Not more than 5.0 mg/litre
9.	Fluoride (as F)	Not more than 1.0 mg/litre
10.	Barium (as Ba)	Not more than 1.0 mg/litre
11.	Nickel (as Ni)	Not more than 0.02 mg/litre
12.	Chlorides (as Cl)	Not more than 200 mg/litre
13.	Sulphate (as SO4)	Not more than 200 mg/litre
14.	Calcium (as Ca)	Not more than 75 mg/litre
15.	Sodium (as Na)	Not more than 200 mg/litre
16.	Arsenic (as As)	Not more than 0.05 mg/litre
17.	Cadmium (as Cd)	Not more than 0.01 mg/litre
18.	Chromium (as Cr)	Not more than 0.05 mg/litre
19.	Mercury (as Hg)	Not more than 0.001 mg/litre
20.	Lead (as Pb)	Not more than 0.01 mg/litre
21.	Iron (as Fe)	Not more than 0.1 mg/litre
22.	Residual free chlorine	Not more than 0.2 mg/litre
23.	Yeast and mould counts	Absent in 250 ml
24.	E.Coli	Absent in 250 ml
25.	Coliform Bacteria	Absent in 250 ml
26.	Faecal streptococci and staphylococcus aureus	Absent in 250 ml
27.	Aerobic microbial count	Shall not exceed 100/ml.

4.4.7 Water Analysis

In the examination of water supplies, the test will depend on the purpose for which the water is used. The initial examination of water, or the testing of supplies from a new source may consist of the following:

I. Sanitary Examination

1. Physical characteristics:

   i) Colour, ii) Odour and taste, iii) Turbidity

2. Chemical characteristics:

   i) Total solids,
   ii) Organic matter,
   iii) Hardness,
   iv) Alkalinity,
   v) Acidity,

vi) pH,
vii) Nitrogen as nitrates, nitrites, free ammonia and albuminoid ammonia,
viii) Chlorides,
ix) Sulphates,
x) Free CO_2,
xi) Oxygen absorption, and
xii) Heavy metals.

II. Microbiological Examination

1. Plate count
2. Coliform count
3. Faecal streptococci test
4. Clostridium welchii test.

4.5 LET US SUM UP

Proteins are macromolecules built up of amino acids. They form the building block of animal and human body structure. Pulses, oil seeds, and animal and marine foods are good sources of protein. The quality of protein greatly depends on its essential amino acid makeup.

Enzymes are biocatalysts, which catalyse biological reactions. All enzymes are proteins but all proteins are not enzymes. Several enzymes find application in food processing.

Water is an essential component of foods. Its state in foods plays an important role in food preservation. Quality of water used in food processing operations and for drinking is of paramount importance. Water is treated in several ways to make it suitable for different purposes.

4.6 KEY WORDS

Amino acids : Nitrogen containing compounds having both carboxyl and amino groups.

Essential amino acids : Amino acids which cannot be synthesised by the human body.

Albumin : Proteins, which are soluble in neutral salt free water.

Denaturation : Change in the structure of protein without breaking covalent bonds.

Immobilised enzymes : Enzymes fixed on water insoluble inert supports.

Chlorine demand : The quantity of chlorine added which reacts with the impurities in water and which does not show up as free chlorine.

4.7 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answer should include the following points:

1. Aliphatic, aromatic, etc.
2. Different classes of simple proteins
3. Conjugated proteins

Check Your Progress Exercise 2

Your answer should include the following points:

1. Coagulation of egg albumin.
2. Deficiency of amino acids like lysine.
3. Pulses, oil seeds.
4. Valine, lysine, methionene, etc.

Check Your Progress Exercise 3

Your answer should include the following points:

1. Bio catalyst.
2. All enzymes are proteins.
3. Enzymes fixed on inert support.

Check Your Progress Exercise 4

Your answer should include the following points:

1. Relationship of water activity to microbial growth.
2. Large ice crystals damage cell structures.
3. Calcium and magnesium salts.

Check Your Progress Exercise 5

Your answer should include the following points:

1. Coliforms.
2. Reaction of added chlorine with impurities in water.
3. Depression in residual chlorine content.
4. Physical, chemical, microbiological.

4.8 SOME USEFUL BOOKS

1. Owen R. Fennema, (1976) Principles of food science, Part I- Food Chemistry, Marcel Decker Inc.; New York.

2. Meyer, L.H. (1969) Food Chemistry, Van Nostrand Reinhold Company, New York, Cincinnati, Toronto, London, Melbourne.

3. Braverman, J.B.S. (1963) Introduction to the Biochemistry of foods, Elsevier Publishing Company, Amsterdam, London, New York.

4. Ranganna, S. (2000) Hand book of Analysis and Quality Control for Fruit and Vegetable Products, Tata McGraw-Hill Publishing Co. Ltd., New Delhi.

UNIT 5 FOOD CONSTITUENTS – VITAMINS AND MINERALS

Structure

5.0 OBJECTIVES

After reading this unit, you should be able to:

- explain the chemistry and properties of different vitamins;
- their physiological functions and deficiency diseases;
- their dietary sources; and
- describe the importance of minerals in human nutrition.

5.1 INTRODUCTION

You have already learnt about the macronutrients viz. carbohydrate, protein and fat. Besides these macronutrients, the human body requires certain accessory factors called vitamins for maintaining the health and well being. The accessory factors were named vitamins because of their vital importance to health. Some of the vitamins are unstable to the adverse storage conditions of foods and also many processing conditions. Since the vitamins are present in foods only in minute concentrations, their protection during preservation and processing of foods is a major concern.

The human body requires several minerals also for maintaining normal health. Iron and iodine deficiencies among populations are well known. Due to various reasons, the foods consumed by sections of the populations are deficient in vitamins and minerals. Therefore, these are some times added to foods. Since vitamins and minerals are collectively termed 'micronutrients', the process of adding them to foods is called micronutrient fortification. You will be learning these aspects in this unit.

5.2 VITAMINS

Vitamins are organic substances of very diverse composition required by the body usually in very minute quantities. Some of them, especially the B-group vitamins, take an active part in enzymatic reactions as co-enzymes. You will be learning more on enzymes in another unit. Most of the vitamins are supplied to the body by plants. Vitamins do not supply energy to the body or any structural units for bodybuilding. They, however, play a most important role in the energy transfer as well as in control of many metabolic processes. Some of the vitamins like vitamin A occur in plant foods as provitamins (e.g. β-carotene), compounds that are not vitamins but can be transformed by the body into vitamins.

Vitamins are generally classified into two groups: a) fat-soluble vitamins i.e., vitamins soluble in fats and fat-soluble solvents (like petroleum ether, chloroform, carbon tetrachloride etc.) but not soluble in water, and b) water soluble vitamins, i.e., vitamins soluble in water but insoluble in fats or fat-soluble solvents.

5.2.1 Fat Soluble Vitamins

Fat soluble vitamins include 1) Vitamin A and Carotene (Provitamins A), 2) Vitamin D, 3) Vitamin E and 4) Vitamin K.

Vitamin A (Retinol)

Osborne and Mendel (1913) and McCollum and Davis (1917) showed that a fat-soluble factor present in butter was essential for the growth of rats on synthetic diet. The latter workers called the factor as "fat-soluble A". Moore (1930) showed that when large amounts of carotene are fed to vitamin A deficient rats, vitamin A was found in large amounts in liver, indicating the conversion of carotene to vitamin A in the animal body.

Chemistry and properties: In 1931, Karrer determined the structure of vitamin A. In 1937, Kuhn and Morris announced a method of synthesis if vitamin.

Vitamin A contains a β-ionone ring and a highly unsaturated side chain. Due to the unsaturated side chain, vitamin A is destroyed easily by oxidation. Being an alcohol, it forms esters such as acetate, succinate, palmitate etc. Vitamin A is stable to heat (100^{o}C) for short periods in the absence of oxygen. Vitamin A is slowly destroyed when exposed to light.

A large number of carotenoid pigments occur in nature. You will be learning their structure and properties in a later section in this unit. Carotenes are converted into vitamin A in the body. Among the carotenes, β-carotene has maximum vitamin A activity.

Functions and deficiency diseases/syndromes: Vitamin A has various functions in the human body. It is essential for the maintenance of normal vision, building and growth of skeletal cells and provides resistance power to the body. Dietary retinoids, especially carotenoid compounds have been found to suppress carcinogenesis (development of cancer).

The most important effect of deficiency of this vitamin in the diet is night blindness. In early stages of vitamin A deficiency, one cannot see well in dim light. In advanced deficiency, the subject cannot see objects in dim light. Night blindness is very common in regions where vitamin A intake is inadequate.

Dietary sources: Vitamin A is present only in fish liver oil and foods of animal origin such as liver, eggs, milk and fatty fish. Plant foods contain only carotenoids, the precursor of vitamin A. Among the plant foods, green leafy vegetables, carrot, mango and other yellow coloured fruits are good sources of carotenes.

Vitamin A levels are frequently expressed in International Units (I.U.). One I.U. equals 0.3 μg of crystalline vitamin A alcohol (retinol) or 0.6 μg β-carotene.

Vitamin D

Mellanby (1919) discovered that cod liver oil can cure or prevent experimentally produced rickets in dogs. McCollum and co-workers (1922) established experimentally that the antirachitic vitamin was different from vitamin A and called the factor vitamin D.

Chemistry and properties: Vitamin D is a group of compounds related to sterols. This vitamin occurs in several forms, the two most important are vitamin D_2 or ergocalciferol and vitamin D_3 or cholecalciferol.

Vitamin D is fairly heat stable. It is unstable on exposure to ultra-violet light. It is soluble in fat solvents.

Functions and deficiency diseases/syndromes: Vitamin D is essential for bone formation. It promotes absorption of calcium and phosphorus and deposition in bones.

In vitamin D deficiency, calcification (calcium deposition) of bone does not take place. This results in the disease called rickets in infants and children. The manifestations of the disease are: bowleg, enlargement of ankles and wrists and deformities of the chest bones called 'pigeon breast'. Exposure of children suffering from rickets to sunlight has a curative effect. Therefore, vitamin D is also called the sunshine vitamin.

Dietary sources: Vitamin D_2 occurs in small amounts in fish liver oils. Vitamin D_3 is widely distributed in eggs, milk, butter and cheese but large amounts occur only in fish liver oils.

One international unit (I.U.) of vitamin D is equivalent to the activity of 0.025 μg of pure crystalline vitamin D_2.

Vitamin E

Evans and Bishop (1922) discovered that for normal reproduction in rats, a fat-soluble factor present in crude vegetable oils was essential. They termed it vitamin E. Evans and co-workers (1936) isolated two compounds α and β-tocopherols possessing vitamin E activity.

Chemistry and properties: Tocopherols are derivatives of 6-hydroxy chroman with a phytyl side chain. Tocopherols are soluble in fat solvents and insoluble in water. Tocopherols have excellent antioxidant properties. The storage stability of unrefined vegetable oils is due to the tocopherols. They are slowly destroyed in alkaline medium and the vitamin activity is destroyed by oxidation.

Functions and deficiency diseases/syndromes: Vitamin E is essential for normal reproduction in several species of animals and also in man. Its deficiency causes several disorders such as reproductive failure, liver necrosis (damage), muscular dystrophy, etc.

Dietary sources: Cereal germ oils like wheat germ oil and corn germ oils are the richest natural sources of the vitamin. Soybean oil is also a good source of tocopherols. Cottonseed oil is found to contain alpha, beta, and gamma tocopherols. Delta tocopherols were isolated from soybean oil. Since alpha tocopherols have the highest biological activity, its content is taken for calculating the human requirements.

One international unit (I.U.) of vitamin E is equal to the activity of 1 mg of synthetic α- tocopherols.

Vitamin K

As early as 1934, Dam and Schonheyder found that chicks fed on purified diets containing all vitamins known at that time developed haemorrhagic condition, which was cured by Lucerne (alfalfa) leaves. They named it vitamin K (Koagulations-vitamin) meaning vitamin responsible for blood coagulation.

Chemistry and properties: Vitamin K belongs to the group of compounds called quinones. Vitamin K_1 is called phylloquinone and K_2 is called menaquinone. Vitamin K_1 is 2-methyl 3-phytyl- 1,4-napthoquinone. It is the only vitamin K found in plants.

The commercially available vitaminK_1 is prepared synthetically from isophytol and a derivative of menadione. Vitamin K is also a fat-soluble vitamin.

Functions and deficiency diseases/syndromes: Vitamin K is essential for blood clotting by increasing the prothrombin levels in blood. Vitamin K deficiency leads to increased blood clotting time. This may lead to haemorrhage conditions. The deficiency can occur either due to inadequate intake or inadequate intestinal absorption of vitamin K. Inadequate intestinal absorption can occur due to disease of the liver or diarrhoea.

Dietary sources: Vitamin K occurs widely in plant foods, especially in leafy vegetables and also synthesised by the intestinal micro flora. It is assumed that almost 50% of the vitamin requirement is derived from intestinal micro organisms. Animal foods contain little vitamin K.

5.2.2 Water Soluble Vitamins

Water soluble vitamins are classified into two groups viz.1) vitamins of the B group to which most of the water soluble vitamins belong and 2) vitamin C.

Vitamin B_1 (Thiamine)

Vitamin B_1 was the first of the B-vitamins discovered. A Dutch doctor, Eijkman, demonstrated in 1897 that a very common disease, beriberi, which prevailed at that time in the Dutch East Indians, was caused through feeding only polished rice. Jansen and Donath (1926) isolated vitamin B_1 in crystalline form from rice polishings. This vitamin is also called thiamine.

Chemistry and properties: Williams and co-workers established the chemical structure of thiamine in 1936. Thiamine contains a pyrimidine ring and thiazole ring. It is a white crystalline powder. Sulphur dioxide destroys the vitamin activity of thiamine. Therefore, sulphites shoud not be added as a preservative to foods rich in thiamine. Thiamine is stable to heat in acid foods but it is less stable in neutral foods. It is destroyed by alkali. During wet processing, thiamine is leached out. Baking of cereal products shows considerable loss in thiamine content.

Functions and deficiency diseases/syndromes: Thiamine functions in carbohydrate metabolism. Free thiamine is readily absorbable by small intestine. It is necessary for nerve function, appetite and normal digestion.

Mild deficiency of the vitamin leads to loss of appetite, fatigue, depression and irritability. Severe deficiency causes a disease called Beriberi. There are three types of beriberi occurring in human beings viz. wet, dry and infantile beriberi.

Wet beriberi produces three general symptoms: a) Polyneuritis (inflammation of nerves), b) Oedema (swelling), and c) Disturbances of the heart. Muscle soreness and loss of reflex of the knee take place. The body tissues swell and oedema develops and it is noticed in the legs and thigh of the patient. Breathing becomes difficult and the heart becomes weak. Death occurs due to heart failure.

Dry beriberi affects the nerves of legs and arms. Calf muscles become tender and swollen. Toes and ankles get numb. The emaciated subject needs the help of sticks to stand and walk and finally becomes bedridden.

Infantile beriberi affects infants below 6 months. Two types of infentile beriberi are known. They are a) cardiovascular type, and 2) neuritic type.

Dietary sources: Whole cereals, pulses (legumes), oilseeds and nuts are good sources of thiamine.

Vitamin B_2 (Riboflavin)

In 1926, Goldberger and co-workers showed that pellagra was cured by autoclaved yeast, which was devoid of thiamine. This factor was called vitamon B_2. However, later studies showed that the vitamin so defined was a complex of several vitamins and riboflavin was one of them. Riboflavin does not cure pellagra.

Chemistry and properties: Riboflavin has a cyclic iso alloxazine nucleus and has a side chain containing a pentose sugar (ribose).

Riboflavin is slightly soluble in water and ethyl alcohol. The solution when exposed to ultra-violet light emits a strong greenish yellow fluorescence. Riboflavin is stable in acid or neutral medium but is destroyed in alkaline medium especially on heating.

Functions and deficiency diseases/syndromes: Riboflavin is concerned in the regulatory function of insulin. The retina contains riboflavin, which is converted by light to a compound involved in stimulation of the optic nerve. It forms a part of enzyme systems involved in the metabolism of carbohydrates, fats and proteins. Flavin Adenine Dinucleotide (FAD) and Flavin Mono Nucleotide (FMN) are formed from riboflavin.

Deficiency of riboflavin in the diet causes oral and facial, scrotal, vulval, and also ocular lesions.

Dietary sources: Liver, dried yeast, egg powder, whole and skim milk powder are excellent sources of riboflavin. Milk, cheese, eggs, whole grain and green leafy vegetables are also good sources.

Niacin (Nicotinic Acid)

The discovery of niacin was also associated with yeast extract as in the case of thiamine and riboflavin. It was isolated from liver and found that it can cure 'pellagra' in man and 'black tongue' in dogs. Niacin (nicotinic acid) is also called vitamin B_3.

Chemistry and properties: Acid or alkaline solutions of nicotinic acid on heating is converted to nicotinamide. It is one of the most stable of the vitamins. It is stable to acids, bases, oxidizing agents, heat and light. However, it is destroyed by autoclaving at 120^0C for 20 minutes. It is sparingly soluble in cold water, but soluble in hot water and alcohol. Nicotinamide exists almost exclusively as a constituent of coenzymes NAD (nicotinamide adenine dinucleotide and NADP (nicotinamide adenine dinucleotide phosphate).

Functions and deficiency diseases/syndromes: Nicotinic acid is essential for the normal functioning if the skin, intestinal tract and the nervous system. Deficiency of Niacin leads to a disease known as pellagra. In pellagra disease dermatitis, glossitis and stomatitis occur. Dermatitis is appears wherever that part of the body is exposed to sunlight. The other symptoms are irritability, mental anxiety and depression, which can develop to delirium and dementia.

Dietary sources: Yeast, liver, meat, poultry, wholegrains, fresh pork are excellent sources of niacin. Good proteins like milk protein are associated with niacin because triptophan, an amino acid, present in the proteins is converted into niacin in the body. It has been estimated that 60 mg of triptophan yield 1 mg of niacin.

Vitamin B_6 (Pyridoxin)

Pyridoxine is one of the vitamins of the B group, which prevents dermatitis. It was isolated in 1938 in pure form by different groups of workers. Pyridoxine is also called vitamin B_6.

Chemistry and properties: Pyridoxine does not belong to only one class of compound. It consists of three related substances namely pyridoxine, pyridoxal and pyridoxamine.

Pyridoxine contains a pyridine nucleus, two primary alcoholic groups and one phenolic hydroxyl group. Pyridoxal contains an aldehyde group in place of one primary alcoholic group and pyridoxal amine contains a primary amine side chain in place of a primary alcohol group. Pyridoxine is readily soluble in water and alcohol. It slowly gets destroyed when exposed to sunlight. Neutral or alkaline solutions of pyridoxine are heat labile. Oxidising substances like potassium permanganate and hydrogen peroxide also destroy it.

Functions and deficiency diseases/syndromes: Pyridoxine is essential for growth of infants. Its deficiency produces degeneration of the nerves. It has also some influence on the functioning of hormones. Besides pyridoxine play important roles in amino acid and lipid metabolism. Pyridoxal phosphate acts as a coenzyme for a number of enzyme systems. It removes carbon dioxide from the acid groups of certain amino acids and transfer amine groups from one compound to another. Pyridotal phosphate helps in transamination reactions, poryphyrin synthesis etc.

Dietary sources: Pyridoxine is widely distributed in both plant and animal foods. Dried yeast, rice polishing, wheat germ and liver are excellent sources. Whole cereals, legumes, oil seeds, nuts, egg, milk, meat and fish and leafy vegetables are good sources of this vitamin.

Pantothenic Acid

Pantothenic acid is one of the B group vitamins. In 1933, Williams reported that a factor present in yeast could prevent a specific type of pellagra (chick pellagra). This factor was named pantothenic acid.

Chemistry and properties: Pantothenic acid is an unstable, viscous oil. It is soluble in water. It contains an amino acid namely alanine. It is stable to heat but destroyed by acid and alkali. It is readily absorbed from small intestines.

Functions and deficiency diseases/syndromes: Pantothenic acid has an important role in the metabolism of Co-enzyme A. Therefore, indirectly pantothenic acid has a role in the utilization of carbohydrates and fats. Deficiency diseases of the vitamin are not often observed in man. However some of the deficiency disease symptoms are headache, fatigue, weakness, sleeplessness, nausea etc.

Dietary sources: It is widely distributed in foods. Dried yeasts, liver, rice polishing, wheat germs, fleshy foods, eggs, fish etc. are good sources of pantothenic acid.

Biotin

In 1916, Bateman showed that when rats were fed with uncooked egg white, they developed the peculiar skin disease. This condition was called egg-white injury. This was due to a toxic component called avidin. Gyorgi in 1931 isolated an anti-egg white injury factor from yeasts and named it as vitamin H. Later this factor was found in egg yolk and it was called Biotin.

Chemistry and properties: Biotin is sparingly soluble in cold water and freely soluble in hot water. It is stable to heat but sensitive to acid, alkali and oxidizing agents. It forms salts with alkali hydroxides.

Functions and deficiency diseases/syndromes: Biotin is essential for the activity of many enzyme systems. It helps in maintaining the skin structure and is necessary for normal gestation and lactation in animals. It is also required for fatty acid metabolism.

Biotin deficiency does not occur in humans frequently. Experimental deficiency in animals has shown skin scaling, dermatitis, muscle pains, anorexia (lack of appetite) and slight anaemia.

Dietary sources: Biotin occurs widely in foods of both vegetable and animal origin. Peanuts, chocolates, egg yolk, liver, kidney, peas, cauliflower, dry yeast, milk products, cereals etc. are good sources. Royal jelly from honeybee is the richest source of biotin (400 μg / 100 g).

Folic Acid

Wills (1934) showed that a vitamin present in autolysed yeast extract cured tropical macrocytic anaemia in humans. Mitchell, Snell and Williams (1941) reported the presence of this factor in spinach leaves essential for the growth of L-casei (a micro organism). They called this factor folic acid (*folium* meaning leaf).

Chemistry and properties: Folic acid is also called pteroyl glutamic acid. It is widely distributed in nature. It is a yellow crystalline compound moderately soluble in hot water and stable to heat. Many bacteria produce this vitamin.

Functions and deficiency diseases/syndromes: It is essential for the maturation of Red Blood Cells (RBC). It acts as co-enzyme in the transfer of single carbon groups such as methyl or formyl. It is essential for reproduction in animals. It also helps in the hair growth and health of skin.

Folic acid deficiency causes megaloblastic anaemia, which is also called macrocytic anaemia. This mainly occurs in pregnant women. This is due to accumulation of immature RBCs in bone marrow. Inadequate supply of folic acid causes glossitis (red sore tongue), diarrhoea, and anaemia.

Dietary sources: Dried yeast, green leafy vegetables, dry beans, cabbage, soybean, yeast, kidney and liver are good sources of this vitamin.

Vitamin B_{12}

In 1926, Minot and Murphy found that feeding liver in large quantities could control pernicious anaemia. In 1929, Castle also found that beef muscle is effective in controlling pernicious anaemia. Both these factors were responsible due to Vitamin B_{12}. It is also called Cyanocobalamin.

Chemistry and properties: Cyanocobalamin has a complicated chemical structure. It contains a porphyrin nucleus and a molecule of cobalt (4-5%).

Vitamin B_{12} is a water-soluble dark red crystalline compound not stable to acids and alkali. When it is exposed to sunlight it gets partially destroyed.

Functions and deficiency diseases/syndromes: Vitamin B_{12} promotes the maturation of Red Blood Cells (RBC). It is essential for the normal function of bone marrow and the nervous system. B_{12} takes part in many enzymatic reactions. It is essential for the absorption of Calcium and Phosphorus. It aids in providing energy to the central nervous system. It also helps in the increase of white blood cells and blood platelet count.

Deficiency of the vitamin causes pernicious anaemia. Life span of RBCs also comes down. The shape and size of RBCs also change. The other symptoms are skin lesions, reduction in gastric secretion, effect on spinal cord, tingling, numbness, loss of sense of limbs, depression etc.

Dietary sources: Vitamin B_{12} is present only in foods of animal origin. Kidney and liver, egg, cheese, milk, fish etc. are good sources of the vitamin.

Vitamin C (Ascorbic Acid)

Man knew the disease scurvy since centuries. It was found that sailors on long voyage were suffering from this disease. This was due to the non-availability of fresh fruits and vegetables to sailors in their long journey. Szent-Gyorgy (1928) isolated an acid with intense reducing properties from cabbage, orange and adrenal glands. Subsequently it was named ascorbic acid due to its antiscorbutic properties.

Chemistry and properties: Haworth and co-workers established the chemical structure of ascorbic acid in 1933. It is a six carbon mono basic acid present in its lactonised form. Its reducing property is due to the presence of a di-enolic configuration.Vitamin-C is a white water soluble crystalline compound stable in acid solution but sensitive to oxidation. Ascorbic acid has strong reducing property. It loses two hydrogen and forms dehydroascorbic acid. It is sensitive to high temperature. Vitamin-C is lost during food processing, storage and cooking.

Functions and deficiency diseases/syndromes: Vitamin C is essential for the formation of collagen and osteoblasts, for carbohydrate and cholesterol metabolism, for oxidation of phenylalanine to tyrosine, for the absorption of iron, and for rapid healing of wounds. Severe deficiency of the vitamin results in the development of the disease called scurvy. The disease is characterised by general weakness, spongy bleeding gums, loose tooth swollen joints and haemorrhages in various tissues.

Dietary sources: Ascorbic acid is widely distributed in the plant kingdom. Many fruits and vegetables like amla, orange, lemon, guava, cabbage, etc. are good sources of the vitamin.

5.3 MINERALS

Proteins, carbohydrates and fats belong to organic compounds whereas minerals are inorganic in nature. When a food material is completely burnt, we are left with ash. This ash is nothing but minerals. These minerals are very essential to our body and they are included under the category called micronutrients.

The body contains about 24 minerals, all of which must be supplied by the diet. These minerals are necessary for the following different functions: 1) as constituents of bones and teeth e.g. Calcium, phosphorus and magnesium; 2) as constituents of body cells of soft tissues like muscles, liver etc. e.g. Phosphorous; 3) as soluble salts which give to the body fluids and cell contents, their composition and stability which are both essential for life, e.g., sodium, potassium, chloride, and phosphorous; 4) some minerals are required in small quantities for specific functions, e.g., iron and copper for formation of hemoglobin; iodine for formation of thyroxine; zinc a constituent of a co-enzyme; cobalt the constituent of vitamin B_{12} and some other elements are essential for the activity of various enzymes. Minerals are classified into macro-minerals and micro minerals. Macro minerals are required in higher quantities and micro minerals are required in much smaller quantities. Calcium, phosphorous, magnesium, sodium and potassium are generally classified as macro minerals while iron, iodine, fluorine, manganese, cobalt, selenium, cobalt etc are classified under micro minerals. The physiological functions and dietary sources of some minerals are given in the following table.

Physiological functions of some minerals

Sl. No.	Mineral	Functions	Sources
1.	Calcium	Essential for the formation of bones and teeth. Absorption of Vitamin B12 and contraction of heart and muscles.	Milk and milk products, green leafy vegetables, ragi, egg and fish, etc.
2.	Phosphorus	Essential for formation and growth of bones and teeth, metabolism and transport of lipids and maintenance of acid base balance.	Rice and wheat bran, cheese, milk, meat and fruits and vegetables, etc.
3.	Sodium	Essential for acid base balance, regulation of osmotic pressure in cell fluids, maintenance of blood pressure and regulation of heart beat.	Table salt, milk meat, shell fish, egg, cheese, leafy vegetables, etc.
4.	Potassium	Essential for acid base balance, conduction of nerve impulses, conversion of glucose to glycogen and growth and build-up for tissues.	Fruits, dry fruits, milk, beans, etc.
5.	Magnesium	Takes part in the activity of more than 300 enzymes, vital for the functions of nerves, bones and muscles and teeth, role in coagulation of blood.	Green vegetables. Nuts, cereals, milk, etc.
6.	Iron	Component of haemoglobin, transport and storage of oxygen, essential for cell respiration.	Cereals, sea foods, meat, egg, vegetables, etc.

7.	Iodine	Normal thyroid function, deficiency causes goiter, i.e. Swelling of the thyroid gland and decrease of thyroidal hormone production.	Drinking water, Iodized salt, marine foods, meat, milk, fruits and vegetables, cereals, etc.
8.	Fluorine	Essential for bone and teeth formation, prevents tooth decay. Deficiency causes dental caries. Excess chlorine causes dental fluorosis.	Drinking water, milk, sea foods, garlic, tea, etc.
9.	Manganese	Takes part in the activity of many enzymes, helps in the development of bones, role in the regulation of fats and carbohydrates	Cereals, pulses , oil seeds, milk, vegetables, etc.
10.	Copper	Helps in the absorption and utilization of iron, influence on the oxygen supply, formation of melanin and phospholipids, takes part in enzyme activity.	Seeds, nuts, mushrooms, etc.
11.	Zinc	Aids in carbohydrate and protein metabolism, role in production of insulin, takes part in enzyme activity.	Cheese, fish, meat, egg, oyster, cereals, etc.
12.	Chromium	Influence on carbohydrate metabolism, stabilization of blood sugar level, influence on appetite.	Poultry, meat, milk, potato, nuts, etc.
13.	Selenium	Component of various enzymes, acts as an antioxidant, has protective effect against cancer.	Soybean, meat, fish, etc.
14.	Cobalt	Component of vitamin B12, Role in carbohydrate and lipid metabolism, role in synthesis of proteins.	Animal foods especially liver

Micronutrient Fortification

As compared to the major nutrients viz. carbohydrate, protein and fat, the other essential nutrients like the vitamins and minerals are required by the human system only in minute quantities. Therefore, they are termed as 'micronutrients'. Due to lack of access to balanced foods, certain sections of the population suffers from severe micronutrient deficiency. To improve the quality of the diet, these nutrients are some times added to foods. This process is called 'micronutrient fortification'. For example, iodine is added to table salt to prevent goiter and iron is added to wheat flour to prevent anemia. Vitamin fortified foods are also not rare. During fortification, the following precautions have to be taken.

1. Only the required concentration of the nutrient should be added to foods.
2. Fortification should not affect the stability of the food product.
3. It should not affect the colour and taste of the end product.

5.4 LET US SUM UP

Vitamins are complex organic substances required by the human body for several vital and well-defined physiological functions. They are mostly derived from plant sources. Because there is no structural relationship among the different vitamins, their classification is practically not possible. However, based on their solubility characteristics they are classified into fat soluble (soluble in fat and fat solvents) and water soluble vitamins. Most of the water-soluble vitamins belong to the group of the B complex. Many of the B complex vitamins take part in various enzymatic reactions as coenzymes.

The human body also requires several minerals for its physiological functions. Many of the minerals are cofactors of enzyme systems. Deficiency of some minerals cause specific diseases like for example, deficiency of iodine causes 'goitre' and deficiency of fluorine causes 'dental caries'.

Since all the vitamins and minerals are not present in sufficient quantities in the staple diets of sections of the population, their deficiencies are common. In order to alleviate the deficiency, some foods are fortified with these nutrients.

5.5 KEY WORDS

Vitamin	:	Of vital importance
Retinol	:	Vitamin A alcohol
Provitamin A	:	Carotenes, which are converted to vitamin A in the body.
Liver necrosis	:	Liver damage due to disease.
Prothrombin	:	Substance in blood responsible for normal blood clotting.
Beriberi	:	The disease caused by the deficiency of vitamin B_1.
FAD	:	Flavin adenine dinucleotide.
FMN	:	Flavin mono nucleotide.
Pellagra	:	The disease caused by the deficiency of niacin.
Scurvy	:	The disease caused by deficiency of vitamin C.
Goitre	:	The disease caused by deficiency of iodine.
Dental caries	:	The disease caused by deficiency of fluorine.
Micro nutrients	:	Vitamins and minerals.

5.6 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - Solubility in fat and fat-soluble solvents and water.
   - Vitamin A, D, E and K

2. Your answer should include the following points:

   - Vitamin A.
   - Beta carotene gets converted to vitamin A in the human body.
   - Green leafy vegetables, yellow fruits and vegetables like mango, papaya, carrot.

3. Your answer should include the following points:

   - Quinone
   - Blood clotting

4. Your answer should include the following points:

   - Vitamin E
   - Cereal germ oils, soybean oil, cottonseed oil

Check Your Progress Exercise 2

1. Your answer should include the following points:

   - Deficiency of vitamin B_1

2. Your answer should include the following points:

   - Nicotinic acid, nicotinamide
   - Pellagra

3. Your answer should include the following points:

   - RBC
   - Pernicious anaemia
   - Absorption of Ca, P
   - Animal foods eg. liver

4. Your answer should include the following points:

   - Six carbon monobasic acid
   - Di-enol
   - Citrus fruits, amla, guava

Check Your Progress Exercise 3

1. Your answer should include the following points:

   - Ca, P
   - Milk, ragi, leafy vegetables, rice and wheat bran, fish

2. Your answer should include the following points:

   - Goitre
   - Dental caries

3. Your answer should include the following points:

   - Haemoglobin
   - Anaemia
   - Oxygen transport
   - Vitamin B_{12}
   - Carbohydrate and lipid metabolism

5.7 SOME USEFUL BOOKS

1. Braverman, J.B.S. (1963) Introduction to the Biochemistry of foods, Elsevier Publishing Company, Amsterdam, London, New York.

2. Meyer, L.H. (1969) Food Chemistry, Van Nostrand Reinhold Company, New York, Cincinnati, Toronto, London, Melbourne.

3. Owen, R. Fennema, (1976) Principles of food science, Part I- Food Chemistry, Marcel Decker Inc.; New York.

4. Swaminathan, M. (1999) Essentials of Food and Nutrition, Vol. I, The Bangalore Printing and Publishing Co. Ltd., Bangalore.

UNIT 6 FOOD ADDITIVES

Structure

6.0 OBJECTIVES

After reading this unit, you should be able to answer:

- the definition of food additives;
- different types of food additives;
- their chemical properties and functions in foods; and
- their legal status for the purpose of adding to foods.

6.1 INTRODUCTION

Food additives have been used for centuries to enhance the quality of food products. Smoke, alcohol, vinegar, and spices were used more than 10,000 years ago to preserve foods. Along with the developments in Food Chemistry and Food preservation in the early 1900s, the use of food additives increased significantly. The demand for new, tasty, convenient, and nutritious foods continued to increase. As a result, by the early 1960s, over 2500 different chemicals were being used in foods in many developed countries.

Different people used to understand food additive in different ways. The widely accepted definition of food additive is:

> "a substance or mixture of substances, other than a basic foodstuff, which is present in a food as a result of any aspect of production, processing, storage, or packaging. The term does not include chance contaminants".

Food additives are substances intentionally added for specific functions. The number of additives being used in food today is very large. However, they can be classified into a few types based on their functional properties. They may include: 1) preservatives, 2) antioxidants, 3) acidulants, neutralizers and buffers, 4) colouring agents, 5) flavouring agents, 6) sweeteners 7) nutritional additives, and 8) miscellaneous additives.

The use of food additives is well-accepted practice but not without controversy. There have been a number of concerns regarding the potential short-term and long-term risks of consuming these substances. Based on the available scientific information on the toxicological status of each additive and the likely quantity of that additive consumed through a particular food, the maximum permissible limits (Acceptable Daily Intake, ADI) of additives have been stipulated. As you will be learning in subsequent units, each country has laid down its own food legislation and The Prevention of Food Adulteration Act (PFA) and Rules, 1954, in India lists the additives permitted in different foods and their maximum permissible limits. You will also be learning that our food standards are in the process of harmonisation with international food standards. Therefore, it is likely that the present list of permitted additives under PFA may increase in the near future. Keeping these points in mind, in this unit some important and versatile food additives are included even though some of them may not be permitted under PFA at present. The nutritional additives viz. vitamins and minerals have already been dealt with in the previous unit; they will not be included in this unit.

6.2 PRESERVATIVES

From prehistoric times humans have attempted to preserve food products from the deteriorative effects of microorganisms. Some chemical food preservatives like salt, nitrites and sulphites have been in use for many years. Even though newer packaging techniques, processing and storage methods are able to preserve foods without chemical preservatives, even today these chemicals play a significant role in protecting the food supply mainly because preservation using chemical preservatives is cheaper and more convenient.

Under PFA, 1954, preservatives are classified into Class I and Class II preservatives. Class I preservatives are also called natural preservatives. They are, common salt, sugar, dextrose (glucose), spices, vinegar or acetic acid, honey, and vegetable oils. There is no restriction to the addition of Class I preservatives to any food.

Class II preservatives are, Benzoic acid and its salts, sulphurous acids and its salts, nitrates or nitrites, sorbic acid and its sodium, potassium and calcium salts, calcium or sodium propionates, lactic acid, sodium or calcium propionate, methyl or propyl parahydroxy benzoic acid, sodium diacetate and sodium potassium and calcium lactate.

Among the above preservatives, benzoates and sulphites are most widely used for preservation of fruit and vegetable products. Sorbates have been permitted for some products lately. Therefore, these and a few natural preservatives will be dealt with in this unit.

6.2.1 Class I Preservatives

1) *Salt (sodium chloride):* Salt has been used as a preservative since the beginning of recorded history. Pickling of fruits and vegetables and salting of fish and meat are widely practiced. The anti- microbial activity of sodium chloride is essentially related to its ability to reduce water activity (a_w) and create unfavourable conditions for microbial growth. As the water activity of the external medium is reduced, microbial cells are subjected to osmotic shock and rapidly lose water through plasmolysis. These results in the cells ceasing to grow and either die or remain dormant. Aside from the osmotic influence on microbial growth, other possible mechanisms include limiting oxygen solubility in the medium and toxicity of chloride ions.

   Sodium chloride-intolerant bacteria are inhibited by concentrations as low as 1%. Some bacteria like the lactic acid bacteria used in producing lactic fermented vegetables (you have learned in the units under 'Food fermentations') can tolerate from 6–15 % sodium chloride. In general, food borne pathogenic bacteria are inhibited by a water activity of 0.92 or less which is equivalent to sodium chloride concentration of 13%. That is why for salt curing, sodium chloride concentration of about 13% is commonly used.

   The inhibitory effect of sodium chloride is dependent on several factors particularly pH. As acidity increases, less sodium chloride is required to inhibit microbial growth.

2) *Acetic acid:* Synthetic vinegar (dilute acetic acid) and brewed vinegar are widely used as acidulants and antimicrobials. Vinegar pickles are common in our country.

   Acetic acid is more effective against yeasts and bacteria than moulds. Only acetic, lactic and butyric bacteria are markedly tolerant to acetic acid. As is the case with most other preservatives, acetic acid is also more effective at lower pH. Generally, 1-2 % acetic acid is sufficient to inhibit most of the organisms.

3) *Sugar and spices:* They also have preservative effects in many food products. The main function of sugar is to reduce the water activity of the medium thus inhibiting the growth of microorganisms. Many chemical substances in spices (terpenes) have been shown to have antimicrobial properties.

6.2.2 Class II Preservatives

As mentioned above, there are a number of chemicals having preservative action. However, only a few of them are permitted for use in foods. So, what are the factors to be considered in selecting a preservative for a food?

How to select a preservative?

Firstly the effectiveness of the preservative against different types of spoilage organisms must be known. This along with the knowledge of the common spoilage organisms associated with the product will allow the selection of the correct preservative for the product. Secondly, the physico-chemical properties of both the preservative and the product should be known. The ionisation and solubility characteristics of the preservative in the product as well as the pH of the product are important factors. Finally, the safety and legality of the preservative chosen must be known.

Benzoic acid and benzoates: Benzoic acid is found naturally in cranberries, plums, prunes, cinnamon, cloves and most berries. It is a strong antimycotic agent. Most yeasts and moulds can be controlled using 0.05–0.1% benzoic acid. Control of many bacteria requires much higher concentration. Benzoic acid is sparingly soluble in water (0.27% at 18^{o}C). As sodium benzoate has higher solubility (66% at 15^{o}C), it is mostly used for preservation. Benzoates are most effective at low pH (pH 2.5–4.0) because the undissociated form is the effective antimicrobial agent.

Benzoic acid is permitted in several products like squashes, syrups, crushes, fruit juices, jams, jellies, marmalade, beverages, pickles and tomato products. You will be learning its maximum permissible limits in these products in the course on different products. Benzoic acid and its sodium and potassium salts have been generally recognised as safe (GRAS).

Sulphur dioxide and sulphites: Sulphur dioxide and its various salts have a long history of use dating back to the times of the ancient Greeks. They have been used extensively as antimicrobials and to prevent enzymatic and nonenzymatic browning in a variety of food products.

Sulphur dioxide is a colourless, non-flammable gas with a suffocating odour. It dissolves readily in water to produce sulphurous acid (H_2SO_3). Sulphur dioxide and its salts (bisulphites and metabisulphites) exist in a pH – dependent equilibrium in solution.

As the pH decreases, the proportion of the undissociated H_2SO_3 increases. As in the case of benzoic acid, the undissociated sulphurous acid has more antimicrobial activity than the dissociated ions.

Sulphurous acid inhibits yeasts, moulds and bacteria. However, yeasts and moulds are less sensitive than bacteria. That is the reason why sulphur dioxide is used at low concentrations (about 100 ppm) during grape juice fermentation to control the growth of other microorganisms and facilitate growth of yeast. Sulphur dioxide and sulphites are permitted under PFA for a number of products like fruit pulps, squashes, syrups, crushes, cordials, wines, RTS beverages, and dehydrated fruits and vegetables. Sulphur dioxide is also used as an antibrowning agent. Fruits are exposed to fumes of burning sulphur before drying to prevent browning and also insect and microbial attack. Sulphite solutions are also used as dip solution for vegetables before drying or dehydration.

Sulphur dioxide and several sulphites have GRAS status. However, sulphites cannot be used in meats and in foods that are sources of the vitamin thiamine. As sulphites have strong bleaching action on plant pigments like anthocyanins, they should not be used for preserving such products. It has been found that sulphites show allergic responses in certain individuals, such as steroiddependent asthmatics. This has led to ban of use of sulphites on raw fruits and vegetables in many countries.

Sorbic acid and sorbates: Sorbic acid and its sodium, potassium and calcium salts are collectively known as sorbates. Sorbic acid is present in some berries like berries of the mountain ash berry (rowanberry). It is a trans-trans, unsaturated monocarboxylic fatty acid.

The acid is a white crystalline powder and is slightly soluble in water (0.16% at 20°C). The potassium salt, which is highly soluble in water (58.2% at 20°C), is mostly used as the preservative. However for preservation of oils like corn oil, the acid is used because the salt is practically insoluble.

In the case of sorbic acid also, the undissociated acid has the highest antimicrobial activity. Therefore, sorbic acid is also more effective at low pH. However the dissociated acid also shows microbial action, though of a lower order. At pH above 6, the dissociated acid is responsible for more than 50% of the inhibition observed. This is the reason why sorbates are preferred for products like chapatti and cheese.

Sorbates inhibit most of the species of yeasts and moulds. Several species of bacteria are also inhibited by sorbates. At present under PFA, sorbates are permitted for only a few fruit and vegetable products. They include jams, jellies, marmalades, glazed or candied fruits, fruit bars, fruit juice concentrates and prunes. Some of the other products include cheese, flour confectionary, smoked fish, preserved chapatties and fat spreads. Sorbic acid and potassium sorbate have GRAS status.

Nitrites: Nitrites have been used in meat curing for many centuries. For meat curing, nitrite is used along with a mixture of salt, sugar, spices, and ascorbate. Nitrite contributes to the development of the characteristic colour, flavour, and texture improvement and preservative effects.

Nitrites are white or pale yellow hygroscopic crystals. Sodium nitrite is quite soluble in water. Nitrite has a strong inhibitory action against *Clostridium botulinum* and several other microorganisms. It is more effective below neutral pH (below 7.0). Along with salt, nitrite exhibits stronger antimicrobial action.

Biologically derived antimicrobials

Antimicrobial substances (antibiotics) produced by microorganisms have been known for many years. However, some of these substances are allowed for food use only in recent years. Nisin, and natamycin have been permitted in some foods.

Nisin is a polypeptide produced by *Steptrococcus lactis* (now called *lactococcus lactis*). The solubility of the compound depends on the pH of the medium. It is more soluble in acidic pH and almost insoluble in neutral pH.

Nisin has a narrow spectrum affecting only gram-positive bacteria, including lactic acid bacteria, streptococci, bacilli, and clostridia. It generally does not inhibit gram-negative bacteria, yeasts or moulds. The antimicrobial action of nisin is pH dependent, increases as the pH decreases. It is effective at very low concentrations of the order of 0.04–2.0 ppm. Nisin has been permitted in packaged coconut water and canned rasagolla under PFA.

Natamycin: It is produced by the bacterium *Streptomyces natalensis*. The compound has a large lactone ring which is substituted with one or more sugar residues. Natamycin is primarily effective against yeast and moulds and is ineffective against bacteria, viruses and actinomyces. Natamycin is also effective at very low concentrations of the order of 5-10 ppm. Natamycin has been permitted for surface treatment of hard cheese.

6.3 ANTIOXIDANTS

Antioxidants play important role in preserving fats, oils and fatty foods. You have already learnt the chemistry of oils and fats. They are essentially fatty acid esters of glycerine. The fatty acids can be either saturated or unsaturated. The unsaturated fatty acids in fats and oils can undergo oxidation during storage leading to rancidity development. Along with rancidity development, vitamin destruction, discolouration and even toxic effects are possible.

Lipid oxidation is often referred to as an autocatalytic reaction. It is a complex reaction, which once initiated will become a chain reaction. Food antioxidants are substances that are able to inhibit or interfere with the autoxidation reaction fundamental to glyceride oxidation. In simple terms, they get oxidised in preference to the fats and oils.

You have already learnt that tocopherols present in many vegetable oils have antioxidant property. Similarly, ascorbic acid and lecithin have antioxidant properties. However, the major antioxidants commercially used in foods, fats and oils are phenolic compounds and are generally referred to as phenolic antioxidants. Certain metals like iron and copper present in foods are strong catalysts of fat oxidation and may react with antioxidants to cause discolouration. Food acids like citric acid have the ability to bind these metals. Therefore, the antioxidants are usually added along with citric acid.

The most widely used phenolic antioxidants for fats and oils are i) butylated hydroxy anisole (BHA), ii) butylated hydroxy toluene (BHT), iii) propyl gallate and iv) tert-butyl hydroquinone (TBHQ).

Butylated hydroxy anisole (BHA): BHA is a white, waxy solid that is usually tableted to minimize caking during storage. It is readily soluble in glycerides and organic solvents and insoluble in water and has a distinct phenolic odour. BHA is quite stable during normal processing and storage of fatty foods. Therefore, it is considered to have good carry-through effect. However, being volatile at high temperatures, BHA may be lost partially during deep fat frying.

Butylated hydroxy toluene (BHT): BHT is a white, crystalline solid. It is also soluble in glycerides, and insoluble in water. It has a fair degree of carry-through effect but partially lost by volatilisation at high temperatures. BHT is less effective as an antioxidant than BHA.

Propyl gallate: Propyl gallate is the n-propyl ester of 3,4,5- trihydroxy benzoic acid or gallic acid. It is a white to light grey powder. It has low oil solubility and significant water solubility. Though it has very good antioxidative properties, due to its heat-labile nature; it has very little carry-through properties especially under alkaline conditions encountered in baked foods. Therefore, propyl gallate is used in combination with other antioxidants like BHA thus providing the combined effects of improved storage stability and carry-through protection.

tert-Butyl hydroquinone (TBHQ): TBHQ is a white to light tan crystalline solid noted for its effectiveness in increasing the storage stability of fats and oils. It is moderately soluble in fats and oils, and only slightly soluble in water. Unlike the other phenolic antioxidants, it does not form coloured compounds with metal ions in foods like iron, which is an advantage. TBHQ provides good carry-through protection to fried foods.

Applications of phenolic antioxidants

As mentioned earlier, among the food additives, perhaps the antioxidants are the most widely used. They are used in vegetable oils, meat products, confections and chewing gums, cereal products like breakfast cereals, bakery products etc. Use of the antioxidants in fruit and vegetable products though limited, is of considerable commercial importance. Some of them include fruit nuts like walnut, almonds, cashew nuts; citrus oils, dehydrated potato products like powder, flakes and granules.

Under PFA, all the above phenolic antioxidants **except BHT** have been permitted with restrictions. Additionally, lecithin and ascorbil palmitate are also permitted for specific food products.

6.4 ACIDULANTS

Acidulants contribute a variety of functional properties that lead to the enhancement of food quality. Most of the acidulants used in food are organic acids. The organic acids and their salts commonly used in foods are acetic, ascorbic, citric, lactic, malic and tartaric acids. Inorganic acids like phosphoric acid is also used extensively in cola type beverages. Organic acids like citric, malic and tartaric acids are widely distributed in pants. Ascorbic acid, which is vitamin C, is also of plant origin. Lactic acid as the name implies is derived from milk. Since some aspects of acetic and ascorbic acids were already covered elsewhere, they are not specifically discussed here.

Citric acid is perhaps the most widely used organic acid. It is a tricarboxylic acid abundantly present in citrus and many other fruits. Even though it used to be produced from citrus fruits, at present most of the commercial citric acid is manufactured by fermentation. Citric acid is a white crystalline powder, easily soluble in water. Commercial citric acid is available as the monohydrate. It is hygroscopic in nature. Therefore, citric acid is not very suitable for use in dry food formulations.

Malic acid is 2-hydroxybutanoic acid, which is a dicarboxylic acid. It is the major acid in apples and mango. It is a crystalline white powder, easily soluble in water. Synthetic malic acid is available commercially. Since it is not hygroscopic, malic acid is preferred for use in dry food formulations.

Tartaric acid is also a dicarboxylic acid. It is the predominant acid in grapes and tamarind. It is also a white crystalline solid, soluble in water. It is usually extracted from the argol sediment formed during fermentation of grapes. Tartaric acid finds application in baking powder and effervescent 'health salts'.

General functions of acidulants

The proper selection of an acid is dependent on which property or combination of properties of the acid is desired as well as its cost. Some of the general functions are given below.

- *Flavouring agents:* They intensify certain tastes and flavours, mask undesirable tastes
- *Buffering action:* The salts of organic acids, especially the sodium salts control the pH of food during various stages of processing as well as of the finished products.
- *Preservation:* By reducing pH, prevent growth of microorganisms and the germination of spores, which lead to spoilage and food poisoning.

- *Sequestering:* Bind metal ions and enhance the function of antioxidants.
- *Viscosity modifiers:* Like in dough, consequently modifying the shape and texture of baked foods.
- *Meat curing agent:* Together with other curing components, enhance colour, flavour and preservative action.

Most of the food acidulants are permitted under PFA with certain restrictions.

6.5 COLOURING AGENTS

Food colouring agents (colourants) may often be considered simply of cosmetic in nature, but the role they play is actually very important. You will be learning more about this quality attribute of food in a subsequent unit.

The addition of colourants to foods in order to make them more attractive is not a new invention. Extracts of spices and vegetables were used for the purpose as early as 1500 B.C. The advent of the use of food colourants in the late 1800s and early 1900s was unfortunately accompanied by their misuse in food adulteration, frequently to disguise food of poor quality. Some of these deceptive practices included colouring of pickles with copper sulphate; cheese with vermillion and red lead; tea with copper arsenite, lead chromate and indigo; and candy and turmeric with lead chromate, red and white lead and vermillion.

Development of synthetic dyes became a boon to the food industry because these colourants were superior to natural extracts in tinctorial strength (colour intensity), number of shades, stability, and easy availability and was cheap. However, safety is the most important aspect of synthetic food colours. Extensive toxicological studies have been carried out on these colourants in different countries. While many of the colourants have been found to be harmful, a few others appeared to be safe for use depending on various factors like the quantity of the colourant consumed. Besides, the test methods followed in different countries varied, which have resulted in much scientific and political debate. Consequently, colourants considered safe in one country may not be considered safe in another country. The toxicological studies are revealing newer information and hence the regulatory status of the colourants used in countries throughout the world is in a state of flux. One common observation is that the number of permitted synthetic colourants is decreasing year by year.

The regulatory status of several natural colourants is less severe mainly because they are mostly extracted from edible plant sources. Another class of colourants are called **nature-identical** colourants. They are those identical counterparts of naturally occurring pigments. Some examples of nature-identical colourants are β -carotene, canthaxanthine, and β -apo-8'-carotenal. Their regulatory status is similar to natural colourants.

Under PFA, the following natural and synthetic colours are permitted at present with restrictions on their maximum levels and the specific food products.

Natural colouring matters

1. Beta carotene
2. Beta – apo -8’-carotenal
3. Methyl ester of beta – apo - 8’- carotenoic acid
4. Ethyl ester of beta – apo - 8’- carotenoic acid
5. Canthaxanthin
6. Chlorophyll
7. Riboflavin (lactoflavin)
8. Caramel
9. Annato
10. Saffron
11. Curcumin (or turmeric)

Synthetic food colours

Sl.No.	Common Name	Shade	Chemical class
1.	Ponceau 4R	Red	Azo
2.	Carmoisine	Red	Azo
3.	Erythrosine	Red	Xanthene
4.	Tartrazine	Yellow	Pyrazolone
5.	Sunset yellow FCF	Yellow	Azo
6.	Indigo carmine	Blue	Indigoid
7.	Brilliant blue FCF	Blue	Triaryl methane
8.	Fast green FCF	Green	Triaryl methane

6.5.1 Natural Food Colourants

Anthocyanins: Anthocyanins are the intense red and blue water-soluble pigments occurring in many fruits, vegetables and flowers like strawberries, cranberries, raspberries, blueberries, grapes (blue), Jamun, and some flowers. Anthocyanins are composed of an aglicone (anthocyanidin) esterified to one or more sugars and may be acylated. The sugars may be glucose, rhamnose, galctose, xylose and arbinose. Grape skin and elderberries are good commercial sources of anthocyanin pigments.

The anthocyanin double ring benzopyran structure is very reactive. The compounds are easily ionised and tend to become colourless above pH 4.5. They exibit their most intense colours below pH 3.5. Therefore, these colourants are only suited for acidic foods. Anthocyanins easily undergo discolouration in the presence of amino acids, phenolic sugar derivatives etc. They are also bleached by ascorbic acid and sulphites.

Carotenoids: Carotenoids are responsible for the yellow, orange and red pigments in a number of plants and animal foods. Carotenoids are classified into three groups. i) Carotenes – These are hydrocarbons containing β-ionone rings and possess vitamin-A activity. Ex. β-Carotene present in carrots, chillies, soybean. ii) Lycopenes – These are carotenoids not having β-ionone rings and do not possess vitamin-A activity. Lycopene is present in tomato, apricot, watermelon, and red guavas. iii) Xantohphylls – These are oxygenated derivatives of carotene. These have β-ionone rings, but do not possess vitamin-

A activity. They are present in papaya, orange peel, and yellow maize. iv) α-Carotene – This is similar to β-carotene in its biological activity.

Chemically carotenoids are poly –enes composed of isoprene units. They are fat soluble and fairly heat stable. During processing of fruits and vegetables, partial loss of carotene takes place. They are stable at pH 2–7. As a result of their chemical structure, which contains conjugated double bonds, carotenoids are very sensitive to oxidation. Ascorbic acid can protect β -carotene by serving as an antioxidant. "Nature-identical" synthetic β -carotene is marketed in forms that confer protection from oxidation.

Betalains: Betalains are found in plants such as red beets, amaranthus flowers, bougainvillea, cactus fruits etc. Betalain colours range from red to yellow. The red beet is the most common commercial source of these pigments. Betalains are sensitive to pH, light and heat. These compounds are most stable at pH 4 – 5. Because of the carbohydrates present in betalains, the colourants tend to impart beet flavour to the food.

Production of colourants like anthocyanins and betalains by tissue culture technique offers the advantage of a more reliable supply of the colours independent of plant variability and elimination of the strong undesirable plant flavours.

Chlorophylls: Chlorophylls, the most abundant naturally occurring plant pigments, are the green and olive green pigments in green plants. Chlorophylls are obtained from a wide variety of sources and they are mixture of 2 compounds namely chlorophyll a and chlorophyll b present in the ratio of 3a: 1b in plants. They belong to a group of important biological pigments called porphyrins, which include haemoglobin, and is composed of four pyrole rings held together. Magnesium is located in the centre of the molecule.

Chlorophylls are soluble in alcohol, diethyl ether, benzene, acetone etc. but insoluble in water. Some metal ions like iron, zinc and copper react with chlorophyll and the green colour becomes brighter. In alkaline pH, the colour of chlorophyll is better retained. Chlorophylls are heat sensitive and during processing of fruits and vegetables containing chlorophyll, the green colour is lost and turns brown. When vegetables containing chlorophyll is cooked, the central Mg atom is replaced by hydrogen atom and loses it's colour forming pheophytin. Chlorophylls may be stabilized by replacement of the magnesium ion in the compound with copper.

Curcumin is the main colourant (yellow) in the oleoresin obtained from turmeric (*Curcuma longa*). Curcumin is fat-soluble, has good tinctoriasl strength, but exhibit slight sensitivity to light, air and pH.

Paprika oleoresin, which is orange red to deep red, is the extract of mild capsicum (*Capcicum annum*). Like curcumin, paprica oleoresin is also water insoluble. Paprika and turmeric oleoresins are available in various standardized forms.

Saffron is generally stable toward light, oxidation and pH and has a high tinctorial strength.

6.5.2 Synthetic Colourants

Synthetic colourants, also known as coal tar dyes or aniline dyes were earlier manufactured from coal tar derivatives. Although the colourants were highly purified before they were added to foods, the negative connotation of their association with coal tar resulted in much unfavourable publicity. As a result, synthetic colourants are no longer manufactured from coal tar derivatives but instead are developed from highly purified petrochemicals.

As can be seen from the table above, the permitted synthetic colorants belong to five chemical classes viz. azo, xanthene, pyrazole, indigoid and triarylmethane. You may notice that all together there are three red, two yellow, two blue and one green colour permitted under PFA. All these colours are water-soluble. As mentioned earlier, these colours are more resistant to chemical reaction, pH and heat compared to natural colourants.

6.6 FLAVOURING AGENTS

Flavour like colour of foods has a great bearing on acceptance of foods and therefore, has enormous commercial importance. It apparently has no nutritional value although some studies have indicated that taste can alter intestinal absorption of glucose and fat metabolism. Flavour is defined in several ways. One definition is: "**sensation produced by a material taken in the mouth, perceived principally by the senses of taste and smell, and also by general pain, tactile and temperature receptors in the mouth".**

Food flavours is a very vast subject. You will be learning sensory perception and analysis of flavour in a subsequent unit. In this section you will learn some essential aspects of the chemistry and application of food flavourings.

During the early days, people used spices to enhance or modify the flavour of foods. Along with the developments in synthetic chemistry and analytical techniques like gas chromatography and mass spectrometry, there was a spurt in synthetic flavour compounds and identification of the flavour compounds in various foods and processed products. The role of sensory analytical techniques in flavour research is very significant. One major finding was that most of the food flavours were due to a combination of a number of chemical compounds and only in a few cases, one single compound was responsible for the characteristic flavour of a food. Few examples are menthol in peppermint, benzaldehyde in bitter almond, citral in lime peel, amyl acetate in ripe banana, cinnamaldehyde in cinnamon etc. Therefore, it became apparent that creation of a food flavour is not an easy task. However, with a combination of art and scientific know-how, today a large number of flavour formulations are available. It is an extremely large industry. Food flavourings are classified into three groups.

1. *Natural flavours and natural flavouring substances:* They are flavour preparations and single substances respectively acceptable for human consumption, obtained exclusively by physical means from vegetable, sometimes animal raw materials, either in their natural state or processed, for human consumption.

2. *Nature-identical flavouring substances:* They are substances chemically isolated from aromatic raw materials or obtained synthetically, they are chemically identical to substances present in natural products intented for human consumption, either processed or not.

3. *Artificial flavouring substances:* They are those substances, which have not been identified, in natural products intended for human consumption either processed or not.

The natural flavours include spice oleoresins and oils, essential oils like citrus oils; fruit aroma concentrates like apple aroma concentrate etc. As indicated earlier, the number of synthetic flavour substances is extremely large. Therefore, instead of listing the permitted flavouring substances, only those, which are not permitted, are specified under PFA. In this connection it is important to note that the concentrations of the flavour chemicals in natural or synthetic flavours to impart the desired flavour perception are extremely low, of the order of parts per million or parts per billion. As they have self-limiting property, maximum permissible limits are not stipulated.

6.7 SWEETENERS

Sweetness is one of the important taste sensations. The importance of sweetness is reflected in huge production of sugar (sucrose) world over. Sucrose is not consumed only for its sweetness. It also has many functional properties in foods like a bulking agent, texture modifier, and preservative.

Like any other carbohydrate, sucrose is also a nutrient providing energy to the human system. Over the years, sucrose has been implicated in obesity development and associated diseases and also dental caries. Besides, diabetes has become a common disease among large sections of the population. As a result there is a general trend towards reducing energy intake. This has resulted in development of sucrose alternatives.

There are two types of sucrose alternatives viz. nutritive and non-nutritive sweeteners. Nutritive sweeteners also called calorie sweeteners are usually carbohydrates or carbohydrate derivatives. Non-nutritive sweeteners include a range of natural products and some synthetic chemicals.

6.7.1 Nutritive Sweeteners

You have already learnt about glucose, glucose syrup, fructose and high fructose syrup and their relative sweetness in an earlier unit. In this section you will be learning about a few other nutritive sweeteners.

Sorbitol: Sorbitol is a six carbon sugar alcohol that was originally found in the berries of mountain ash. It is chemically produced from glucose for commercial use. It is highly soluble in water (72% at 25^{o}C). Sorbitol has half the sweetness of sucrose.

As it has a much lower caloric content compared to sucrose, sorbitol is used as a sweetener for diabetic foods, sugar-free candies and chewing gums.

Xylitol: Xylitol (xylit) is a pentiol found in most fruits and berries as well as xylan (a polysaccharide) containing plant materials. It is also produced by microbiological methods. Xylitol is a crystalline substance, having good water solubility (64 % at 25^{o}C). It has sweetness and caloric content equal to sucrose. However, because xylitol is absorbed slowly, it does not cause increase in blood glucose level as glucose or sucrose. Therefore, it is used in diabetic foods also.

Isomalt: Isomalt is also called hydrogenated isomaltulose. It is an equimolar mixture of 6-0-β-D-glucopyranosyl-Dglusitol and 1-0-β-D-glucopyranosyl-D-mannitol. Isomalt is produced by the enzymatic transglucosidation of sucrose to isomaltulose and hydrogenation. It is of about half the sweetness of sucrose. It is stable in acid and alkaline media under conditions normally occurring in food processing. It has no impact on blood sugar. Isomalt is used as a sugar substitute in confectionaries, chewing gum, soft drinks and desserts.

6.7.2 Non-Nutritive Sweeteners

Saccharin: Saccharin was synthesised way back in 1879. During the two world wars, the use of saccharin as a sweetener increased due to the scarcity of sugar and became an accepted sweetener for special dietary and dietetic foods even though its safety has repeatedly been questioned.

Saccharin is a general name used for saccharin, sodium saccharin and calcium saccharin. Chemically saccharin is 1,2-benzisothiazol-3 (2H)-one-1, 1-dioxide. Saccharin and sodium saccharin are white crystalline powders soluble in water. They are about 500 times sweeter than sucrose. It has good stability during cooking and baking of food products but leaves a slight bitter metallic aftertaste. It is permitted as a sweetener in several countries including India with restrictions.

Available toxicological information does not conclusively implicate saccharin for any serious health hazard. The Acceptable Daily Intake (ADI by WHO) of saccharin is fixed at 2.5 mg/Kg body weight. However, as more and more research results accumulate, safer alternates for saccharin is bound to emerge.

Cyclamates: Although sodium cyclamate was synthesized in 1937, its actual use as a sweetener started only in 1950. Cyclamates is a group name used for cyclamic acid, sodium cyclamate and calcium cyclamate. They are synthesized from cyclohexylamine by sulphonation. They are not found in nature. Cyclamates are stable at high temperatures, are easily soluble in water. They are about 30 times sweeter than sucrose and can be used as a noncalorie sweetener in a variety of products. Some times it is used as a mixture along with saccharin.

Cyclamates are not without safety questions. Therefore its usage is only allowed with restrictions like most other non-nutritive sweeteners. The use of cyclamates is not permitted under PFA. Its ADI value is 11 mg/Kg body weight.

Aspartame: Aspartame was discovered only in 1960. It is the methyl ester of L-aspartyl-L-phenylalanine. Aspartame is produced from the amino acids phenylalanine and aspartic acid. It is an odourless white crystalline powder, slightly soluble in water and almost 150-200 times sweeter than sucrose.

Aspartame provides 4 Kcal/g energy. Aspsrtame provides sugar like sweetness in foods, but under certain moisture, temperature and pH conditions, it is hydrolysed and loses its sweetness. Therefore, aspartame is more suitable for dry products or as a table top sweetener although it is widely used in soft drinks, dairy products etc. Soft drinks are usually sweetened with a mixture of saccharin and aspartame.

Available evidence suggests that normal consumption of aspartame is safe because consumption of asprtame from foods is far below any suspected toxic levels. Its ADI value is fixed at 40-mg/Kg body weight. The use of asprtame is permitted in many countries including India.

Acesulfame K: Acesulfame K is one of the most recently introduced (1967) non-nutritive sweeteners. Acesulfame K is the potassium salt of 6-methyl-

1,2,3-oxathizine-4(3)-one-2,2-dioxide. It is a white crystalline powder, freely soluble in water, non hygroscopic and 150-200 times sweeter than sucrose. Acesulfame K is used in soft drinks, chewing gum and as a table-top sweetener. More food applications are being investigated.

The available toxicological data on acesulfame K do not show any serious safety implications. The ADI value is fixed at 9-mg/Kg body weight. Its use as a sweetener is permitted in some countries including India with restrictions.

6.8 MISCELLANEOUS ADDITIVES

The number of substances in this category though very large, is not used extensively in fruit and vegetable products. Therefore, only a few of them will be dealt with in this section. They include emulsifiers and stabilizers, firming agents, anticaking agents, clarifying agents etc.

Emulsifying and stabilizing agents are essentially used for emulsifying and stabilizing dispersions of oils and fats in aqueous media. They include different types of gums (you have learnt under 'carbohydrates'), esters of fatty acids, lecithin, ester gums (glycerol esters of wood rosin) etc.

Firming agents like calcium chloride are used to firm the texture of canned fruits and aluminium sulphate added to pickles.

Anticaking agents are used to impart free flowing properties to dry products. Examples are silicates in potato flakes, dehydrated vegetable powders, cocoa powders, salt; tricalcium phosphate in spices, and fruit powders; and starches in icing sugar etc.

Clarifying agents are used to clarify fruit juices and wines and chill proofing of beer. Gelatin is a typical example of a clarifying agent.

6.9 LET US SUM UP

A large number of additives are used in foods for different functions. Some are used as preservatives, which prevent microbial spoilage while antioxidants preserve food against oxidative deterioration. Acidulants have dual roles of preservation as well as imparting the desired taste. Colourants and flavouring agents are added essentially to enhance the acceptability of foods. There are also other additives having functions like texture modification, clarification, imparting free flowing characteristics to food powders etc.

All the food additives are not free from suspected health hazards. Therefore, their use in foods is restricted by food legislations.

6.10 KEY WORDS

Additive : Substance added intentionally

Class I preservatives : Natural preservatives

Class II preservatives : Chemical preservatives

Antioxidant : Substance, which prevents oxidation

Nutritive sweeteners : Sweeteners having calorific value.

6.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - Other than basic foodstuff
   - Added, not chance contaminant

2. Your answer should include the following points:

   - Class I and class II preservatives
   - Salt, sugar, spices, vinegar etc.

3. Your answer should include the following points:

   - Benzoates, sulphites, sorbates etc
   - Antimicrobial, anti browning

Check Your Progress Exercise 2

1. Your answer should include the following points:

   - Inhibit autoxidation of glycerides
   - Get oxidised in preference to fats and oils

2. Your answer should include the following points:

   - Tocopherols, ascorbic acids
   - BHA, BHT, TBHQ

3. Your answer should include the following points:

   - PH reduction
   - Buffering
   - Flavouring

4. Your answer should include the following points:

   - Ponceau
   - Carmoisine
   - Erythrosine
   - Sunset yellow etc

Check Your Progress Exercise 3

1. Your answer should include the following points:

   - Natural flavouring substances isolated by physical means
   - Chemically identical to natural substances but chemically isolated from aromatic substances or synthetically prepared

2. Your answer should include the following points:

   - Calorie sweeteners
   - Sucrose, glucose, fructose etc
   - Non calorie sweeteners
   - Synthetic
   - Saccharin, cyclamate, aspartame, acesulfame K

3. Your answer should include the following points:

   - Calcium chloride
   - Tri calcium phosphate
   - Gelatine

6.12 SOME USEFUL BOOKS

1. Larry Branen, A., Michael Davidson, P., and Seppo Salminen (1990) (Eds.) Food Additives, Marcel Dekker, Inc., New York and Basel.

2. Owen R. Fennema (1976) Principles of food science, Part I- Food Chemistry, Marcel Decker Inc.; New York.

3. Meyer L.H. (1969) Food Chemistry, Van Nostrand Reinhold Company, New York, Cincinnati, Toronto, London, Melbourne.

4. Ranganna, S. (2000) Handbook of Analysis and Quality Control for Fruit and Vegetable Products, Tata McGraw-Hill Publishing Co. Ltd., New Delhi.

UNIT 7 ETHYLENE LIBERATION AND ITS CONTROL

Structure

7.0 OBJECTIVES

After going through this unit, you should be able to:

- know the role of ethylene in fruit physiology;
- tell how ethylene is synthesized in fruit tissues;
- explain the mechanism of action of ethylene; and
- state the different methods to remove ethylene from storage rooms.

7.1 INTRODUCTION

Ethylene is the simplest chemical compound known to cause a significant physiological effect. It is also known as ripening hormone and is effective at very low concentration. Ripening is the result of complex changes; many of them probably occur independent of each other. Respiration and ethylene production are the two of the major processes occurring during ripening. Ethylene plays a role in post-harvest life of many horticultural crops, which is often deleterious, speeding senescence and reducing shelf life, but sometimes beneficial, improving the quality of the product by promoting faster, more uniform ripening.

Ethylene is a gaseous harmone with a characteristic suffocating sweetish odour. It is both an anaesthetic and asphyxiant. High vapour concentration can cause rapid loss of consciousness and perhaps death by asphyxiation. Removal to fresh air usually results in prompt recovery if the person is still breathing. When the gas is handled in liquefied form, skin and eye burns can result from contact with the liquid. Cases in which liquid ethylene contacts, a physician must see to the eye.

7.2 SOURCES OF ETHYLENE

Ethylene gas is relatively inexpensive industrial chemical, but it is often more convenient or safer to provide ethylene by means other than the gas. Regardless of the source of ethylene, the treatment conditions are important for the ripening process.

Explosion-proof Ethylene Mixtures

Using mixtures of ethylene with inert gases can eliminate the danger of explosions from oversupply of ethylene to a ripening room. The proportion of the inert gas should be such that at high concentrations of ethylene not enough oxygen remains in the ripening space to provide an explosive mixture. Ripegas, a commercial formulation of ethylene contains 6 percent C_2H_4 in CO_2 by weight.

Ethylene Generators

Ethylene generators, in which a liquid products ethylene when heated in the presence of a catalyst, are now widely used for supplying ethylene in ripening rooms. The liquid comprises of ethanol and agents that catalyze its dehydration.

Ethephon

Ethephon (2-chloroethyl phosphonic acid) is strongly acidic in water. In solutions above pH of about 5, the ethephon molecule spontaneously hydrolyses, liberating ethylene molecule. Ethephon is commercially available (Ethrel, Florel, Cepa) and is used for preharvest treatment on a variety of crops for controlling developmental processes, or inducing ripening. For enhancing postharvest ripening, it has the disadvantage as it has to be applied to the fruit in liquid form as a spray or as a dip. This extra step in handling may cause microbial infection. But compared to ethylene treatment, it has the advantage, as no special facilities are required to ripen fruit with ethephon, if the ambient temperatures are within the range required to ripen the commodity.

Calcium Carbide

Heating calcium oxide with charcoal, under reducing conditions, readily produces calcium carbide. When hydrolyzed, calcium carbide produces acetylene, containing trace amounts of ethylene that are sufficient to trigger fruit ripening. Simple generators can be used in partially vented spaces to ripen or degreen fruits. In some instances CaC_2 wrapped in newspaper can be used as the generator. Water vapour from the fruit releases sufficient ethylene from CaC_2 to cause ripening.

7.3 USES OF ETHYLENE

Post-harvest Uses

Post harvest uses of ethylene include its uses as ethephon, an ethylene-releasing chemical, as a growth regulator. Fruit ripening is by far the largest application of ethylene gas in post-harvest technology. Other uses of ethylene in crops include-

Flower and Sprout Induction

The stimulation of flowering of pineapples by ethylene treatment is important for pineapple industry. Japanese bulb growers discovered that iris bulbs from fields that had been burned at the end of the season to control leaf diseases flowered earlier and more prolifically than controls. It was found that smoke did the same for bulbs that had been harvested, and smoking of bulbs is still practiced in Japan. The active ingredient in the smoke is ethylene, and it has now been shown that ethylene treatment of the propagules of a number of flowering crops stimulates flowering. Narcissus bulbs normally do not flower without ethylene treatment, and treatment with ethylene for a few hours just after lifting induces almost 100 per cent flowering.

Ethylene is also used as a short treatment to enhance the sprouting of seed potatoes. Ethylene treatment breaks the dormancy of the buds, but prolonged treatment inhibits their extension growth.

Shuck Loosening and Fruit Release

Ethylene is also used to induce the abscission of leaves, flowers, and fruit from many plants. Pre-harvest application of ethylene to walnut and pecan trees induces shuck loosening and improves harvest efficiency. Similarly, these chemicals are used to loosen the abscission zone on the stalk of fruits that are mechanically harvested (e.g. sour cherries), for improving harvest yields.

Chlorophyll Destruction

In many plant tissues, ethylene treatment result in rapid loss of cholorphyll, the green colour in leaves and unripe fruit. This property is used for degreening of citrus, where the orange colour is revealed as the chlorophyll is destroyed during ethylene treatment. Ethylene also helps in bleaching of celery and accelerated curing of tobacco.

Fruit Ripening

The concentrations of ethylene (in the range of 0.1 to 1 ppm) are required for the ripening in most of climacteric fruits. The time of exposure to initiate ripening depends on type of fruit, but usually exposures of 12 hours or more are usually sufficient. Full ripening sometimes takes several days after the ethylene treatment. The effectiveness of ethylene in achieving faster and more uniform ripening depends on the type of fruit being treated, its maturity, the temperature and relative humidity of the ripening room, ethylene concentration and duration of exposure to ethylene.

Control of temperature is critical to good ripening with ethylene. Optimum ripening temperatures are 18° to 25°C. At lower temperatures ripening is slowed; at temperatures over 25°C bacterial growth and rotting may be accelerated, and above 30°C ripening may be inhibited. Fruit that have been cool-stored must be warmed to 20°C to ensure that ripening proceeds rapidly. As ripening starts, the burst of respiration can generates heat, therefore it is essential to ensure that this heat does not increase pulp temperatures to the point where ripening is inhibited

7.4 ETHYLENE AS RIPENING INDUCER

Ethylene is regarded as an agent that can induce ripening. It has been established that all the fruits produce minute quantity of ethylene during development, but climacteric fruits produce much larger amounts of ethylene as compared to non-climacteric fruits during ripening. Further, the internal ethylene concentration of climacteric fruits varies widely, but that of non-climacteric fruits changes little during development and ripening. A concentration of 0.1-1.0 μl/l ethylene for one day is sufficient to hasten ripening of climacteric fruits, but the magnitude of climacteric is relatively independent of the concentration of ethylene. In contrast, applied ethylene merely increases the respiration of non-climacteric fruits, and the magnitude of increase depends upon the concentration of ethylene. Further, the rise in respiration in response to ethylene may occur more than once in non-climacteric fruits in contrast to single respiration increase in climacteric fruits.

The significance of ethylene for fruit ripening was established during the early part of this century when heaters burning kerosene were used to degreen or colour yellow lemons. Ethylene was regarded as an external agent that could promote the ripening of fruit, and other plant tissues, produced extremely small quantities of ethylene.

7.5 BIOGENESIS OF ETHYLENE

It was shown that application of an amino acid methionine greatly stimulated ethylene production in apples, and this compound was then considered to be the starting point for ethylene biosynthesis. Then s-adenosyl-methionine (SAM) was identified as another important compound in pathway, which is converted to 1-aminocyclopropane-1-carboxylic acid (ACC). ACC is now regarded as the immediate precursor for ethylene and ACC synthase controls the rate at which pathway operates. ACC synthase is activated by an enzyme cofactor, known as pyridoxal phosphate. Inhibitors of enzyme that require pyridoxal phosphate, such as aminoethoxy vinyl Glycine (AVG) and amino-oxyacetic acid (AOA) can be used to inhibit ethylene production.

It is generally agreed that the amino acid methionine is the precursor of ethylene in plants, with the conversion having an absolute requirement for molecular oxygen. Small amounts of ethylene probably can also be formed in plant tissues from the oxidation of lipids involving a free radical mechanism. As yet, the ethylene-producing system has not been isolated from fruit tissues for in vitro studies and the site or the organelle where ethylene is synthesized is still not very clear. The unravelling of the bio-chemical pathway of ethylene biosynthesis in plants has been one of the most interesting bio-chemical stories of recent years. Application of the amino acid, methionine greatly stimulated ethylene production in apples, and this compound was then considered to be the starting point for ethylene biosynthesis. Researchers at Davis, USA identified SAM (S-adenosyl-methionine) as another key compound in the pathway and then, almost simultaneously, Amrhein in West Germany and Adams and yang at Davis, USA discovered that SAM was converted to an unusual cyclic amino acid, ACC (1 aminocyclopropane-1-Carboxylic acid) which is now thought to be the immediate precursor for ethylene.

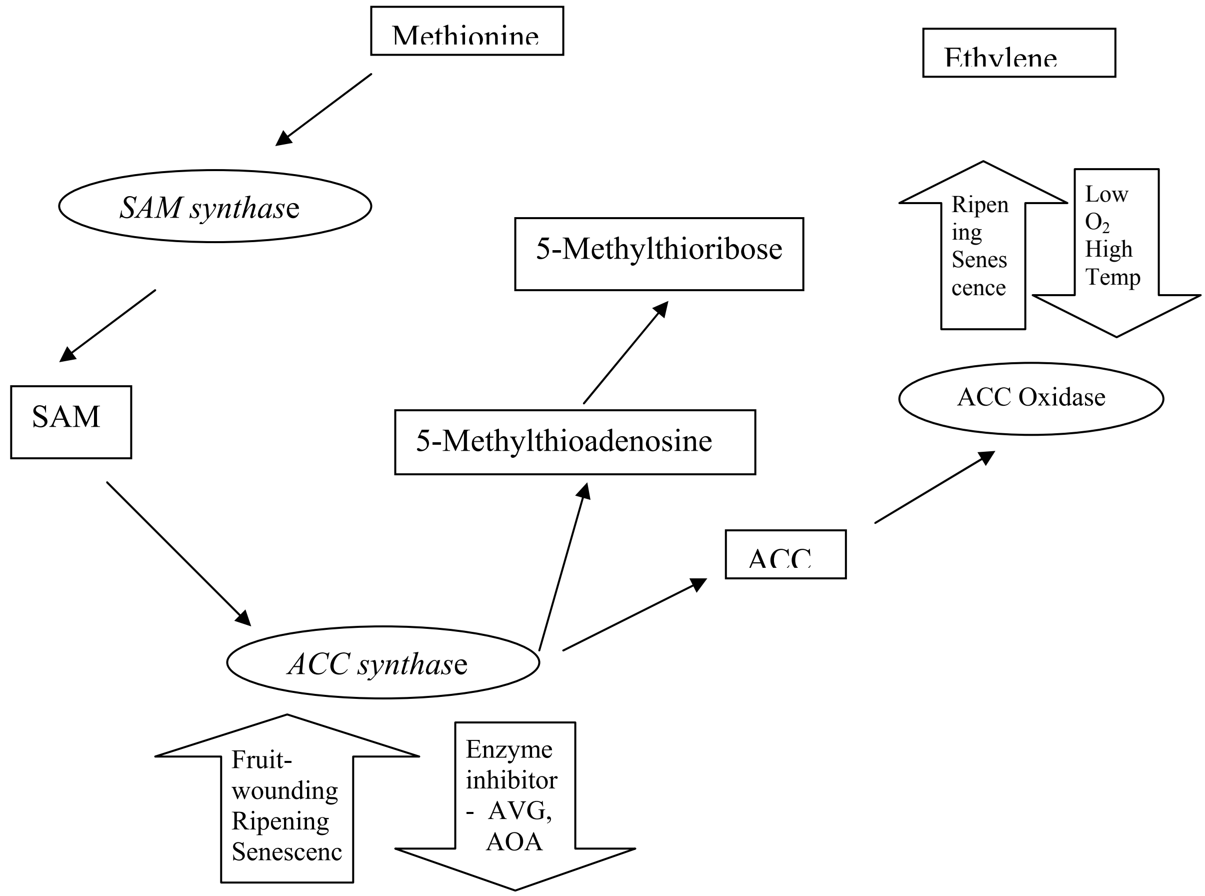

Figure 7.1: Biosynthetic pathway of ethylene

The enzyme which controls the rate at which the pathway operates, ACC synthase, is activated by a common enzyme co-factor, pyridoxoal phosphate such as AVG (amino-ethoxyvinyl gylcine) and AOA (aminooxyacetic acid) which inhibit ethylene production. Cobalt ion and low O_2, which inhibit the final step in the pathway, the Acc oxidase can also reduce ethylene production.

7.6 MECHANISM OF ETHYLENE ACTION

Although applied ethylene will initiate the ripening of climacteric fruits and will cause some ripening like changes in non-climacteric fruits similar to those in senescing tissue, it has not been possible to prove that ethylene acts in vivo as a true plant hormone, that is, acts in fruit tissues at trace levels, in promoting and controlling fruit ripening. A considerable amount of circumstantial evidence is available which suggests that ethylene, probably in concert with the other plant hormones (auxins, gibberellins, kinins and abscisic acid) exercises hormonal type control over the fruit ripening process. The relationship of the other plant hormones to ripening is as yet not clearly defined.

In some fruits, such as banana, avocado and melons, there is a small rise in endogenous (internally produced) ethylene concentration preceding the commencement of the respiratory climacteric. For example, the internal ethylene concentration of Honey Dew melon rises from the pre-climacteric level of 0.04 microlitre/litre to 3.0 microlitres/litre at which concentration the fruit commences to ripen. Other fruits, such as mango and apple, do not show this rise in internal ethylene concentration before ripening. Once ripening has commenced, the large amount of ethylene synthesized by climacteric fruits is thought necessary to promote all of the aspects of ripening.

It is well known that many fruits as they develop and mature, become more sensitive to ethylene. For sometime after anthesis (flowering) young fruit can have high rates of ethylene production. Early in the life of fruit can have high rates of ethylene production. Early in the life of fruit the concentration of applied ethylene required to initiate ripening is high and the length of time to ripen is prolonged, but decreases as the fruit matures. The tomato is an extreme case of tolerance to ethylene. Banana and melons, in contrast, can be readily ripened with ethylene even when immature. Nothing is known about the factors that control the sensitivity of the tissue to ethylene.

There is also no clear evidence to suggest the mechanism by which ethylene initiates and controls fruit ripening and little is known about the site of action of ethylene and the mechanism by which ethylene either promotes ripening or increases respiration in non-climacteric fruits or in other tissues such as the potato tuber. Ripening has long been considered to be a process of senescence and to be due to a breaking down of the cellular integrity of the tissue; some ultrastructural and bio-chemical evidence supports this view. There is now considerable evidence for ripening being a phase in the differentiation of plant tissue, with altered nucleic acid and protein synthesis occurring at the commencement of the respiratory climacteric. Both views fit in with the known degradative and synthetic capacities of fruit during ripening, but this type of study is unlikely to determine how ethylene initiates ripening.

Although applied ethylene initiates ripening in fruits, it is not proved how ethylene acts in vivo as a true plant hormone. Some evidence suggests that probably in combination with other hormones it exercises hormonal type control over the fruit ripening process. Some fruits show a rise in internal ethylene concentration before ripening, whereas others do not. The factors that control the sensitivity of the tissues to ethylene are yet to be known. But once ripening has commenced the large amount of ethylene produced by climacteric fruits is thought to be necessary to promote all aspects of ripening. It has been proposed that two systems exist for the regulation of ethylene biosynthesis. System I is initiated or perhaps controlled by an unknown factor, probably involved in the regulation of senescence. System I then triggers system II, which is responsible for production of large amounts of ethylene in climacteric fruits. Non-climacteric fruits lack an active system II.

Recently a model for the way in which ethylene induces a host of effects was introduced. According to this ethylene binds to a protein, called a binding site, and stimulates the release of a so called second message instructing the DNA to form mRNA molecule specific for the effects of ethylene. These molecules are translated into protein by polyribosomes, and the proteins so formed are the enzymes that cause the actual ethylene response.

7.7 ETHYLENE TREATMENT SYSTEMS

For ethylene treatment ripening rooms or specially built chambers with automatic control of temperature, humidity, and ventilation are used. It is not essential that the rooms be hermetically sealed, but they should be as tight as practicable to prevent leakage. Because of the rapid increase in respiratory heat production following ethylene treatment, ripening rooms should be equipped with refrigeration systems adequate to hold the temperature.

Several methods are used to provide the proper ethylene concentration in the ripening room.

The "shot" System

In the shot system, measured quantities of ethylene are introduced into the room at regular intervals. The shots may be applied by weight, or by flow. The required ethylene application is made by adjusting the regulator to give an appropriate flow rate and, the time of delivery of the gas. Any piping leading into the ripening room should be grounded to prevent possible electrostatic ignition of the explosive concentrations of ethylene that are always present near the orifice when ethylene is being introduced. Sometimes the ethylene is administered by weight also.

Because the room containing the product being ripened is sealed in the shot system, CO_2 accumulates in the room and may inhibit the ripening process. Therefore the room should be well ventilated before each application, particularly if it is well sealed, by opening the doors for about half an hour. In large ripening rooms, ventilating fans should be provided. Where the ripening rooms are near rooms used for storage or handling of ethylene-sensitive commodities, the room should be ventilated to the exterior to prevent contamination.

The Trickle or Flow-through System

The ethylene is introduced into room continuously, rather than intermittently. As the flow of ethylene is very small, it has to be regulated carefully. This is usually done by reducing the pressure using a two-stage regulator and passing the gas into the room through a metering valve and flowmeter.

To prevent a build up in either CO_2 or C_2H_4 fresh air is drawn into the ripening room at a sufficient rate to ensure a change of air every 6 hours. The air is vented through a small exhaust port to the rear of the room.

A convenient way of monitoring gas being supplied in a trickle system is a simple "sight glass" in which, the ethylene bubbles through a water trap on its way to the ripening room. As in the shot system, correct temperature maintenance and adequate air circulation are essential for good ripening.

7.8 CONTROL

Ethylene is produced whenever organic materials are stressed, oxidized or combusted. There are many sources of ethylene pollution during post-harvest handling of perishables, but the most important are internal combustion engines, ripening rooms and ripening fruits. Other sources are aircraft exhaust, decomposing produce and sometimes fungi growing on it, cigarette smoke, rubber materials exposed to UV light and virus infected plants. Sometimes ethylene contamination of flowers takes place from propane-powered floor polishers. The undesirable effects of ethylene that must be controlled are as follows:

Accelerated Senescence

In green tissues, ethylene commonly stimulates senescence, as indicated by loss of chlorophyll, loss of protein, and susceptibility to desiccation and decay. Ethylene pollution can result in yellowing of leafy vegetables (spinach, fresh herbs, parsley, broccoli and other green vegetables). The senescence of some flowers is also stimulated by ethylene at very low concentrations. These effects occur in flowers where increased ethylene production is part of natural senescence (sweet peas) and in others where it is not a part of natural senescence (roses).

Accelerated Ripening

Although acceleration of ripening is a beneficial use of ethylene, it can also be undesirable, as the presence of ethylene in the cucumber causes premature yellowing. Most climacteric fruits senescence faster if ethylene is present in the atmosphere, therefore ethylene in the storeroom may reduce storage life. The firmness of kiwi fruit in storage was dramatically reduced at 20 ppb ethylene concentration in the cool store.

Induction of Leaf Disorders

In many plants, exposure to ethylene results in darkening or death of portions of their leaves. This response is commonly seen in foliage plants and is of major economic consequence in lettuce, where ethylene causes the disorder known as russet spotting. In lettuce, the browning results from collapse and death of areas of cells following increased synthesis of phenolic compounds in response to ethylene.

Sprouting

The ethylene-stimulated sprouting is useful in propagules, but undesirable in commodities intended for consumption. Sprouting of potatoes increases water loss, leading to early shriveling and makes them unmarketable.

Abscission of Leaves, Flowers and Fruits

Ethylene induced abscission is most often a problem in ornamental plants, where low concentrations can cause complete loss of flowers or leaves. The Christmas cactus is sold when the first flowers are open, but exposure to ethylene may cause all the flowers fall in the bottom of the box during transportation.

Toughening of Asparagus

Ethylene stimulates the lignification of xylem and fiber elements in the growing asparagus spear, leading to undesirable touchiness and reducing the portion of the spear that is edible.

Induction of Physiological Disorders

Ethylene sometimes induces or hastens the appearance of physiological disorders of stored commodities. Rapid ripening of apples with low calcium contents induces high levels of the bitter pit storage disorder. Similarly, high ethylene levels in the storage chamber reduce the effectiveness of controlled atmospheres in maintaining quality of apples. While useful in inducing flowering in bulbs and other propagules, ethylene damages these propagules after the flowers have started to develop.

A number of techniques have been developed to protect sensitive commodities from the effects of ethylene. Selection of the appropriate method obviously depends on the commodity and the handling techniques used in its marketing.

Removing ethylene from the atmosphere around the commodity is the preferable method of preventing deterioration of ethylene sensitive products. Most of the times, removing the sources of ethylene can do it. Combustion gases exhaust should be avoided from handling and storage rooms. A good sanitation by removing overripe and rotting produce will help in reducing ethylene levels. Ventilation of storage rooms can also help in reducing ethylene concentration.

Eliminating Sources of Ethylene

High levels of ethylene in storage and handling areas can be avoided by removing sources of ethylene. In particular, commodities sensitive to ethylene, should be handled using electric forklifts. Internal combustion engine vehicles should be isolated from handling and storage areas and engines should never be left idling in an enclosed space during loading and unloading operations. Where these techniques are not feasible, it is possible to fit combustion engine exhausts with catalytic converters, which will reduce C_2H_4, emissions by 90 percent. Rigorous attention to sanitation will remove overripe and rotting produce which can be a source of ethylene.

Ventilation

Where the air outside storage and handling areas is not polluted, simple ventilation of these areas can reduce ethylene concentrations. An exchange rate of one air change per hour can readily be provided by installing an intake fan and a passive exhaust.

Chemical Removal

Ethylene can be removed by a number of chemical processes; the most important are described below:

- Using potassium permanganate
- Using ultraviolet lamp (by ozone)
- Activated or brominated charcoal
- Catalytic oxidizers

Potassium permanganate: Commercial materials, such as Purafil, utilize the ability of potassium permanganate ($KMnO_4$) to oxidize ethylene to CO_2 and

H_2O. The requirements for such materials are a high surface area coated with the permanganate and ready permeability to gases. Many porous materials have been used to manufacture permanganate absorbers, including vermiculite, pumice and brick. The type of material may depend on the purpose for which the absorber is required. For removing ethylene from room air, the absorber should be spread out in shallow trays, or air should be drawn through the absorber system.

Ultraviolet lamps: Commercial equipment for ultraviolet lamps draws the air from the storage room through the lamps. Ultraviolet lamps produce ozone, which is an active ethylene-removing agent. As the ozone produced by the lamps is very toxic to fresh produce, it must be removed from the produce.

Activated or brominated charcoal: Charcoal air purifiers, especially if brominated, can absorb ethylene from air. These systems are largely confined to use in the laboratory, as potassium permanganate absorbers are cheaper and more widely available.

Catalytic oxidizers: If ethylene and oxygen are combined at high temperature in the presence of a catalyst (e.g. platinized asbestos) the ethylene will be oxidized. Ethylene scrubbers overcome the difficulty of heating the incoming air by using the bed of ceramic as a heat sink and reversible flow of gas through the bed. These scrubbers are very efficient in reducing the ethylene concentration in the air to 1/100th of original concentration.

Bacterial systems: Approximately 30,000 metric tons of ethylene is liberated into the atmosphere each day from internal combustion engines, but the concentration of ethylene in air remains very low. The bacteria that use ethylene as a bio-chemical substrate are able to remove ethylene from the atmosphere.

Hypobaric Storage

Hypobaric storage helps in reducing the levels of ethylene as the relative concentration of all the gases in storage room goes down. Many of the benefits of hypobaric storage are due to reduction in the partial pressure of oxygen, which accompanies reduction in the atmospheric pressure.

Inhibition of Effects of Ethylene

Sometimes it is not possible to ensure low concentration of ethylene. In such cases attempts should be made to inhibit the effect of ethylene. Different techniques used are:

- Controlled atmosphere storage
- Use of antiethylene compounds (NBD, STS)
- Inhibition of ethylene biosynthesis

Controlled atmospheres: Low concentrations of O_2 and high concentrations of CO_2 in the storage atmosphere reduce the rates of respiration, ethylene production and other metabolic processes. CO_2-enriched atmospheres also may inhibit the action of ethylene on tissues sensitive to it. Accumulation of CO_2 produced by the fruits may help in preventing the action of ethylene.

Use of anti-ethylene compounds: Compounds that inhibit the action of ethylene include silver ion and 2, 5 norborneadiene (NBD). Complex between silver and thiosulfate (STS) is being used for ornamental commodities. It has a very low stability constant and therefore it moves readily from the vase solution to the head of cut flowers. Flowers pulsed with this material last two to three times as long as control flowers. Potted flowering plants do not lose their flowers during transportation if they are first sprayed with STS.

Inhibition of Ethylene Biosynthesis

Ethylene may reduce quality even when it is not present as a pollutant if the tissue itself produces ethylene. Inhibitors of ethylene biosynthesis, such as AVG and AOA have been used in laboratory experiments to extend flower vase life and fruit storage life but not on commercial scale.

7.9 LET US SUM UP

Ethylene, a ripening hormone plays an important role in post-harvest life of many commodities. Sometimes its effect are beneficial where it is used for uniform ripening or degreening, but mostly it is considered deleterious as it hastens senescence and reduces post-harvest life. Simple practices of good sanitation and ventilation of storage room can help in reducing ethylene concentration. Use of chemicals or advanced storage techniques can also reduce the deleterious effects of ethylene.

7.10 KEY WORDS

Physiology	:	Study of the functions and vital processes of living organisms or their parts.
Ethylene	:	A colourless flammable gas which stimulates ripening.
Ripening	:	The advance stage in the development at which fruit and vegetable are suitable for consumption/ utilization.
Climacteric	:	Fruits/vegetables showing a sudden upsurge in respiration couples with ethylene evolution.
Non-climacteric	:	Fruits/vegetables who do not show a sudden upsurge in respiration couples with ethylene evolution.
Biosynthesis	:	The formation of chemical compounds by the enzyme action of living tissues.
Hormone	:	A substance which is synthesized at one tissue and has specific effect on another tissue.
Ventilation	:	To circulate fresh air or drive out foul air.
Hypobaric	:	Less than normal air pressure.
Degreening	:	Removal of chlorophyII pigment form the tissue.

UNIT 8 GROWTH, MATURATION AND SENESCENCE

Structure

8.0 OBJECTIVES

After going through this unit, you should be able to:

- know the chemical changes taking place during growth, ripening and senescence;
- tell about respiratory climacteric;
- explain the factors affecting respiration; and
- mention the morphological changes in fruit tissues during ripening and senescence.

8.1 INTRODUCTION

The life of fruits and vegetables can be divided into three major physiological stages following germination- growth, maturation and senescence. Ripening is considered to begin during the later stages of maturation and to be the first stage of senescence. Development and maturation of fruit are completed only when it is attached to the plant, but ripening and senescence may proceed on or off the plant. Major changes in carbohydrates, organic acids, pigments and volatiles are observed during growth of the produce, which continue during ripening and senescence.

Food may be stored in various storage organs, such as roots, shoots tubers, rhyzomes, bulbs, corms, fruits and seeds. Storage may take place at different seasons of the year and may in some plants be controlled by the length of the day, the length of the night period and the day & night temperatures. In many plants that live for more than one season (perennials), accumulation in the underground storage organs takes place at a rapid rate in the fall of the year.

Fresh fruits, as well as fresh vegetables are essential components of human diet. Both contain a number of nutritionally important compounds, such as vitamins, which cannot be synthesized by the human body; vitamin C is the most important and essential nutritive substance found mainly in fruits and vegetables.

The fruits are used as a table commodity whereas the vegetables are usually cooked and then served as food. Some of the vegetables are "fruit-vegetables" and most of the vegetables are the other vegetative organs of the plant that include root, stem, flower, shoot, leaves and associated parts.

Fruits and vegetables are highly perishable products with active metabolism during the post-harvest period. Proper handling plays an important role in increasing their availability. On removal from the parent plant, vegetative parts, such as fruits, roots, stems etc are deprived of their normal supply of minerals, water, and also in some instances, simple organic molecules [e.g. sugars, hormones] that normally would be translocated from other parts of the plant. Innumerable physiological and biochemical processes are initiated and continued in the edible plant tissues at the time of harvest. Although the photosynthetic activity is negligible, most tissues remain capable of transforming many of the constituents already present in them. The diversity of metabolic shifts, which are specific to a given commodity [and often variety] are manifest in events such as 'rotting', 'ripening', 'sprouting', 'scald', 'brown core', 'hard core', 'toughening', and 'yellowing'.

The kind and intensity of physiological activity in detached plants determines their storage longevity. Some plant parts, such as seeds, fleshy roots, tubers, bulbs are morphologically and physiologically adapted to maintain the tissue in a dormant state until environmental conditions becomes favourable for germination or growth. Metabolic activity, though depressed, is not completely halted in such tissues. Fleshy fruits are unusual in that maturation is followed by a ripening process, which is associated with the development of optimal eating quality.

The diversified visible physiological changes, like sprouting, browning, toughening etc are desirable in some commodities and undesirable in others in relation to the eating quality. Almost all such changes are observed during ripening.

Physiology of Ripening

The term "ripening" is generally referred to the physical and biochemical changes taking place in the fruits after the cessation of growth till the onset of senescence and decay. The ripening process is dependent upon maturity, since a given stage of development must be attained before ripening progresses. The process of ripening continues while the fruit is on the tree, but the damage caused by the birds, insects etc makes it uneconomical to allow it to ripen on the tree. Hence, the fruits are usually harvested at the horticulturally mature stage. Fruits being living entities continue to carry on the normal physiological processes resulting in the ripening and finally decay or death of the fruit even after they are separated from the parent plant/tree. Most of the fruits show the ripening changes after harvest with a few exceptions like grapes, which are to be ripened only on the vine, as they do not ripen well after harvest. Since the changes taking place in a fruit during ripening greatly influence the eating quality and the monetary value of the commodity depends on it, a detailed knowledge of the physiology and biochemistry of ripening is desirable for the successful storage and marketability of fruits.

8.2 PHYSICOCHEMICAL CHANGES DURING GROWTH OF STORAGE ORGANS

Carbohydrate

Sugars are important for pleasing fruit flavour (sugar acid ratio) and texture. As the ripening starts these sugars undergo metabolic transformation both quantitatively and qualitatively. Most of the soluble carbohydrates are metabolized completely as the fruit ripens. Pectic substances and cellulose are the reserve carbohydrates that also serve as potential sources of acids, sugars and other respiratory substances during ripening.

Many changes occur in carbohydrate fraction of fruit during ripening, the climacteric and senescence. Green or raw fruit usually contains starch in abundance, but is short of soluble sugars that provides sweetness to it. During ripening, the starch is enzymatically [hydrolysis by alpha- and beta-amylases] converted into sugars. Thus, the major bulk of carbohydrate fraction of a fully ripened fruit consists of sugars. The sugars commonly found in fruits are glucose and fructose [invert sugars] and sucrose.

Organic Aacids

The organic acids are among the major cellular constituents undergoing changes during ripening. In most of the fruits there is a considerable decrease in the acidity of fruits during ripening.

The sourness of fruits is due to the presence of organic acids like citric, malic, succinic, tartaric, oxalic etc. These acids usually decide the quality of fruits as the blending of sugar and acids render the fruits tasty, besides flavour. Though these organic acids are present in varying amounts in raw or unripe fruits, but the concentration considerably changes as the fruits ripen. In fruits like oranges, the acids are converted enzymatically into sugars rendering them sweet as they ripen, whereas there is no change in lemons. So they remain sour till they start decaying. But, in some fruits like mangoes, there is a considerable decrease in acidity when the fruits fully ripen. This is partly due to the utilization of these acids in respiration through Kreb's Cycle. Generally, in fruits the total acidity shows a decrease with the increase in ripeness of the fruits.

Amino Acids and Proteins

A major turnover of amino acids in mango takes place during ripening, whereas in carombola shows a continuous decline. Small increase in protein content was also observed in mango, tomato and avocado.

The nitrogen content of fruit is due to proteins forming insoluble fraction and the soluble fraction comprised of amino acids. The total nitrogen content of fruits at the early stages is high, but with the advancement in growth, shows gradual decrease. This is probably due to increase in other constituents like water, starch, sugar, organic acids etc. During ripening, the total nitrogen may show a further decrease in some cases.

Lipids

Phospholipids occur in the cytoplasm and in many structural units of plant tissues. They are physiologically more important than neutral lipids in storage organs. Considerable increases in the level of total lipids and fatty acids have been observed in ripening mango in contrast to many fruits and vegetables. However in fatty fruits of avocado the oil composition during maturation remains more or less constant.

Chlorophyll

Disappearance of green colour marks the initiation of ripening in most of the fruits. Chlorophyll content of ripening fruit decreases universally.

Carotenoids

A dramatic synthesis of carotenoids occurs during the last step of ripening. It has been reported that the levels of carotenes, free geraniol, mevalonic acid, all precursors of carotene biosynthesis increases progressively during ripening.

Other Pigments

The colour imparted to raw or ripe fruits and vegetables are due to presence of various pigments. The pigments of different tissues are the chlorophylls (green), anthocyanin [reddish to purple], flavonoids [yellow], leucoanthocyanins [colourless], tannins [colourless to yellow or brown], betalains [red], quinones and xanthones [yellowish] and carotenoids [yellow and red].

During storage, some of these pigments undergo considerable changes. Carotenoids formation and destruction may be affected by the storage conditions. In certain instances, these reactions are stimulated by O_2, inhibited by light and high temperature. Carotenoids include lycopene, alpha, beta and gamma carotenes are synthesized enzymatically in the fruits. Anthocyanin synthesis is stimulated by light and is often affected by temperature. Purple colour of red cabbage intensifies when stored below 10^o C. Chlorophyll degradation is accompanied by synthesis of other pigments as the fruits ripen. Chlorophyll metabolism is markedly influenced by environmental parameters, such as light, temperature and humidity and the effects of these factors are specific for the tissues. For example, light accelerates degradation of chlorophyll in ripening tomatoes and promotes formation of the chlorophyll pigment in cold stored potatoes.

Tannins

The tannins and other polyphenolic constituents are present in abundant quantities in immature, raw or developing fruits. As the maturity and ripening progresses the total polyphenolic content reduces gradually.

Pectic Substances

The most obvious change during ripening of fruit is the alteration in texture. The plant cell wall is made up of cellulose fibrils embedded in a matrix consisting largely of pectic substances, hemicellulose, proteins, lignins etc and water. Cell wall and middle lamella components increase during development of fruits, but as the fruit ripens the content of soluble pectates and pectinates increase, while total pectic substances decrease.

The cell walls are surrounded by parenchymatous cells which will absorb water and generate hydrostatic pressure within the living cells. This is called tugor pressure which gives the desirable property of crispness to the commodity. During storage, the loss of moisture due to transpiration and respiration results in the loss of crispness or the turgidity of the commodity. In addition, the changes in the pectic substances (which forms a component of the cell wall of the fruit cells) account for the firmness of the fruits. During ripening, the proto-pectin, which is insoluble and forms, the middle lamella of the cell wall, decreases in quantity and the soluble pectin content rises, thereby making the flesh less firm or soft. A decrease in the chain length and loss of methyl groups of proto-pectin probably occurs during ripening, accounting for the rise in soluble pectin. This is brought about enzymatically mainly by the activity of the enzymes pectinase and pectin methyle esterase.

Volatile Products

Each fruit has specific aroma which ripened fruit emanates. Although different fruits vary in nature of volatile compounds, they are emitted in noticeable amount only when the fruit starts ripening. Although the degree of maturity is the main physiological factor affecting aroma production, the aroma composition is also affected by environmental conditions during maturation. In overripe fruits mostly alcohol and esters are formed when fermentation develops.

One of the marked differences between an unripe and ripe fruit is the intensity of flavour of the fruit. The flavour of fruits or vegetables are considered to originate by the presence of basic constituents, such as carbohydrates (particularly mono- and disaccharides], proteins [particularly free amino acids] and fats [triglycerides or their derivatives], as well as vitamins and minerals. These constituents are produced through photosynthetic and related metabolic activities occurring in the commodities. Some volatile compounds may exist in the tissues as such but in some it may be formed enzyatically upon rupture of cells or by microorganisms. Besides ethylene, a number of other volatile odorous constituents like amyl esters of formic, acetic, valeric and caprylic acids have also been identified. These organic emanations produced during ripening of fruits contribute to the aroma of fruits and hence are of considerable importance from the standpoint of fruit quality.

Enzymes

Enzyme action is responsible for many chemical and physical effects during ripening. Softening of fruits, conversion of starch to sugar or vice versa, changes in amino acid content, and in colour.

Most of the biochemical changes occurring in fruits during ripening can be attributed to enzyme reactions. The change from starch to sugar, sucrose to invert sugar or protopectin to pectinic acid are all due to enzymic reactions.

Oxidative enzymes like catalase and peroxidase were shown to have increased to a considerable extent in 'Alphonso' and 'Neelam' varieties of mangoes during ripening as indicated by the higher rate of respiration. Similarly, glycolytic and hydrolytic enzyme activity was also found to increase in ripening mangoes, particularly during climacteric and post-climacteric period. Aspartie aminotransterase activity also increased in mangoes, resulting in the increased amounts of amino acids. Chlorophyllase activity followed the climacteric pattern in bananas, but suggested that the ensuing chlorophyll degradation may not be relevant to ripening. Other enzyme that increases in activity during ripening and following respiratory climacteric is fatty acid synthatase in Avocado fruit.

8.3 MECHANISM OF NUTRIENT MOBILIZATION AND ACCUMULATION

A developing commodity is the complex system of actively metabolizing tissue. Fruit growth generally starts by a short but rapid cell multiplication followed by cell enlargement. Initially cell division and enlargement contribute towards growth, but later cell division becomes major contributory factor. Large quantity of food is accumulated in storage tissue, the composition of which varies with the type of produce. Starch is stored in potato, garlic, banana; fat in avocado; malic acid in apple; citric acid in citrus and pineapple; ascorbic acid in guava; tartaric acid in grapes. Although the nature of chemical stored is a genetic characteristic, the mechanism of storage is physiologically controlled.

Concentration gradient is partly responsible for movement of nutrients from leaves to storage organs. Soluble carbohydrates from leaves are converted to insoluble carbohydrates in storage structure, thus create a gradient for further accumulation. Organic acids are contained inside the vacuoles. Once products are accumulated inside the organ some form of controls occurs to prevent their drain.

Some hormones are involved in the nutrient accumulation in storage organs. Stimulation of nucleic acid and protein synthesis by hormone treatment may cause translocation of nutrients, which establishes a physiological sink.

8.4 RESPIRATION AND RESPIRATORY CLIMACTERIC

A major metabolic process occurring in harvested produce or in any living plant product is respiration. Respiration can be described as the oxidative breakdown of the more complex materials normally present in cells, such as starch, sugars and organic acids, into simpler molecules, such as carbon dioxide and water, with the concurrent production of energy and other molecules which can be used by the cell for synthetic reactions. Respiration can occur in the presence of oxygen (aerobic respiration) or in the absence of oxygen (anaerobic respiration, sometimes called fermentation).

Respiration rate of produce is an excellent indicator of metabolic activity of the tissue and thus is a useful guide to the potential storage life of the produce. If the respiration rate of a fruit or vegetable is measured as either oxygen consumed or carbon dioxide evolved – during the course of its development, maturation, ripening and senescence periods, a characteristic respiratory pattern is obtained. Respiration rate per unit weight is highest for the immature fruit or vegetable and then steadily declines with age. A significant group of fruits that includes tomato, mango, banana and apple shows a variation from the described respiratory pattern in that they undergo a pronounced increase in respiration during ripening. Such an increase in respiration is known as a respiratory climacteric and this group of fruit is known as the climacteric class of fruits. The intensity and duration of the respiratory climacteric, varies widely amongst fruit species. The commencement of the respiratory climacteric coincides approximately with the attainment of maximum fruit size and it is during the climacteric that all the other characteristic changes of ripening occur. The respiratory climacteric, as well as the complete ripening process, may proceed while the fruit is either attached to or detached from the plant. Those fruits such as citrus, pineapple and strawberry that do not exhibit a respiratory climacteric are known as the non-climacteric class of fruits. Non-climacteric fruits exhibit most of the ripening changes, although these usually occur more slowly than those of the climacteric fruits. All vegetables can also be considered to have a non-climacteric type of respiratory pattern.

Respiration Rate

Respiration is the process by which stored complex materials are broken into simple products and energy is released. While respiration is essential to maintain the state of living of the produce, it causes deterioration due to losses in food reserves, food value, flavour, and dry weight. The rate of deterioration of harvested produce is generally proportional to their respiration rate. Respiration is linked to many quality parameters, which are responsible for spoilage. The rate of respiration is a good index of post-harvest life of fruits and vegetables as it is directly related to the rate of metabolism. According to respiration rate commodities can be classified as-

Class	Respiration rate (mg CO_2/ Kg/h at 5°C)	Examples
Very low	5	Nuts, dates, dried fruits and vegetables
Low	5-10	Apple, citrus, grape, garlic, onion, potato
Moderate	10-20	Apricot, banana, cherry, peach, plum, pear, cabbage, carrot, tomato, pepper
High	20-40	Strawberry, blackberry, cauliflower, lima beans
Very high	40-60	Snap beans, Brussels sprout
Extremely high	>60	Asparagus, mushroom, pea, spinach

Respiratory Climacteric

Many fruits and vegetables show a rapid increase in respiration during ripening and they are called as climacteric. Fruits that do not show such phenomenon are referred as non-climacteric. Although non-climacteric fruits are also reported to have rise in respiration rate with a concomitant rise in ethylene production or may show this effect at appropriate stage or under appropriate storage condition.

Factors affecting Respiration

A number of factors are responsible for variation in respiration rate. They include internal factors such as stage of development and chemical composition of fruit tissues. External conditions also change respiration rate of the produce.

Stage of Development

During development as fruit size increases the total amount of CO_2 emitted by fruit also increases. In climacteric fruits, the respiration rate is minimum at maturity and remains rather constant, even after harvest. When ripening is about to start, respiration rate rises up to climacteric peak, then it slowly declines. Non-climacteric fruits ripen on tree, and if harvested early, a decline in respiration rate is observed. Actively metabolizing tissue has higher respiration rate. Small sized tissues will have higher respiration rate as they are having larger total surface area.

Chemical Composition of Tissue

The relationship between respiration rate and chemical composition varies among produce. Respiratory quotient varies with the type of substrate being used for respiration. It is 1 when substrate is sugar and less or more than 1 when lipids or organic acids, respectively, are the substrate. The level of moisture can also affect the respiration. Commodities with good natural coatings exhibit low respiration.

External Factors

Temperature: Respiration rate of fruits and vegetables increases 2-2.5 times for every 10°C rise in temperature.

Ethylene: In climacteric fruits exogenous application of ethylene advances the respiratory peak. In the non-climacteric fruits, respiration may be stimulated anytime during the life of the detached fruit, and an immediate rise in respiration occurs after ethylene application.

Oxygen and carbon dioxide: Rate of respiration increases with the increasing supply of oxygen, and carbon dioxide has an opposite effect.

Growth regulators: Depending on the time of application and quantity absorbed by the fruits, growth regulators may inhibit or stimulate the rate of respiration.

Fruit injury: Depending on the fruit variety and severity of bruising, injury can stimulate the respiration. This effect is indirectly attributed to ethylene production.

8.5 CLIMACTERIC AND NON-CLIMACTERIC FRUITS AND VEGETABLES

Climacteric fruits show a large increase in respiration rates and ethylene production as they ripen. In contrast non-climacteric fruits exhibit low CO_2 and C_2H_4 evolution rates during ripening. A non-climacteric fruit reacts to ethylene treatment at any stage of its pre-harvest or post-harvest life, whereas a climacteric fruit exhibit a respiratory response only if ethylene is applied during the pre- climacteric stage, and it becomes insensitive to ethylene treatment after the onset of the climacteric rise Table 8.1.

Table 8.1: Some Examples of climacteric and non-climacteric fruits and vegetables

Climacteric	Non-climacteric
Apricot, banana, mango, avocado, cherry, peach, plum, pear, cabbage, carrot, tomato, pepper Apple, garlic, onion	Strawberry, blackberry, cauliflower, citrus, lima beans, Snap beans, Brussels sprout, grape, cucumber, pomegranate

8.6 MORPHOLOGICAL AND CHEMICAL CHANGES DURING RIPENING AND SENESCENCE

Compositional changes take place in harvested fruits and vegetables, which influence their colour, firmness, taste and aroma. During ripening there is change in colour of many products as the chlorophyll breakdown takes place, and new pigments are synthesized. Changes in carbohydrates include starch to sugar conversion and vice-versa, breakdown of pectins and other polysaccharides, which results in softening of fruit. Changes in organic acids and lipids influence flavour development. Synthesis of volatile organic compounds during ripening emits typical aroma of the commodity.

Many structural changes occur during ripening and senescence. In the sequence of events that leads to senescence of plant cell decrease in ribosome population and chloroplast breakdown are the first detectable symptoms.

Ribosomes

No change in ribosome population during maturation and ripening of tomato was observed as they were distributed throughout the cytoplasm and along the rough endoplasmic reticulum at all stages of fruit development, although a decrease was observed in post climacteric stage.

Mitochondria

A general degradative process is characterized by the reduction in the number of intact mitochondria, as senescence can be termed as the failure of the system responsible for keeping the cells in good repair. In the final stage of senescence, a shortage of ATP resulting from fewer active mitochondria can cause a loss of membrane integrity and redistribution of enzymes and substrate. In general mitochondria appears to be more resistant to breakdown than other organelles, and they persist till late stages of senescence.

Cell Wall

Differences occur in cell wall structure at different stages of fruit development. Loosening of cellulosic fibrillar structure is seen during ripening depending on the degree of solubilization of pectic and hemicellulosic substances between the microfibrils. Thickness of cell wall changes and cells turn round and tend to dissociate.

Plastids

Plastids show more striking changes than all other organelles. As fruit matures, starch granules disappear and the osmophilic granules increase in number and size. With maturity grana disappear and structure similar to thylakoid plexes are seen. In ripe stage, chromoplast development takes place with granal lyses and increase in size and/or number of lipid granules. Generally chlorophyll disappears from senescing plant tissue with degeneration of granal lamellae, formation of a single membrane system, and an increase in size and/or osmiophilic globules.

Intracellular Spaces

Intracellular spaces are formed by separation of cells along the middle lamella. A decrease in porosity is observed with ripening.

Other Cell Organelles

The endoplasmic reticulum vesiculates and disappears with senescence. Golgi apparatus also disappears and tonoplast breakdowns with senescence. The nucleus and plasmalemma are the last structure to vanish and it brings about the death of cell.

8.7 LET US SUM UP

Taste of fruits and vegetables is associated with the amount and type of chemical constituents and the physical nature of the commodity at harvest. During ripening a series of changes in colour, texture and flavour are evident. These changes are influence by respiration and ethylene production by the produce. It is important to realize that no improvement in quality can be done in post harvest stage; only efforts can be made to keep intact the quality attained at harvest.

8.8 KEY WORDS

Physiology : Study of the functions and vital processes of living plants.

Ethylene : A colourless flammable gas which stimulates ripening.

Ripening : The advance stage in the development at which fruit and vegetable are suitable for consumption/ utilization.

Climacteric : Fruits/vegetables showing a sudden upsurge in respiration coupled with ethylene evolution.

Non-climacteric : Fruits/vegetables who do not show a sudden upsurge in respiration coupled with ethylene evolution.

Respiration : Process of inhaling oxygen and exhaling carbon-di-oxide.

Development : A process of growth towards more perfect stage.

Maturation : Becoming full grown or fully developed.

Senescence : Beginning of final phase in the life of plant.

Volatiles : A substance having the quality of gas.

Pigments : Colouring matter in the cells or tissue of fruits and vegetables.

Aroma : A smell coming out of the product.

Fermentation : The breaking down of complex organic compound by microorganisms.

Coating : Layering of the outer surface of fruits or vegetables.

Bruising : To injure the surface without breaking the skin, but causing Discoloration.

8.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answers should include following points:
   - Pectic substances
   - Starch
2. Your answers should include following points:
   - Chloroplast
   - Chromoplast
   - Mevalonic acid
   - Chlorophyllase
3. Your answers should include following points:
   - Starch
   - Acids
4. Your answers should include following points:
   - Insoluble carbohydrates
   - Gradient

Check Your Progress Exercise 2

1. Your answers should include following points:
   - Fruit size
   - Size and metabolic stage of tissues
2. Your answers should include following points:
   - Sugars
   - Organic acid
   - Lipoids
3. Your answers should include following points:
   - More resistant
   - Membrane integrity
4. Your answers should include following points:
   - Cellulosic fibrillar
   - Pectin solubilization

UNIT 9 PHYSIOLOGICAL DISORDERS

Structure

9.0 OBJECTIVES

After going through this unit, you should be able to:

- know the reason for different physiological disorders;
- mention the symptoms of major physiological disorders;
- state the importance of minerals in fruit quality; and
- tell how the occurrence of physiological disorders can be avoided.

9.1 INTRODUCTION

Physiological disorders are related to exposure of undesirable environmental condition such as temperature, very low oxygen or high carbon dioxide, humidity and nutritional disorders etc. In general any breakdown of tissues other than invasion of pathogens or mechanical damage is termed as physiological disorder.

Different fruits and vegetables have different tolerance limits to cold (low) temperature, storage below which the stored commodity is susceptible to various kinds of disorders including fungal infections.

9.2 PHYSIOLOGICAL DISORDER OF TROPICAL AND SUB-TROPICAL PRODUCE

Many tropical and sub-tropical varieties of fruits and vegetables when stored below 10°C for a longer time suffer physical and physiological injuries. These injuries are of the following types:

i) Superficial scald
ii) Carbon dioxide injury
iii) Core flush

iv) Breakdown of the flesh of the stored commodity:
  a) Low temperature breakdown [LTB]
  b) Senescent breakdown
v) Water core
vi) Bitter pit
vii) Freezing injury
viii) Chilling injury

1. Superficial scald

The common feature of this is that the areas of the skin of the stored commodity turn brown. These areas are very slightly sunken and the lenticels look as injured spots, e.g. apples, pears, and peaches.

2. Carbon dioxide injury

Usually occurs in CA storage when carbon dioxide concentration goes higher. The periphery of the internal tissue turns slightly brown initially and as the time of exposure to CO_2 prolongs the tissue turns deep brown, e.g. apples, pears, mangoes.

3. Core flush

Core flush is yellowish-pinkish discolouration of the core of the apples. It may appear as a ring of damaged tissue or it may involve the whole area of the core.

The incidence of the core flush is aggravated by increased CO2 concentrations in the core atmosphere. Storage in the absence of CO2 and in low concentration of oxygen gives good control of core flush.

4. Low temperature breakdown [LTB]

Low temperature breakdown of apple is seen in the cortical tissue as a general browning of the flesh that can vary in intensity from season to season.

As the disorder progresses the skin becomes discoloured and water logged, giving a dark translucent appearance. The cut surface looks moist.

5. Senescent breakdown

Senescent breakdown of apples and pears is a disorder associated with over maturity and it develops further at high temperatures when the fruit is removed from store. It is variable in appearance but fruit looks drier as compared to low temperature breakdown. Sometimes the flesh also becomes mealy.

6. Water core

Water core is a condition in which parts of the flesh of the commodity appear to be translucent and glossy because the intercellular spaces have become injected with the sap. It is more prominent in the flesh and may also appear near to the surface of the skin. Water core disappears rapidly at higher storage temperatures, but badly affected fruits cannot recover from water core disorder.

7. **Bitter pit**

Bitter pit is appearance of small brown dry areas on the skin, which also disfigures the flesh. The location of the pit is usually below the skin, but in severe cases the pits may extend right up to the cortex. Under the microscope the pitted areas are seen to consist of dead collapsed cells. Deficiency of calcium in the soil causes bitter pits, and it can be avoided by pre-harvest spray of calcium. The bitter pit mainly occurs in pears, apples, and guavas.

8. **Freezing injury**

Freezing injury occurs when storage temperature falls below 0°C. The affected fruit externally has an irregular shape caused by tissue collapse, and the juice streams out of the injured or cut tissue even under slight pressure.

In apples, freezing injury characteristically occurs in cone-shaped segments with the apex at the core.

9.3 LOW TEMPERATURE DISORDER – CHILLING INJURY

Chilling injury is a major problem in post harvest handling of fruits and vegetables. This injury occurs at temperatures which are lower, but much above the freezing point of the tissues. Chilling injury is manifested in a variety of symptoms such as surface pitting, discolouration, appearance of water soaked areas, increased susceptibility to decay, loss of sprouting ability, etc. Some of the important physiological responses to chilling injury are stimulation of ethylene production, and failure of colour development.

Chilling injury is a phenomenon during which many tropical and subtropical fruits and vegetables when stored below 10°C develop the symptoms of skin discolouration and browning, pitting of the skin, water soaked spots, soggy flesh and failure to ripen when the commodity is removed to room temperature [RT].

The chilling injury symptoms are visible only after 2 or 3 days storage at room temperature.

9.3.1 Control of Chilling Injury

Temperature Pre-conditioning

Gradual reduction of storage temperature of the cold room is found beneficial in alleviation of CI. Pitting in stored banana was found reduced from 90.6 to 8.9% when stored at 13°C-12°C-11°C-10°C at 4 days intervals.

Regulating Humidity

Storage humidity at 95-100% was found to reduce CI symptoms in bananas stored at 11°C when they are covered in polythene bags.

Intermittent Warming

Intermittent warming [IW] of the commodity for every 5 days at low temperature/2 days at Room Temperature was found effective to control CI. Raw green mature papaya stored at 7°C for 5 days when transferred and kept for 2 days at RT did not exhibit CI symptoms for 3 weeks storage. Similarly, green mature bananas responded to this treatment with control of CI symptoms when removed to RT after 3 weeks I.W. at 8°C.

Wax Coatings

Suitable concentrations of wax coatings of the skin of papaya, banana and mango stored at 8°C for 2 weeks did not develop CI symptoms when removed to RT.

Modified Atmosphere Storage [MA Storage]

When the fresh commodity is enclosed in the thin low density polyethylene (LDPE) bags and stored at chilling temperature, the commodity stored, resisted CI up to 2 weeks. Banana, papaya and mango when enclosed in sealed polythene bags develop modified atmosphere and humidity inside the bag, which helps to alleviate CI symptoms. The fruits when removed to RT after 2 weeks of storage at chilling temperature and 8°C did not show CI symptoms.

9.3.2 Chilling Injury Symptoms

Fruit	Safe storage temperature (°C)	Symptoms
Banana	12	Brown streaking on screen
Cucumber	7	Dark coloured water soaked areas
Brinjal	7	Surface scald
Lemon	10	Pitting, red blotches, membrane staining
Mango	12	Dull skin, brown areas on skin
Papaya	7	Pitting, water soaked areas
Pineapple	10	Brown or black flesh
Tomato	12	Pitting

9.4 HIGH TEMPERATURE DISORDERS

Exposure to high temperature or direct sunlight can cause bleaching, scalding, uneven ripening and desiccation in horticultural produce. Sunburn scald in apple is an example of high temperature disorders and its symptoms vary from brown to black areas damaged by sunlight.

9.5 DISORDERS DUE TO ALTERED ATMOSPHERIC COMPOSITION

Although modification of atmosphere around produce is done to extend the shelf life of horticultural commodity, they are very sensitive with regards to the concentration of carbon-di-oxide and oxygen. High carbon-di-oxide levels cause uneven colour development and excessive softening in tomatoes. Reduced oxygen levels cause internal browning of pears. Some physiological disorders of fruits are shown in Table 9.1.

Table 9.1: Physiological disorders of fruits

Product	Disorder	Symptoms
Apple	Superficial scald	Sunken skin discolouration
	Sunburn scald	Brown to black area damaged by sunlight
	Senescent breakdown	Brown, mealy flesh
	Low temperature breakdown	Browning in cortex
	Water core	Translucent areas in flesh
	Brown heart	Brown areas in flesh
Pear	Core breakdown	Brown, mushy core
	Neck breakdown	Brown to black discolouration of vascular tissues connecting stem to core
	Superficial scald	Grey to brown skin speckles
	Brown heart	Brown areas in flesh
Grape	Storage scald	Brown skin discolouration
Citrus	Storage spot	Brown sunken spots on skin
	Cold scald	Superficial grey to brown patches
	Stem end browning	Browning of shrivelled area near stem end
Peach	Wooliness	Red to brown dry areas in flesh

9.6 MINERAL DEFICIENCY DISORDERS

Plants require a balanced mineral intake for proper development; if any of the essential minerals are deficient it will be manifested during plant development or in the plant or plant parts. Many times the browning symptoms in certain fruits and vegetables are attributed to the deficiency in some mineral constituents of the produce. These disorders can be prevented by either pre-harvest or post harvest application of specified minerals.

Calcium deficiency is one of the major problems. Calcium is physiologically important mineral as its deficiency may suppress respiration and several other metabolic sequences in plant tissues. Further, calcium is associated with pectic substances in the plant cell that helps in strengthening of tissue. Potassium is other mineral that manifests its symptom both during excessive application and deficiency. Other minerals may also play role in maintaining proper plant and produce health. Toxicity of copper, iron and cobalt may cause similar symptoms to low temperature break down and superficial scald in apples. Copper also acts as a catalyst to browning enzymes (Table 9.2).

Table 9.2: Mineral deficiency disorders in fruits and vegetables

Fruit	Mineral	Disorder
Apple	Calcium	Bitter pit, cork spot, cracking, low temperature break down, senescent breakdown, water core
	Boron	Internal cork
	Potassium (High)	Bitter pit
Beans	Calcium	Hypocotyls necrosis
Cabbage	Calcium	Internal tipburn
Carrot	Calcium	Cavity spot, cracking
Mango	Calcium	Soft nose
Pear	Calcium	Cork spot
Pepper	Calcium	Blossom end rot
Potato	Calcium	Tipburn
Tomato	Calcium	Blossom end rot, cracking, black seed
	Potassium	Uneven ripening

Blotchy Ripening, Greenback or Solar Yellowing of Tomatoes

It is green, yellow or translucent hard patches of tissue spread over the red colour of ripe tomatoes. The parenchyma surrounding the vascular bundles of the outer fruit walls are necrotic and disorganized. The affected tissues may either be opaque or brownish in colour and are lignified and starchy.

The green areas of blotchy fruit contain less solids, nitrogenous compounds and sugars; more total and insoluble pectic substances; less pectinesterase and polygalacturonase activity; and lower titratable and total acids than the red parts.

Blotchy ripening of fruit may be affected by the nutrition of the plant. Potassium deficiency or excess nitrogen nutrition may bring about more blotchy fruits. Blotchy fruit may be not only a nutritional effect but also a result of stress leading to tissue compartmentalization. The blotchy section has different metabolic pattern than the normal tissue development.

Shading fruit with aluminium foil caused a decrease in the severity of greenback, whereas shading with black PVC foil increased its occurrence. Green back is caused by variations of temperature on the tomato fruit pericarp during maturation. The higher the temperature at any part of the fruit, the greater the incidence of greenback. Temperature is a direct effect of incoming radiation and heat transfer coefficient. Factors such as variation in the chlorophyll content around the fruit, position of the fruit relative to the sun, stages of maturity, size and variety will produce localized temperature differentials. Metabolic activity would likewise differ, leading to blotchy ripening.

It is commonly observed that large fruits are more frequently and severely damaged by greenback than small fruits. The intensity of greenback depends on length of exposure and degree of temperature. Defective colouration of tomato shoulders is not primarily a heat effect but mainly a result of short-wave radiation. Short-wave radiation not only reduces the carotenoid synthesis in blotchy fruits, but also inhibits the C2H4 production.

Blossom-end Rot

This disorder is described as brown proteinaceous inclusions occurring in the epidermis and pericarp, at the stylar-end of the fruit. Cell membranes become disorganized and tissue necrosis develops underneath, the skin remaining intact. The causal factor for blossom end rot may be the Ca deficiency. This can be effectively reduced by application of Ca $(NO_3)_2$ and gypsum or by spraying with $CaCl_2$ solution. Excess K may also result in the production of blossom-end rot, probably through a Ca deficiency-induced effect. Water stress may aggravate this disorder.

Cuticle Cracks

Shallow, slightly dark, tiny but well healed cracks on tomato fruit surface are referred to as cuticle cracks or skin checks. Because the waxy covering is removed, water loss is rapid and shrivelling and discolouration follow. Cuticle crack is probably caused by the fluctuations in moisture regime and temperature.

Fruit Tumor or Waxy Blister

This disorder consists of a wax-like irregular tumor on the fruit surface starting as smooth, turgid blisters, which turn brown, depressed and cracked as the fruit ripens. Blisters may be induced by rubbing green fruits and storing at 20-35°C. The injury caused by rubbing apparently sparks the synthesis of more growth hormones with kinin like activity, which causes increased cell division and result in tumorous growth. Blister is mainly a handling disorder and may be controlled by careful picking, proper packing and minimizing damage during transport. Ripening at lower temperature is also recommended for avoiding this disorder.

Growth Cracks

This disorder is characterized by rupturing or cracking of the fruit, usually either around the stem-end (concentric) or from the stem-scar down the fruit shoulders (radial). Abundant rainfall and high temperatures favours rapid growth and predispose tomato fruits to growth cracks. The specific cause of rupturing could be an uncoordinated tissue expansion during growth or simply a turgidity phenomenon. It may be controlled by picking before the fruits are ripe and by planting crack-resistant varieties.

Puffiness

Puffy tomato fruits are downgraded or are rendered unmarketable in serious cases. Affected fruit is hollow and light in weight. The surface between the internal cross walls is usually flattened or sunken. The large pockets are observed in cut tomatoes in the cavities occupied by the seed-bearing tissues.

Factors, which inhibit normal pollination, may cause poor development of seed-bearing tissues, and growth in such fruits lags behind the normally developing peel tissues leaving empty spaces between them. A too high or too low growing temperature, drought, excessive moisture supply and heavy N application interferes with normal pollination and hence should be avoided to reduce the incidence of puffy fruits.

Sunscald or Sunburn

Cabbage: Sunscald in cabbage starts as blistered, irregularly shaped areas that become papery and bleached later. Exposed leaves on the top of the head are usually affected. Because of possible secondary infection by decay-causing microorganisms, affected leaves should be removed prior to packing.

Pepper: The sunscald in pepper is due to exposure of the fruit to the intense heat of sunlight. Sunburn appears as light-coloured and soft areas on the fruit surface, which eventually becomes papery. Another type of injury, termed delayed sunscald, which appears after harvesting. Initially the fruit is water soaked and becomes dry and brown, but lacks the bleaching and papery symptoms.

Pomegranate: Exposure to the sun during fruit growth produces a brown, tough, leathery and slightly russetted patch on the rind.

Beans: Beans affected by sunscald appear first as tiny reddish spots forming reddish-brown streaks across the pods. At an advanced stage of sunscalding, pods become water-soaked followed by browning and shrinking of the affected tissue. This occurs only on one side of the pod, and is more serious during moist weather.

High Temperature – Induced Desiccation

Avocado (Heat Injury): Prolonged exposure of some cultivars of avocados to a temperature of 20°C causes damage to the fruit and the fruits held at 25°C to 30°C will not ripen normally. It causes uneven softening and discolouration may occur which makes fruit unpalatable due to off-flavours. The flesh darkens and brown spots appear on the skin. At 32°C, the flesh becomes rubbery and pitting like symptoms on the skin may occur.

Banana (Dehydration): Water loss in banana results in shrinkage of tissue or may even cause symptoms similar to severe chilling. Pitting in bananas may be induced either by high temperature or low RH. RH below 80% may produce symptoms characteristic of low-temperature breakdown. These effects lead to abnormal ripening. Therefore to avoid dehydration, bananas should be promptly cooled after harvesting and stored at humidities between 90 and 95%.

Lychees (Browning): Lychee browning is a desiccation phenomenon due to exposure to dry air. It starts at tubercle tips, creeping downward and spreading on the bright-red shell. At an advanced stage, the entire surface of the fruit may turn completely brown. Browning may be reduced by storing at 2°C for up to 5 wk or at 7°C for less than 2 wk in polyethylene bags.

Onions (Translucent Scales): Translucent scale of onions consists of clearing of the normally opaque cells due to a disintegration of the parenchyma walls. It looks similar to freezing injury, however the distinguishing features are mentioned below:

	Freezing Injury	**Translucent Scale**
Pattern of damage	From the surface inward	No pattern
Stem plate	May be affected	Not affected
Scales	Outer more affected than inner	Inner may be more affected than outer
Freshly cut surface	Dry	Moist
Areas of white opaque tissues	Present	Lacking
Epidermis of affected scales	Loose	Loose only in severe cases
Texture of surface with epidermis removed	Grainy, rough	Smooth, slick

Major factors influencing the severity of this disorder include delays at 15 to 30 days between the end of curing and the start of storage at 0°C during 7 months storage. Tropical conditions where the temperatures goes above 32°C for about 50% of the growing period or above 35°C for about 30% of growth period of the plant, have high probability of developing this disorder during storage. Prompt cold storage and early covering the bulbs with soil reduces the incidence.

Growth Cracks and Splitting

Pomegranate (Splitting): Cracking of pomegranate during ripening is a natural characteristic believed to be due to humidity fluctuations, dry winds and irrigation. Picking over-mature fruit should be avoided to prevent cracking during storage. Cracked fruit may serve as an avenue for entrance of decay-causing organisms

Sweet potatoes (Growth cracks): Fairly deep fissures may develop on sweet potatoes due to successive growth interruptions in the field. In some cultivars, high N fertilization and irrigation followed by a dry weather may induce growth cracks.

Disorders Related to Certain Field Conditions

Carrots (Scab Spot complex): Early signs of scab spots of carrots are pockets of black necrotic tissues occurring usually at or near the lateral rootlets, which later become sunken and scab-like. The cause of this disorder could be related to nutritional, climatic and genetic factors.

Potatoes (Surface Browning): Under conditions of low RH and high harvest temperatures, some portions of mechanically injured tubers undergo oxidation, resulting in objectionable surface browning. The affected area darkens with time and becomes much more noticeable after a few days. Surface browning may be induced at RH ranging from 25 to 30%. Temperature is secondary to RH as a factor in browning, but higher temperatures are associated with low RH, thus compounding the predisposition of tubers to oxidation.

Mango (Black-tip): Orchards near the brick kiln suffer heavily every year due to black tip necrosis of mango. Small-etiolated area at distal-end of the fruit appears after 3 to 4 days of fruit setting. It gradually increases in size and the tip becomes necrotic, often exposing the stone of the fruit as a result of disintegration of outer tissues. Affected fruits do not mature properly and tip becomes hard and black.

Regular sprays of boron from the flowering stage can control this disorder. Spraying mango tree with aqueous solutions of NaOH and Na_2 CO_3 minimizes losses due to black-tip.

Pineapple (Endogenous brown spot or black heart): This physiological disorder in its early stages is characterized by the formation of watery spots at the base of fruit lets near the fruit core. With increase in severity of the disease, the spots enlarge and turn brown; with further increase in severity, the spots turn darker and may join together to form a dark mass in the centre of the fruit.

It can develop in the fruit if the pineapples are chilled at low temperatures. There are no visible symptoms of the disease in uncut fruit either before or after the onset of the spots in the pulp, thus making it impossible to remove affected, fresh fruit prior to shipment. Hence, losses in commercial surface shipments of refrigerated fruit have been high, but no losses occur in non-refrigerated air shipments.

Storage Disorders

Onions and other commodities (Ammonia injury) Accidental exposure of onions to ammonia during cold storage may bring about marked discolouration. Red onions change to blackish-green and then dull greenish-black later. Yellow onions show initial yellowish-green colour on the edges of scales, turning bronze to brownish-black at an advanced stage. White onions become greenish-yellow on exposure to ammonia. Discolouration is always much more rapid and pronounced in a more humid atmosphere. Exposure to a 1% ammonia vapour for one hour is sufficient to initiate discolouration. Exposure to higher concentration of ammonia from leaks in cold storage may bring about colour changes almost immediately, and brownish-black areas may be seen within a few minutes.

Other Fruits and Vegetables are also Injured by Exposure to Ammonia

Banana	-	brown to black and tissue breakdown;
Grapes	-	discolouration of berry and complete breakdown of the tissue;
Citrus (sweet orange and lime)	-	dark brown discolouration of the rind;
Mango	-	brown surface, pitting and breakdown of the tissue;
Potato	-	brown to dark brown pock marks, pitting, internal discolouration and watery breakdown
Tomato	-	impaired colour development, discolouration of the skin and breakdown of the tissue.

Potatoes (Greening): Greening of potatoes exposed to light during storage occurs due to synthesis of bitter, toxic alkaloid solanine. Although chlorophyll formation is independent of solanine synthesis the same factors, i.e., light quality and intensity, storage duration and age of tuber, affect solanine formation.

Sweet potatoes (Internal breakdown): Internal breakdown is a storage disorder where the internal tissues of sweet potatoes are pithy, dry and spongy. This usually occurs late in the storage season in warm and dry storage rooms, or in rooms with chilling temperatures.

CA Storage Disorders

Two types of disorder may be developed under a CA storage condition: injury due to sub oxidation and that due to CO_2 accumulation. Other volatiles may accumulate in the storage rooms above the critical level resulting in the development of off-flavours and off-odours and progressive death of the tissue.

Sub-oxidation causes blackheart in potatoes, promotes browning in limes, or produces off-flavour and objectionable alcoholic odour in many fruits and vegetables. High CO_2 on the other hand, (a) produces a slight carbonated taste in melons; (b) a general browning of surface (e.g. asparagus) and internal tissue (e.g. cabbage); (c) a stimulation of ethyl acetate production on strawberries (d) off-flavour; (e) off-odour; (f) pitting; (g) impaired ripening; (h) susceptibility to decay-causing microorganisms; and (i) mild necrosis in some fruits and vegetables.

Disorders of Uncertain Causes

Escarole (Marginal browning)

Edges of leaf blade become dry, dark, curly and brittle. The control measures include refrigerated transit, adequate refrigeration, prompt pre-cooling and marketing, removal of old leaves and discarding over-mature escarole may minimize the occurrence of marginal browning

Garlic (Waxy breakdown)

Garlic bulbs are seriously affected by a yellow waxy breakdown believed to be a physiological disorder. The flesh of the clove is somewhat sticky or waxy to the touch but not disintegrated. The outer scales show no indications of breakdown.

Lettuce (Marginal browning: Pink rib and russet spotting complex)

Marginal browning is a physiological disorder characterized by yellowing, followed by browning or necrosis of wrapper-leaf margins. Adverse growing conditions or improper transit and storage conditions, which accelerate senescence, appear to be the origin of this disease. Control measures include refrigerated transit, adequate refrigeration, prompt pre-cooling and marketing, removal of old leaves and discarding over-mature lettuce may minimize the occurrence of marginal browning.

Heads of lettuce affected by pink rib have pinkish, wrinkled and pebbly textured midribs. Over-mature lettuce or plants held long in storage show higher incidence of pink rib. The causative factor is not known. The control measure includes the measures adopted to delay senescence.

Russet spotting complex includes several types of discolouration originating from the field, transit and storage, but distinction among them is uncertain. These symptoms include russet, vein browning, C_2H_4 burn, red heart, internal browning, brown spot, brown blight, rust or storage breakdown. In general, the variable symptoms are irregularly shaped specks ranging in colour from light yellow, pink to dark brown, affecting the ribs, veins and interveinlet tissues. Because of the complexity of origin, only routine quality control measures may help to ameliorate the disorder. Thus, harvesting properly matured heads, rigid grading and culling at handling points, use of refrigerated trucks during transport and prompt pre-cooling and marketing may reduce its incidence.

Mango (Internal breakdown): This physiological disorder is most common in ‘Alphonso’ mango. It is termed as ‘internal breakdown’, ‘spongy tissue’, or ‘soft centre’. So far it is observed only in this cultivar. Externally, the fruit appears to be sound. The disorder is noticed when the fruit is cut into halves. It is observed only in semi-ripe and ripe fruits. The breakdown tissue is characterized by pale yellow colour, soft or spongy texture with or without off-flavour. It starts from the tissue adhering to the stone and gradually spreads to the periphery. In extreme cases, the whole flesh portion becomes too soft resembling bacterial rot. The causative factors for the onset of this breakdown and its control are not known.

Pomegranate (Internal breakdown): Internal Breakdown of pomegranate is characterized by arils, which become light in colour; flat in taste; and sticky in appearance. White lines radiate in all directions from the seed to the outer wall or aril.

9.7 LET US SUM UP

Different advance techniques are used during production as well as storage of products. It is important to use these techniques properly so that spoilage of product due to physiological disorders can be avoided. Preventing the metabolic sequences that leads to the development of disorder can prevent disorders. Sometimes chemicals are used to prevent the disorders. Genetic improvement of horticultural cultivars may also help in alleviating the occurrence of disorder. Physical methods of maintaining optimum storage temperature and storage atmosphere may help in reducing many disorders.

9.8 KEY WORDS

Disorders	:	Not a normal growth or product.
Symptoms	:	The condition that accompanies something and indicates its existence.
Nutritional	:	Substances that promote growth.
Ethylene	:	A colourless flammable gas which stimulates ripening.
Browning	:	To become dark or surface develops brown pigments.
Deficiency	:	Absence of some essential thing forms the nutrition.
Toxicity	:	Consumption of which acts as a poison.
Genetic improvement	:	Improvement of quality of a product by using the improved hereditary material.

9.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answers should include following points:

   - Low temperature storage
   - Surface pitting
   - Ethylene production
   - Uneven ripening

2. Your answers should include following points:

   - Pitting
   - Dull skin
   - Skin discolouration

3. Your answers should include following points:

   - Bleaching
   - Scalding
   - Desiccation

4. Your answers should include following points:

   - High temperature disorder
   - Sun scorching

Check Your Progress Exercise 2

1. Your answers should include following points:

   - Softening
   - Improper colour development

2. Your answers should include following points:

   - Proper development
   - Deficiency manifested in form of disorders

3. Your answers should include following points:

   - Pectic substances
   - Deficiency suppresses respiration

4. Your answers should include following points

   - Catalyst
   - Deficiency causes disorder

UNIT 10 FERMENTATION, METHOD OF FERMENTATION AND INDUSTRIAL SIGNIFICANCE

Structure

10.0 OBJECTIVES

After studying this unit, you should be able to:

- state the meaning of biotechnology and fermentation;
- infer the historical importance of different varieties of fermented foods prepared all over the world from various agricultural commodities;
- know the nutritional significance and beneficiary effects of fermented foods and their classification;
- describe the general methods in fermentations for the cultivation of microorganisms;
- state the importance of aerobic and anaerobic fermentations; and
- discuss the difference between solid state fermentation and submerged fermentation.

10.1 INTRODUCTION

In recent years, biotechnology and information technology have been given much importance. It is believed that these areas of Science and Technology would help to improve the standard of living as well as the life span all over the world. Biotechnology is the integrated use of biochemistry, microbiology and chemical engineering to achieve industrial application of microorganisms and tissue culture. Unlike material sciences, in biotechnology the key of any process or activity is the biological source viz., microorganisms (bacteria, yeasts, fungi and virus) plants and animals. If we scan the books and journals, we find most of the processes are based on microbes through fermentation. These microorganisms produce newer types of products (vitamins, antibiotics, hormones, amino acids, enzymes, beverages, fuels and solvents, life saving drugs) or convert raw food stuffs (cereals, pulses, fruits, vegetables, animal, fish, poultry and dairy products) into palatable, nutritious and processed foods with longer shelf life.

Fermentation is the oldest word used for biotechnology from time immemorial when nothing was known about microorganisms or technology. Bread-making, cheese manufacture and production of wine and alcoholic beverages are the certain examples. *Fermentation can be defined as the chemical modification of organic compounds or raw materials or agricultural commodities with the aid of enzymes produced by microorganisms*. With respect to foods, it is the transformation of physical structure and chemical constituents (carbohydrate, proteins, fats and nucleic acids) by microorganisms and their enzymes under aerobic (presence of oxygen) or anaerobic (absence of oxygen) conditions. Examples are wine from grapes, cider from apples, beer from malted barley, whisky, gin, rum, pickles, curds, idli and dosai, bread and nan, cheese and lactic beverages.

10.2 HISTORY OF FOOD FERMENTATIONS

When we go through several books and research articles we find a number of definitions of fermentation. The most frequently used names were: respiration, fermentation, putrefaction, decay, digestion, dissimilation and ferment. However, the major developments in the twentieth century in the field of microbiology, molecular biology, chemical engineering and biochemical engineering and biochemistry have resolved this confusion.

If we look at the human's civilization, the man has passed through several stages viz., hunting, gathering food to this stage of collective cultivation and processing of foods. During the early stages, sun-drying, salting and fermentation were practiced and in certain pockets especially in tribals and rural areas in India and other countries, these are in vogue sometimes singly or in combinations.

The Egyptians, Sumarians, Babylonians, Assyrians and Indians knew the technique of alcoholic beverages production. Indians were used to *Ashwas* and *Arishtas*. Drinking wine was common in the Roman Empire throughout Europe and North Africa. Mead was prepared from honey. Idli, dosai and other fermented foods were introduced in South Indian dietary system since time immemorial. Soy sauce, miso and tempeh were known to Chinese as early as 1000 BC and the techniques were passed on to Japan around 600 AD. Fermented dairy products such as curds and butter milk are referred in early Sanskrit literature. The word fermentation comes from the Latin word *ferveo* meaning to boil. From this *fermentum* was derived which means yeast or leaven. The evolution of bubbles due to carbon dioxide production was noticed in alcoholic fermentation and hence this name was given. Louis Pasteur in France in 1861 was first to declare that a group of microorganisms viz., yeasts are responsible for fruits and grains fermentation for the manufacture of wine and beer. He also described that along with desirable type of microorganisms, undesirable types also grew in the ferment and also these were responsible to spoil the quality of final product. He was first to suggest heating at $62.8^{o}C$ for

30 minutes (pasteurization) to eliminate the undesirable microorganisms from the fruit juice before fermentation.

10.3 MICROBIOLOGY AND BIOCHEMISTRY

As you have become aware, food fermentations started with the development of man's civilization purely due to necessity. During those days nothing was known about science and technology of fermentation and also causitive agents viz., microorganisms and their enzymes responsible for it. It was also not known that these microorganisms fall under two categories: **useful** producing life saving drugs, chemicals and fermented foods and products and **harmful** causing spoilage of the products and responsible for many deadly diseases (Cholera, typhoid, plague, small pox etc.). These became evident after the discovery of microorganisms and their systematic scientific studies in the middle of nineteenth century when Louis Pasteur established their role in fermentations and human and animal diseases. In India, food prepared if left over night outside, gets spoiled due to the growth of microorganisms. Microorganisms spoil the food by damaging the structure, colour, and chemical and physical characteristics both in raw as well as processed foods. Bread (*Rhizopus nigricans, Aspergillus niger, Penicillium notatum)* fresh fruits and vegetables (*Rhizopus* and *Erwinia)* Pickles (*Rhodotorula, Candida, Pichia),* meat (*Alcaligenes, Clostridium, Proteus vulgaris, Pseudomonas fluorescens),* fish (*Flavobacterium, Alcaligenes)* eggs (*Pseudomonas fluorescens)*, orange juice (*Lactobacillus, Leuconostoc, Alcaligenes)* and poultry (*Pseudomonas, Alcaligenes)* are spoiled by a number of microorganisms and thus become unfit for consumption.

Some bacteria such as *Salmonella* spp., *Shigella dysenteriae, Vibrio cholerae, Clostridium botulinum, Clostridium perfringens, Listeria* spp. and *Campylobacter* spp. produce toxins causing food poisoning. *Aspergillus flavus, Pencilllium citrinum, Fusarium graminarium* and many strains and species of fungi in under humid and hot conditions grow on agricultural commodities and food materials and produce different types of toxins which are deleterious to human and animal health.

The growth and activity of microorganisms thus are important in controlling the quality and safety of food. Both harmful and useful microorganisms grow in their environmental and ecological conditions in food commodities, food preparations and processed foods and other systems and produce enzymes, metabolites and toxins depending on nutritional and physical factors. These factors are water activity, pH, temperature, chemical constituents and the buffering compounds. In natural fermentation (without addition of microorganisms, inoculum or starter culture) and controlled fermentation (addition of starter culture/s), microorganisms bring about many chemical and structural changes in organic constituents of foods and thus check the growth of pathogenic microorganisms. Examples are lactic acid producing bacteria, alcoholic fermentations, oxidation of alcohol to acetic acid, production of other organic acids and amino acids and nucleotides and changes in cellulose, hemicellulose, pectins, gums, fats and proteins.

Lactic acid producting bacteria have been used since time immemorial all over the world in preserving and modifying foods such as cereals (idli, dosai, nan) milk (curds), cheeses and fermented meat and fish.

The lactic acid bacteria convert available carbohydrate to lactic acid where by lowering the pH and changing the conditions suitable for the growth of yeast. Some times propionic acid is also produced which acts as a preservative. They also produce flavour compounds e.g. diacetyl, acetaldehyde and acetoin. This action of lactic acid producing bacteria is observed in the production of many traditional and indigenous foods from fruits and vegetables, legumes, cereals, milk, meat, poultry and fish etc. The acids developed by the organisms during the processing of foods contribute to the flavour of the final product and also act as preservatives preventing the growth of undesirable pathogenic and spoilage microorganisms.

Some of these lactic acid producing bacteria produce lactic acid only or acetic acid, formic acid and ethyl alcohol. The organisms producing only lactic acid are known as *homofermentative* and those producing lactic acid with other compounds are *heterofermentative*. Lactic bacteria normally isolated from vegetable fermentations are: *Lactobacillus plantarum, Lactobacillus brevis, Pediococcus cerevisiae, Leuconostoc mesenteroides* and *Lactococcus lactis.*

10.4 NUTRITIONAL VALUES OF FERMENTED FOODS

It is clear now that early man or our ancestors used to store fruits, vegetables, seeds, cereals and even fish and meat for the lean period when the supply of these commodities were scarce. The first reason was storage in order to check the spoilage. The other reason was to improve the nutritional quality and also palatability and acceptability. Certain flavours such as sweet, sour, alcoholic, meat like are obtained in the final fermented products through microorganisms by fermentation. Soybeans and many legumes are difficult to digest and therefore many fermented products are prepared in the oriental countries e.g., China, Japan, Indonesia and African Countries. Besides flavours, these fermentation also increase the levels of vitamins and also amino acids. In general the important beneficial changes obtained through fermentation are:

- Improvement in the profile of flavours, aromas and textures in food substrates.
- Preservation through lactic acid, alcohol, acetic acid and alkaline fermentations.
- Enrichment with essential amino acids, essential fatty acids and vitamins.
- Detoxification of certain toxic constituents during food fermentations.

10.5 NUTRITIONAL QUALITY OF FERMENTED VEGETABLES AND FRUITS

When we consider this aspect of fermentation, most of the vegetables e.g., cabbage (Sauerkrauts and Korean Kimchi), cucumber, green olives, carrots, onion and various others (tomato, pepper, green peas, cauliflower and mustard leaves) are fermented in European countries. Relatively few vegetables are fermented in India. However, the beneficial effect of fruits and vegetables is as follows:

10.5.1 Beneficial Dietary Effects

As reported by nutritionists and health experts, fermented vegetables are rich in fibre, vitamins and minerals. We all are fully aware regarding the importance of fibre in our dietary system. Many intestinal and heart problems are associated with less consumption of fibre especially the processed foods. There are several benefits in consuming fermented vegetables with live lactic acid producing bacteria:

Lactic acid bacteria if taken along with fermented vegetables or fruits in the diet lower the blood serum cholesterol level.

These bacteria produce a number of metabolites which are beneficial to human health.

They help in preventing tumor formation in the body due to stimulation of factors responsible for immunity.

Lactic acid producing bacteria inhibit the formation of carcinogenic compounds in the gastrointestinal tract.

They reduce the growth and enzyme production by the intestinal bacteria e.g., enterobacters.

These bacteria and fermented foods if taken as a food, change the microflora by eliminating pathogenic and undesirable organisms in our intestine and colon.

10.5.2 Protection of Vitamin C in Fermented Vegetables

In India, we do not include fermented vegetables in our dietary system. However, in Europe, North America and Korea, cabbage and several other vegetables are fermented and higher levels of vitamin C is found in them due to its synthesis by microorganisms.

10.5.3 Mineral Preservation in Fermented Vegetables

The fermented vegetables in a meal help higher assimilation of iron. Iron bioavailability is better in lactic acid producing bacteria fermented carrots.

10.5.4 Reduction in Nitrate Content

Due to the widespread use of nitrogenous fertilizers, high quantities of nitrates are sometimes found in food products. This nitrate which is harmless as such, is reduced and converted into nitrites which finally gets transformed into highly carcinogenic nitrosamines. During lactic acid fermentation of vegetables, nitrites are converted into NO_2 which goes out as a gas.

10.5.5 Improved digestibility

Many indigestible compounds responsible for gas and flatulence and also sulphur compounds in garlic or onion are broken down to inoccous break down products.

10.6 POSSIBLE HARMFUL EFFECTS

a) A number of amines are formed during the fermentation of cabbage, carrot, pepper and turnip etc., and thus their higher concentrations cause unpleasant flavour to the final product or toxic effect. Ingestion of certain amines can cause headaches, fever and vomiting almost similar to microbiological food poisoning. Histamine, tyramine, putrescine, and cadaverine are normally noticed in the fermented vegetable products.

b) During the fermentation process D(-)lactic acid is also produced depending on the type and number of lactic acid producing bacteria. D(-) form of lactic acid is not assimilated in the body and thus gets eliminated by the kidney in the form of salts which results in the loss of calcium and magnesium. Normally D(-) lactic acid concentration in the fermented vegetables is low without having any adverse effect on the human health. However, care is needed to restrict the quantity in the meals.

10.7 CLASSIFICATION OF FERMENTED FOODS

It is important to know about different varieties of fermented foods prepared and consumed all over the world depending upon the agricultural and food raw materials produced in that region. These fermented foods can be classified into the following categories:

i) Fruit and Vegetable products

ii) Beverages (alcoholic and non-alcoholic)

iii) Cereal products

iv) Milk Products

v) Fish Products

vi) Products from Legumes

vii) Meat products

viii) Starch Crop products

i) Fruits and Vegetable Products

You are now fully convinced that the fermentation of food commodities was practiced by the early man and by trial and error many technologies were developed. Vegetables have been preserved throughout the world by fermentation. Examples are cabbage (Sauerkraut, Korean Kimchi), radish, mustard leaf, gherkins and cucumbers, ginger onion, chilli and bambooshoots (Malaysian pickles), carrot, turnips and peppers. In India, relatively very few vegetables are fermented and preserved for consumption. Among fruits, olives are commercially fermented and consumed in European countries as an appetizer.

ii) Beverages (alcoholic and non-alcoholic)

Beverages are produced in large quantities in all regions of the world. We normally find two types of beverages which are common everywhere. The first group comprises of alcoholic beverages in which fermentation plays a major role in contributing the flavour and chemical and physical characteristics of the fermented products. Beer and wine fall under this category. After fermentation further distillation is done and thus a variety of products termed 'spirits' such as whisky, gin, brandy, rum etc., are produced.

The second category of beverages are non-alcoholic e.g., coffee, cocoa and tea. All of them involve fermentation. India is a major producer of tea and coffee. If you look at the worlds map, you find an interesting observation that these are based on the type of agricultural crops cultivated in that particular area depending on the geographical and climatic conditions. The colder countries of Europe including Britain, Scandinavia, Netherlands and Poland consume beer which is manufactured mostly from barley. The southern countries of Europe grow grapes extensively and produce different varieties of wine. These beverages have spread to many countries wherever the European settled e.g. Northern America (The United States of America, Canada), Australia and South Africa. Rice beer in Indian sub-continent, sorghum beer in Africa, sake (rice) in Japan and a variety of alcoholic beverages are produced in different parts of the world. In Europe and North America apples are used for cider production. In warmer climate in Africa, Asia, Oceania (Australia and New Zealand), the Indian subcontinent and South America the sweet liquid sap of palm trees is fermented to wine. In India, it is known as '*Toddy*'. Cashew apple pulp is extensively is used for the preparation of Feni in Goa.

The alcohol content of most of the fermented materials varies between 5-18%. Its concentration is increased in the range of 35-55% by distillation and thus brandy, whisky rum and gin are manufactured. Consumption of excessive amounts of alcoholic beverages leads to intoxification and loss of body control. Therefore it is prohibited in many countries and also many religions of the world.

In contrast to alcoholic beverages, the non-alcoholic beverages most widely consumed throughout the world are coffee, tea and cocoa and these are largely produced in India especially in southern part of the country. The tea leaves are fermented as such by the natural microorganisms. In the case of coffee and cocoa the pulp surrounding the beans are removed by the natural fermentation. This process contributes to the flavour of the final product. Bacteria, yeasts and moulds are involved in the fermentation of these commodities.

iii) Cereal Products

Cereals are the major staple food in every parts of the world. These are wheat, rice and maize. The most popular fermented cereal product is bread which is consumed in every region. It is done by fermenting wheat flour dough with the yeast *Saccharomyces cerevisiae*. Lao-Chao is a fermented rice product of China prepared by natural fermentation containing strains of *Rhizopus oryzae,Rhizopus chinensis* and *Endomycopsis* species etc., Puto of Philippines, Ang-Kak of China, Ragi of Indonesia, Tape-Ketan of Indonesia, Ogi of Nigeria, Injera of Ethopia and Banku of Ghana are produced extensively and consumed regularly in these countries. In India, mixed fermented preparations of rice and pulses and other commodities are idli, dhokla, khaman, papad and jalebies etc., Ambali, bhatura, kulcha and warri are also Indian fermented foods prepared and used in different parts of the country.

iv) Milk Products

Milk products have been included in our diets since time immemorial. In early days, natural fermentation of milk was the best method of preserving milk. Dahi and Chhanchh (butter milk) are important ingredients of every day's meal all over the country. The other products are youghurt, cultured milk acidophilus milk, cheese, Srikhand, Kefir and Kumiss etc., Fermented milk products have therapeutic properties along with their nutritional characteristics, wholesomeness and good flavour and digestibility. These qualities are introduced in the product by a number of lactic acid producing bacteria e.g. *Lactococcus lactis* subsp. *lactis, Lactococcus lactis* sub-sp. *cremoris* (cultured butter milk, sourcream, cottage cheese, other soft and hard cheeses), *Lactococcus lactis* sub-sp. *diacetylactis* (sour cream, butter, cheese, butter milk), *Streptococcus thermophilus* (yoghurt, *Lactobacillus delbrueckii* sub-sp. bulgaricus (yoghurt, kefir, kumiss, bulgarian butter milk), *Lactobacillus acidophilus* (Acidophilus butter milk).

Realising the health giving properties of fermented milk products, different varieties of preparations are being marketed all over the world. These are acid alcohol fermented milk products, high acid fermented products, medium acid fermented products, low acid fermented products and whey based beverages.

v) Fish Products

The fermented fish products are popular in some countries. Philippine fish sauce and Vietnamese Nuoc-mam are prepared by fermenting sardines, shrimps and small sea fish etc., Malaysian budu is consumed as a condiment on rice and as a flavouring ingredient in various dishes. Baloa baloa is a fermented rice shrimp mixture of Phillipine and consumed by most of the people.

vi) Legumes Products

Pulses constitute an important component of diet after cereals in Asian countries, especially in India. In India we consume tur or arhar, black gram, green gram, Bengal gram, lentils and a range of beans. Soybeans is also gaining popularity in India. Legumes are rich in proteins, and also in oil and carbohydrates. Unlike cereals, their digestibility is poor and therefore, they are fermented to different products in oriental countries e.g., China, Japan, Indonesia, Malysia, Thailand and several African Countries. Majority of these pulses and beans contain oligosaccharides such as stachyose and verbascose which cause flatus in the intestine. Trypsin inhibitors are also present in these agricultural commodities. Fermentation stimulates these undesirable constituents. Thus the fermentation improves digestibility, nutritional quality and textural characteristics of the fermented products. Tempeh, sufu, soybean milk, soy sauce, natto, bangkrek, khaman, warries and mixed fermented foods containing cereals and pulses e.g., idli, dosai, dhokla etc., are consumed in different regions of the world.

vii) Meat Products

There are not many fermented meat products. These products are dry and semi-dry sausages. In the United States of America, the commercial sausages are Genoa and Salami. Among the popular European brands (dry) are summer sausage, cervelet, thurunger, and Teewurst. Semi-dry-sausages are turkey sausage, fermented frankfurter and Frischwurst etc., In Europe and Western World, fermented sausages are preferred whereas in India, their consumption is almost negligible. The lactic acid producing bacteria e.g., *Lactobacillus plantarum, L. sake, L. curvatus, Pediococcus acidilactici, P. pentosaceus, Lactococcus lactis* are mainly responsible for fermentation of meat. The safety and shelf life of the products are important because these products are contaminated easily and frequently by pathogenic microorganisms.

viii)Starch Crop Products

Cassava (tapioca) is a major food crop cultivated in several African Countries. It is a staple food to most of the people. It contains cyanogenic glucosides and therefore it must be processed. During fermentation, the cyanide content is reduced completely. Gari, lafun, fufu, peujeum, poi and tape are some of the products. Maize, Sorghum and millets are used for the preparation of fermented products like ogi, uji, koko fube and chika etc.

10.8 GENERAL METHODS OF FERMENTATION

The purpose and importance of food fermentation in our life including food preservation, textural modification and nutritional improvement, has already been highlighted earlier. In recent years, the fermentation industry stands next to information technology (IT) and software industries. It is therefore, pertinent to know general method's used in fermentation for the production of fuels, food and pharmaceutical products and life saving drugs.

There are two distinct types of fermentation which are commonly used for the above-referred purpose. These are:

a) Aerobic fermentation

b) Anaerobic fermentation

Aerobic Fermentation

These are carried out under the aerobic conditions in the presence of oxygen which is required for the growth and product formation by the microorganisms. Majoirty of the fermentations such as antibiotics, single cell protein, enzymes and amino acids come under this category. As listed above, the key of these fermentations is the microorganism/s and raw materials (ingredients) and cultural (pH, temperature, humidity and water content) and nutritional characteristics influence the product formation significantly. In many of the fruit and vegetable and agricultural commodities fermentations, the microorganisms grow at very low moisture level whereas in others contrary to this, it is carried out at very high levels of moisture in the range of 85-90% with adequate supply of oxygen. The former is termed as the solid-state fermentation (SSF) and the latter is called as the submerged culture fermentation.

Solid-State Fermentation (SSF)

SSF refers to the growth of microorganisms on solid materials without the presence of free liquid. It is considered to be economical since low moisture content is used and also does not require expensive equipments e.g, sophisticated fermentors. It is extensively practiced in the oriental food fermentations (miso, tempeh, soysauce, natto), secondary metabolites, enzymes, organic acids and composting etc. Although solid-state fermentation is a simpler and less expensive process of growing microorganisms, recovery of the final product adds finally to the cost during the down stream processing step. However it is widely followed for food and feed enrichment, food and feed enzymes production and composting and waste minimization.

Submerged Culture Fermentation

This method of fermentation has been practised for several years for the production of life saving drugs, enzymes, amino acids and organic acids by bacteria, yeasts, fungi and actinomycetes etc. Oxygen is supplied by either shaking or bubbling air through the liquid medium. Agitation, aeration and temperature affect the fermentation. Batch culture or continuous culture methods are followed for the production of fermented products - commercially.

Anaerobic Fermentation

These are carried out by strict anaerobes or facultative anaerobes such as bacteria and yeasts in the absence of oxygen. Examples of anaerobic fermentation are:

Ethanol (ethylalcohol)	→	*Saccharomyces cerevisiae* *Saccharomyces ellipsoideus*
Brewing (beer)	→	*Saccharomyces carlsbergensis* *Saccharomyces cerevisiae*
Lactic Acid Food preservation and fruit and vegetable fermentation	→	*Leuconostoc mesenteroides* *Pediococcus* spp., *Lactococcus* spp.
Acetone and butanol	→	*Clostridium acetobutylicum* *Clostridium Saccharoaceto butylicum*
Biogas (Methane carbon dioxide and other gases)	→	Strict anaerobic fermentation

10.9 PRE-REQUISITES FOR INDUSTRIAL FERMENTATIONS

After knowing these preliminary information about the fermentations, it is necessary to know what are the important points to be considered before starting laboratory or industrial scale fermentation.

a) Microorganism/s is the key for any fermentation whereas fermentor is the heart of the process. The choice of a good medium/substrate/raw-material is virtually as important as selecting a right type of strain or microorganism for the success of fermentation. The medium serves the following purposes:

i) It supplies nutrients for growth.
ii) It supplies nutrients for energy.
iii) It supplies nutrients for building of cell substance.
iv) It is required for the production of final product.

Nutrients needed for the growth and product formation are:

i) Carbon compounds derived mostly from starch, sugar and molasses.

ii) Nitrogeneous compounds.

iii) Inorganic salts.

iv) Water.

v) Vitamins.

vi) Growth factors.

vii) Precursors of fermentation products.

viii) Dissolved oxygen and other gases.

ix) Buffers.

x) Antifoam substances.

xi) Lysate of dead cells.

b) As you have become familiar that fermentation is a microbiological processes hence a potent strain of fungi; yeasts and bacteria is required for desired results. The choice depends upon many factors, the most important being the nature of the raw material. The youghurt preparation requires a strain of *Lactobacillus delbrueckii* sub sp. *bulgaricus* and *Streptococcus salvarius* subsp. *Thermophilus* and milk whereas *Leuconostoc mesenteroides, Lactobacillus, plantarum* and *Pediococcus cerevisiae* become predominant in cabbage for sauerkraut fermentation. In the mixed natural fermentation, it is not possible to control the number and type of microorganisms. Contrary to this in controlled fermentations such as alcoholic beverages, brewing and life saving drugs, an ideal microorganism is needed having the following characteristics:

i) The strain should grow profusely either in liquid or solid state conditions.
ii) The strain should be a pure culture and free of phages.
iii) The strain can be stored for a long period without any genetic change.
iv) The strain should always produce the predictable amounts of metabolite.
v) The strain should be amenable to strain improvement.

c) In nature, microorganisms exist as a mixed culture system and based on the chemical and physical characteristics of the substrate and environmental factors, one or two organisms dominate and thus desired fermentation is achieved. But in monoculture system, these have to be eliminated by sterilization using dry heat, moist heat (autoclaving), radiation and filteration. Sometimes tyndallization and pasteurization are also practiced depending on the nature of substrate and final product. For pharmaceutical and chemical productions, this step has to be strictly followed as per need of the process.

d) The next step followed is the inoculum preparation and then fermenter has to be inoculated containing cooled sterilized medium at the rate of 1-10%. The fermentation is carried out by controlling all the parameters strictly for a certain period and thereafter the product is obtained by filteration, purification, concentration and drying. The quality of product is monitored at this stage.

10.10 COMPUTER APPLICATIONS IN FERMENTATIONS

The computer application is gaining importance in fermentation industries. It serves two distinct purposes: i) evaluation of fermentation parameters and their impact on the synthesis of desired product in the cell; ii) on line fermentation control especially at the production scale.

Computers find wide acceptability in high valued low volume product formation mainly costly life saving drugs and chemicals. It is used for data acquisition such as information on pH, temperature, viscosity, aeration rate and O_2 and CO_2 content. It also helps in data analysis.

10.11 LET US SUM UP

Biotechnology has emerged as an important tool to improve the life of people. It implies the application of microorganisms, plants and animals. Fermentation is an important aspect of biotechnology and it has been in practice since time – immemorial. Both harmful (pathogenic) and useful (beneficial) microorganisms grow on different commodities and environment when physical (water activity, pH, temperature, humidity) and nutritional factors become favourable for their growth. These microorganisms modify the textural and chemical characteristics of food materials and thus make them highly nutritious and palatable. They enrich some of these agricultural food commodities with vitamins, minerals, amino acids and essential fatty acids. These fermented foods are classified into several categories based on the raw materials used for fermentation (fruits and vegetables, cereals, milk and fish and meat products etc.)

The methods of fermentation normally employed are solid state fermentation (SSF) and submerged culture fermentation both aerobic (presence of oxygen and anaerobic (absence of oxygen) conditions. In nature many microorganisms grow together thus mixed culture fermentation takes place whereas in industries one (monoculture) or two microorganisms with improved strains are used and their growth conditions are strictly monitored. Computers are employed in fermentation industries for different purposes.

10.12 KEYWORDS

Fermentation : Fermentation is the chemical transformation of the constituents of raw materials with microorganisms and their enzymes.

Harmful microorganisms : Spoilage and pathogenic microorganisms.

Useful microorganisms : Beneficial microorganisms (wine and beer producing, curd, cheese and bread making and ethanol production).

Homofermentative : The microorganisms only producing lactic acid.

Heterofermentative : Those microorganisms produce lactic acid along with acetic acid, formic acid and ethanol.

Aerobic fermentation : It is carried out in the presence of oxygen.

Anaerobic fermentation : Microorganisms grow in the absence of oxygen (Ethylalcohol, lactic acid, acetone, acetic acid, butanol).

Solid state fermentation (SSF) : Microorganisms grow on solid materials without the presence of free liquid.

Submerged culture fermentation : Microorganisms grows in the liquid medium in the presence of oxygen mostly.

10.13 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

- Emerging area of Science and technology.
- Application of microorganisms, plants and animals.
- Production of chemicals, value added products, food materials, medicines etc., commercially.
- A boon to people all over the world.
- A myriad of chemicals and products are produced by only microorganisms unlike plants and animals.

2. Your answer should include the following points:

- Change in chemical and physical characteristics of the raw materials.
- A process in which innumerable strategic chemicals (ethanol, medicines, harmones, vitamins) are produced by microorganisms.
- Production of bread, curds, cheese, wine, beer, whisky, rum and brand etc.,

3. Your answer should include the following points:
   - Causing fatal infectious and contagious diseases to human being, animals and plants.
   - Commercially producers of alcoholic beverages of different types from varieties of agricultural commodities, bread, lactic acid fermentation, amino acids, vitamins and antibiotics.
4. Your answer should include the following points:
   - Improves the shelf life of fruit and vegetables.
   - Improves the organoleptic quality.
   - Improves the nutritional quality and health benefits in foods.
   - A good method of storage of agriculture and food commodities.
   - Cheapest and simplest method of preservation.
5. Your answer should include the following points:
   - Fermented fruits and vegetables taken along with lactic acid bacteria lower the cholesterol level in blood.
   - Lowers the number of cardiovascular diseases.
   - Lactic acid producing bacteria present in foods inhibit the formation of carcinogenic compounds.

Check Your Progress Exercise 2

1. Your answer should include the following points:
   - Fruits and vegetables, alcoholic and non-alcoholic beverages, cereals, milk products, fish products, products from pulses, legumes, meat products, starch crop fermented products.
2. Your answer should include the following points:
   - Growth of microorganisms in the presence of oxygen.
   - Growth of microorganisms in the absence of oxygen.
   - Ethanol, beer, acetone, butanol, biogas (aerobic).
   - Enzymes, aminoacids, vitamins and organic acid (anaerobic).
3. Your answer should include the following points:
   - Growth of microorganisms on solid materials for examples grits of cereals, fruits and vegetables, wheat and rice bran etc.,
   - The moisture content is usually maintained around of 32-35% (SSF: Solid state fermentation).
   - Tray fermenters are conventionally used (SSF).
   - Fermentation is carried out in a liquid medium containing 85% moisture (submerged).
   - Sophisticated expensive fermenters along with other equipments are needed (submerged).
4. Your answer should include the following points:
   - Microorganisms are responsible for the conversion of constituents into the desired product.
   - Needs highly potent strains of microorganisms.
   - A good medium for the growth of culture.

- The medium should have optimum quantity of carbon source, nitrogen source, vitamins, minerals, water, pH and oxygen.

5. Your answer should include the following points:

- Monitoring the functions of fermenters during operation.
- Data acquisition and data analysis.

10.14 SOME USEFUL BOOKS

1. Steinkraus, K.H. (1995) Hand Book of Indigenous Fermented Foods, Second Edition, Marcel Dekker, New York.

2. Campbell-Platt, G. (1987) Fermented Foods of the World, Butterworths, London.

3. Wood, B.J.B. (1985) Microbiology of Fermented Foods Vol. 1&2, Elsevier Applied Science Publishers.

4. Reed, G. and Nagodawitana, T.W. (1995) Biotechnology, Second Edition, VCH, New York.

UNIT 11 FRUIT AND VEGETABLE-BASED FERMENTATIONS AND THEIR COMMERCIAL PRODUCTS

Structure

11.0 OBJECTIVES

After studying this unit, you should be able to:

- infer the commercial importance of fruit and vegetable based fermentations;
- state the significance of lactic acid fermentation in fruits and vegetables; and
- describe the state of art of sauerkraut, cucumber, kimchi, sinki and fermented pickles production.

11.1 INTRODUCTION

The importance of food fermentation has been highlighted earlier. It is evident that fermented foods are an intricate part of the diet of people in all parts of the world. These are always used as condiments accompanying the main dish. These foods are prepared from plant and animal sources. Fermentation primarily to preserve these commodities and also add flavour and change the texture in order to suit palatability and acceptability. Another important purpose is adding variety to the monotonous diet. Since it has been practiced since time immemorial, it is a house-hold art throughout the world. In recent years, a number of technological and biotechnological developments are taking place and several products are produced on commercial scale.

In early days, people used to collect vegetables and tried to preserve by adding salt. Chinese used to take acid-fermented vegetables during the 3rd century. Korean developed *Kimchi* made from acid fermented cabbage, radish etc., Fermented cabbage is popular in the Western World. Africans evolved the process for acid fermentation of maize, sorghum and tapioca. Even though nothing was known about the technology or microbiology and also about the nutritional quality of the products, the advantages of acid fermented vegetables, fruits, cereals and milk were well known to people during those days.

During the early twentieth century, it became known that microorganisms are responsible for physico-chemical textural and flavour and taste changes in fermented products. In recent years, some of the fermented foods have been scientifically investigated and based on the microbiological and biochemical information, technologies have been developed for commercial production. Since microorganisms are the key to these fermented food production, these fermented foods can be grouped for convenience as follows:

i) Acid fermentation preserving fruits, vegetables, milk, cereals, fish and meat etc., and enhancing orgnoleptic and nutritional quality.

ii) Protein rich vegetarian foods from legumes and seeds (Tempeh, Oncom etc.).

iii) Alkaline fermentation from beans (Kinema and African fermented foods).

iv) Alcoholic foods and beverages (Ethanol is a major product).

v) Sauces, pastes etc.

Microorganisms grow on the substrate and based on the chemical nature of the substrate, they bring about changes. Two types of acids are predominantly produced viz. lactic acid and acetic acid by microorganisms and thus a variety of products from agricultural commodities are produced especially from milk, cereals, and fruits and vegetables. The other important group of fermented foods is the protein enrichment and modification mainly from soybeans, peanuts and other legumes and pulses. Among beverages, alcoholic fermented beverages e.g., wine, beer top the list all over the world.

In recent years, vegetarian foods are considered to be ideal for human health. Among these lactic acid producing bacteria fermented foods are the best as these organisms tend to help in avoiding cardiovascular and heart diseases, cancer and several other gastrointestinal problems. The advantages of acid food fermentation are:

i) They avoid spoilage of foods and mould and bacterial toxins production.
ii) They preserve the food and assure the foods safety.
iii) They modify the flavour of the original ingredients and improve the nutritional value.

Since canned and frozen foods are beyond the reach of majority of people especially in rural areas, acid fermentation of agricultural commodities remains one of the most simplest and inexpensive method. However, in India acid fermentation of vegetables and fruits are not common as compared to European, Oriental and African countries. The raw materials containing high sugar content favour usually ethanol generation and its conversion to acetic acid. The fruits and vegetables having low level of sugar, allow lactic acid producing bacteria to proliferate which lowers the pH around4.0 due to lactic acid production.

11.2 LACTIC ACID FERMENTED FRUITS AND VEGETABLES

Fermented vegetables are common ingredient of European diet. Sauerkraut, olives and cucumbers are often fermented. The method of vegetable fermentation has been standardized over the centuries both for natural (spontaneous) or addition of starter cultures. The lactic acid producing bacteria grow on the substrate (vegetables) and convert sugar into acids (lactic and acetic). The gradual disappearance of carbohydrate (carbon content) leads to the production of lactic acid which ensures food stability. The pH about 4 of the fermented products inhibits the growth of spoilage microflora and pathogenic organisms.

Salt is added in good quantity which promotes the growth of lactic acid producing bacteria and checks proliferation of contaminating and spoilage microorganisms.

Fruits and Vegetables suitable for Lactic Fermentation

- Cabbage, cauliflower, broccolys, mustard
- Carrots, turnips, beetroots, radish
- Cucumber, Olives, tomatoes, peppers, green-beans and green peas
- Onion and garlic
- Apples, pears, green mangoes, banana, lemon, lime

11.3 SAUERKRAUT (CABBAGE) FERMENTATION

Sauerkraut or Sauerkohl is a German term which means *'Sour Cabbage'* Sauerkraut is extensively used in the North America (Canada and U.S.A.), Germany, Holland, France, U.K. and other European countries. Cabbage ('*Brassica oleracea*) normally grown in cold climate is found to be suitable for the fermentation purpose.

i) Processing

Fresh cabbage is taken, cleaned, trimmed and shredded into 2-5mm size and finally filled into wooden vats or cement tanks. Salt is added at the rate 2.25% and mixed thoroughly. The top portion of the vat or tank is covered with plastic and enough weight is applied in order to make it compact and allow anaerobic conditions prevail for fermentation. When weight is applied, the salt dissolves in the sap which is expressed by the pressure and by osmosis it comes out from the cells. The leaves respire for sometime and oxygen is utilized and thus anaerobic conditions are created. The leaves shrink in size due to water removal. A spontaneous lactic acid fermentation follows. Fermentation is done for about 30 days or more until 1% lactic acid is formed. The Sauerkraut is removed from the vat and packed in cans, glass or plastic containers. In cans the fermented product is pasteurized at 74^{o}C for 3 minutes. Sodium benzoate or potassium metabisulphite is added when product is packed unpasteurized. It is stored at $\pm$ 5^{o}C.

Figure 11.1: Sauerkraut (Cabbage) Fermentation

ii) Microorganisms Involved in Fermentation

Initially the shredded and processed cabbage leaves contain very high number of aerobic bacteria with low counts of lactic acid bacteria. During fermentation, the number of lactic acid bacteria increases suppressing the growth of undesirable organisms and a distinctive flavour of sauerkraut develops with about 1% of lactic acid content. The microorganisms follow usually the following pattern in succession: *Streptococcus faecalis, Leuconostoc mesenteroides, Lactobacillus brevis, Pediococcus cerevisiae, Lactobacillus plantatrum.* Initially heterofermentative nominate the numbers which is taken over by the homofermentative type of microorganisms. Sometimes a previous batch brine is added as a starter culture to facilitate quick fermentation.

iii) Spoilage

Sometimes fermented products are very badly spoiled by contaminating bacteria causing off flavours and colour and undesirable texture. Temperature, salt concentration and sanitary conditions are important to control the desired fermentation. Lower temperature around 7-10^{o}C favours slow growth of bacteria and thus allows good fermentation. In traditional system, fermentation is allowed for 6 months.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. List some of fruits and vegetables used commonly for fermentation and the mode of lactic acid production by the lactic acid producing bacteria.

11.4 CUCUMBERS FERMENTATION

Cucumbers (*Cucumis sativus)* are grown throughout the world. It is reported to have been originated in India. A number of varieties of cucumbers are cultivated in fields or greenhouses for table or pickling purposes.

i) Processing

Cucumbers are washed after selecting them and placed in a covered tank containing a salted and acidified brine. The brine is normally acidified (vinegar or acetic acid) to pH 4.5.The salt concentration of the brine is maintained between 5-8%. Too little salt less than 5% favours the growth of enterobacteriaceae bacteria. Higher levels of salt allows growth of yeasts. After the initiation of fermentation, almost everyday the brine is buffered with sodium acetate. During fermentation, contamination with yeasts is observed and therefore, to avoid bloater formation, the brine is purged with nitrogen or air. Potassium sorbate (0.035%) is also added to check the growth of yeasts and moulds preferably if fermentation is done at smaller scale. Fermentation if it is carried out at 15-20^{o}C, it takes normally 3 weeks to 1 month.

ii) Microorganisms involved in the fermentation

Streptococcus faccalis, Streptococcus lactis, Leuconostoc mesenteroides, Pediococcus pentosaceus, Lactobacillus brevis, Lactobacillus plantarum, Lactobacillus bavaricus are usually noticed during the fermentation. Controlled fermentation and pure culture fermentation have been studied but not commercially exploited. Glucose and fructose are converted to lactic acid, acetic acid, ethanol, mannitol and carbon dioxide. About 1.1%, lactic acid is present after the fermentation. Textural properties after fermentation is important. A firm and crisp texture is desired. A clean flavour is also desired.

iii) Spoilage

Bloater formation is observed due to the growth of gas forming microorganisms e.g. yeasts, bacteria and other contaminating organisms. Bleaching of the green colour of cucumbers takes place due to exposure of fruits to sunlight. Offensive flavours are produced due to the formation of butyric and propionic acids.

11.5 KIMCHI FERMENTATION

Kimchi is a major condiment of Korean diet. It is a popular dish served at every meal along with cooked rice. Kimchi is a fermented product, gaining popularity in the United States of America and other countries. It is made from cabbage and other vegetables like radish, mustard greens, cucumbers, green onions, Chinese leeks, turnips and green peppers, spinach, pumpkins and egg plants.

i) Processing

Good quality cabbages are selected, cleaned and cut into smaller pieces. The cut cabbage is placed in a brome solution containing 5-7% salt concentration for 12 hours. The brined vegetables are rinsed and drained. Seasoning ingredients are thoroughly mixed and filled in earthen jars or glass jars. The jars are buried (80-90% of container depth) underground. These are covered on the top with bundles of rice straw to protect from sunlight and rain. This technique is followed in the rural areas. In urban areas the mouth of the jar is covered with a cloth piece and kept in shaded places. Low temperature is considered to be ideal for slow fermentation. Usually less than 15^{o}C temperature is optimum for good quality Kimchi.

ii) Microorgansims involved in the fermentation

The microorganisms involved in Kimchi fermentation are *Leuconostoc mesenteroides, Streptococcus faecalis, Lactobacillus brevis, Lactobacillus plantarum, Pediococus cerevisiae.* The aerobic bacteria found are species of *Achromabacter, Flavobacterium* and *Pseudomonas.* The main bacterium responsible for Kimchi fermentation is *Leuconostoc misenteroides.* The fermentation is initiated by *Leuconostoc mesenteroides* and terminated by *Lactobacillus plantarum / Lactobacillus brevis.*

The organic acids produced during fermentation contribute to the final flavour of Kimchi. The organic acids normally noticed in Kimchi are citric, fumaric, oxalic, malonic, malic and succinic acids. Freshly fermented, good quality Kimchi should have distinct red or green colour with pleasant flavour and taste.

iii) Spoilage

Softening is the major problem in Kimchi fermentation. Yeasty and off flavours also effect the quality of the fermented product.

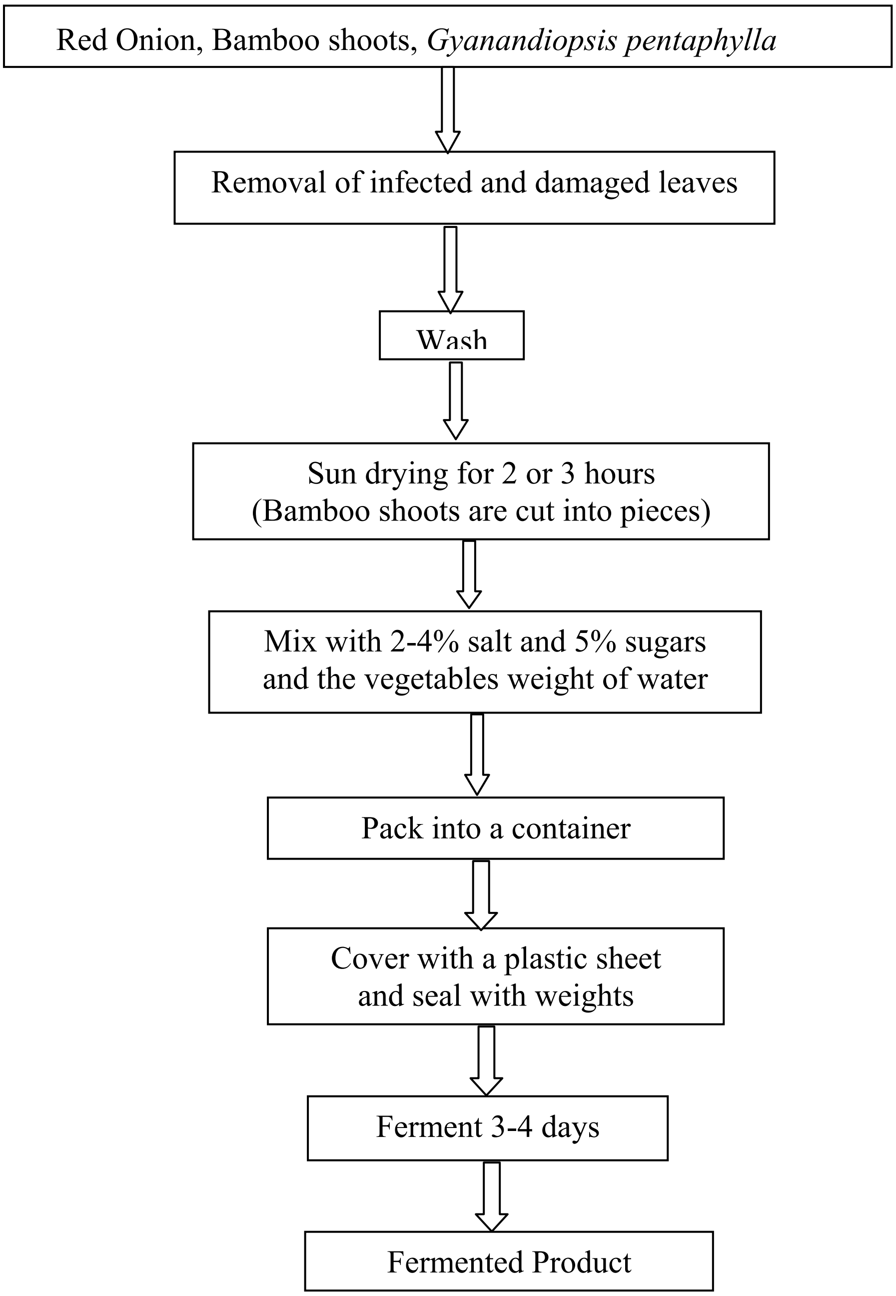
11.6 INDIAN SINKI FERMENTATION

Sinki is consumed as a pickle in the Himalayan belt of India, Nepal and Bhutan. It is prepared from the tap root of radish. Fresh radish roots are washed and placed outside for sun drying for 1 or 2 days. These are shredded and washed again and packed tightly into an earthen ware or glass jars, sealed and left for fermentation. Fermentation is carried out for 15-30 days at room temperature around 30^{o}C. Initially *Lactobacillus fermentatum* grows followed by *Lactobacillus brevis* and *Lactobacillus plantarum.* The pH drops to3.3 and acidity rises to 1.28%. When fermentation is over, the fermented radish is sundried for 3-5 days. It is fried with salt, tomato and green chilli. The fried mixture is then boiled in rice water and served hot as soup along with the main meal.

11.7 FERMENTED PICKLES

i) **Pak-Sian-dong and Related Fermentations** (Fermented bamboo shoots and fermented red onion)

These are the common pickles of Thailand. The fresh vegetable is washed thoroughly and spread on a mat in the air or sunlight in order to loose water and tissues to wilt. It is mixed with 2% salt, 4% sugar and the same quantity of water and kept in a tight container. It becomes ready for consumption in 3-4 days. Acidity normally reaches to 0.8% with pH around 3.9-4.0.



Microorganisms involved : *Leuconostoc mesenteroides, Pediococcus cerevisiae, Lactobacillus plantarum, Lactobacillus brevis, Lactobacillus fermentii.*

Figure 11.2: Pickles (fermented) of Thailand

ii) Malaysian Pickles

Home made pickles are common in most of these countries especially in rural areas. Fruits and vegetables which are relatively sour, are used for pickle preparation. Many types of fruits and vegetables are used depending upon the availability and seasonality. The common vegetables used are: gherkins, cucumbers, ginger, onion, leek, chilli, bamboo shoots, unripe

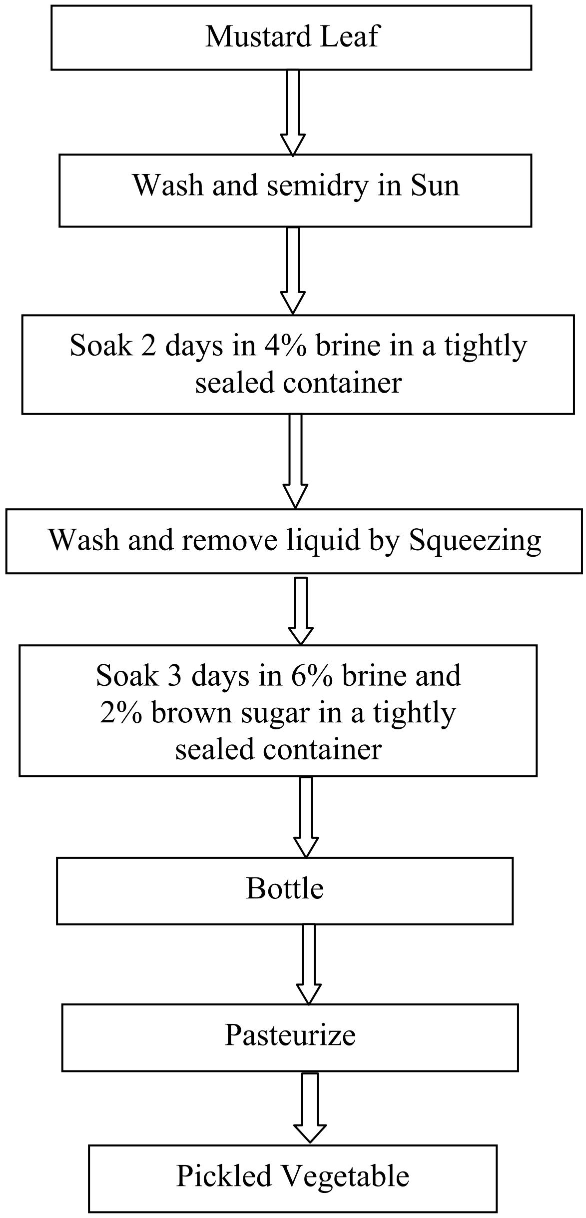


Figure 11.3: Malaysian pickled vegetable

mango, papaya, lime, lemon and nutmeg. In all these fermentations higher level of crystal salt or brine is used in curing the tissues. Sugar and other fermentable carbohydrates, dilute vinegar, and spices are also added. It appears to be a simple process but the quality differs from house to house. Pickles undergo a bacterial lactic acid fermentation. The same group of microorganisms are involved in the fermentation. Fermentation takes about 8 days depending upon the substrate.

In India, several varieties of pickles are prepared both for indigenous consumption and export purposes. We usually prefer non-fermented pickles preserved in edible oils. The quality and taste differ based on the ingredients used. Bamboo shoots pickles, brinjal and mixed vegetable pickles are common in North India. Some of these are exotic in nature prepared at house-hold level.

iii) Lactic Fermented Fruits in European Countries

Fruits are cleaned and blanched at 50-60°C to destroy undesirable bacteria. After the addition of *Lactobacillus acidophilus* or *Lactobacillus bifidus* the product undergoes to lactic acid fermentation. The fruit is shredded and pulverized and pasteurized and finally goes for marketing.

11.8 LET US SUM UP

Fermentation of different types of agricultural commodities has been practiced with an aim to preserve them and also add exotic flavour and change the texture. Fermented fruits and vegetables have been in use mostly as condiments in order to avoid monotonous diets. Lactic acid producing bacteria grow luxuriantly in favourable conditions on fruits and vegetables and produce good quantity of lactic acid and other acids and antimicrobial substances which lower down the pH and thus check the growth of spoilage and pathogenic microorganisms. It is a simplest method of preservation. Sauerkraut and cucumber fermentations are the typical examples. Kimchi of Korea, Sinki of Indian sub-continent, fermented bamboo shoots and red onion and Malaysian pickles are produced commercially and consumed by the people. Lactic fermented fruits are becoming popular in European countries.

11.9 KEYWORDS

Sauerkraut	:	Fermented cabbage.
Kimchi	:	Korean fermented product (cabbage).
Sinki	:	Indian fermented product from radish.
Pak-Sian-dong	:	Fermented bamboo shoots of Thailand

11.10 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - Cabbage, cauliflower, broccoli, mustard, carrots, turnips, beetroots, radish, cucumber, olives, tomatoes, peppers, green beans, peas, onion, garlic, apple, pears, green managoes, banana, lemon and lime.
   - Lactic acid producing bacteria grow on vegetables and fruits and convert sugars into acids (lactic and acetic).

2. Your answer should include the following points:

   - A German term meaning ‘Sour Cabbage’.

3. Your answer should include the following points:

   - Fresh cabbage → trimming, cleaning and shredding → salting → filling into vats → covering the vat and applying weight on the top → allowing fermentation → pasteurization → packing with preservatives.

4. Your answer should include the following points:

   - *Streptococcus faecalis, Leuconostoc mesenteroides, Lactobacillus brevis, Pediococcus cerevisiae.*

5. Your answer should include the following points:

   - Good sanitary conditions needed while processing cabbage for fermentation.
   - Low temperature and appropriate salt concentrations favour good fermentation and the final product.

Check Your Progress Exercise 2

1. Your answer should include the following points:

   - Widely cultivated in India in all the States irrespective of climatic changes Selection of fruits → washing → placing fruits in brine 5-8% (pH 4.5 adjusted with vinegar) → allowing natural fermentation at 15^{o}C → purging nitrogen to avoid bloater formation → fermentation for one month.
   - *Streptococcus faecalis, Streptococcus lactis, Leuconostoc mesenteroides, Lactobacillus brevis, Lactobacillus plantarum*.

2. Your answer should include the following points:

   - A major condiment of Korean diet.
   - Vegetables like cabbage, radish, mustard (green), cucumbers, green onions, Chinese leeks, turnips, green peppers, pumpkins, etc.

3. Your answer should include the following points:

   - Radish roots → sundrying for 1-2 days → shredding → packing tightly in an earthen vessel → sealing of the mouth of vessel → allowing fermentation for 15-30 days → fermented radish sundried → used as a condiment for soup.

4. Your answer should include the following points:

   - Fermented vegetables of Thailand.
   - Fresh vegetables washed and spread on a mat and sundried.
   - After sundrying 2% salt and 4% sugar are added and mixed with the vegetables quantity of water and placed in a container.
   - Fermentation normally takes 3-4 days.

4. Vaughn, R.H. (1985) The Microbiology of Fermented Foods, B.J.B. Wood (ed.) Vol. 1, Elsevier Applied Science Publishers, U.K.

UNIT 12 FRUIT-BASED ALCOHOLIC BEVERAGES

Structure

12.0 OBJECTIVES

After studying this unit, you should be able to:

- discuss about different varieties of wine produced commercially in different parts of the world;
- know the microorganisms involved in wine fermentation and factors influencing its quality;
- explain the method of wine production and different practices involved before and after fermentation; and
- get information on clarification of fermented juice and maturation of wine.

12.1 INTRODUCTION

Production and consumption of fermented beverages is an old practice. It has been referred in Vedas. In the previous chapter, how lactic acid from plant constituents is produced to preserve the food along with favourable organoleptic changes are discussed. Similarly many fruits contain very high amounts of free sugars which are readily converted into ethanol and carbon dioxide with the help of yeasts and thus alcoholic beverages are produced.

Wine is normally referred as a by-product of grapes (*Vitis vinifera*). However, wine can be produced from any fruit or flower rich in soluble sugars. Still most of the wines are produced from grapes throughout the world. European, Western World, North America especially colder climate countries are the major producers and consumers of alcoholic beverages. In these countries, 75% of the crop is diverted for wine production. France and Italy are the major producers of quality wine. Due to several reasons including the taboo attached to consumption of alcoholic beverages, fruit wine and brandy industries have not developed well in India. We meet most of our demand through import although India is the second largest producer of fruits and vegetables.

12.2 TYPES OF WINE

As stated already, the pressed juice of grapes or any fruit rich in soluble sugars if fermented by yeast/s or spontaneous natural fermentation, it results in the ethanol (wine) production and its disstilate is known as “Brandy”. White wine is produced from the grapes usually cultivated whereas the red variety or Bangalore blue grapes having purplish red skin give rise to “Red Wine”.

Different types of commercial wines are listed below:

- *Champagne* is a foaming wine which contains dissolved carbondixoide.
- *Sparkling* wine is produced by carbonation by injecting carbondixoide into the wine.
- *Liqueur Wine* is sweet with a higher content of alcohol.
- *Sherry* is a fortified wine with two distinct styles, the first being dry wine (without any sweet taste) consumed as an appetizer before meals and the other being olorosos sweetened wine taken after meals.
- *Port* in which wine is stored in a wooden cask or Hintage ports. During maturation the type of barrel used for aging contributes to quality of wine.
- *Vermouth* is a flavoured wine in which different varieties of herbs and spices are added.
- *Brandy*: It is a distilled wine stored mostly in wooden cooperage or casks.

12.3 FRUITS USED FOR WINE-MAKING

Sugars present in fruits are responsible for quick fermentation and other constituents contribute to the flavour and aroma of the wine. Grapes, apple, pear, custard-apple, mango, jamun, coconut sap, palm sap, pomegranate, banana, guava, ber, plum, orange, litchi, dates, pineapple, strawberry, raspberry, cherry, grape - fruit etc. can be used for wine making. The technology for grape wine has been developed in the western world and thus quality products are produced commercially. There are many reasons for non-acceptability of non-grape fruits for commercialization. Many of these fruits contain low levels of soluble sugars and their fermentability is poor. Extraction of juice from these fruits poses serious difficulties. Some of these have very high or low concentrations of acidity which influences the quality of wine considerably. Bitterness and some other organoleptic defects of the final product are the other serious problems for commercialization.

12.4 IMPORTANT FACTORS INFLUENCING THE QUALITY OF WINE

i) Fruits and their chemical composition

Grapes are the best fruit for quality wine production. It has been found that the cultivation conditions of grapes influence the quality of wine. Fruit variety, sugar content, additives, pulp or juice yield, yeast strain for fermentation, filteration, maturation and preservation of wine, all affect the final quality of wine. Yeast is the key for alcoholic fermentation or ethanol production and the factors which influence the growth of yeast also affect the quality of the wine. The sugar content of selected fruits is given in Table 12.1.

Table 12.1: Sugar and acids composition of fruits

Fruit	Total Sugar (% Fresh Weight)	Acid (% of Tartaric acid)
Apple	8-10	0.9 - 1.4
Banana	18	0.3 - 0.4
Grape	15 - 22	0.4 - 1.3
Orange	9 - 10	0.8 - 1.1
Pear	9 - 11	0.2 - 0.4
Strawberry	5 - 6	0.6 - 1.5

ii) Temperature

The temperature of must (fruit juice) strongly influence the yeast growth. The yeast normally used for wine fermentation is strain of *Saccharomyces cerevisiae*. The optimum temperature for wine fermentation ranges between 22-27^{o}C. Quality white wine is produced at lower temperature 10-15^{o}C where as red wine needs higher temperature which ranges between 20-30^{o}C.

iii) Ethanol Content

As we know one mole of glucose gives rise to two moles of ethyl alcohol (ethanol) and two moles of carbon dioxide during the fermentation.

$$C_6H_{12}O_6 = 2C_2H_5OH + 2CO_2$$

Beyond certain concentrations of sugar in the must/mashes, the yeast growth is stopped. Similarly after 10-12% (v/w) ethanol in the must, the growth of yeast declines considerably. There are a number of methods known to enhance the ethanol tolerance of the selected strain used for fermentation.

iv) Carbohydrate and Energy Sources

It is apt to think that the wine is produced from the sugar and flavour containing chemicals present in the fruits with the help of yeast/s. It is, therefore, important to know the type of sugars and their quantity present in the must. Glucose, fructose, sucrose and maltose are easily utilized by the yeast (*Saccharomyces cerevisiae*) for its growth and ethanol and carbon dioxide production. Lactose, pentoses, dextrin, starch or higher molecular weight carbohydrates or poly-saccharides are not utilized by the yeast. Usually 0.8-1.3% of sugar is utilized for the growth and rest is used for ethanol generation. At sugar concentration of 25% and above in the must, the yeast growth is slowed down. Except grapes, due to low concentration of sugars in other fruits, the mash has to be supplemented with sugars.

v) Carbon dioxide and Pressure

Carbon dioxide is produced during the fermentation and if higher pressure is built then it inhibits the growth of yeast. However, the sparkling wine is produced under the carbon dixoide pressure in a closed container.

vi) Sulphur Dioxide (SO_2) and other Agents

Sulphur dioxide is added to the must or juice in order to bring down the number of contaminating microorganisms viz., moulds, yeasts and bacteria. The other chemicals tried are salicylic acid, bromoacetic acid, ethylene oxide, benzoic acid and sorbic acid. SO_2 is preferred because it is less toxic to human beings.

vii) pH and Acids

Normally the organic acids present in fruits do not interfere with yeast fermentation. Other organic acids such as acetic, butyric, propionic and fatty acids have inhibitory effect on yeasts. If the pH is below 3.0, the alcoholic fermentation is delayed considerably.

viii) Growth Factors

Biotin, inositol, nicotinic acid, pantothenic acid, p-aminobenzoic acid, pyridoxine and thiamine are needed for the growth of yeast.

ix) Minerals and Pesticides

Iron, copper, zinc and aluminium are present in the final product. Fermentation is not usually affected by the presence of lower concentrations of these metals. They normally come through presses or other equipments used. Pesticides are normally used to control pests which infest trees and fruits. Their residues in the wine is highly objectionable.

x) Nitrogen Sources

For the growth of yeast, nitrogenous compounds are needed. The amino nitrogen present in the must supports the growth of yeast. There are many factors e.g. method of juice preparation, ripening of the fruit, variety and several other cultivation parameters, which influence the amounts of these chemicals. Some of the fruits are deficient in them and therefore, supplementation is necessary. The inorganic nitrogenous salts usually used in wineries are: $(NH_4)_2$ HPO_4 or $(NH_4)2SO_4$ upto 0.3 g/l.

xi) Tannin/Phenolic Compounds

Tannin and phenolic compounds are present in the fruit juice. Their concentrations differ from fruit to fruit. Tannin normally does not affect the growth of *Saccharomyces cerevisiae* (yeast).

xii) Juice Clarification

In recent years, grape and apple juices are being treated with pectinolytic enzymes for better yield and quality of wine. However, in wine manufacture, cloudy or turbid juice is preferred. Bentonite is added to improve the fermentation. However, the fruit pulp of non-grape fruits have to be treated with pectinolytic enzymes. There are many reports that musts which contain insoluble particles ferment quickly. Therefore, insoluble materials such as filter aids or wheatflour is added in the musts.

12.5 MICROORGANISMS INVOLVED IN WINE-MAKING

i) Yeasts

The quality of wine depends on the yeast strain used for fermentation. The quick growth of yeast and an efficient conversion of sugar into ethanol decide mostly the quality of wine. *Saccharomyces cerevisiae* is the most important yeast for the juice (must) fermentation. Besides this yeast, there are numerous other species of yeasts which are also present and some times they spoil the wine.

Saccharomyces cerevisiae and numerous other yeasts such as *Kloeckera apiculata, Hansenula anomala, Candida stellata, Candida krusei* are also present in grapes. Besides these, *Schizosaccharomyces pombe, Saccharomyces bayanus, Saccharomyces fermentii* have also been isolated from grapes and various other fruits.

When grapes are crushed, within a few days *Saccharomyces cerevisiae* grows and multiplies to a higher number of cells. In the case of spontaneous fermentation, inoculum is not added and the yeasts present on the substrate and equipments serve as a source of starter culture. In order to maintain the quality and yield of wine, wineries all over the world are using a particular standard strain of *Saccharomyces cerevisiae.* It also provides protection from the 'Killer yeast'. Killer yeasts are infected with a virus that destroys the used strain of yeast for fermentation. Some times an active dry yeast culture about 0.1 g/L is also added to accelerate the fermentation.

It is an important question why wineries prefer *Saccharomyces cerevisiae?* It is tolerant to high levels of sugar of fruit juices, tolerates high ethanol concentration, invariably grows even at low pH, ferments must at low temperature and resistant to sulphur dioxide level which suppresses the growth of bacteria, yeasts and moulds. Apart from these, it induces desirable aroma in the wine. That is the reason it is called as wine yeast.

Morphology of *Saccharomyces cerevisiae*

It is spherical to ellipsoidal in shape with 8 × 7μ of size depending on the growth medium. It multiplies by budding.

Most strains of *Saccharomyces cerevisiae* are capable of producing alcohol upto 16%.

ii) Microorganisms other than yeasts in Winemaking

Bacteria

Lactic Acid Bacteria *Leuconostsoc oenos* *Pediococcus pentosan, Pediococcus purvislus, Lactobacillus* plantarum *Lactobacillus* fermentum	Responsible for malo-lactic fermentation and spoilage

Acetic Acid Bacteria

Acetobacter and *Glucanobacter spp.*	Responsible for Vinegar taste, spoilage and stuck fermentation.
Bacillus and *Clastridium* spp.	Spoilage

Fungi

Botrytis cinerea *Penicillium* sp. *Aspergillus* sp.	Botrytized wine, spoilage, corkytaints
Actinomycetes *Actinomyes* spp. *Streptomyces* spp.	Earthy and corky taints.

12.6 PREFERMENTATIVE PRACTICES IN WINE-MAKING

i) Stemming, Crushing and Juice Separation

Fruit stalks, seeds and skins (pomace) are removed and then fruits are crushed and macerated. To check initiation of fermentation, white grape juice is chilled to about 10°C. Sulphur dioxide is also added to retard the multiplication of microorganisms. Red grapes are given longer time for maceration at 24-27°C which helps the extraction of pigments and phenolic compounds. Pressing separates the juice from the seeds and skins of the fruit. Large wineries use dejuicers for this purpose.

ii) Clarification

If juice is allowed for some hours for settling, the solid materials and suspended particles get separated and a clear juice is obtained. However, in commercial wineries filter aids such as bentonite is used and juice is centrifuged at low speed or passed through filter press.

iii) Juice/Must Adjustment

Total acidity of must is important for the final quality of wine. If acidity is less than the desired concentration, citric or tartaric acid is added appropriately. Higher level of acidity is retarded by the supplementation of calcium or potassium salts. Sugar is added in the must when sugar content is too low in the fruits. It is known as chaptalization in wine making. The other techniques followed for increasing sugar concentration are reverse-osmosis, cryoextraction and entropie concentration.

12.7 FERMENTATION

Fermentation is an energy releasing metabolism in which the electron donor and electron acceptor are organic compounds. In wine fermentation, glucose and fructose are the electron donors and ethanol is the acceptor. Glycerol, acetic acid, acetaldehyde and succinic acid are also electron acceptors which are produced in the must along with traces of diacetyl and fusel (higher alcohols).

Fermentation is done in a vat (open top) or tanks (sealed top). As stated earlier, both spontaneous and starter (inoculum) addition fermentation is practiced for wine making. During the initial stages, aerobic yeasts *Hansenula anomala* and *Klockera apiculata* are active. Subsequently they are taken over by the *Saccharomyes cerevisiae. S. cerevisiae* multiplies at a fast rate within 3 to 4 days and then ethanol production follows rising its level gradually and steadily.

12.8 SPOILAGE OF FERMENTATION AND WINE

Due to over clarification of juice/must and the presence of high number of wild yeasts having killer viruses and some other reasons some times fermentation does not proceed well. It is referred as the 'Stuck Fermentation'. Several species of lactic acid bacteria e.g. *Leuconostoc oenos, Lactobacillus* and *Pediococcus* spp. grow in the must and convert malic acid into lactic acid. Malic and tartaric acids are the major constituents of grape juice. They spoil the taste of wine. The wine and cider are spoiled by the acetic acid producing bacteria. They grow on the surface and oxidize ethanol to acetic acid. Similarly wild yeasts grow on the surface of stored wine and spoil the product. The sugar present in wine is converted into lactic acid by several spoilage microorganisms. Butyric acid bacteria, slime producing bacteria and moulds spoil the final stored product. Changes in colour of wine take place due to oxidation. It is, therefore, necessary to take care while carrying out the fermentation and during the maturation and storage of wine.

12.9 POST-FERMENTATION PRACTICES

i) Clarification and Stabilisation

Clarification refers to methods adopted for clear wine for bottling while stabilization assures that wine remains clear after bottling. Fermented must is allowed to settle for clarification. Dying yeast cells, grape cell remains, precipitated tannins and crystallized salts are removed. Clarification of wine is sometimes achieved by centrifugation.

ii) Fining

To remove colloidal materials, fining is practiced using filter aids bentonite, kiesselghur, silicondioxide, gelatin, albumin and isinglass.

iii) Centrifugation

It is done to remove fine particles.

iv) Filtration

Sometimes filtration is done with a courser filter but membrane filters are used to remove fine particles and live cells of microorganisms.

v) Crystallization

Crystallization of potassium and calcium tartrate salts occurs in wines. It has to be removed by the cold filtration adding salt at low temperature (-5^{o}C). Crystallization is undesirable for expensive wines.

vi) Haze formation

Normally soluble proteins and tannins precipitate in the must and lead to haze formation. The judicious addition of pectinase, β-glucanase or mixture of Kisselghur and gelatin prevents the haze formation.

vii) Adjustment of Factors

Adjustment of acidity, pH, sweetness, alcohol content and decolouration of wines are practiced based on the requirement of the product in the market. Blending is done all over the world in order to get the desired fragrance.

viii) Maturation

Freshly prepared wine is always found to be harsh with yeasty flavour. Maturation develops the mellowed wine taste with fruity and desired flavour. The quality of wines depend on the maturation and ageing. The maturation period extends upto 6 to 12 months. There are several methods used for maturation. The oldest and traditional method is to allow maturation of wine in the same barrel in which fermentation occurred. The other method is to employ oak wood barrels which results in the best quality of wine. Long oak strips or chips are dipped in the filtered wine and maturation is allowed to take place for more than a 6 months. Several chemical changes take place during this process.

Bottling

Dark amber colour glass bottles with a distinctive neck are commercially used. Usually oak cork are used as a closure conventionally.

12.10 WINE FROM DIFFERENT VARIETIES OF FRUITS

i) Apples

Cider and wine is produced from apple. Cider is a low alcoholic drink, contains alcohol between 4 to 6%. The apple varieties should have moderate amounts of phenolics. The higher juice containing varieties are preferred for cider fermentation. Apple juice or concentrate is used for wine fermentation. The alcohol content in apple wine ranges between 11 to 14%. Before fermentation apple juice is supplemented with cane sugar. Sometimes ammonium chloride or phosphate are also supplemented in the juice for fermentation.

ii) Custard apple

Annona squamosa is a tropical fruit. Since it is rich in fermentable sugars and delicate flavour, its pulp after the removal of seeds and skin can be used for wine making. The juice obtained is ameliorated to 23^{o} brix and acidity 0.7%, phosphate 0.05% and 125 ppm SO_2 and nitrogenous salts. The must (juice) is inoculated with *Saccharomyces cerevisiae* and fermentation is carried out.

iii) Pear wine

Perry or pear wine of good quality is prepared from pears with high tannin contents. Since it is deficient in nitrogen, an exogenous addition of nitrogen is necessary. Perry fermentation is carried out at temperature of 20-22^{o}C.

iv) Mango wine

Mangoes (*Mangifera indica* Linn.,) is a tropical fruit extensively cultivated in India. Mango fruits and several processed preparations are exported to different countries. It contains high amounts of total solids, vitamins and minerals. Among the numerous varieties 'Safaida, Dashehari, Langra, Chaussa of U.P., Alphanso of Ratangiri, Badami of Mysore, Raspuri and Mulgoa of Tamilnadu and Karnataka are rich in total soluble solids and also in fermentable sugars (glucose, fructose and other sugars). In majority of mangoes, juice extraction is a problem and therefore pectinolytic enzymes are suitably added and the sugar level is raised to 20^{o} brix using cane sugar. Fermentation is done at 22^{o}C with 100 ppm of SO_2. Different varieties of mangoes results in products having varied taste and body.

v) Jamun wine

Jamun fruit is also native to Indian fruit and grown in every part of the country. Jamun fruits have therapeutic properties especially in diabetes and its products have wide acceptability everywhere. This fruit is also deficient in nitrogen, rich in pectin and hence amelioration with sugar (23^{o}Brix) diammonium hydrogen phosphate (0.2%), 0.25% pectinolytic enzyme and 150 ppm of SO_2 is required. The other factors remain the same as with other fruits (grapes etc.,) Popularization of the product is needed for indigenous and export purposes.

vi) Coconut and Palm wine or Toddy

Toddy is an alcoholic beverage produced from the sap of palm trees (*Acrocomia mexicana*) and coconut inflorescence sap. It is consumed in several parts of the country. The sap is collected in clay pots. The middle aged (fully grown) tree is selected and triangular or rectangular cut is made on the top of the tree and the earthen pot is hanged. The foamy sap flows and collects in the pot in the morning and evening. Freshly collected sap is sweet, relishing and invigorating. The fermentation starts as soon as sap starts collecting in the pot. The palm sap contains 10-12% sugar whereas coconut sap generally has about 15-18% sugars. Mostly toddy contains about 6-7% of ethanol. Natural fermentation takes place by the microorganisms present in the earthen pot. *Saccharomyces cerevisiae* is mostly present along with *Lactobacillus plantarum* and *Leuconostoc mesenteroides*. If fermented sap "toddy" is stored for longer time, acetic acid production ensues resulting in the spoilage of the product.

vii) Pomegranate and other fruit wines

Pomegranate (*Pumica grantum)* fruits are pressed as such to get astringency in the wine. Sugar is ameliorated in the pressed juice getting brix around 22-23^{o}B. Potassium metabisulphite is added to the must and it is inoculated with the starter culture (*Saccharomyces cerevisiae)* at the rate of 5%. Wine is produced in the California belt of the United States of America.

Litchi, Apricot, Pineapple, Date, Red Raspberry, Strawberry, Kiwi fruit, peach, Kinnow fruits, grape fruit, orange and plum, ber, guava and banana fruits can be used for wine production with certain modifications in the method of preparation. Majority of these fruits require enzymatic treatment to release the sugars and supplementation of juice with cane sugar and nitrogeneous salts. The other steps remain the same as followed for production of grape wine.

viii) Mead

Mead is a wine prepared from honey. The procedure followed for mead is the same which is employed for wine making from different types of fruits. Light coloured honey is preferred for this purpose. Honey is diluted to 22-23^{o}Brix, it is boiled and cooled and appropriately tannin, acid and diammonium hydrogen phosphate and SO_2 added to it. The must is inoculated with the active starter culture of *Saccharomyces cerevisiae* and fermentation is carried out at low temperatures. Mead is relished in European countries and several other parts of the world.

12.11 CHEMICAL COMPOSITION OF WINE

The chemical composition of the wine relates to its quality. There are several factors which influence the quality of wine. The most important factors affecting the quality have already been highlighted earlier. The typical wine contains ethyl alcohol, sugars, acids, higher alcohols, tannins, aldehydes, esters, amino acids, minerals, vitamins, anthocyanins, fatty acids, flavouring compounds and traces of methanol.

12.12 LET US SUM UP

Alcoholic beverages have been consumed all over the world since time-immemorial. Their (wine, beer, brandy, whisky, rum) consumption is gradually and streadily increasing in developed and developing countries equally inspite of several restrictions. Wine and beer if taken moderately, have health giving properties. When fruit juices (grapes, apple, pear etc.,) are allowed to spontaneous alcoholic fermentation or with addition of yeast culture, the sugar present in these get converted into ethanol and carbon dioxide and thus wine, cider, perry and if distilled, brandy are produced. The yeast, *Saccharomyces cerevisiae* or *Saccharomyces cerevisiae* var. *ellipsoideus* are primarily responsible for good alcoholic fermentation. The fermentation of fruit juices initially requires some oxygen for the growth of yeast and after its exclusion, ethanol and carbon dioxide are produced anaerobically. Several prefermentative and post fermentative practices are followed and when fermentation is complete, it is clarified with bentonite or gelatin. Maturation of wine (clarified and filtered fermented juice) is carried out in oak wood barrels and finally it is bottled in dark amber colour glass bottles. Apples, grapes, pears, mango, pomegranate, jamun can be utilized for wine production. Honey is used for mead production. Toddy another alcoholic beverage of India, has good invogirating and relishing effect if taken directly from the tree without any storage.

12.13 KEY WORDS

Wine	:	Alcoholic fermented juice of fruits
Cider	:	Wine from apples
Perry	:	Wine from pears
Mead	:	Wine from honey
Brandy	:	Distilled wine
Rum	:	From fermented molasses or canesugar
Whisky	:	Distillation of mash of malted grains
Beer	:	From malted barley
Toddy	:	Palm trees sap or coconut influorescence sap

12.14 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - The juice of grapes or any other fruits if allowed to ferment by natural fermentation or by addition of starter culture viz., yeast for some time and the resultant product after fermentation is wine.
   - Types of Wines are:
     - Champagne: foaming containing dissolved oxygen.
     - Sparkling wine: produced by injecting carbon dioxide into the wine.
     - Liqueur Wine: Sweet with higher content of alcohol.
     - Sherry: Fortified wine.
     - Port: Wine is stored in a wooden cask.
     - Vermouth: Flavoured wine
     - Brandy: Distilled wine
     - Cider: Produced from apple.
     - Perry: Produced from pears.

2. Your answer should include the following points:

   - The juice of grapes or some fruits contain high amounts of sugar mainly glucose and fructose sometimes 20-25%. The wine yeast present in the juice or added separately grows profusely and convert sugars into ethanol.

   - One mole of glucose gives rise two moles of ethanol and two moles of carbondioxide.

   - Usually 8-10% ethanol is obtained after fermentation.

3. Your answer should include the following points:

   - Grape juice or any other fruit juice.
   - The commercially used yeast strains for wine *Saccharomyces cerevisiae, Saccharomyces cerevisiae* var. *ellipsoideus*.

4. Your answer should include the following points:

   - Killer yeast/s infected with a virus that kills the wine yeast.

5. Your answer should include the following points:

   - *Saccharomyces cerevisiae* strains tolerate high levels of sugars in the fruit juices.

   - Tolerate high levels of ethanol.

   - Grow even at low pH.

   - Ferment fruit juices at low temperature.

   - Resistant to sulphur dioxide which checks the growth of bacteria, yeasts, moulds.

6. Your answer should include the following points:

   - Stemming, crushing and juice separation → clarification → adjustment of sugar level and acidity → fermentation

7. Your answer should include the following points:

   - The growth of wine yeast: *Saccharomyces cerevisiae* is checked due to the presence of Killer viruses and fermentation does not proceed well. A number of metabolites (chemicals) are released causing defective flavour and body of wine (Stuck Fermentation).

   - Clarifications and Stabilization, fining, centrifugation, filteration, removal of crystals, avoidance of haze formation maturation and bottling.

Check Your Progress Exercise 2

1. Your answer should include the following points:

    - Cider (A low alcoholic 4-6% ethanol) from apples.
    - Custard apple seeds and skin are removed and juice is supplemented with sugar and fermented.
    - Perry or pear wine from pears prepared by extra addition of nitrogen in the juice.
    - Juice extraction a big problem and therefore pectinolytic enzyme is used for the recovery of juice and which is supplemented with sugar and fermented (mango).
    - Jamun wine has therapeutic properties and good for diabetes patients.

2. Your answer should include the following points:

    - An alcoholic beverage produced from palm and coconut trees.
    - The sap is collected from the trees in the morning.
    - Freshly collected sap is sweet, relishing and invigorating.

3. Your answer should include the following points:

    - Prepared from honey.
    - Honey appropriately diluted and supplemented with tannic acid and phosphate and nitrogenous salts and fermented.

4. Your answer should include the following points:

    - Contains usually ethyl alcohol, sugar, acids, higher alcohols, tannins, aldehydes, esters, amino acids, minerals, vitamins, anthocyanins, fatty acids, flavouring compounds and traces of methanol.

UNIT 13 TECHNOLOGICAL ASPECTS OF INDUSTRIAL PRODUCTION OF ALCOHOLIC BEVERAGES AND RELATED PRODUCTS

Structure

13.0 OBJECTIVES

After studying this unit, you should be able to:

- state the necessity of technology in alcoholic beverages production;
- describe the vats and tanks used for industrial production of alcoholic beverages;
- know how different types of beverages are manufactured and various steps involved in their production; and
- describe the method of vinegar production.

13.1 INTRODUCTION

In Unit 10, the industrial significance and necessity of fermentation and its relevance to the society have been highlighted in detail. Fermentation or production of wine, beer, cheese or bread is an art and has been practiced from time immemorial throughout the world. However, to meet the demand of the society, large scale operations are needed for any type of product. Therefore, for all the stages of commercial production, engineering involvement is warranted. The scientific knowledge on production of a product either developed in research laboratories or house-holds or cottage level, has to be developed in the form of a commercial process with the help of engineers, scientists and other experts. There are a number of commercial processes developed for alcoholic beverages and related products, and improvement in the quality and also cost reduction of the final products are made more often.

In brief, various aspects of industrial production of selected wines, distilled alcoholic beverages of fruit origin (Brandy) and vinegar are highlighted here.

13.2 FERMENTERS

In wine production, any non-porous, non-toxic vessel can be used as a fermenter. These are constructed of non-aromatic wood, cement, stainless steel or fiberglass. Only two types of fermenters: Vats and Tanks are employed for fermentation. The size of fermenter differs but most of the wineries use 20000 liters and above capacity vessels either open or closed. Sometimes smaller, barrels are employed in which fermentation and maturation both take place. All these are batch fermentation carried out for certain periods and then again recharged with must and restarted. Hydraulic press, filteration equipments and other machines and equipment are used for commercial production.

13.3 TECHNOLOGY FOR CIDER-MAKING

Cider is a low alcoholic drink prepared from the apple juice. Depending on the ethanol content, it is considered soft cider (1-5%) or hard cider (6-7%). In India, cider is not produced commercially. But the Indian varieties of apple cultivated in Jammu and Kashmir and Himanchal Pradesh e.g., Ambiri-Kashmiri, Red Delicious, Gold Pippin, Maharaji Apples and Golden Delicious can be utilized for cider making. A method for cider manufacture at a commercial scale is shown through flow diagram in Figure 13.1.

13.4 TECHNOLOGY OF SPARKLING CIDER

Sparkling cider is prepared by artificial carbonation. The secondary fermentation is carried out for 3-4 days at 21.0 ^{0}C. A protocol for carbonated cider is given in Figure 13.2.

13.5 TECHNOLOGY OF FORTIFIED WINES: VERMOUTH

Wines which are flavoured with herbs and spices and contain ethanol content in the range of 15-21%, are classed under 'Vermouth'. Both dry and sweet vermouth are prepared in European countries and relished in cocktails. It is prepared by making the wine and then extracting the spices and herbs mixture in wine and Brandy and blending with the wine produced and also adjusting the alcohol level. Grapes, apples apricots, mango, plum, even tamarind can also be used for vermouth production. Pear or similar types of fruit which are produced in abundance and commercially do not find much market, can be profitably used for vermouth manufacture. It is schematically illustrated in Figure 13.3.

13.6 TECHNOLOGY FOR BRANDY-MAKING (DISTILLED ALCOHOLIC BEVERAGES)

Brandy is defined as a distilled alcoholic beverage prepared from the distillation of wine or any fermented fruit juice. Usually brandy denotes the distilled wine of grapes whereas for other fruits it is prefixed with the fruit name e.g. apple brandy, plum brandy etc., Sometimes 'Cognac' word is also used for brandy. Cognac is produced in France. There are many varieties of wines mostly based on their place of manufacture.

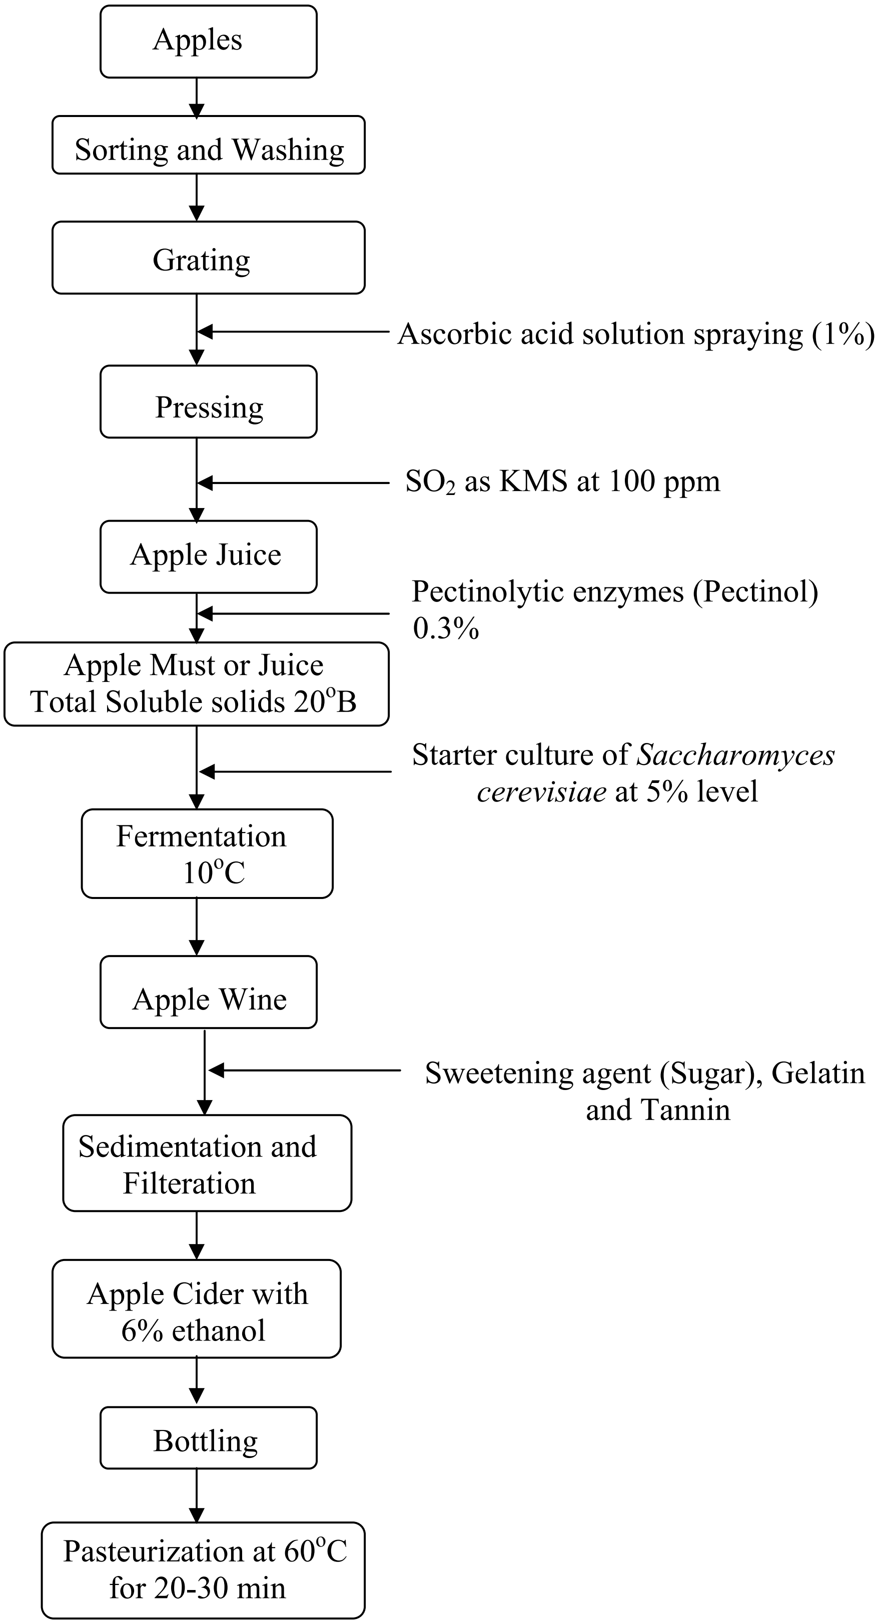

Figure 13.1: A protocol for cider production

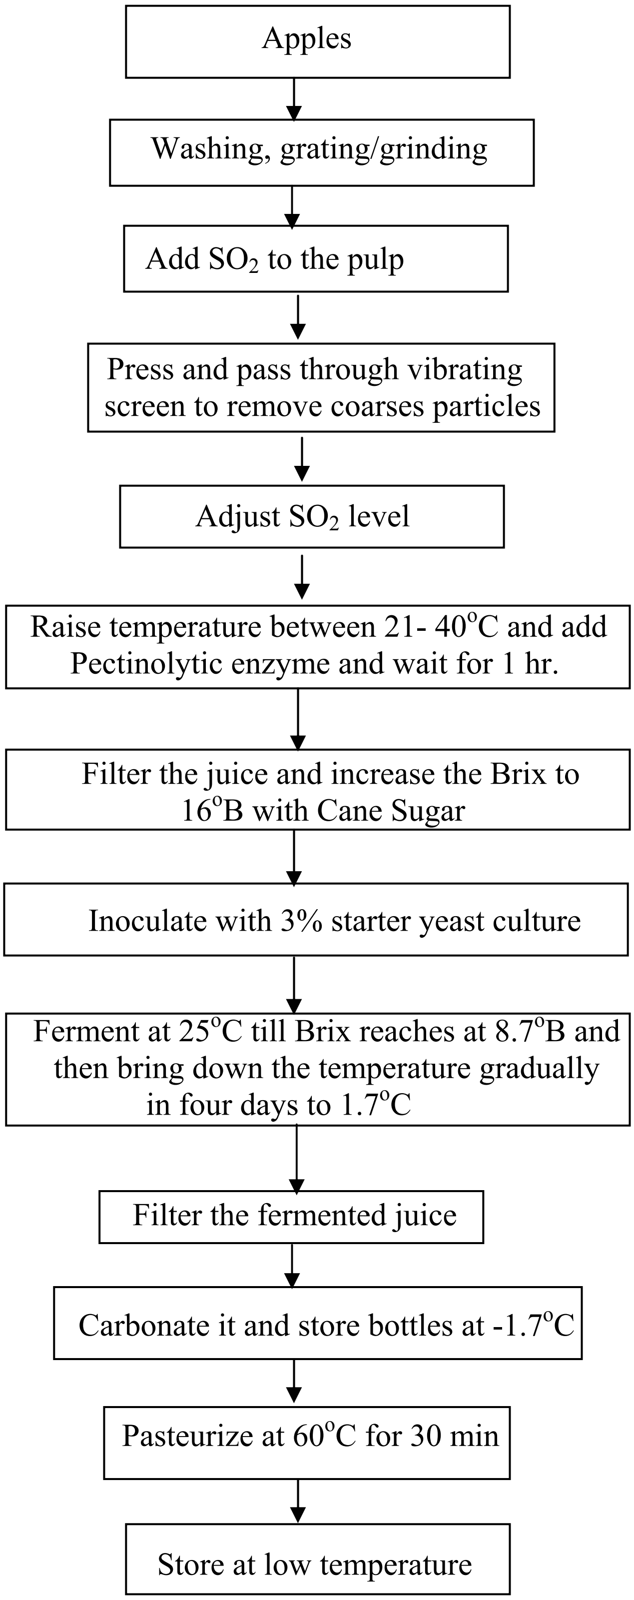

Figure 13.2: A protocol for carbonated cider production

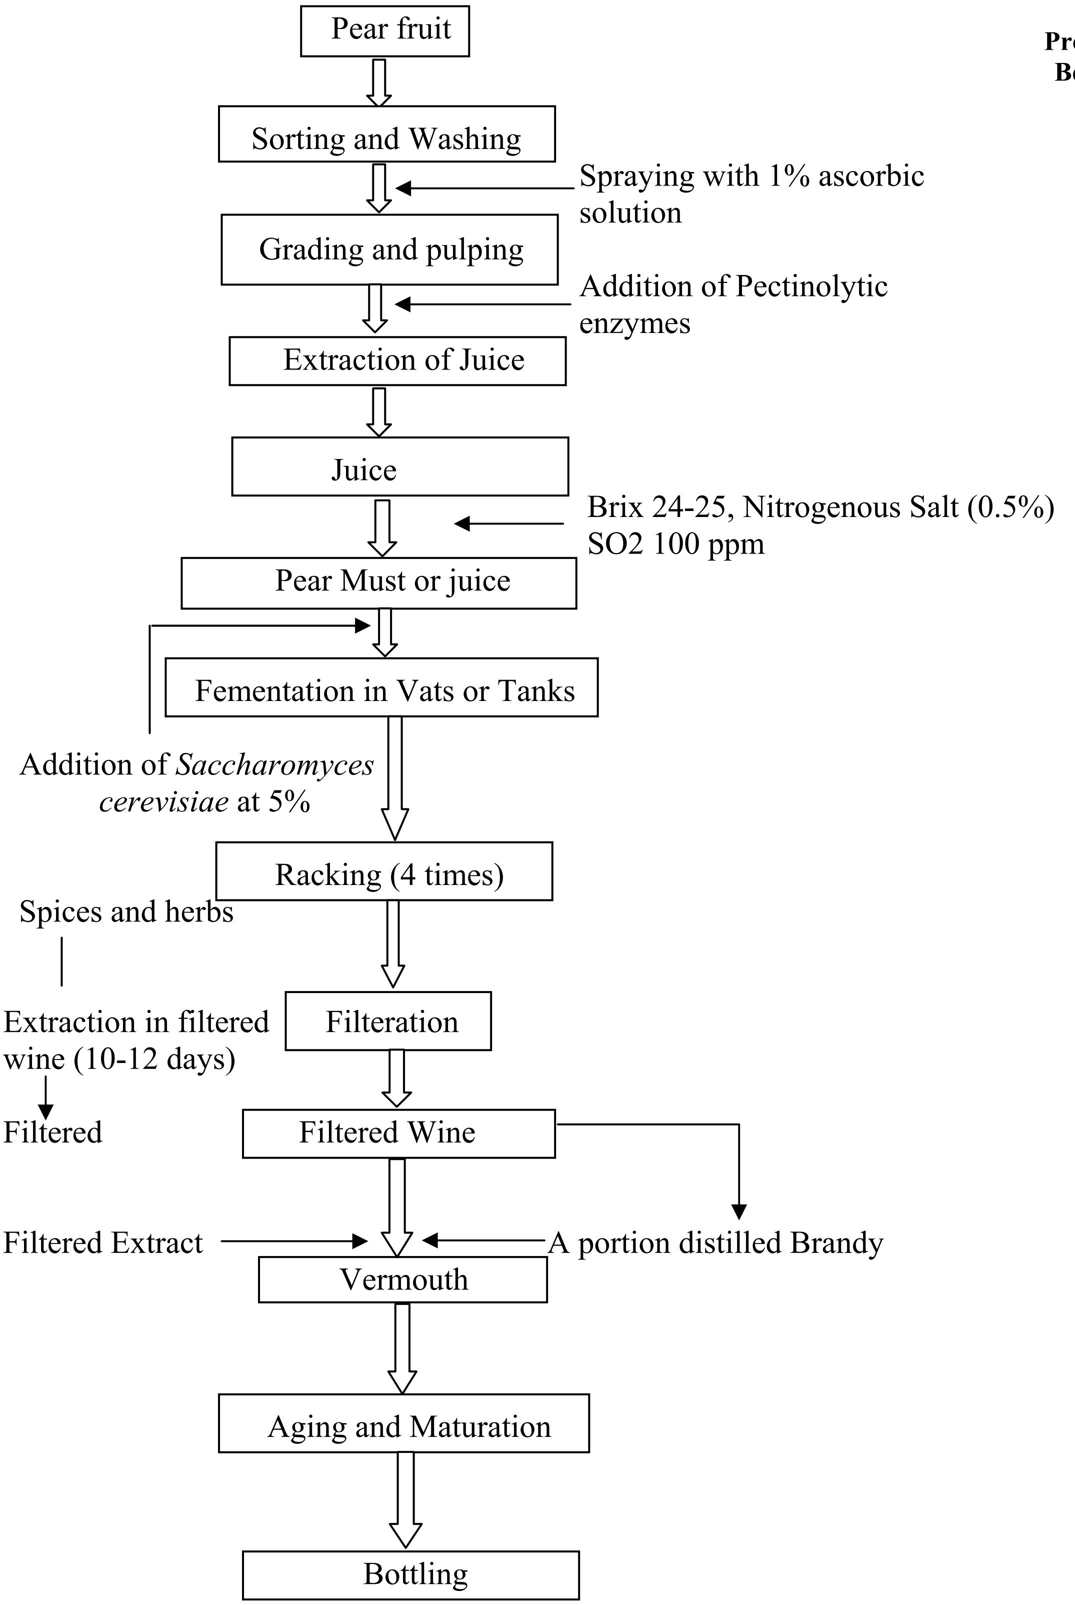

Figure 13.3: Manufacture of vermouth of pears

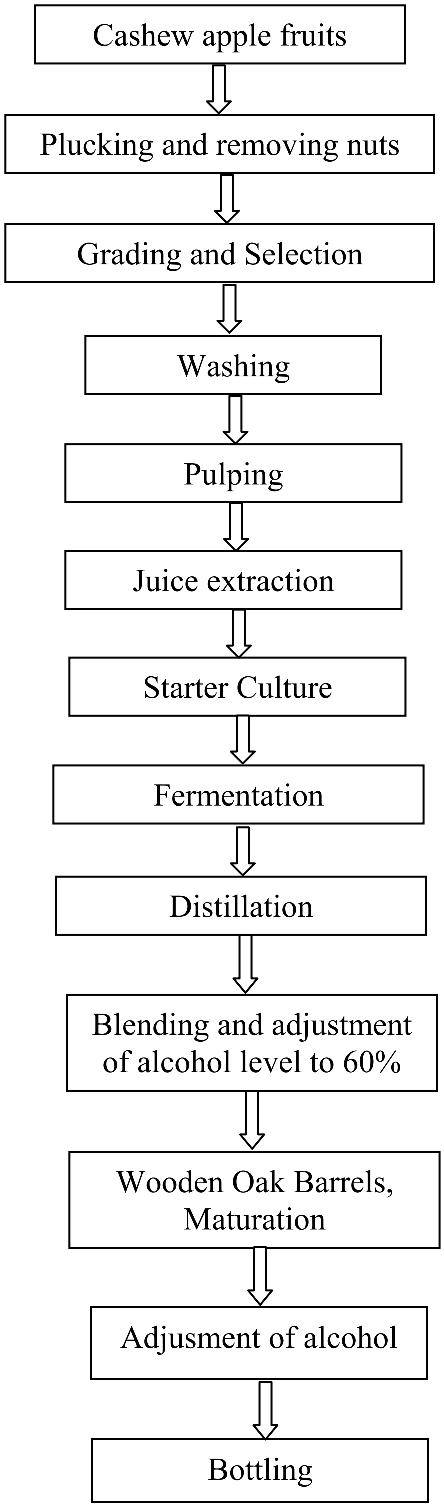

Figure 13.4: Manufacture of Feni from cashew apple

Like wines, brandy also contains many constituents. The major being ethyl alcohol (ethanol) along with fusel oil (higher alcohols e.g. n-propyl alcohol, isobutyl alcohol etc.,), traces of aldehydes esters (ethyl acetate) furfural and several other constituents. The method of base wine production for brandy is as employed for other wine manufacturing.

Distillation of fermented wine is carried out mostly in copper pot distillation unit but column stills (a vacuum distillation) is also adopted in some of the wineries. Distillation is carried out along with some fermented fruit materials and yeast cell biomass (lees). It is done in two steps. The first step results in about 28% of ethyl alcohol in the distillate whereas in the second stage of distillation of the distillate yields 70% of ethanol by volume. Brandy is stored in oak barrels. Some of the products are stored for several years e.g. 15 to 50 years and the quality improves during maturation. The final product has mostly 40-45% of ethyl alcohol by volume.

In the United States of America and several other countries, the strength of alcohol is measured in terms of proof. It denotes usually the twice the percent of ethyl alcohol content of a liquid at 60^{o}F.

13.7 TECHNOLOGY OF FENNY AND BRANDY OF CASHEW APPLE

Cashew apple is grown in large areas of the western coast of Karnataka, Goa and other states for cashew nuts. The nut is attached to the fleshy fruit and while processing, the fruit pulp is mostly wasted or a part is utilized for wine-making. It is rich in fermentable sugars and ascorbic acid. In Goa 'Kaju Feni' is quite popular. In Tanzania, Brazil and several other countries, alcoholic beverages are produced and used as a wine or occasionally distilled and consumed in the form of brandy. The word 'Feni' comes from the Konkani language, which means 'froth'. It is mostly produced at a cottage scale level. However, technical know-hows are available for commercial production of feni and brandy from it.

The cashew apple fruits are crushed and pulped and juice is extracted using extractors. The juice is left as such for spontaneous natural fermentation or inoculum of *Saccharmyces cerevisiae* at 5% is added, stirred and mixed evenly. Normally 2-3 days are taken for the fermentation. The feni is obtained by distilling the fermented juice with Urak* (2:1) containing 60% alcohol. Aging and maturation at 15^{o}C is carried out in oak wood barrels. After aging the product is marketed in bottles adjusting alcohol content to 42-43%.

The process of feni production is illustrated in Figure 13.4.

13.8 TECHNOLOGY OF VINEGAR PRODUCTION BY FERMENTATION

Vinegar is consumed in almost every part of the world. Sugars mostly glucose, fructose and sucrose in appropriately diluted concentration are converted to ethyl alcohol by yeast/s and acetic acid producing bacteria convert this alcohol into ethanol by acetification thus producing vinegar. Vinegar contains at least 4% of acetic acid with some other solids. It is made from distilled alcohol prepared from cane molasses or other sugar sources. According to Indian Standards Vinegar should not contain arsenic, mineral acid, lead, copper, or colouring matter except caramel.

i) Method of Vinegar Preparation

Two distinct processes are involved in the preparation of vinegar:

a) Transformation of sugars of fruits or any sugary materials into alcohol by yeast anaerobically;

b) conversion by acetic acid producing bacteria of alcohol oxidatively in the presence of air into acetic acid.

$$\underset{\text{Fermentable Sugar}}{C_6H_{12}O_6} \xrightarrow{\text{Yeast}} \underset{\text{Ethylalcohol}}{2C_2H_5OH} + \underset{\text{Carbon dixoide}}{2CO_2}$$

$$\underset{\text{Ethyl alcohol+ Oxygen Sugar}}{2C_2H_5OH + 2O_2} \xrightarrow[\text{Producing bacteria}]{\text{Acetic acid}} \underset{\text{Acetic acid}}{2CH_3COOH} + \underset{\text{water}}{H_2O}$$

ii) Types of Vinegar

Cider Vinegar (apple juice)
Wine Vinegr (grape juice)
Spirit Vinegar (Dilute ethylalcohol from molasses)
Malt Vinegar (barley malt)
Orange, pineapple, banana, pear, peach, apricot, onion vinegars

iii) Process of Vinegar Preparation

There are a number of processes commercially used for vinegar production. The most commonly used are:

a) *Slow process:* The juice or sugary solution is filled into barrels and allowed to undergo alcoholic fermentation and acitification slowly. The mouth of the barrel or container is covered with a piece of cloth and placed in a damp and warm place. In about 5 to 6 months, the sugar solution turn into vinegar. This process is time-taking.

b) *Oreleans Slow Process:* The barrel used is filled three-fourth with the juice and two holes above the juice level on the either side of barrel are made in addition to top hole or mouth. These holes are tightly covered with cheese cloth to protect from insects and flies. The filled barrel is placed in a warm place (21-27^{o}C) and fermentation is allowed to take place. It takes about 3 months for complete fermentation. About three fourth of the fermented liquid (Vinegar) is withdrawn without making any hole in the top thick film of *Acetobacter* and again filled with the fresh juice.

c) *Quick Process:* It is known as the 'Generator' or the 'German' process. The generator is in the form of a cylinder 3.6 to 4.2 meters high and 1.2 to 1.5 meters in diameter. It has a false bottom and head, vent holes and sparge for discharging the liquor. It has three compartments. The central compartment is filled with beech wood shavings, corn cobs, pumice stone, straw to increase the surface area for the growth of acetic acid producing bacteria. The other distribution compartment is above 30 centimeters of the central compartment. It is separated by a partition perforated plate having a number of holes. A revolving sprinkler or a fitting trough is fitted in order to allow liquid to trickle slowly over the shavings of the Central Compartment. The third compartment is the bottom compartment separated from the central compartment by a perforated partition above 1.5 Meters the bottom of the generator.

Initially beech wood shavings are wetted with unpastuerized vinegar and then two parts of alcoholic juice and one part of vinegar is charged slowly to allow bacteria to colonize the shavings. When the generator becomes ready then alcoholic juice or liquid is passed through the generator on the top and acetified liquid (Vinegar) is collected having 3 to 4% acetic acid (volume). The air passage is cleaned from time to time. The optimum temperature is around 27-30^{o}C for this operation.

d) *Fringe Process:* The quick process has been improved by the addition of forced aeration and temperature control of trickling generators.

e) *Submerged Culture Process:* It has been tried for Vinegar production but *Acetobacter aceti* is quite sensitive to oxygen. Therefore, the aeration of the liquid is significantly important. However, it is 80 times faster oxidation of ethanol to acetic acid.

iii) Post-fermentation Process

a) *Aging:* Vinegar produced by quick process is kept for aging for about six months.

b) *Clarification:* Before bottling, vinegar is made sparkling clear.

c) *Pasteurization:* It is heated in an open vessel to about 60^{o}C and then cooled and bottled.

d) *Spoilage of Vinegar:* Lactic acid producing bacteria grow initially and spoil the vinegar. It should be fully avoided. Film yeast growing on the top also spoil the process of vinegar generation. Vinegar flies are well known to affect the quality of vinegar. Vinegar eels, louse and vinegar mites are the enemies of vinegar production. They should be completely eliminated.

At present a large proportion of our demand for vinegar is being met by synthetic vinegar. However, the fruit vinegar may be encouraged for consumption. People are not familiar with fruit vinegars and therefore, these have to be popularized highlighting their therapeutic importance in human health.

13.9 LET US SUM UP

Production of exotic beverges in smaller quantities is an art but to meet the increasing demand of the people, large-scale operations at commercial scales are required. Therefore economically viable technologies are warranted for industrial production. All the beverages are commercially produced and marketed all over the world. Commercial vats or tanks with juice extractor and filteration or clarifier units are employed for these alcoholic beverages. Brandy manufacture requires a distillation unit along with the modern bottling plant. Vinegar is also a commercial fermentation produced throughout the world. There are a number of quick processes which take considerably shortertime for vinegar generation.

13.10 KEY WORDS

Vats and Tanks	:	Open or closed mouth vessels for wine fermentation.
Sparkling cider	:	Artificially carbonated cider.
Vermouth	:	Wine flavoured with herb and spices containing 15-21%, ethanol.
Brandy	:	Distilled wine or fermented fruit juice.
Fenny	:	Wine from cashew apple pulp.
Vinegar	:	Prepared from sugary materials by fermentation containing 4 grams of acetic acid/100 ml.

13.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - It is an art at house-hold or small scale production.
   - For Commercial production, large scale operation needed.
   - For large scale operations, engineering inputs needed for fermentation, filtration, maturation and bottling.

2. Your answer should include the following points:

   - Unlike other fermentations (antibiotic, citric acid), non porous and non-toxic vessels are used.
   - They are constructed from non-aromatic wood, cement, stainless steel or fibre glass.
   - Vats and tanks used for wine fermentation.

3. Your answer should include the following points:

   - Prepared by carbonation.
   - Secondary fermentation done at lower temperatures.
   - Wine which flavoured with herbs and spices and contain ethanol in the range of 15-21%: vermouth.

4. Your answer should include the following points:

   - Distilled wine or any fermented juice (brandy).
   - Mostly 40-45% ethanol volume (brandy).

5. Your answer should include the following points:

   - Produced from fleshy pulp
   - Sorting of pulp → extraction of juice → allowing spontaneous fermentation or addition of starter culture for 2-3 days → distillation of the fermented juice.
   - Distilled product contains 42% ethanol.

Check Your Progress Exercise 2

1. Your answer should include the following points:

   - A fermentation derived product, containing not less than 4 grams of acetic acid per 100 ml.
   - Prepared in the household in small quantities from sugarcane juice in India or cider or wine of fruits.

2. Your answer should include the following points:

   - Two distinct processes: the first being sugar fermentation to ethyl alcohol by *Saccharomyces cerevisiae* and the next being conversion of ethyl alcohol to acetic acid by *Acetobacter* spp.
   - Commercially available vinegar: Vinegar from jaggery, vinegar from cider, Barley malt vinegar.

3. Your answer should include the following points:

   - Slow process
   - Oreleans process
   - Quick process
   - Fringe process
   - Submerged process

13.12 SOME USEFUL BOOKS

1. Boulton, R.B., Singleton, V.L., Bisson, L.F., and Kunker, R.E. (1995) Principles and Practices of Wine Making. Chapman and Hall, New York.

2. Jackson, R. (1994) Wine Science: Principles and Applications. Academic Press, San Diego.

3. Zoecklein, B.W., Fuselang, K.C., Gump, B.H., and Nurry, F.S. (1995) Wine Analysis and Production. Chapman Hall, New York.

EXPERIMENT 1 DETERMINATION OF ACIDITY AND pH

Structure

1.1 INTRODUCTION

Acidity of foods is usually determined by acid, base titration using standard sodium hydroxide. The reaction being between a weak acid and a strong alkali, phenolphthalein is used as the end point colour indicator, which produces a faint pink colour around pH 8. For dark coloured solutions, alkali titration can be carried out to pH 8.1 using a pH meter.

pH of foods is determined using a pH meter having glass electrode and calomel electrode or a combination electrode.

Objectives

After studying and performing this experiment, you should be able to

- determine the acidity of food products by alkali titration; and
- determine the pH of the product using a pH meter.

1.2 EXPERIMENT 1a: DETERMINATION OF ACIDITY

1.2.1 Principle

Organic acids react with sodium hydroxide to form their corresponding sodium salts. The common organic acids are mono- carboxylic (acetic acid, lactic acid), dicarboxylic (malic and tartaric acids) and tri- carboxylic (citric acid) acids. The general reaction between an organic acid and sodium hydroxide is as follows.

$$R\text{–}(COOH)n + n\ NaOH = R\text{–}(COONa)n + n\ H_2O$$

By knowing the equivalent weight of the acid, the acid content can be calculated based on the alkali required for neutralization.

1.2.2 Requirements

Equipment and Apparatus

Chemical balance	
Conical flask – 250 ml	–3
Beaker – 100 ml	–1
Volumetric flask – 100 ml	–1
Burette – 10 ml	–1
Pipette – 5 and 10 ml	–1 each

Chemical and Reagents

Sodium hydroxide solution – 0.1 N

Phenolphthalein indicator – 0.1% in alcohol

1.2.3 Procedure

Acidity determination
Sample preparation

Thin Juices, RTS beverages etc.: Mix thoroughly and filter through previously washed and dried muslin cloth. Use 5-10 ml for titration.

Fresh fruits & vegetables, dried fruits, preserves, jams, marmalades pickles etc.: Pulp the material in a blender or mortar and mix thoroughly. Accurately weigh 10 to 20 g of the pulped material in a beaker, add about 50 ml distilled water and boil gently for 15 to 30 min replacing the water lost by evaporation. Cool, transfer to a volumetric flask (say 100 ml) and make up the volume. Filter through Whatman No.1 filter circle, if necessary.

Fruit pulps, squashes, syrups, cordial etc.: Weigh 10-20 g of the material, mix with distilled water, heat on steam bath to dissolve, cool and make up the volume in a volumetric flask (say 100 ml).

Pipette out suitable aliquot (5-10ml) of the prepared sample (quantity depending on the acidity of the sample) into a 250 ml. conical flask. Add about 50 ml of distilled water and few drops of phenolphthalein indicator. Titrate to light pink end point with 0.1 N NaOH solution. Products like juices and beverages may be directly weighed (5-10g) and transferred into 250 ml conical flask with about 50 ml distilled water and titrated.

1.2.4 Observations

Where samples are boiled with water and made up to volume:

Weight of sample	= W	= ---------- g
Volume made up to	= V_1	= ----------ml
Volume of aliquot taken for titration	= V_2	= ----------ml
Volume of NaOH required	= V_3	= ---------- ml
Normality of the NaOH solution	= 0.1	

Where sample is weighed and directly taken for titration:

Weight of sample	$= W_1$	= ---------- g
Volume of NaOH required	$= V_4$	= --------- ml
Normality of the NaOH solution	= 0.1	

1.2.5 Calculations

1000 ml 1N NaOH = One gram equivalent of organic acid.

Calculate the acidity in terms of the predominant acid present in the product. The equivalent weights of some common organic acids and the foods in which they are the major acids are given below. However, unless specifically required, it is customary to calculate the acidity of food materials as anhydrous citric acid.

Organic acid	**Equivalent Wt. (E.W.)**	**Foods**
Anhydrous citric acid	64	Citrus fruits
Malic acid	67	Raw mango, apple
Tartaric acid	75	Grapes, tamarind
Lactic acid	90	Milk foods
Acetic acid	60	Vinegar containing foods

For samples boiled with water and made up to volume:

$$\% \text{ acid} = \frac{\text{E.W. of acid} \times \text{Titer} \times \text{Normality of NaOH} \times \text{Volume made up} \times 100}{1000 \times \text{Aliquot taken} \times \text{Weight of sample}}$$

$$= \frac{\text{E.W. of acid} \times V_3 \times 0.1 \times V_1}{10 \times V_2 \times W}$$

For sample taken directly for acidity estimation:

$$\% \text{ acid} = \frac{\text{E.W. of acid} \times V_4 \times 0.1}{10 \times W_1}$$

For carbonate beverages, expel carbon dioxide by warming or just heating to boil, cool and then titrate.

1.2.6 Result

Acidity of the given product = Percent (w/w)

1.3 EXPERIMENT 1b: DETERMINATION OF pH

1.3.1 Principle

Acidity of any solution is dependant on the pH and in turn pH depends on the Hydrogen ion concentration of solution. pH can be calculated by the equation pH = negative logarthim of Hydrogen ion concentration i.e.,

$$pH = -\log (H^+)$$

1.3.2 Requirements

pH meter

Buffer solutions – pH 4.0, 7.0 and 9.0

1.3.3 Procedure

Sample preparation

Liquid samples are used as such for pH measurement. Solid and semi-solid materials have to be homogenized well before the measurement.

Procedure

The pH meter should be switched on for at least 30 min before taking measurements for stabilization. The pH meter is calibrated against standard buffers before measuring the pH of sample. pH meters are provided with operating instructions, which should be followed. Rinse the electrode(s) with water and wipe dry using a filter paper in between buffer and sample pH measurements.

1.3.4 Results

The pH of the sample is recorded usually to the first decimal place

1.4 PRECAUTIONS

The general precautions mentioned in the course 'Introduction' and those indicated in the experiments should be followed meticulously.

EXPERIMENT 2 DETERMINATION OF MOISTURE

Structure

2.1 INTRODUCTION

Moisture content of vegetables and most of their products can be determined by drying the material in an air oven. A fairly high temperature of the order of 105^{0}C is required to remove the bound water in foods. However, at that temperature, foods containing appreciable proportion of sugars like fruit products decompose giving wrong results. Therefore, it is advisable to dry such products at lower temperature, such as $60\text{-}70^{0}$C, preferably in a vacuum oven.

Objectives

After performing this experiment, you should be able to:

- determine the moisture content of foods by air oven method; and
- determine the moisture content of sugary products by vacuum oven method.

2.2 EXPERIMENT

2.2.1 Principle

Moisture in foods exists both as free water and bound water. Bound water is more difficult to remove by heat. Therefore, the time required for complete removal of water from a food material varies. Hence drying has to be continued till constant weight is reached.

2.2.2 Requirements

Apparatus

Hot air oven (thermostatically controlled)	–1
Vacuum oven	–1
Chemical balance, 1 mg sensitivity	–1
Desiccator (with active desiccant)	–1

Moisture dishes with tight fitting lids –6

Aluminium dishes (7 cm. Dia.)
Sea sand (washed and ignited)
Glass rods

2.2.3 Procedure

a) Air oven method

Weigh accurately 5 g of the material in a dish previously dried and weighed. Place the dish along with lid in an electric air oven maintained at 70^{0}C in the case of fruits or their products, or 100^{0}C in the case of vegetables or their products. Cool the dish to room temperature in a desiccator and weigh with the lid on. Repeat the process of heating, cooling and weighing until the loss in weight between two successive weighings do not vary by more than 3-5 mg. For most of the samples 16-18 hr heating is sufficient. Record the lowest weight obtained.

b) Vacuum oven method

Place 20-25 g pure sea sand and a short glass rod in an aluminium dish having a tight fitting cover. Dry thoroughly and cool in a desiccator and weigh. Accurately weigh 5 g sample and transfer completely to the dish by rinsing with water. Mix well with the glass rod and heat on steam bath for partial drying. Transfer the dish to vacuum oven and dry the sample at 70^{0}C at a pressure not more than 100 mm Hg pressure. Cool in a desiccator and weigh. Repeat the process of drying, cooling and weighing until consecutive weighings made at intervals do not vary by more than 3 mg. Drying for 6 to 7 hr is generally found sufficient.

2.2.4 Observations

a) Air oven method

Weight of the weighing dish with lid = W_1 = ------- g

Weight of the dish with lid and material = W_2 = ------- g

Weight of the dish with lid and dried material = W_3 = ------- g

b) Vacuum oven method

Weight of the dish with sand and glass rod = W_1 = ------- g

Weight of the dish with glass rod and material = W_2 = ------- g

Weight of the dish with glass rod and dried material = W_3 = ------- g

2.2.5 Calculations

a) Air oven method

Weight of the material = (Weight of the dish with sample – weight of the dish)

= $(W_2 – W_1)$ = ------- g

Quantity of moisture in the material = (Weight of the material before drying – weight of the material after drying)

$$= (W_2 - W_3) = \text{-------}\ g$$

$$\text{Per cent moisture in the material} = \frac{\text{Quantity of moisture in the material}}{\text{Weight of the material}} \times 100$$

$$= \frac{(W_2 - W_3)}{(W_2 - W_1)} \times 100 = g/100g \text{ or } \%$$

b) Vacuum oven method

Weight of the material $= W_2 - W_1$ = ------- g

Quantity of moisture in the material $= W_2 - W_3$ = ------- g

$$\text{Per cent moisture in the material} = \frac{\text{Quantity of moisture in the material}}{\text{Weight of the material}} \times 100$$

$$= \frac{(W_2 - W_3)}{(W_2 - W_1)} \times 100 = g/100g$$

2.2.6 Results

Moisture content of the sample = ----------- Percent (%) by weight

2.3 PRECAUTIONS

The general precautions mentioned in the course ‘Introduction’ and those indicated in the experiments should be followed meticulously.

EXPERIMENT 3 DETERMINATION OF ASH AND ITS CHARACTERISTICS

Structure

3.1 INTRODUCTION

Ash content of foodstuffs represents inorganic residue remaining after destruction of organic matter. Acid- insoluble ash is a measure of sand and other silicious matter present. High ash content and/or low alkalinity of the ash in some cases could be due to the presence of adulterants.

Objectives

After studying and performing the experiments, you should be able to:

- determine the total ash content in
  - water-soluble ash;
  - acid-insoluble ash; and
  - the alkalinity of the ash in food products.

3.2 EXPERIMENT 3a: DETERMINATION OF TOTAL ASH

3.2.1 Principle

When a sample of a food material is ashed around 525^0C, the organic matter present is decomposed and expelled. The residue remaining is the mineral matter. The ash content is expressed as per cent weight by weight.

3.2.2 Requirements

Equipment and Apparatus

Silica dish (100ml cap.)
Chemical balance, 1mg sensitivity
Hot plate or burner
Muffle furnace
Desiccator (with an active desiccant)

Precautions

Do not transfer the hot silica dish directly from the muffle furnace to the desiccator. Cool to 100^oC and transfer to desiccator.

3.2.3 Procedure

Note the tare weight of three silica dishes. Accurately weigh 5 g of sample into each. Char the material carefully on a burner or hot plate and transfer the dishes to a muffle furnace and ash at a temperature of around 525^0C until a white ash is obtained. Moisten the ash in dishes with water. Dry on steam bath and on hot plate and re-ash at 525^0C. Cool in a desiccator and weigh. Reserve the ash in one dish for determination of water-soluble and water-insoluble ash, in second dish for acid-insoluble ash, and the ash in the third dish for determining alkalinity of ash.

3.2.4 Observations

Weight of silica dish $= W_1$ = ------- g

Weight of the silica dish with sample $= W_2$ = --- --- g

Weight of the silica dish with ash $= W_3$ =------- g

Calculation

$$\text{Total ash (\%) in the sample} = \frac{\text{Weight of ash}}{\text{Weight of sample}} \times 100 = \frac{(W_3 - W_1)}{(W_2 - W_1)}$$

If the ash content has to be calculated on dry weight basis:

$$\textbf{Total ash content (\%) on dry weight basis} = \frac{(W_3 - W_1) \times 100}{(W_2 - W_1) \times (100 - M)}$$

Where, M is the moisture content (%) of the sample in percent by weight (determined as in experiment 2)

Expression of Results

Ash Content = % by weight or % by dry weight

3.3 EXPERIMENT 3b: DETERMINATION OF WATER-SOLUBLE AND WATER-INSOLUBLE ASH

3.3.1 Principle

When the total ash obtained from the above experiment is boiled in water, part of the ash dissolves (water-soluble ash) and part remains as insoluble ash. The insoluble ash can be estimated gravimetrically. The difference between total ash and water-insoluble ash gives water-soluble ash.

3.3.2 Requirements

Same as used for total ash

Reagents/chemicals

Whatman No. 41 filter circles
Red litmus paper

3.3.3 Procedure

Transfer the ash from one of the three silica dishes, with the aid of about 20 ml distilled water, into a beaker. Cover with a watch glass and boil for 5 min. Filter through an ashless filter paper (Whatman No. 41). Wash the entire residue with hot water until the filtrate no longer turns red litmus blue. (Reserve the entire filtrate for the determination of alkalinity). Dry the ashless paper with residue (water isolubles) in the same silica dish and transfer to muffle furnace and ignite at 525^{o}C for 2 hours. Cool in a desiccator and weigh.

3.3.4 Observations

Weight of silica dish No.1	= W_1 --- g
Weight of the silica dish with sample	= W_2 --- g
Weight of the silica dish with total ash	= W_3 --- g
Weight of the silica dish with water-insoluble ash	= W_4 --- g

3.3.5 Calculations

$$\text{Water-soluble ash (\%)} = \frac{\text{Total ash} - \text{water-insoluble ash}}{\text{Weight of sample}} \times 100$$

$$= \frac{(W_3 - W_1) - (W_4 - W_1)}{(W_2 - W_1)} \times 100 = \frac{(W_3 - W_4)}{(W_2 - W_1)} \times 100$$

$$\text{Water-soluble ash (\%) on dry wt.} = \frac{(W_3 - W_4) \times 100 \times 100}{(W_2 - W_1) \times (100\text{-}M)}$$

Where, M = Moisture % of sample.

3.3.6 Results

Water-soluble ash = % by weight on dry basis.

3.4 EXPERIMENT 3c: DETERMINATION OF ACID-INSOLUBLE ASH

3.4.1 Principle

Acid insoluble ash refers to the portion of ash, which does not dissolve in 1:2.5 HCl under the experimental conditions. This can be estimated either from the total ash (as obtained in Experiment 3a) or water-insoluble ash (as obtained in Experiment 3b).

Preparation of Sample

Use the ash of second disk obtained from the Experiment 3a.

3.4.2 Requirements

Apparatus

Same as used for total ash

Chemicals/ regents

Hydrochloric acid - dilute with distilled water (1: 2.5)
Whatman No. 41 filter circles
Blue litmus paper

Precautions

Do not inhale the vapours of Conc. Hydrochloric acid.

3.4.3 Procedure

To the ash of the second silica dish, add 25ml of hydrochloric acid, cover with a watch glass and boil gently for 5 min. Filter through ashless filter paper. Wash the entire residue with hot water (> 85^{o}C) until the filtrate no longer turns blue litmus paper red. Dry the ashless paper with the residue in the same dish and transfer to Muffle furnace and ignite at 525^{0}C for 2 hrs. Cool in a desiccator and weigh.

Alternatively, water-insoluble ash as obtained in Experiement 3b can also be used.

3.4.4 Observations

Weight of silica dish No. 2	= W_1	= --- g
Weight of silica dish with sample	= W_2	= --- g
Weight of the silica dish with ash insoluble in acid	= W_3	= --- g

3.4.5 Calculations

$$\text{Ash insoluble in acid (\%)} = \frac{\text{Acid-insoluble ash}}{\text{Weight of sample}} \times 100$$

$$= \frac{(W_3 - W_1)}{(W_2 - W_1)} \times 100$$

$$\text{Ash insoluble in dilute HCl (\%) on dry wt.} = \frac{(W_3 - W_1) \times 100 \times 100}{(W_2 - W_1) \times (100 - M)}$$

Where, M = Moisture of the sample.

3.4.6 Results

Ash insoluble in dilute HCl = % by weight on dry basis.

3.5 EXPERIMENT 3d: DETERMINATION OF ALKALINITY OF ASH

3.5.1 Principle

Dissolving the total ash in a known volume of standard dilute HCl and titrating the excess acid with standard NaOH determine alkalinity of ash.

Preparation of Sample

Use the ash of the third dish obtained from Experiment 3a.

3.5.2 Requirements

Apparatus

Burette, 10 ml cap.
Conical flask, 250 ml

Chemicals and Reagents

Methyl orange, 0.1% in water
Hydrochloric acid – 0.1N
Sodium hydroxide – 0.1N

3.5.3 Procedure

To the ash in the third silica dish from Experiment 3a, add 10 ml of 0.1 N HCl. Dissolve by warming on a water bath, cool and titrate the excess acid with 0.1 N NaOH using methyl orange indicator. Alkalinity of ash is calculated as potassium carbonate (K_2CO_3).

3.5.4 Observations

Weight of empty dish No. 3	$= W_1$	= ----- g
Weight of dish with sample	$= W_2$	= ----- g
Weight of dish with ash	$= W_3$	= ----- g
Volume of 0.1 N HCl added to the ash	= A	= ----- ml
Titre value (ml 0.1 N NaOH)	= B	= -----ml
Normality of the acid	= N	

3.5.5 Calculations

One ml of 0.1 N HCl is equal to 0.00691 g of potassium carbonate

Therefore, g of potassium carbonate per g of ash =

$$\frac{\text{ml 0.1 HCl required to neutralize the alkalinity of the ash} \times 0.00691}{\text{Weight of the ash}}$$

$$= \frac{(A - B) \times 0.0061}{(W_3 - W_1)}$$

Alkalinity may also be expressed as number of ml of 0.1 N acid required to neutralize the ash from 100 g of the sample.

Alkalinity of ash from 100 g sample =

$$\frac{\text{ml 0.1 N HCl required}}{\text{Weight of sample}} \times 100 = \frac{(A - B) \times 100}{(W_2 - W_1)}$$

3.5.6 Results

Alkalinity of ash = g of potassium carbonate per g of ash, or ml 0.1 acid required to neutralize ash from 100g sample

3.6 PRECAUTIONS

The general precautions mentioned in the course 'Introduction' and those indicated in the experiments should be followed meticulously.

Use a tongs with long handle for keeping and removing dishes from the muffle furnace.

EXPERIMENT 4 DETERMINATION OF REDUCING SUGARS, TOTAL REDUCING SUGARS, SUCROSE AND STARCH

Structure

4.1 INTRODUCTION

Several methods are available for estimation of reducing sugars. They include chemical, polarimetric and chromatographic methods. However, for routine analysis of food products, Lane and Eynon chemical method is most widely used. Non-reducing sugars and starch are first converted into reducing sugars for estimation.

Objectives

After studying and performing this experiment, you should be able to:

- prepare food products for estimation of reducing sugars, total sugars and starch; and
- determine reducing sugars, total sugars and starch in food products by Lane and Eynon method.

4.2 EXPERIMENT 4a: REDUCING SUGARS

4.2.1 Principle

Lane and Eynon method is based on the principle of reduction of Fehling's solution by reducing sugars. Fehling's solution is a mixture of copper sulphate and alkaline Rochelle salt (sodium potassium tartarate). Rochelle salt complexes with the cupric hydroxide formed in alkaline solution and prevent it from precipitation. Reducing sugars reduces the complexed cupric hydroxide to red, insoluble cuprous oxide under the experimental conditions. An oxidation-reduction indicator, usually methylene blue, detects the end point of the reaction.

The first step in the estimation of reducing sugars by Lane and Eynon method is the determination of Factor for Fehling's solution. Fehling factor is the quantity of invert sugar in grams required to completely reduce the Fehling's solution (usually 5 ml each of Fehling's A and B solutions).

Total sugars include reducing sugars and non-reducing di - and oligo-saccharides like sucrose, which on mild acid hydrolysis are converted into reducing sugars. Starch is hydrolysed by strong acids into glucose.

4.2.2 Requirements

Equipment and Apparatus

Chemical balance, 1mg sensitivity

Hot plate

Burette (50 ml cap.) with an off-set tip

Volumetric flask, 250 ml

Pipette, 5 ml and 25 ml

Conical flask, 250 ml

Weighing bottle

Funnel (small)

Whatman No. 1 filter circles

Chemicals and Reagents

Fehling's solution A: Dissolve 69.28 g copper sulphate ($CuSO_4.5H_2O$) in distilled water and dilute to 1000 ml. Filter and store in amber colour bottle.

Fehling's solution B: Dissolve 346 g Rochelle salt (Potassium sodium tartrate: KNa $C_4H_4O_6$. $4H_2O$) and 100 g NaOH in distilled water. Dilute to 1000 ml. Filter and store in amber colour bottle.

Neutral lead acetate solution: Prepare 20% neutral lead acetate solution.

Potassium oxalate solution: Prepare 10% potassium oxalate ($K_2C_2O_4$. H_2O) solution.

Methylene blue indicator: Prepare 1% methylene blue solution in distilled water.

4.2.3 Procedure

i) Standardization of the Fehling's Solution for Invert Sugar

Accurately weigh 4.75g of AR grade sucrose. Transfer to 500 ml volumetric flask with 50 ml distilled water. Add 5 ml conc. HCl and allow to stand for 24 hr. Neutralise the solution with NaOH using phenolphthalein as end point indicator and make up to volume. Mix well and transfer 25 ml to a 100 ml volmetric flask and make up to volume (1 ml = 2.5 mg of invert sugar). Transfer to a burette having an off-set tip and titrate against Fehling's solution as described below for sample.

Observations

Titre = V_1 = ------ ml

Calculations

$$\text{Factor for Fehling's solution (g of invert sugar)} = \frac{\text{Titre} \times 2.5}{1000}$$

$$= 0.0025 \times V_1 = \text{-------} \text{ g}$$

ii) Determination of Reducing Sugars

Preparation of sample

Weigh accurately 10-50 g sample as such (juices, beverages etc.) or homogenized sample (jams, preserves etc.) and transfer to 500 ml volumetric flask. Add about 100 ml water and neutralize with NaOH solution to phenolphthalein end point. Add 10 ml neutral lead acetate solution, shake and let stand for 10 min. Add potassium oxalate solution in small amounts until there is no further precipitation. Make up to volume, mix the solution well and filter through Whatman No. 1 filter circle. Transfer the filtrate to a 50 ml burette having an off-set tip.

Preliminary titration: Pipette out 5 ml each of Fehling A and B solutions into 250 ml conical flask. Mix and add about 10 ml water and a few pumice stone or glass beads. Dispense the sugar solution from the burette. Heat the solution to boiling. Add 3 drops of methylene blue indicator. Continue the addition of the sugar solution drop wise until the blue colour disappears to a brick-red end point. (The concentration of the sample solution should be such that the titre value is between 15 to 50 ml). Maintain a total boiling peiod of 3 min. Note down the titre value.

Final titration: Pipette out 5 ml each of Fehling A and B solutions into a 250 ml conical flask. Add sample solution about 0.05 to 1.0 ml less than titre value of the preliminary titration. Heat the flask to boiling. Add 3 drops of methylene blue indicator. Complete the titration within 1 min by adding 2 to 3 drops of sugar solution at a time, until the indicator is decolourized. At the end point, the boiling liquid assumes the brick red colour. Note down the titre value. Perform the titration in duplicate and take the average.

Note: i) Preliminary titration must be finished within 3 min.
ii) Conical flask should not be disturbed or removed from the burner before the titration is finished.

4.2.4 Observations

Weight of the sample = W = ------- g

Dilution volume for the sample = V_2 = ------ ml

Volume of clarified sample solution required for Fehling's reaction (titre) = V_3 = ------- ml

4.2.5 Calculations

Based on the factor for Fehling's solution, V_3 ml sample solution contains:

0.0025 V_1 g reducing sugar (as invert sugar)

$$\text{Therefore, \% Reducing Sugars in the sample} = \frac{0.0025 \times V_1 \times V_2 \times 100}{V_3 \times W}$$

$$= \frac{0.25 \times V_1 \times V_2}{V_3 \times W} = X\ \%$$

4.2.6 Results

Reducing sugars (as invert sugar) = % by wt.

4.3 EXPERIMENT 4b: TOTAL REDUCING SUGARS

4.3.1 Principle

Total reducing sugars represent reducing sugars and non-reducing di and oligo saccharides, which can be hydrolysed into reducing sugars with dilute acids.

4.3.2 Requirements

Same as for experiment 4a.

4.3.3 Procedure

Pipette an aliquot of 50 ml of the clarified, de-leaded filtrate to a 100 ml volumetric flask. Add 5 ml of conc. HCl and allow to stand at room temperature for 24 hours. Neutralise with conc. NaOH solution followed by 0.1N NaOH using phenolphthalein as end point indicator. Make up to volume and transfer to 50 ml burette having an off-set tip. Perform the titration against Fehling's solution similar to the procedure described for reducing sugars, and determine the total sugars as invert sugars.

4.3.4 Observations

Volume of the acid hydrolysed sample solution required for Fehling solution (titre) = V_4 = ------ ml

4.3.5 Calculations

Based on the factor for Fehling's solution, total reducing sugars in

V_4 ml = 0.0025 × V_1 g

As 50 ml of the clarified and de-leaded solution is diluted twice (50 ml to 100 ml) after hydrolysis, dilution volume of the sample = ($2 \times V_2$).

Therefore, % Total reducing sugars (as invert sugars) $= \dfrac{0.0025 \times V_1 \times 2 \times V_2 \times 100}{V_4 \times W}$

$$= \frac{0.5 \times V_1 \times V_2}{V_4 \times W} = Y\ \%$$

Total reducing sugars comprises of reducing sugars and non-reducing sugars, which can be hydrolysed into reducing sugars under the experimental conditions. This non-reducing sugar is usually expressed in terms of sucrose.

As 0.95 g sucrose on hydrolysis yields 1 g invert sugar (glucose + fructose):

% Sucrose in the sample = (Total reducing sugars – % Reducing sugars originally present) × 0.95

$$= (Y - X) \times 0.95$$

[% Total sugars = (% Reducing sugars + % Sucrose)]

4.3.6 Results

Sucrose content in the sample = % by weight

4.4 EXPERIMENT 4c: STARCH

4.4.1 Principle

Starch is hydrolysed to glucose with strong acid and the reducing sugar formed is estimated by Lane and Eynon method. Sample containing sugars are washed to free it from them before hydrolysing the starch. Traces of lipids present are also washed off with petroleum ether before hydrolysing the starch.

4.4.2 Requirements

500 ml conical flask with std. joint to fix Liebig condenser
Petroleum ether
Alcohol – 95%and 50%
10% Alpha naphthol solution in alcohol
Sulphuric acid- conc.
Stainless steel vessel (5 lit. cap.), 10” dia.
Test tube – 10 ml
Centrifuge

4.4.3 Procedure

For samples containing sugars and less starch, to weighed quantity (50-100 g), add a little of water and heat to 60°C. Allow to stand for some time to obtain a solution of starch. Add about 100 ml 95% alcohol and centrifuge (2000 rpm, 10 min.) to settle the precipitate. Filter and wash the residue with about 50% alcohol until the filtrate gives no positive test for sugars. To test for sugars, to a few ml of the filtrate in a test tube, add a drop of 10% alpha naphthol reagent. Allow 1 ml of pure conc. H_2SO_4 to flow slowly down the side of the test tube so as to form a layer beneath the aqueous solution. If sugars are present, a red ring will appear within a few seconds at the junction of the two layers. Use the 50% alcohol-washed and dried precipitate for starch hydrolysis as below.

For starchy materials, weigh accurately about 2-5 g sample in a beaker. Add ether and stir well. Allow to settle and decant the ether portion and discard. Repeat the step 3-4 times and dry the sample.

Transfer the prepared sample to a conical flask and add 200 ml water and 20 ml conc. HCl. Place the flask in a steel vessel filled with 2/3rds volume of water. Connect the flask to a water-circulating condenser. Heat the vessel and allow the water to boil for exactly 2 hr. Shake the digestion flask intermittently during boiling. Remove the flask and cool the contents. Transfer the contents to a 500 ml volumetric flask and neutralise with sodium hydroxide. Filter through Whatman No. 1 filter circle. From the filtrate determine the reducing sugar content using Lane and Eynon titrimetric procedure.

4.4.4 Observations

Weight of sample	= W	= ------ g
Hydrolysed sample volume made up to:	= V_5	= ----- ml
Titre	= V_6	= ----- ml

4.4.5 Calculations

Based on the factor for Fehling's solution, reducing sugar content of V_6 ml of the hydrolysed starch solution = $0.0025 \times V_1$ g

The theoretical yield of reducing sugars (glucose) on complete hydrolysis of starch is: 0.90 g starch = 1 g glucose. However, for practical purposes, the currently accepted factor is: 0.925 g starch = 1 g glucose.

$$\text{Therefore, \% Starch content of the sample} = \frac{0.0025 \times V_1 \times V_5 \times 100 \times 0.925}{V_6 \times W}$$

4.4.6 Results

Starch content of the sample = per cent by weight.

4.5 PRECAUTIONS

The general precautions mentioned in the course 'Introduction' and those indicated in the experiments should be followed meticulously.

EXPERIMENT 5 DETERMINATION OF CRUDE FIBRE

Structure

5.1 INTRODUCTION

Crude fibre is the organic residue, which remains after the food sample has been treated with petroleum ether, boiling dilute sulphuric acid, dilute sodium hydroxide solution and alcohol under the standardized conditions. The crude fibre consists largely of cellulose together with a little lignin.

Objectives

After studying and performing this experiment, you should be able to:

- estimate the crude fibre content of food materials and products.

5.2 EXPERIMENT: DETERMINATION OF CRUDE FIBRE

5.2.1 Principle

By treating a food material successively with petroleum ether, sulphuric acid and sodium hydroxide, all the lipids, carbohydrates etc. are removed/ hydrolysed leaving only the crude fibre along with some insoluble mineral matter. The insoluble residue is freed of the soluble materials by water washing and filtration, and ashed. The difference in weight of the alcohol washed residue (dried) and the ash give the weight of true crude fibre.

5.2.2 Requirements

Equipment and Apparatus

Chemical balance, 1 mg sensitivity

Air oven (maintained at 100 ± 2 ^{0}C)

Muffle furnace (525 ± 5°C)

Hot plate

Digestion flask – 500ml

Water-jacketed condenser

Desiccator

Sintered glass crucible (porosity 100-160 µm) or

Linen cloth having 45 threads / inch.

Chemicals

0.255 N Sulphuric acid solution – 1.25 g H_2SO_4/100 ml

0.313 N Sodium hydroxide solution – 1.25 g NaOH/100 ml, free or nearly so from sodium carbonate.

Petroleum ether

Ethyl alcohol

5.2.3 Procedure

Grind the sample in a grinder to pass through No. 30 mesh sieve. Mix well to get a homogenous sample. Extract 2 g sample with ether and transfer residue to the digestion flask. Add 200ml hot sulphuric acid (1.25%) and connect to the reflex condenser and heat (it is essential that the solution boils within one minute). Boiling is continued briskly for exactly 30 min. Rotate flask frequently until sample at sides is thoroughly wetted. Take care to keep material from remaining on the sides of the flask. Immediately filter through linen cloth and wash with boiling water until the washings are acid free. Wash the residue back into the flask with 200ml hot sodium hydroxide solution (1.25%). Connect flask to reflux condenser and boil briskly exactly for 30 min. Remove the flask immediately and filter the contents through sintered crucible. Carefully transfer the entire residue to the flask with hot water. Wash the residue in the sintered crucible with hot water until the filtrate is alkali free. Wash with ethyl alcohol followed by ether. Then, dry at 100^0C to constant weight (W_1). Transfer the sintered crucible to a muffle furnace at 525^0C and ash the material. Cool and weigh (W_2). The loss in weight represents crude fibre.

5.2.4 Observations

Weight of the sample taken for ether extraction = W = ---- g

Weight of the sample after acid and alkali treatment along with sintered crucible = W_1 = -----g

Weight of residue after ashing along with the sintered crucible = W_2 ---- g

5.2.5 Calculations

Weight of crude fibre in the sample = Weight of acid and alkali digested residue minus weight of the ash = $W_1 – W_2$

$$\text{Crude fibre \%} = \frac{(W_1 - W_2) \times 100}{W}$$

$$\text{Crude fibre \% on dry wt.} = \frac{(W_1 - W_2) \times 100 \times 100}{W \times (100 - M)}$$

Where, M = % moisture content of the sample.

5.2.6 Results

Crude fibre = % by wt. on dry basis

5.3 PRECAUTIONS

The general precautions mentioned in the course 'Introduction' and those indicated in the experiments should be followed meticulously.

EXPERIMENT 6 DETERMINATION OF ALCOHOL BY SPECIFIC GRAVITY METHOD

Structure

6.1 INTRODUCTION

Alcohol content in alcoholic beverages like wines, beer, distilled spirits etc. is routinely determined. Good quality fruit juices contain practically no alcohol. The trace amount measured by distillation method is due to the other volatile components. However, if over ripe fruits are used for juice production or the juice has undergone some fermentation due to improper handling of the juice, the alcohol content will increase. Therefore, high alcohol content in fruit juices is an indication of poor quality.

Objectives

After studying and performing this experiment, you should be able to:

- carry out distillation of beverages to recover alcohol; and
- determine alcohol content by specific gravity method.

6.2 EXPERIMENT: DETERMINATION OF ALCOHOL

6.2.1 Principle

Alcohol present in fruit juices and beverages can be distilled out completely along with water. Based on the differences in specific gravities of water and alcohol, the alcohol content can be determined.

6.2.2 Requirements

Apparatus and Reagents

Alcohol distillation apparatus

Specific gravity bottle, 50 ml capacity

Electronic balance, 0.1 mg sensitivity

Volumetric flask

Thermostatically controlled water bath

Chemicals

Bromothymol blue indicator (1% solution)

0.1 N Sodium hydroxide solution

6.2.3 Procedure

Expel CO_2 from the sample if present by shaking thoroughly. Fill the sample in a 100 ml volumetric flask to just below the mark and immerse the flask in a water bath maintained at a constant temperature (usually 25^0C). After the sample has attained the bath temperature, make up the volume with more sample. Transfer the contents of the volumetric flask to the distillation flask (300 – 500 ml round bottomed flask) using 10 – 15 ml distilled water to rinse the flask thrice. Add a few drops of bromothymol blue indicator and titrate with 0.1 N NaOH to a distinctive blue colour to neutralize any volatile acids present. Connect the condenser to the distillation flash and let the tip of the condenser dip into about 10 ml of distilled water contained in the original 100 ml volumetric flask. Distil and collect the distillate almost to the 100 ml mark. Place volumetric flask in the water bath to attain the same temperature as was done for the sample and make up the volume with distilled water.

Weigh a specific gravity bottle accurately. Fill the bottle with the alcohol distillate, insert the stopper, remove the spill-over solution with a tissue paper and weigh. Transfer the solution back to the volumetric flask, clean and fill the bottle with distilled water and weigh as done for the sample. Calculate the specific gravity of the sample distillate and read the alcohol percentage from table of specific gravity vs. alcohol % by volume.

6.2.4 Observations

Weight of the empty sp. gravity bottle	= W_1	= ----- g
------ do ---- with sample distillate	= W_2	= ----- g
------ do ---- with distilled water	= W_3	= ----- g

6.2.5 Calculations

Specific gravity of the sample distillate =

$$\frac{\text{Weight of a known volume of sample}}{\text{Weight of same volume of distilled water}} = \frac{(W_2 - W_1)}{(W_3 - W_1)}$$

Determine ethyl alcohol content (per cent by volume) corresponding to the specific gravity by using the following Table

6.2.6 Results

Alcohol content of sample = percent (v/v).

Ethyl alcohol content (v/v) at 15.56°C (60°F) corresponding to specific gravity

Apparent sp.gr	Alcohol conc. %	Apparent sp.gr	Alcohol conc. %
0.9992	0.53	0.9813	14.05
0.9990	0.66	0.9801	15.06
0.9985	1.00	0.9790	16.00
0.9976	1.60	0.9778	17.04
0.9970	2.01	0.9767	18.00
0.9955	3.04	0.9755	19.06
0.9941	4.02	0.9744	20.03
0.9927	5.02	0.9622	30.02
0.9913	6.06	0.9472	40.05
0.9900	7.05	0.9288	50.04
0.9887	8.06	0.9075	60.03
0.9875	9.01	0.8837	70.02
0.9862	10.05	0.9572	80.02
0.9850	11.00	0.8270	90.02
0.9837	12.06	0.7981	100.00
0.9825	13.04		

6.3 PRECAUTIONS

The general precautions mentioned in the course ‘Introduction’ and those indicated in the experiments should be followed meticulously.

Avoid holding the body of the specific gravity bottle, especially after filling solutions. This will cause expansion of the solution, which will flow out resulting in wrong results. Hold the bottle at the neck.

EXPERIMENT 7 DETECTION AND DETERMINATION OF SYNTHETIC COLOURS

Structure

7.1 INTRODUCTION

Only eight synthetic coal-tar dyes are permitted under PFA for addition to food products. PFA also specifies the foods to which such colours should not be added as well as the maximum permissible limits (0.2 g per kg) of the colours in the foods in which the colours are permitted.

Among the food additives, synthetic colours are viewed with extreme caution due to their potential toxicity to the human system. Therefore, identification and quantification of synthetic food colours in foods is very important.

Objectives

After studying and performing this experiment, you should be able to:

- identify coal-tar dyes added to foods; and
- determine the concentration of the colour(s) in the food product.

7.2 EXPERIMENT

7.2.1 Principle

Synthetic acidic colour(s) is dyed on to wool in acidic medium and extracted (stripped) from the wool into aqueous alkaline medium. The extracted colour(s) is developed (separated) by paper chromatography along with standard dyes using a suitable solvent system. Comparing their Rf values with that of standard colours identifies the sample colours. Quantification of the colours is done by spectrophotometry.

7.2.2 Requirements

Instruments and Apparatus

Chemical balance

Spectrophotometer with 1 cm quarts cells

Measuring cylinders – 25 ml, 50 ml

Volumetric flasks – 50 ml, 100 ml

Conical flasks – 100 ml, 250 ml

Beakers – 100 ml

Wool

Chromatographic chamber

Thin layer chromatogrphic plates

Chromatography column – glass column with tapered end (2.1 × 45 cm) filled with alumina

Glass capillaries

Chemicals

Butanol: Acetic acid: Water (BAW) solvent: 20: 5: 12 (v/v/v)

Liquor ammonia

Acetic acid

Sodium citrate

pH paper strips

Alumina (acidic aluminium oxide)

Standard reference colours

White knitting wool: Successively boiled in dilute ammonia, washed in water, boiled in dilute acetic acid, again washed in water and dried.

Whatman No. 1 and No.3 Chromatographic paper, 20 × 20 cm

7.2.3 Procedure

I. Detection

1. *Wool dyeing:* Take 50 ml or 50 g of the sample, add enough distilled water and prepare a free-flowing solution. Add 4 to5 pieces of 5 cm long woollen thread to the solution and acidify the solution with acetic acid (few ml, check with pH paper) and boil for 10 to 20 minutes. Take out the pieces of wool from the solution and wash in water. Transfer the woollen pieces to a beaker and strip (extract) the colour by boiling with dilute ammonia (1 part of liquor ammonia + 50 parts of distilled water) and remove the wool. Make the extracted solution acidic with acetic acid. Immerse fresh small pieces of wool in the extract and boil for 10 min. If the wool is not dyed then report absence of added artificial colouring matter. If the wool is dyed, it indicates the presence of a coal-tar dye. Wash the wool with water and again strip the colour in boiling ammonia solution, filter; evaporate to a small volume in a beaker for chromatography. The above method is not suited for basic dyes.

   For basic dyes reverse the method i.e. dye the wool first in dilute ammonia and then strip in acetic acid. At present, all the permitted water-soluble coal-tar dyes are acidic and hence an indication of the presence of basic dye at this stage indicates presence of unpermitted colour.

2. *Paper chromatography:* Draw a horizontal line 2.5 cm from base of the filter paper (Whatman No.1). Spot the extracted colour solution on the line along with standard colour (dye) solutions and develop the chromatogram using one of the most effective solvent system viz. "BAW" – Butanol : Acetic acid : Water (20:5:12). When solvent front runs to a height of about 15 cm, remove the chromatogram and dry. Compare the sample Rf with the standard Rf, and identify the colour.

$$\text{Rf value} = \frac{\text{Distance moved by the solute (colour)}}{\text{Distance moved by the mobile phase (solvent)}}$$

Standard colour spot(s) corresponding to the sample colour(s) = -------- name of the standard colour(s)

II. Quantification

Samples containing single colour

Weigh about 5-10 g sample. Add about 25 ml water and mix well. Pass the solution through a column containing acidic aluminium oxide. Wash the column with water to remove sugars and natural colours. Elute the adsorbed colour with 1% ammonia. Transfer the eluate to a volumetric flask (25 ml) and make up to volume with 0.1 N HCl. Determine the absorbance of the dye solution at the absorption maxima (λ max).

Samples containing mixture of colours

Elute the mixture of colours by column chromatography and make up to a known volume (5 to 10 ml). Streak an aliquot of 0.5 ml on Whatman No. 3 paper and develop the chromatogram using the solvent system. Dry the paper and cut out the individual colour bands and elute with 0.1 N HCl. Make up to a known volume and determine the absorbance of each of the dye solutions at their absorption maxima.

7.2.4 Observations

a) Sample containing single colour

Weight of the sample	= W = ------ g
Volume of column eluate made up	= V = ------ ml
Absorbance of the solution	= A ----------
$E^{1\%}_{1cm}$ of the dye at λ max	= E ----------

b) Sample containing mixture of colours

Weight of the sample	= W_1= ------ g
Volume of column eluate made up	= V_1 = ------- ml
Volume of the eluate streaked on chromatographic paper	= V_2 = ----- ml
Volume of made up HCl extract of each colour band	= V_3 = ----- ml
Absorbance of the made up HCl extracts	= A1, A2, A3 ---- An
$E^{1\%}_{1cm}$ of the dye	= E1, E2, E3 ----- En

7.2.5 Calculations

a) Dye content of the product (%) = $\dfrac{\text{Absorbance} \times \text{Volume of eluate made up} \times 100}{E^{1\%}_{1cm} \text{ of the dye} \times 100 \times \text{Wt. of sample}}$

$$= \frac{A \times V}{E \times W}$$

Therefore, dye content of the product (ppm) = $\dfrac{A \times V}{E \times W} \times 10{,}000$

b) Calculate the content of each dye separately. Here, calculation for the dye having absorbance = A1 and $E^{1\%}_{1cm}$ = E1 is given as an example.

Content of the dye in the product (ppm) = $\dfrac{A \times V_3 \times V_1 \times 10{,}000}{E \times V_2 \times W_1}$

$E^{1\%}_{1cm}$ for standard permitted food colours are given below.

$E^{1\%}_{1cm}$ = Extinction (Absorbance) of 1 % solution of a dye at its absorption maxima when measured in a 1 cm cell.

Colour	λ_{max} (nm)	$E^{1\%}_{1cm}$
Tartrazine	426	527
Sunset Yellow FCF	480	551
Ponceau 4R	505	431
Carmoisine	515	545
Erythrosine	526	1154
Indigo carmine	610	489
Fast Green FCF	625	1560
Brilliant Blue FCF	629	1637

7.2.6 Results

The quantity of added colour is expressed in parts per million (ppm) or mg/kg.

7.3 PRECAUTIONS

The general precautions mentioned in the course 'Introduction' and those indicated in the experiments should be followed meticulously.

While handling the dye solutions care should be taken to prevent it from getting them into the mouth because some of them may be unpermitted and harmful.

The spectrophotometer is a very costly instrument. Use it only after carefully understanding its operation. Similarly, the silica cells used are very costly and brittle. Handle them with utmost care. The silica cells should be wiped only with soft tissue to prevent scratching the transparent glass surface.

UNIT 1 UNIT OPERATIONS

Structure

1.0 OBJECTIVES

By the time you have studied this unit, you should be able to:

- comprehend the use and utility of food engineering in the food processing sector;
- know various systems of units and dimensions of quantities used in food engineering; and
- understand the principles of thermal processing and effective utilization of freezing, evaporation and dehydration in food processing and preservation.

1.1 INTRODUCTION

Most food processing operations are designed to extend the shelf-life of the product by reducing or eliminating microbial activity. This general objective implies that the processing operation meets the minimum requirement of ensuring any human health safety concerns associated with microbial activity. It must be acknowledged that most, if not all, food processing operations will influence the physical and sensory characteristics of the product. It is now a common practice within the food industry to utilize processing operations as an approach to enhance the physical and sensory characteristics of food products for better consumer acceptance.

The aims of the food processing are fourfold:

1. To extend the period during which a food remains wholesome (the shelf life) by preservation techniques which inhibit microbiological or biochemical changes and thus allow greater time for distribution and home storage;

2. To increase variety in the diet by providing a range of attractive flavours, colours, aromas and textures in food (collectively known as *eating, sensory* or *organoleptic quality);* a related aim is to change the form of the food to allow further processing (for example the pulping of fruits);

3. To provide the nutrients required for health (termed as *nutritional quality*);

4. To generate income for the entrepreneur or manufacturing company.

All the food processing activities involve a combination of procedures to achieve the intended changes to the raw materials. These procedures are conventionally categorized as *unit operations,* each of which has a specific, identifiable and predictable effect on a food item. A number of unit operations, same or different in nature form a process. The combination and sequence of operations, same or different in nature determines the nature of the final product.

In this unit, we will take up some basic concepts and unit operations that are important in food engineering.

1.2 DIMENSIONS

In food processing, we will talk of several parameters/quantities that make sense of when their dimensions and units are known. A dimension defines a physical entity, which can be observed and / or measured, quantitatively. For example, time, length, area, volume, mass, force, temperature, and energy are all considered dimensions. A unit expresses the quantitative value of a dimension. For example, length may be measured as metres, centimetres, or millimetres. According to the selected unit, the magnitude would be different.

Primary dimensions, such as length, time, temperature, mass, and force, express a physical entity. Secondary dimensions involve a combination of primary dimensions (e.g., volume is length cubed; velocity is distance divided by time).

It is necessary for equations to be dimensionally consistent. Thus, if the dimension of the left-hand side of an equation is “length,” it is necessary that the dimension of the right-hand side is also “length” otherwise the equation is inconsistent. In solving numerical problems, it is always useful to write units for each of the dimensional quantities within the equations. This practice is helpful to avoid mistakes in calculations.

1.3 ENGINEERING UNITS

Physical quantities are measured using a wide variety of unit systems. The most common systems are the Imperial (English) system; the centimeter, gram, second (CGS) system; and the meter, kilogram, second (MKS) system. The use of these systems, along with a myriad of symbols to designate units, has often caused considerable confusion. International organizations have attempted to standardize unit systems, symbols and the quantities to avoid confusion. As a result of international agreements, the "System International" or the SI system has emerged. The SI system consists of seven basic units, two supplementary units, and a series of derived units.

1.3.1 Base Units

The SI system is based on a choice of seven well-defined units, which by convention are regarded as dimensionally independent. The seven base units are as given in Table 1.1

Table 1.1: SI base units

Measurable attribute of phenomenon or matter	Name	Symbol
Length	metre	m
Mass	kilogram	kg
Time	second	s
Electric current	Ampere	A
Thermodynamic temperature	Kelvin	K
Amount of substance	mole	mol
Luminous intensity	candela	cd

1.3.2 Derived Units

Derived units are algebraic combinations of base units expressed by means of multiplication and division. Often, for simplicity, derived units carry special names and symbols that may be used to obtain other derived units. Some commonly used derived units are summarized in Table 1.2.

Table 1.2(a): Derived units expressed in terms of base units

Quantity	SI Units	
	Name	Symbol
Derived units expressed in terms of Base Units		
Area	square metre	m^2
Volume	cubic metre	m^3
Acceleration	metre per second squared	m/s^2
Density	kilogram per cubic metre	kg/m^3
Magnetic field strength	Ampere per metre	A/m
Concentration (of amount of substance)	mole per cubic metre	mol/m^3
Specific volume	cubic metre per kilogram	m^3/kg

Table 1.2(b): Derived units with specific names

Quantity	SI Units			
	Name	Symbol	Expression in terms of other units	Expression in terms of SI base units
Derived units with specific names				
Frequency	hertz	Hz		cycles.s^{-1}
Force	newton	N		m.kg.s^{-2}
Pressure	pascal	Pa	N/m^2	m^{-1}.kg.s^{-2}
Energy	joule	J	N/m	m^2.kg.s^{-2}
Power	watt	W	J/s	m^2.kg.s^{-3}
Capacitance	farad	F	C/V	$m^{-2}.kg^{-1}.s^{-4}.A^2$
Conductance	siemens	S	A/V	$m^{-2}.kg^{-1}.s^{-3}.A^2$

Table 1.2(c): Derived units expressed by means of special names

Quantity	SI Units		
	Name	Symbol	Expression in terms of SI base units
Derived units expressed by means of special names			
Dynamic viscosity	pascal second	Pa.s	m^{-1}.kg.s^{-1}
Moment of force	newton metre	N.m	m^2.kg.s^{-2}
Surface tension	newton per metre	N/m	kg.s^{-2}
Heat capacity, entropy	joule per kelvin	J/K	$m^2.kg.s^{-2}.K^{-1}$
Specific heat capacity	joule per kilogram kelvin	J/(kg.K)	$m^2.s^{-2}.K^{-1}$
Specific energy	joule per kilogram	J/kg	$m^2.s^{-2}$
Thermal conductivity	watt per metre kelvin	W/(m.K)	$m.kg.s^{-3}.K^{-1}$

1.3.3 Supplementary Units

This class of units contains two purely geometric units, which may be regarded either as base or derived units. Both of them are given in Table 1.3.

Table 1.3: SI supplementary units

Quantity	SI Units	
	Name	Symbol
Plane angle	radian	rad
Solid angle	steridian	sr

1.4 SYSTEM AND PROPERTIES

1.4.1 System

A careful description of the system is vital in engineering analysis. A region prescribed in space or a finite quantity of matter is called a system and that is enclosed by an envelope, which is stated to be the boundary of the system. The boundary of a system can be real, such as walls of a tank, or it can be an imaginary surface that encloses the system. For example, in Figure 1.1, the boundary in system A is along the walls of a storage tank; thus it does not include the pipe and the valve. However, in system B, the boundary envelops the tank, valve and the pipe. The composition of the system is described by the components present inside the system boundary.

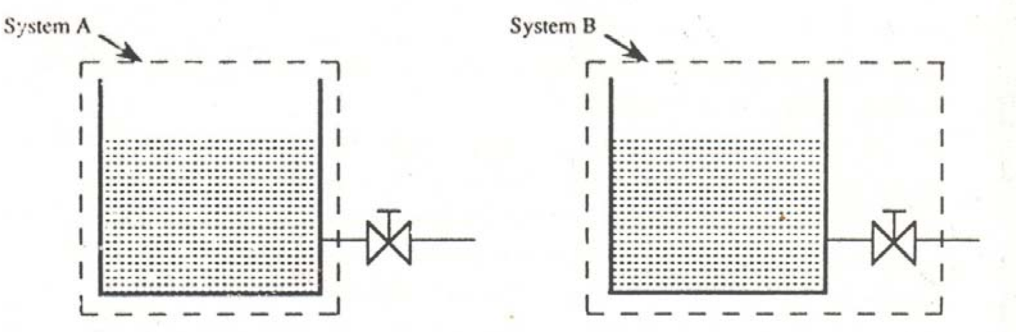

Figure 1.1: Examples of systems and their boundaries

Both closed and open systems are often encountered. In closed systems, the boundary of the system is impervious to any flow of matter. In an open system, heat and/or matter can flow into or out of the system. For example, a system boundary that contains only a small section of the wall is impervious to the flow of matter, and may be considered a close system. On the other hand, system B in Figure 1.1 is an open system since both heat and liquid can flow through the system.

1.4.2 Properties

Properties are those observable characteristics, such as pressure and temperature, which define the equilibrium state of a thermodynamic system. Properties do not depend on how the state of a system is attained: they are only functions of the state of a system. Thus, properties are independent of the process by which a system attained a certain state.

Intensive Properties

Intensive properties do not depend on the size of a system, such as temperature, pressure and density.

Extensive Properties

An extensive property depends on the size of the system: for example, mass, length, volume, energy. This definition implies that an extensive property of a system is a sum of respective partial property values of the components of a system. These properties, one of which may be mass are required to uniquely give an extensive property of a single component system.

The ratio of two extensive properties of a homogenous system is an intensive property. For example the ratio of two extensive properties mass and volume is density, which is an intensive property.

The state of a system is defined by independent properties. Once the properties become fixed, when the state of the system is defined, they are called dependent properties.

1.5 THERMAL PROCESSING

Since many of the processes utilized to preserve food products depend on the addition of thermal energy, it is important to understand the principles associated with food preservation through the addition of thermal energy. The design of a thermal process to achieve food preservation involves two principles: (a) the use of elevated temperatures to increase the rate of reduction in the microbial population present in the raw food material and (b) the transfer of thermal energy into the food product required to achieve the desired elevated temperatures.

The information in this section will address the typical parameters used to quantify the influence of elevated temperatures on reduction of microbial populations. Details will be presented in subsequent sections.

1.5.1 Influence of Elevated Temperatures on Microbial Populations

When microbial population in a food is exposed to an elevated temperature, changes in individual microbial cells within the population and a reduction in the viability of the microorganisms result in a reduction of the population with time of exposure when quantified by standard microbiological procedures. A typical pattern of microbial population change as a function of time when the population is exposed to an elevated temperature is illustrated in Figure 1.2. The reduction in population occurs in a logarithmic manner with increasing time at a given constant elevated temperature.

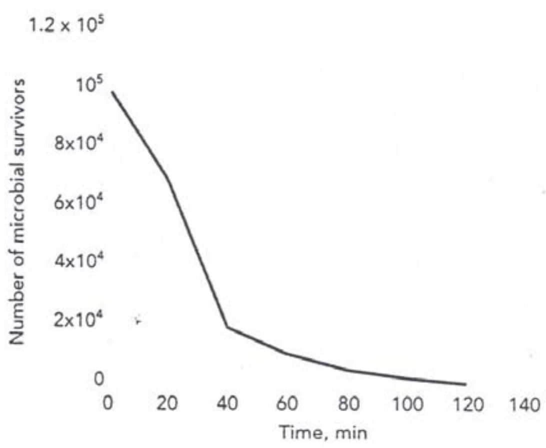

Figure 1.2: Changes in microbial population as a function of time at a constant elevated temperature

Decimal Reduction Time

The decimal reduction time (D Value) is defined as the time necessary for 90% reduction in the microbial population. When the microbial population is plotted against corresponding heating time on semi log coordinates, the D value is the time required for a one log cycle reduction in the number of microorganisms (Figure 1.3). The initial microbial population has no influence on the D value since the magnitude is directly related to the slope of the straight line. Exposure of the microbial population to higher temperatures results in a decrease in the D value. In fact, a plot of decimal reduction time as a function of temperature on semi log coordinates results in a linear relationship (Figure 1.4). This curve is known as thermal resistance curve.

Based on the definition, the following equation can be used:

$$\log N_0 - \log N = t/D \qquad (1.1)$$

or,

$$N/N_0 = 10^{-t/D} \qquad (1.2)$$

where N_0 is the initial number of microorganisms (t=o), N is the number of microorganisms surviving after heating for time 't' at a temperature and D is decimal reduction time for the microorganism under conditions of heating.

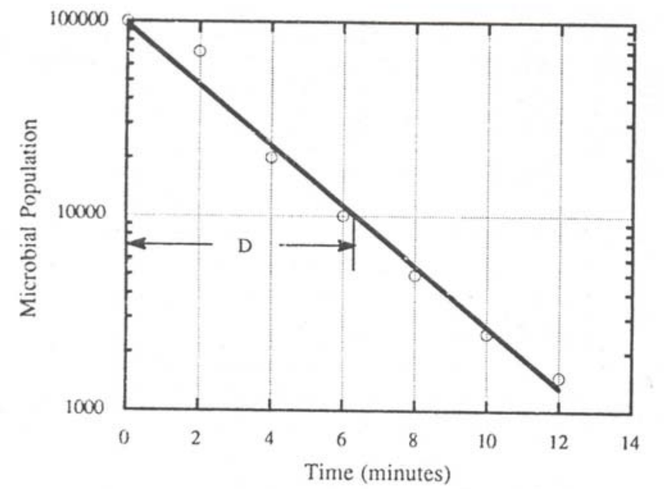

Figure 1.3: Semi-logarithmic plot of microbial population versus heating time at an elevated temperature

Thermal Resistance Constant

The temperature increase required to cause a one log cycle reduction in the decimal reduction time is defined as the thermal resistance constant (z). The thermal resistance constant, or z-value, is a second quantitative parameter normally used to quantify the thermal process required for a given microbial population. A large z-value suggests that a given increase in temperature of exposure for the microbial population results in a small change in decimal reduction time. In most situations, this observation would indicate that the microbial population contains vegetative cells or microbial spores; the spores exhibit greater heat resistance or higher z-value than vegetative populations which are characterized by a lower z-value. It is important to note that the complete characterization of the impact of elevated temperature on microbial population requires reference to both the decimal reduction time (D) and the thermal resistance constant (*z*). The *z*-value as shown in Figure 1.4 can be expressed by the following equation:

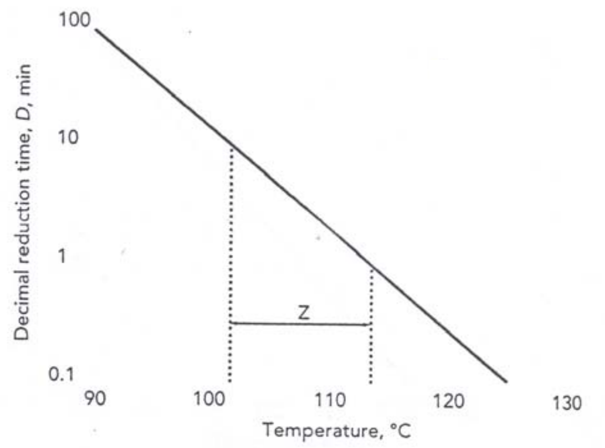

Figure 1.4: Thermal resistance curve of microbial population

$$z = \frac{T_2 - T_1}{\log D_{T_1} - \log D_{T_2}} \tag{1.3}$$

where D_{T_1} and D_{T_2} are decimal reduction times for micro-organisms at temperatures T_1 and T_2, respectively and 'z' is thermal resistant constant.

Thermal Death Time

The third quantitative parameter found frequently in thermal processing is the thermal death time, or F-value, which finds use in the actual thermal process. Thermal death time is defined as the time required for achieving a *stated reduction* in the microbial population at a given temperature. The key part of the definition is the stated reduction, which may be the reduction in the population of microbial pathogens required to establish product safety. Alternatively, the stated reduction may be the reduction in the population of a vegetative microorganism causing product spoilage, and the stated reduction is that required to achieve the desired product shelf-life.

A thermal death time curve would appear to be very similar to a thermal resistance curve (Figure 1.4), but would cover the entire range of times required to achieve the desired or stated reduction in microbial population. A typical thermal death time curve is presented in Figure 1.5. Note that the curve describes the entire reduction in microbial population from time zero until the population has been reduced to a defined level of microbial survivors. This point has been defined as the thermal death time, or F-value.

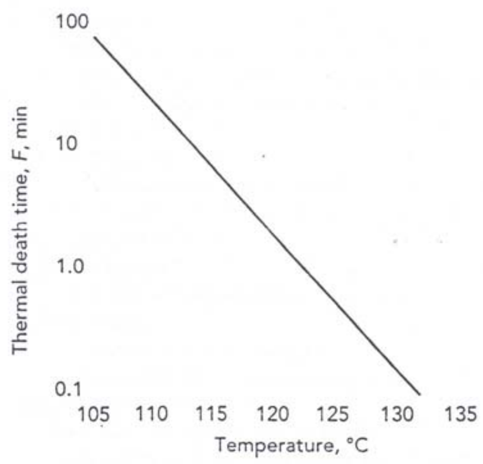

Figure 1.5: Thermal death time curve

The similarity in the thermal resistance and the thermal death time curve is evident from Figures 1.4 and 1.5. Each log cycle reduction in the microbial population on the thermal resistance curve represents a decimal reduction time, or D-value. It follows that F-values may be expressed as multiples of D-values. The most common of these relationships is F = 12D for *Clostridium botulinum* in *com*mercial sterilization of low acid foods. It must be emphasized that any given F-value will apply to a single elevated temperature. In other words, different elevated temperatures result in different F-values or times required achieving the same stated level of reduction in microbial population.

Inter-relationships

The relationships between microbial populations and time, as well as the impact of temperature, are very similar to the relationships used to describe kinetic parameters in first-order chemical reactions. The reaction rate constant *(k)* is used to describe the change in concentration of a reactant as a function of time. In microbial populations, the D-value is utilized to describe the same relationship. It follows that the relationship between the reaction rate constant *(k)* and the decimal reduction time (D) is given by Eq. (1.4):

$$k = \frac{2.303}{D} \tag{1.4}$$

The influence of temperature on reaction rate is described by Q_{10} or the activation energy constant (E). It follows that a relationship between Q_{10} and thermal resistance constant (z) must exist. It is relatively easy to demonstrate that this relationship is as shown in Eq. (1.5):

$$Q_{10} = 10^{\frac{10}{z}} \tag{1.5}$$

The relationship between the activation energy constant (E) and the thermal resistance constant (z) is more complex. It must be noted that the activation energy constant (E) is obtained from an Arrhenius plot: the natural logarithm of the reaction rate constant *(k)* versus the inverse of absolute temperature. Nevertheless, the relationship has been derived and presented in Singh and Heldman (1993) as Eq. (1.6):

$$E = \frac{2.303RT_A^2}{z} = \frac{19.15T_A^2}{z} \tag{1.6}$$

where R is the universal gas constant and T_A, represents the mid-point between two absolute temperatures used to define the z-value in the relationship. The relationship between the activation energy constant and the thermal resistance constant applies over limited ranges of temperature where the experimental data utilized to quantify the z-value were measured.

1.6 REFRIGERATION

Refrigeration system allows transfer of heat from the cooling chamber to a location where the heat can be discarded. The transfer of heat is accomplished by using a refrigerant, which like water changes state – from liquid to vapour. The primary purpose of refrigerating foods is to extend shelf-life by slowing down degradatory reactions and limiting microbial growth. Through reduction in rates of chemical, biochemical and microbial kinetics (rates of lipid oxidation, non enzymatic browning, sugar conversion, enzymatic browning, and respiration reactions), low temperature storage can extend the shelf-life of fresh and processed foods. Typically, refrigerated storage means holding food in a temperature range of –1 to 8°C.

Other factors besides low temperature may influence shelf-life of refrigerated foods. For fresh foods, these include the type of food and variety, the condition of the food at harvest (mechanical damage, microbial contamination, and degree of maturity), and the relative humidity of storage atmosphere. For processed foods, factors affecting shelf life include type of food, degree of microbial or enzyme destruction during processing, hygienic factors during processing and packaging, and the nature of the package (barrier properties).

1.6.1 Components of a Refrigeration System

The major components of a simple mechanical vapour compression refrigeration system are shown in Figure 1.6. As the refrigerant flows through these components its phase changes from liquid to gas and then back to liquid. At location D, just prior to the entrance of the expansion valve, the refrigerant is in a saturated liquid state. After passing through the expansion valve, the refrigerant experiences a drop in pressure accompanied by a drop in temperature. Due to the drop in pressure, some of the liquid refrigerant changes to gas. The liquid gas leaving the expansion valve is termed 'flash gas'.

The liquid/gas mixture enters the evaporator coils at location E. In the evaporator, the refrigerant completely vaporizes to gas by accepting heat from the media surrounding the evaporator coils. The saturated vapour may also get superheated due to gain of additional heat from the surroundings.

The saturated or superheated vapours enter the compressor, where the refrigerant is compressed to a high pressure. This high pressure must be below the critical pressure of the refrigerant and high enough to allow condensation of the refrigerant at a temperature slightly higher than that of commonly available heat sinks, such as ambient air or water. Inside the compressor, the compression process of the vapours occurs at constant entropy (called an isentropic process). As the pressure of the refrigerant increases, the temperature increases, and the refrigerant become superheated.

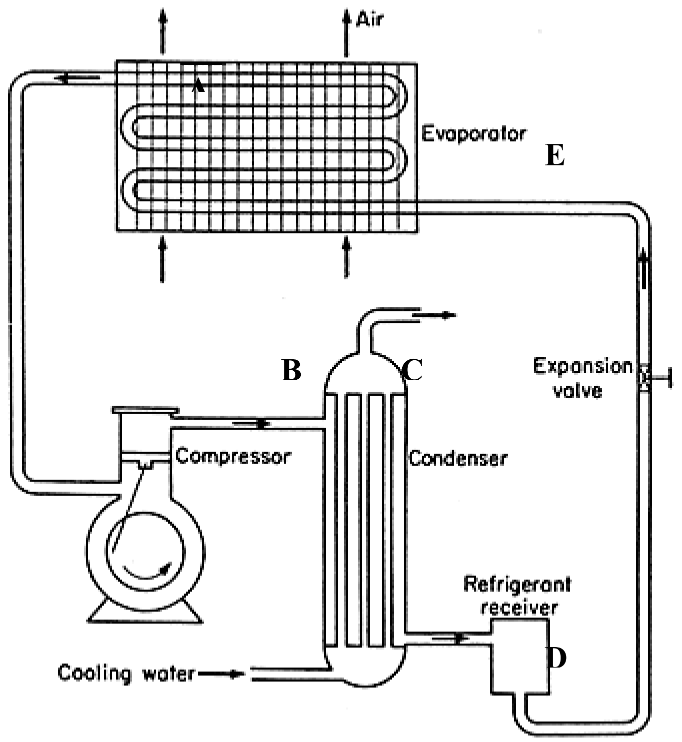

Figure 1.6: Mechanical refrigeration circuit

The superheated vapours are then conveyed to the condenser. Using either an air cooled or water cooled condenser, the refrigerant discharges heat to the surrounding media. The refrigerant condenses back to the liquid state in the condenser (saturated liquid). The temperature of the refrigerant may decrease below that of its condensation temperature (sub cooled) due to additional heat discharged to the surrounding media. The saturated or sub cooled liquid then enters the expansion valve and the cycle continues.

The process can also be followed on the pressure-enthalpy chart shown in Figure 1.7.

1.6.2 Some Useful Mathematical Expressions

Cooling Load

The cooling load is the rate of heat energy removal from a given space (or object) in order to lower the temperature of that space (or object) to a desired level. A typical unit of cooling load used in commercial practice is 'ton of refrigeration'. One ton of refrigeration is equivalent to the amount of heat required to melt one ton of ice in one day at 0^0 C {(1000 kg x 336 kJ/kg)/24 hr} = (336000 kJ / 86400 s) = 3.888 kW. Thus a mechanical refrigeration system that has a capacity to absorb heat from the refrigerated space at the rate of 3.888 kW is rated as one ton of refrigeration.

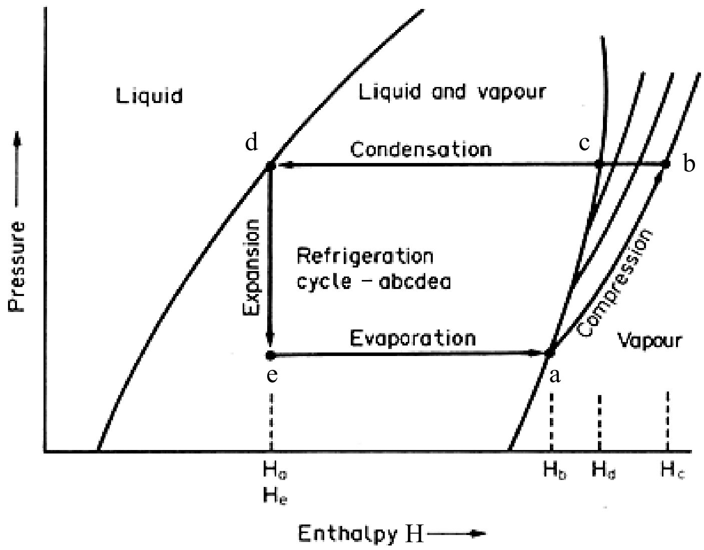

Figure 1.7: Pressure/enthalpy chart

The factors which contribute to the cooling load include the sensible heat, heat of respiration (in case of fresh produce); heat infiltration through walls, floor and ceiling; heat gain through doors; heat given by lights, people and use of fork lifts for material handling; etc.

Coefficient of Performance

The coefficient of performance (C.O.P.) is defined as a ratio between the heat absorbed by the refrigerant as it flows through the evaporator to the heat equivalence of the energy supplied to the compressor. In other words, it is the ratio of the useful refrigeration effect obtained from the system to the work expended on it to produce that effect.

$$C.O.P. = \frac{H_a - H_e}{H_b - H_a} \tag{1.7}$$

where H_a is heat content of vapour learning evaporator, H_b is heat content of vapour learning compressor, H_d or H_e is heat content of liquid entering evaporator.

1.7 FOOD FREEZING

Food freezing is a preservation process that depends on the reduction of product temperatures to levels well below the temperature at which ice crystals begin to form within the food. By reducing the temperature of the product to –10°C to –20°C, the normal reactions that cause deterioration of foods are reduced to negligible or minimal rates. These temperature levels eliminate microbial growth as a concern in shelf-life of the food product. As would be expected, the shelf-life of a frozen food is a function of temperature, with lower temperatures leading to longer shelf-life.

The limitations of freezing as a food preservation process include both quality concerns and energy requirements. The formation of ice crystals within the structure of most food products creates changes in the structure that are at times irreversible and most often cause negative changes in the quality characteristics of the product. The refrigeration requirements associated with the food-freezing process, as well as maintaining the low temperatures associated with frozen food storage and distribution are factors that must be considered while evaluating the costs of this preservation process. The value of the shelf-life extension achieved by food freezing must be balanced against the added costs associated with energy requirements for the production and storage of the frozen foods.

1.7.1 Theory

In theory, the freezing process is the removal of the thermal energy from the food product to the extent required to reduce the temperature below the freezing temperature of water. The thermal energy removed, as a part of freezing is primarily latent heat of fusion required to convert water to ice within the product.

If the temperature is monitored at the thermal center of food (the point that cools most slowly) as heat is removed, a characteristic curve is obtained (Figure 1.8).

The six portion of the curve are as follows:

AS The food is cooled to below its freezing point θ_f which, with the exception of pure water, is always below 0°C. At point S the water remains liquid although the temperature is below the freezing point. This phenomenon is known as sub-cooling and may be as much as 10°C below the freezing point

SB The temperature rises rapidly to the freezing point as ice crystals begin to form and latent heat of crystallization is released.

BC Heat is removed from the food at the same rate as before. Latent heat is removed and ice forms, but the temperature remains almost constant. The freezing point is depressed by the increase in solute concentration in the unfrozen liquor, and the temperature therefore falls slightly. It is during this stage that the major part of the ice is formed.

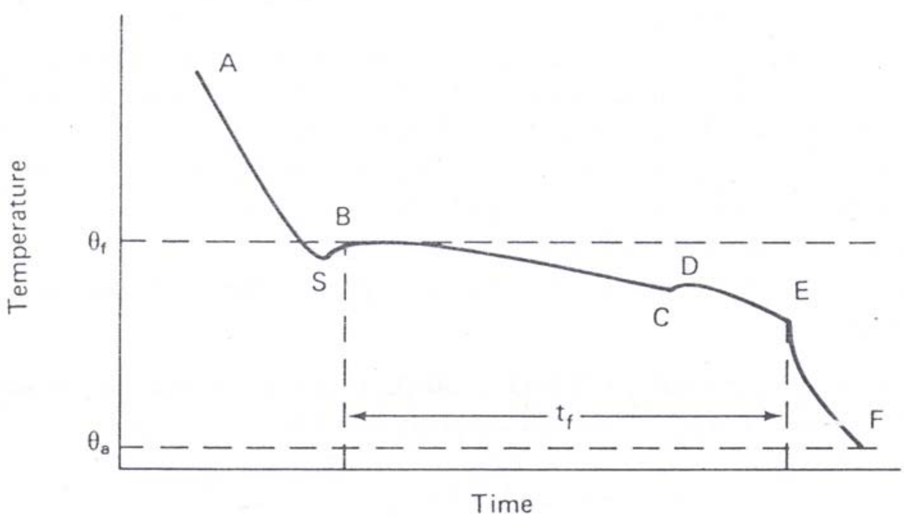

Figure 1.8: Time temperature relationships during freezing

CD One of the solutes becomes supersaturated and crystallizes out. The latent heat of crystallization is released and the temperature rises to the eutectic temperature for that solute

DE Crystallization of water and solutes continues. The total time t_f taken (the freezing plateau) is determined by the rate at which heat is removed.

EF The temperature of the ice-water mixture falls to the temperature of the freezer. A proportion of the water remains unfrozen at the temperature used in commercial freezing; the amount depends on the type and composition of the food and the temperature of freezing.

Ice Crystal Formation

The freezing point of a food is the temperature at which a minute crystal of ice exists in equilibrium with the surrounding water. However, before an ice crystal can form, a nucleus of water molecules must be present. Nucleation therefore precedes ice crystal formation. The rate of ice crystal growth during freezing is controlled by the rate of heat transfer for the majority of the freezing plateau. The rate of mass transfer does not control the rate of crystal growth except towards the end of the freezing period when solutes become more concentrated. The time taken for the temperature of the food to pass through the critical zone (Figure 1.9) therefore, determines the number and the size of the ice crystals.

Solute Concentration

The increase in solute concentration during freezing causes changes in pH, viscosity and redox potential of the unfrozen liquor. As the temperature falls individual solutes reach saturation point and crystallizes out. The temperature at which a crystal of an individual solute exists in equilibrium with the unfrozen liquor and ice is its eutectic temperature. However, it is difficult to identify individual eutectic temperatures in the complex mixture of solutes in foods, and the term final eutectic temperature is used. This is the lowest temperature of the solutes in the food. Maximum ice crystal formation is not possible until this temperature is reached. Commercial foods are not frozen to such low temperatures and unfrozen water is therefore always present.

Volume Changes

The volume of ice at 0^0 C is 9% greater than that of pure water, and an expansion of foods after freezing would therefore be expected. However, the degree of expansion varies considerably owing to the moisture content (higher moisture content produce greater changes in volume), cell arrangement, the concentration of solutes (high concentrations reduce the freezing point) and the freezer temperature (this determines the amount of unfrozen water and hence the degree of expansion). Temperatures below 0^0 C cause shrinkage in the volume of ice formed during freezing process.

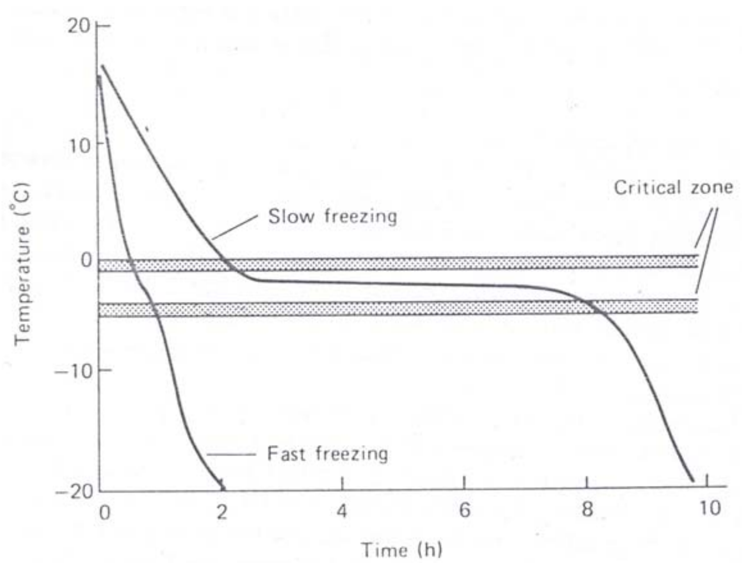

Figure 1.9: Temperature changes of food through the critical zone during freezing

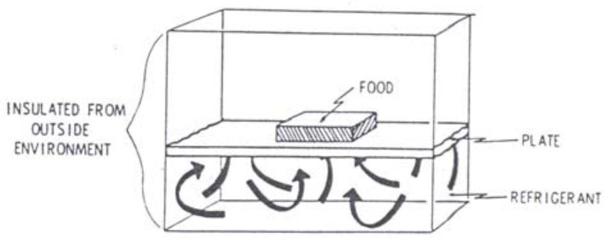
1.7.2 Freezing Systems

The freezing process can be accomplished using either indirect or direct contact systems. Most often, the type of system used will depend on the product characteristics, before and after freezing is completed.

Indirect Contact Systems

In numerous food products freezing systems the product and the refrigerant are separated by a barrier throughout the freezing process. This is called an indirect contact system (Figure 1.10). Although many systems use a non-permeable barrier between product and refrigerant, indirect freezing systems include any system without direct contact, including those where the package material becomes the barrier. These include plate freezer, air blast freezer and freezer for liquid foods.



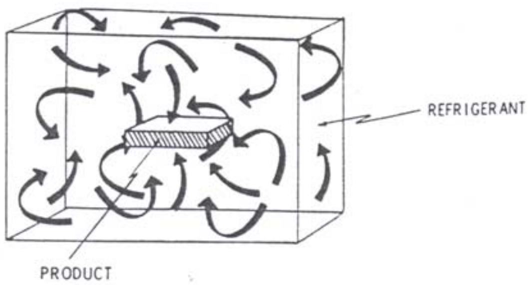


Figure 1.10: Schematic diagram of indirect contact freezing

Figure 1.11: Schematic diagram of direct contact freezing

Direct Contact Systems

Direct contact freezing systems operate with direct contact between the refrigerant and the product (Figure 1.11). In most situations these systems operate more efficiently since there is no barrier to heat transfer between the refrigerant and the product. All direct contact freezing systems are designed to achieve rapid freezing, and the term individual quick freezing (IQF) applies. This includes fluidized bed freezing immersion freezing and cryogenic freezing.

1.8 EVAPORATION

Evaporation is an important unit operation commonly employed to remove water from dilute liquid foods to obtain concentrated liquid products (for e.g. manufacture of tomato puree from juice). Removal of water from foods provides microbiological stability and assists in reducing packaging, transportation and storage costs. Evaporation is also a necessary step before drying and crystallization process. Evaporation differs from dehydration, since the final product of evaporation process remains in liquid state.

The evaporator in which the vapour produced are discarded without further utilizing its inherent heat is called a single effect evaporator, whereas the evaporator in which the inherent heat of the vapour is reused again as heating medium is called a multiple effect evaporator.

The evaporation process is largely dependent on the principle of heat transfer and the factors, which hamper heat transfer, are the major impediments for the process. Some of these factors are: (1) Boiling point rise, (2) Heat sensitivity of the liquid, (3) Fouling & foaming properties of the food, etc.

1.8.1 Boiling Point Elevation

Boiling point elevation of a solution (liquid food) is defined as the increase in boiling point over that of pure water, at a given pressure. A simple method to estimate boiling point elevation is the use of Duhring's rule. The Duhring's rule states that a linear relationship exists between the boiling point temperature of a solution and the boiling point temperature of water at the same pressure. Duhring lines for sodium chloride – water system are shown in Figure 1.12.

1.8.2 Types of Evaporators

Several types of evaporators are used in the food industry. In the following paragraphs we would discuss some of the most commonly used evaporators.

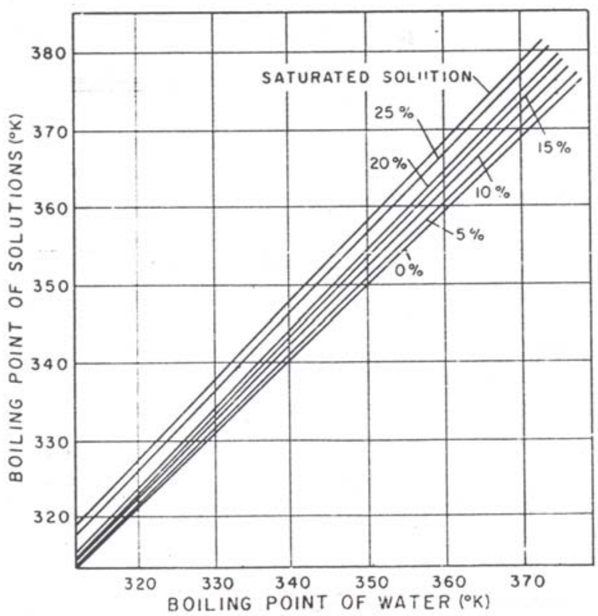

Figure 1.12: Duhring lines for sodium chloride – water system

Batch Type Pan Evaporator

One of the simplest and perhaps oldest types of evaporators used in food industry is the batch-type pan evaporator (Figure 1.13). The product is heated in a steam jacketed spherical vessel. The heating vessel is either open to atmosphere or connected to a condenser and vacuum system.

Heating of the product occurs mainly due to natural convection, resulting in smaller convective heat transfer coefficients. The poor heat transfer coefficients substantially increase the residence time of the product and reduce the processing capacities of these evaporators.

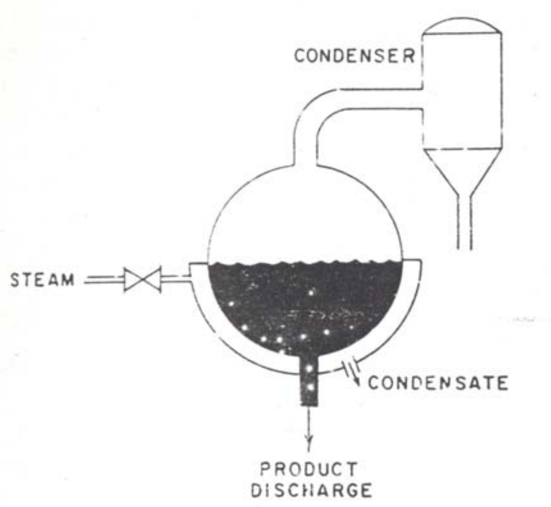

Figure 1.13: Batch type pan evaporator

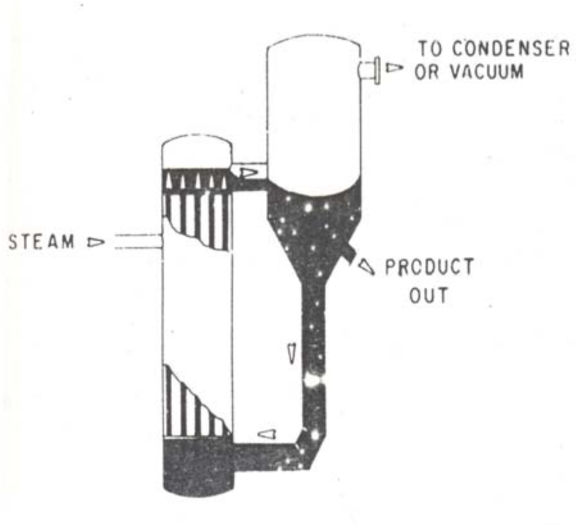

Figure 1.14: Natural circulation evaporator

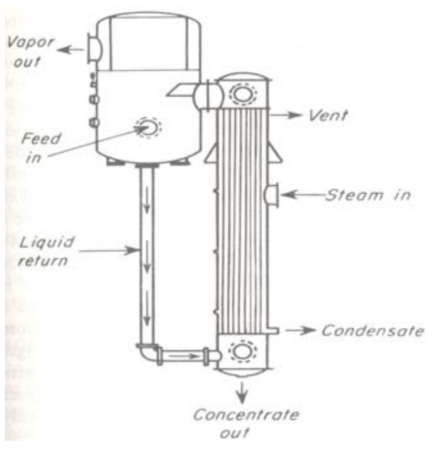
Natural Circulation Evaporators

In natural circulation evaporators (Figure 1.14), short vertical tubes are arranged inside a steam chest. The whole calendria (tubes and steam chest) is located at the bottom of the vessel. The product when heated rises through these tubes by natural circulation while steam condenses outside the tubes. Evaporation takes place inside the tubes and the product is concentrated. The concentrated liquid falls back to the base of the vessel through a central annular section.

Rising Film Evaporator

In a rising film evaporator (Figure 1.15), a low viscosity liquid food is allowed to boil inside 10-15 m long vertical tubes. The tubes are heated from outside with steam. The liquid rises inside these tubes by vapours formed near the bottom of the heating tubes. The upward movement of vapour causes a thin liquid film to move rapidly upward. A temperature differential of at least 14°C between the product and the heating medium is necessary to obtain a well-developed film. High convective heat-transfer coefficients achieved in these evaporators mostly makes the operation once through. However, liquid can be recirculated to obtain the required solid concentration.



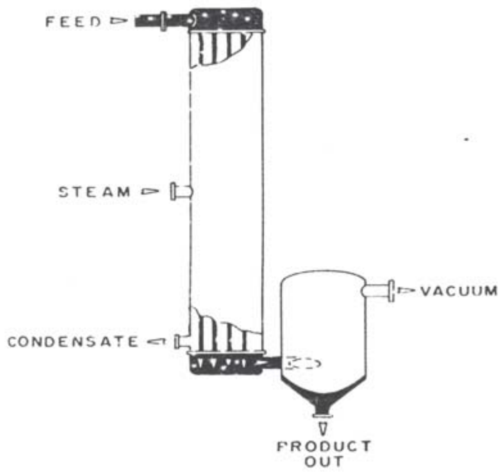


Figure 1.15: Rising film evaporator

Fig 1.16: Falling film evaporator

Falling Film Evaporator

In contrast to the rising film evaporator, the falling film evaporator has a thin liquid film moving downward under gravity on the inside of the vertical tubes (Figure 1.16). The distribution of liquid in a uniform film flowing downward is accomplished by the use of specially designed distributors or spray nozzles. The falling film evaporator can handle more viscous liquids than the rising film type. These evaporators are best suited for highly heat sensitive products. Typical residence time in a falling film evaporator is 20-30 seconds, compared with residence time of 3-4 minutes in a rising film evaporator.

Rising / Falling Film Evaporator

In the rising / falling film evaporator, the product is concentrated by circulation through a rising film section followed by a falling film section of the evaporator. As shown in Figure 1.17, the product is first partially concentrated as it ascends through a rising tube section, followed by the pre-concentrated product descending through a falling film section; there it attains its final concentration.

Forced Circulation Evaporators

The forced circulation evaporator involves a non contact heat exchanger where liquid food is circulated at high rates (Figure 1.18). A hydrostatic head, above the top of the tubes, eliminates any boiling of the liquid. Inside the separator, absolute pressure is kept slightly lower than that in the tube bundle. Thus, the liquid entering the separator flashes to form a vapour. The temperature difference across the heating surface in the heat exchanger is usually 3-5°C. Axial flow pumps are generally used to maintain high circulation rates with linear velocities of 2-6 m/s, compared with a linear velocity of 0.3 – 1 m/s in natural convection evaporators. Both capital and operating costs of these evaporators are very low in comparison to other types of evaporators.

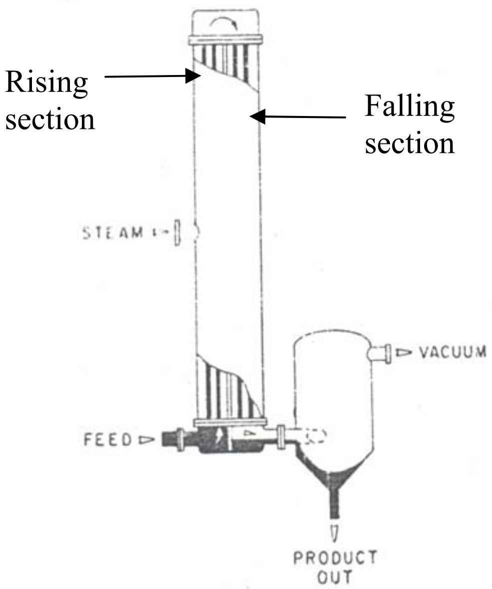

Figure 1.17: Rising / Falling film evaporator

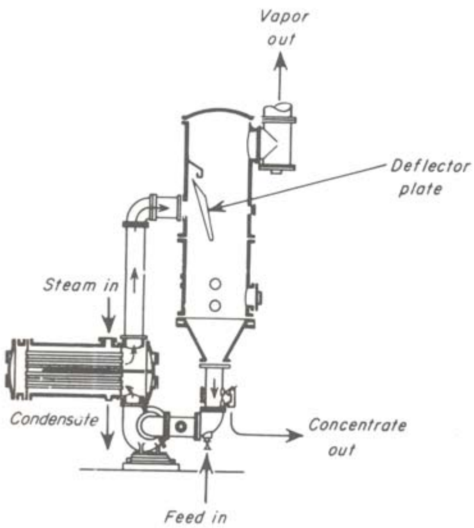

Figure 1.18: Forced circulation evaporator

Agitated Thin Film Evaporator

For very viscous fluid foods, feed is spread on the inside of the cylindrical heating surface by wiper blades, as shown in Figure 1.19. Due to high agitation, considerably higher heat transfer rates are obtained. The cylindrical configuration results in low heat transfer area per unit volume of the product. High pressure steam may be used as the heating medium to obtain high wall temperatures for reasonable evaporation rates. The major disadvantages are the high capital and maintenance costs and low processing capacity.

In addition to the tubular shape, plate evaporators are also used in the industry. Plate evaporators use the principles of rising / falling film, falling film, wiped film and forced circulation evaporators.

1.9 DEHYDRATION

Drying is one of the oldest methods of preserving food. Primitive societies practiced the drying of meat and fish in the sun long before recorded history. Today the drying of foods is still important as a method of preservation. Dried foods can be stored for long periods without any deterioration in quality. The principal reasons for this are that the microorganisms, which cause food spoilage and decay, are unable to grow and multiply in the absence of sufficient water and many of the enzymes which promote undesired changes in the food cannot function without water.

Preservation is the principal reason for drying, but drying can also occur in conjunction with other processing. For example, in the baking of bread, application of heat expands gases, changes the structure of the protein and starch molecules and dries the loaf.

Drying of foods implies the removal of water from the foodstuff. In most cases, drying is accomplished by vaporizing the water that is contained in the food, and to do this the latent heat of vaporization must be supplied. There are, thus, two important process-controlling factors that enter into the unit operation of drying:

a) Transfer of heat to provide the necessary latent heat of vaporization,

b) Movement of water or water vapour through the food material and then away from it to effect separation of water from foodstuff.

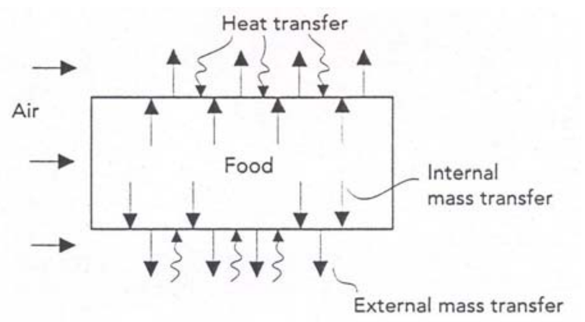

Figure 1.20: Principle of drying of food

1.9.1 Basic Drying Theory

Pure water can exist in three states, solid, liquid and vapour. The state in which it is at any time depends on the temperature and pressure conditions and it is possible to illustrate this on a phase diagram, as in Figure 1.21.

If we choose any condition of temperature and pressure and find the corresponding point on the diagram, this point will lie, in general, in one of the three-labelled regions, solid, liquid, or gas. This will give the state of the water under the chosen conditions.

Under certain conditions, two states may exist side by side, and such conditions are found only along the lines of the diagram. Under one condition, all three states may exist together; this condition arises at what is called the triple point, indicated by point O on the diagram. For water it occurs at 0.0098°C and 0.64 kPa (4.8 mm of mercury) pressure.

If heat is applied to water in any state at constant pressure, the temperature rises and the condition moves horizontally across the diagram, and as it crosses the boundaries a change of state will occur. For example, starting from condition A on the diagram adding heat warms the ice, then melts it, then warms the water and finally evaporates the water to condition A'. Starting from condition B, situated below the triple point, when heat is added, the ice warms and then sublimes without passing through any liquid state.

Liquid and vapour coexist in equilibrium only under the conditions along the line OP. This line is called the vapour-pressure line. The vapour pressure is the measure of the tendency of molecules to escape as a gas from the liquid.

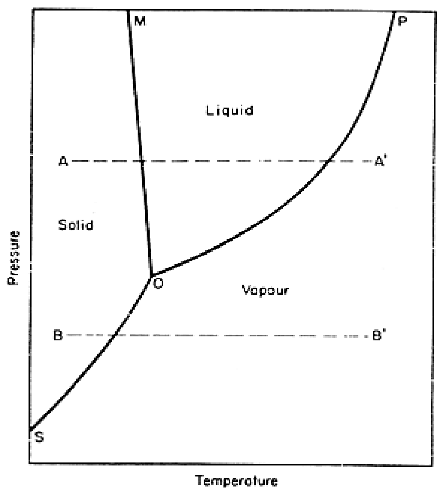

Figure 1.21: Phase diagram for water

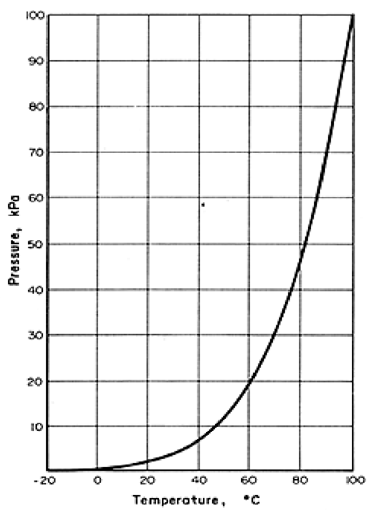

Fig 1.22: Vapour pressure/temperature curve for water

Boiling occurs when the vapour pressure of the water is equal to the total pressure on the water surface. The boiling point at atmospheric pressure is of course 100°C. At pressures above or below atmospheric, water boils at the corresponding temperatures above or below 100°C as shown in Figure 1.22 for temperatures below 100°C.

Recently, state diagrams have been employed to depict conditions of water in foods and its use has improved our knowledge of drying technology. The state diagram shown in figure 1.23 for simple system of solute and solvent, is a phase diagram based on components of the food product supplemented by the glass transition curve. The glass transition curve represents a meta stable transition where viscosity is effectively so high that the product does not 'flow' over time scale of importance to food stability. Below this curve on the state diagram, the food is stable to diffusion related processes (such as moisture migration) for extremely longer times.

Heat Transfer in Drying

The rates of drying are generally determined by the rates at which heat energy can be transferred to the water or to the ice in order to provide the latent heats, though under some circumstances the rate of mass transfer (removal of the water) can be limiting. All three of the mechanisms by which heat is transferred - conduction, radiation and convection - may enter into drying. The relative importance of the mechanisms varies from one drying process to another and very often one mode of heat transfer predominates to such an extent that it governs the overall process.

As an example, in air drying the rate of heat transfer is given by:

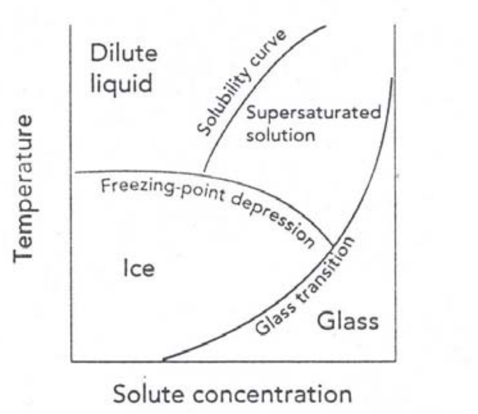

Figure 1.23: State diagram for a simple binary mixture

$$q = UA\,(T_a - T_s) \tag{1.8}$$

where q is the heat transfer rate in J s^{-1}, U is the overall heat-transfer coefficient in J s^{-1} m^{-2} k^{-1}, A is the area through which heat flow is taking place, T_a is the air temperature and T_s is the temperature of the surface which is getting dried.

In cases where substantial quantities of heat are transferred by radiation, it should be remembered that the surface temperature of the food might be higher than the air temperature. Estimates of surface temperature can be made using the relationships developed for radiant heat transfer although the actual effect of combined radiation and evaporative cooling is complex. Convection coefficients also can be estimated using the standard equations.

As drying proceeds, the character of the heat transfer situation changes. Dry material begins to occupy the surface layers and conduction must take place through these dry surface layers that are poor heat conductors. Therefore, the heat is transferred to the drying region progressively more slowly.

Mass Transfer in Drying

In heat transfer, heat energy is transferred under the driving force provided by a temperature difference, and the rate of heat transfer is proportional to the potential (temperature) difference and to the properties of the transfer system characterized by the heat-transfer coefficient. In the same way, mass is transferred under the potential gradient force provided by a partial pressure or concentration difference. The rate of mass transfer is proportional to the potential (pressure or concentration) gradient and to the properties of the transfer system characterized by a mass-transfer coefficient.

Writing the relationship symbolically, analogous to heat transfer (Eq. 1.8), we have

$$w = k_G A(H_a - H_s) \tag{1.9}$$

where w is the mass being transferred kg s^{-1}, A is the area through which the transfer is taking place, k_G is the mass-transfer coefficient in this case in units kg m^{-2} s^{-1}, and the quantity within brackets i.e., $(H_a - H_s)$ is the humidity difference in kg kg^{-1}(kg of moisture per kg of air).

Unfortunately the application of mass-transfer equation is not as straightforward as heat transfer, one reason being because the movement pattern of moisture changes as drying proceeds. Initially, the mass (moisture) is transferred from the surface of the material and later, to an increasing extent, from deeper within the food to the surface and thence to the air. So the first stage is to determine the relationships between the moist surface and the ambient air and then to consider the diffusion through the food. In studying the surface/air relationships, it is necessary to consider mass and heat transfer simultaneously. Air for drying is usually heated and it is also a major heat-transfer medium. Therefore, it is necessary to look carefully into the relationships between air and the moisture it contains.

Factors Influencing Drying

There are many factors that influence the rate of drying. These are related to either: (1) the process conditions present during drying, as determined by dryer type and operating conditions, or (2) the nature of the food product placed inside the dryer. The process conditions include dry look temperature, air velocity, wet bulb depression, pressure etc. whereas those of food product include surface area, constituent orientation, cellular structure, type and concentration of solutes.

Drying Methods

The methods involved in industrial drying of foods include: (1) Cabinet drying, (2) Tunnel drying, (3) Spray drying, (4) Vacuum drying, (5) Foam mat drying, (6) Freeze drying, (7) Fluidized bed drying, (8) Microwave drying, (9) Drum drying etc. The principles of different drying methods and the equipments used will be dealt in detail in subsequent blocks.

1.10 LET US SUM UP

We have learnt that there are magnitudes of various quantities and properties, which do not make sense unless, qualified with appropriate units. Although there are different systems of units such as MKS, CGS, FPS and SI, it is the SI system of units that is internationally accepted. A system for the purpose of analysis may be either a closed or an open system. Thermal processing of food is required to ensure that the population of harmful micro-organisms is reduced to acceptable level and then not allowed to grow for an intended period of time. The concepts of Decimal reduction time, thermal resistance constant and thermal death time have been presented. Then, the processes of evaporation, refrigeration and dehydration as they relate to food processing have been introduced. Simple relationships for estimating the extents of these unit operations have been presented.

1.11 KEY WORDS

Dimensions : A dimension defines a physical entity, which can be observed and / or measured, quantitatively.

Units : A unit expresses the quantitative value of a dimension.

Open system : The composition of the system is described by the components present inside and outside the system boundary.

Close system : The composition of the system is described by the components present inside the system boundary.

Intensive Properties : Properties that does not depend on the size of a system.

Extensive Property : Depends on the size of the system: for example, mass, length, volume, energy. This definition implies that an extensive property of a system is a sum of respective partial property values of the components of a system.

Decimal reduction time : The decimal reduction time (D) is defined as the time necessary for 90% reduction in the microbial populationly heating at a constant temperature.

Thermal resistance constant : It is defined as the temperature increase required to cause a one log cycle reduction in the decimal reduction time.

Thermal death time : Thermal death time is defined as the time required for achieving a *stated reduction* in the microbial population at a given temperature.

Evaporator : Completely vaporizes the refrigerant by heating it.

Compressor : Compresses the refrigerant at constant entropy.

Condenser : Condenses the refrigerant after going the heat to the surrounding medium

Expansion valve : It is the point of differentiation between the high pressure and low pressure sides of the refrigeration cycle.

Cooling load : The cooling load is the rate of heat energy removal from a given space (or object) in order to lower the temperature of that space (or object) to a desired level.

Coefficient of performance : The coefficient of performance (C.O.P.) is defined as a ratio between the heat absorbed by the refrigerant as it flows through the evaporator to the heat equivalence of the energy supplied to the compressor.

Eutectic temperature : The temperature at which a crystal of an individual solute exists in equilibrium with the unfrozen liquor and ice is its eutectic temperature.

Boiling point elevation : Boiling point elevation of a solution (liquid food) is defined as the increase in boiling point over that of pure water, at a given pressure.

Triple point : Triple point of water is defined as a condition in which pure water can exist in all the three states i.e., solid, liquid and vapour.

1.12 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. A dimensionally consistent equation is the one, which is balanced on both of its sides in terms of the dimensions, i.e. the LHS & RHS are dimensionally equal.
2. The different measuring systems are FPS, CGS, MKS and SI. The most acceptable and standard among them is the SI system.
3.

Quantity	Unit	Quantity	Unit
Length	m	Frequency	s^{-1}
Thermodynamic temperature	K	Pressure	$m^{-1}.kg.s^{-2}$
Amount of substance	Mol	Power	$m^2.kg.s^{-3}$
Area	m^2	Moment of Force	$m^2.kg.s^{-2}$
Density	Kg m^{-3}	Specific Energy	$m^2.s^{-2}$
Concentration	Mol m^{-3}	Thermal conductivity	$m.kg.s^{-3}.K^{-1}$

4. i) Open system is one which allows flow of heat and/or matter into or out of the system along its boundary whereas closed system is one in which the boundary is impervious to any flow of matter.

   ii) Intensive properties are those, which do not depend on the size of the system whereas extensive properties are those, which are dependent on the size of the system.

Check Your Progress Exercise 2

1. Thermal death time is defined as the time required to achieve a *stated reduction* in the microbial population at a given temperature, whereas, the decimal reduction time D is defined as the time necessary for 90% reduction in the microbial population.

2. $$k = \frac{2.303}{D} = \frac{2.303}{4.1} = 0.56/\min..$$

3. $$Q_{10} = 10^{10/z} = 10^{10/11} = 8.1$$

4. $$E_A = \frac{19.15}{z} T_A^2 = \frac{19.15}{11}(383)^2 = 2.55X10^5\, kJ/kg$$

Check Your Progress Exercise 3

1. Refrigeration involves the principle of transfer of heat from the cooling chamber or object to a location where the heat can be discarded with the use of a refrigerant, which like water changes state – from liquid to vapour.

2. a) Evaporator: It completely vaporizes the refrigerant by accepting heat from the media surrounding the coils.

   b) Compressor: It compresses the refrigerant to a high pressure so as to condense it at a temperature slightly higher than the heat sink.

   c) Condenser: Condenses the refrigerant to saturated / sub-cooled liquid by discharging heat to the surrounding media.

   d) Expansion valve: It is essentially a metering device that controls the flow of refrigerant into the evaporator. It separates the high pressure region from the low pressure region.

3. Cooling load is defined as the rate of heat energy removal from a given space (or object) in order to lower the temperature of that space (or object) to a desired level whereas C.O.P. is defined as the heat absorbed by the refrigerant as it flows through the evaporator to the heat equivalence of the energy supplied to the compressor.

Check Your Progress Exercise 4

1. Food freezing is defined as a preservation process that depends on the reduction of product temperatures to levels well below the temperature at which ice crystals begin to form within the food.

2. Eutectic temperature is defined as the temperature at which a crystal of an individual solute exists in equilibrium with the unfrozen liquor and ice.

3. The factors affecting volume changes during freezing are: (1) moisture content, (2) cell arrangement, (3) concentration of solutes and (4) freezer temperature.

4. In indirect contact freezing systems the product and the refrigerant are separated by a barrier throughout the freezing process whereas in direct contact freezing systems there is no such barrier between the refrigerant and the product.

Check Your Progress Exercise 5

1. Evaporation is a unit operation commonly used to remove water from dilute liquid foods to obtain concentrated liquid products whereas dehydration is used to remove water and obtain dry solid product i.e evaporation involves partial removal of water from the food products whereas drying involves complete removal of moisture from the foods.

2. Boiling point elevation of a solution (liquid food) is defined as the increase in boiling point over that of pure water, at a given pressure.

Check Your Progress Exercise 6

1. Drying of foods implies the removal of water from the foodstuff, which is accomplished by supplying the latent heat of vaporization.

   The two important process-controlling factors that enter into the unit operation of drying are:

   a) Transfer of heat to provide the necessary latent heat of vaporization,

   b) Movement of water/water vapour through the food material and then away from it to effect separation of water from foodstuff.

2. Triple point of water is defined as a condition in which pure water can exist in all the three states i.e., solid, liquid and vapour.

3. 0.0098°C and 0.64 kPa.

4. Vapour-pressure line is defined as a line along which liquid and vapour coexist in equilibrium.

5. The glass transition curve represents a metastable transition where viscosity is effectively so high that the product does not ‘flow’ over time scale of importance to food stability.

6. The driving force for heat transfer is temperature gradient whereas that of mass transfer is pressure or concentration.

7. The factors that influence the rate of drying are (1) the process conditions present during drying, as determined by dryer type and operating conditions (temperature, air velocity, relative humidity, pressure etc.), or (2) the nature of the food product placed inside the dryer (surface area, constituent orientation, cellular structure, type and concentration of solutes).

UNIT 2 MOISTURE CONTENT AND EQUILIBRIUM MOISTURE CONTENT

Structure

2.0 OBJECTIVES

By the time you have studied this unit, you should be able to:

- understand the importance of water in food preservation and its related issues;
- understand the importance of moisture content in food materials & methods of their determination and control; and
- understand equilibrium moisture content (EMC), its importance in food processing operations and methods of determination of EMC.

2.1 INTRODUCTION

Water is abundant in all living things and, consequently, in almost all foods, unless steps have been taken to remove it. It is essential for life, even though it contributes no calories to the diet. Water also greatly affects the texture of foods, as can be seen when comparing grapes and raisins (dried grapes), or fresh and wilted green leafy vegetables.

Almost all food processing techniques involve the use of water or modification of water in some form. Further, because micro-organisms cannot grow without water, the water content has a significant effect on the keeping quality of a food. This explains why freezing, dehydration, or concentration of foods increases shelf life and inhibits microbial growth.

Water is important as a solvent or dispersing medium, dissolving small molecules to form true solutions and dispersing larger molecules to form colloidal solutions. Acids and bases ionize in water, and water is also necessary for many enzymes to catalyze and chemical reactions to occur, including hydrolysis of compounds such as sugars. It is also important as a heating and cooling medium and as a cleansing agent.

2.2 CHEMISTRY OF WATER

The chemical formula of water is H_2O. Water contains strong covalent bonds, which hold the two hydrogen and one oxygen atoms together. The oxygen can be regarded as being at the center of a tetrahedron, with a bond angle of 105° between the two hydrogen atoms in liquid water and a larger angle of 109° 6' between the hydrogen atoms in ice.

The bonds between oxygen and each hydrogen atom are polar, having a 40% partial ionic character. This means that the outer shell electrons are unequally shared between the oxygen and hydrogen atoms, the oxygen atom attracting them more strongly than each hydrogen atom. As a result, each hydrogen atom is slightly positively charged and each oxygen atom is slightly negatively charged. They are therefore, able to form hydrogen bonds.

2.3 PROPERTIES OF WATER

2.3.1 Specific Heat

Specific heat is the energy required to raise the temperature of unit quantity of water by unit temperature and is the same whether heating water or ice. It is relatively high as compared to other substances, due to the hydrogen bonds. The unit of specific heat in SI system is $J\ Kg^{-1}\ K^{-1}$.

2.3.2 Latent Heat

Latent heat is the amount of heat uptake by unit quantity of water to change its state (liquid to solid & vice versa or liquid to vapour & vice versa) without any change in its temperature.

Latent heat of Fusion

It is the energy required to convert unit quantity of ice to water at freezing point and the unit is J/g of ice at the freezing point.

Latent Heat of Vaporization

It is the energy required to convert unit quantity of water to vapour at boiling point and is expressed in J for 1 g of water at the boiling point.

The specific and latent heats of water are all fairly high as compared to most other substances, and this is an important consideration when water is used as a medium of heat transfer. It takes considerable energy to heat water, and that energy is then available to be transferred to the food. Foods heated in water are slow to heat. Water also must take up considerable heat to evaporate. It takes heat from its surroundings; thus it is a good cooling agent.

2.3.3 Vapour Pressure

If a puddle of water is left on the ground for a day or two, it will dry up because the liquid evaporates. The water does not boil, but individual water molecules gain enough energy to escape from the liquid as vapour. Over time, an open, small pool of water will dry up in this way. If the liquid is in a closed container, at equilibrium, some molecules are always evaporating and vapour molecules are condensing, so there is no overall change in the system. The vapour (gaseous) molecules that have escaped from the liquid state exert a pressure on the surface of the liquid known as the vapour pressure.

When the vapour pressure difference is high, the liquid evaporates (is vaporized) easily and many molecules exist in the vapour state; the boiling point is low. Conversely, a low vapour pressure difference indicates that the liquid does not vaporize easily and that there are few molecules existing in the vapour state. There is a higher boiling point for these liquids. When the vapour pressure reaches the external pressure, the liquid boils.

The vapour pressure difference increases with increasing temperature. At high temperatures, the molecules have more energy and it is easier for them to overcome the forces holding them within the liquid and to vaporize, so there are more molecules in the vapour state.

The vapour pressure decreases with addition of solutes, such as salts or sugars. In effect, the solutes dilute the water; therefore, there are less water molecules (in the same volume) available to vaporize and, thus, there will be fewer in the vapour state, and the vapour pressure will be lower. There is also attraction to the solutes, which limits evaporation.

2.3.4 Boiling Point

Anything that lowers the vapour pressure increases the boiling point. This is due to the fact that the vapour pressure is lowered at a particular temperature, more energy must be put in; in other words, the temperature must be raised to increase the vapour pressure again. The external pressure does not change if salts or sugars are added, but it is harder for the molecules to vaporize so the temperature at which the vapour pressure is the same as the external pressure (boiling point) will be higher. One mole of sucrose elevates the boiling point by 0.52°C, and one mole of salt elevates the boiling point by 1.04°C. Salt has double the effect of sucrose because it is ionized, and for every mole of salt, there is one mole of sodium ions and one mole of chloride ions. Salts and sugars decrease the freezing point of water in a similar fashion.

If the external pressure is increased by heating in a pressure cooker or retort (commercial pressure cooker), the boiling point increases, and a shorter time period than normal is required to process the product (the basis of preserving food by canning). For example, food may be heated in cans in retorts, and the steam pressure is increased to give a boiling point in the range of 115-121°C. Conversely, if the external pressure is decreased, for example, at high altitude, water boils at a lower temperature, and requires a longer amount of time to process canned product.

2.3.5 Water as a Dispensing Medium

Substances can be dissolved, dispersed or suspended in water, depending on their particle size and solubility. Water dissolves small molecules such as salts or sugars or water-soluble vitamins to form a true solution, which may be either ionic or molecular.

Solution

An ionic solution is formed by dissolving substances, which ionize in water, such as salts, acids, or bases forming ionic solution. Taking sodium chloride as an example, the solid contains sodium (Na^+) and chloride (Cl^-) ions held together by ionic bonds. When placed in water, the water molecules reduce the attractive forces between the oppositely charged ions, the ionic bonds are broken, and the individual ions become surrounded by water molecules, or hydrated.

Polar molecules such as sugars, which are associated by hydrogen bonding, dissolve to form molecular solutions. When a sugar crystal is dissolved, hydrogen bond interchange takes place and the hydrogen bonds between the polar hydroxyl groups of the sugar molecules are broken and replaced by hydrogen bonds between water and sugar molecules. Thus, the sugar crystal is gradually hydrated, each sugar molecule being surrounded by water molecules.

Colloidal Dispersion

Molecules that are too big to form true solutions can be dispersed in water, depending on their size. Those with a particle size range of 1 nm to 100 nm are dispersed to form a colloidal dispersion or a sol. Examples of such molecules include cellulose, cooked starch, pectic substances and some food proteins. Colloidal dispersions are often unstable; thus proper care must be taken to stabilize them where necessary if they occur in food products. They are particularly unstable to such factors as heating, freezing, or pH change. Changing the conditions in a stable dispersion can cause precipitation or gelation; this is desirable in some cases, for example when making pectin jellies.

Sol is a colloid that pours – a two phase system with a solid dispersed phase in a liquid continuous phase, for example a hot sauce. A gel is also a two phase system, but it is an elastic solid with a liquid dispersed phase in a solid continuous phase.

Suspension

Particles that are larger than 100 nm are too large to form a colloidal dispersion. They form a suspension when mixed with water. The particles in a suspension separate out over time, whereas no such separation is observed with colloidal dispersions. An example of a suspension would be uncooked starch grains in water. They can be suspended throughout the liquid by stirring, but if left undisturbed, they will settle down, and sediment will be observed at the bottom of the container.

2.4 TYPES OF WATER AND WATER ACTIVITY

2.4.1 Types of Water

Water is abundant in all living things and, consequently, in almost all foods, unless steps have been taken to remove it. Most natural fresh foods contain 70% of their weight, or greater of water, and fruits and vegetables contain upto 95% or greater water. Water that can be extracted easily from foods by squeezing, or cutting or pressing is known as free water, whereas water that cannot be extracted easily is termed bound water.

Bound water is usually defined in terms of the way it is measured; different methods of measurement give different values for bound water in a particular food. Many food constituents can bind or hold on to water molecules, so that they cannot be easily removed and they do not behave like liquid water. Some characteristics of bound water include the following:

- It is not free to act as a solvent for salts and sugars.
- It can be frozen only at very low temperatures (below the freezing point of water).
- It exhibits essentially no vapour pressure.
- Its density is greater than that of free water.
- It has more structural bonding than liquid water, thus it is unable to act as a solvent.

Water may also be entrapped in foods such as pectin gels, fruits, vegetables and so on. Entrapped water is immobilized in capillaries or cells, but if released by cutting or damage, it is free to flow. Entrapped water has the properties of free water and has no properties of bound water.

2.4.2 Water Activity (A_w)

Water activity or A_w, is a ratio of the vapour pressure of water in a solution (P_s) as compared to the vapour pressure of pure water (P_w) at a given temperature.

$$A_w = \frac{P_s}{P_w} \qquad (2.1)$$

Living tissues require sufficient levels of water to maintain turgor, and the A_w must be high. However, micro-organisms such as bacteria, mould and yeast multiply at high A_w. Because their growth must be controlled, prevention techniques against the spoilage these micro-organisms cause take into account the water activity of the food.

Jam, jellies and preserves and pickles are prepared using a high concentration of sugar, and salt. Sugar and salt are both effective preservatives due to the fact that they lower A_w. Salt lowers the A_w more effectively than sugar due to its chemical structure that ionizes and attracts water.

Properties of Food that Control the Water Activity

Certain properties of the food and the way water interacts with the components of a food result in different degree of binding or tying up of the water. The more tightly water is bound; the lower is its water activity (A_w). The three major physical effects that lower water activity are:

1. **Colligative effect**: When a solid solute dissolves in water, it interacts with water in three dimensions through dipole – dipole, ionic and hydrogen bonds. These interactions affect the properties of water based on the amount of the added molecules relative to the amount of water molecules present. This interaction is called a colligative effect.

2. **Capillary effect**: A second effect that depresses water activity is the capillary effect. The vapour pressure of water above a curved liquid meniscus is less than that of pure water because of changes in the hydrogen bonding between water molecules as a result of the surface curvature. Since foods have a myriad of capillaries, some lowering of the water activity should result. The Kelvin equation predicts this lowering by:

$$A_w = \exp - \frac{2\gamma_s \cos\theta \overline{V_L}}{rRT} \qquad (2.2)$$

where,

γ_s = surface tension of liquid in a pore,

θ = wetting angle,

$\overline{V_L}$ = molar volume of liquid in cm^3/mole,

r = capillary radius,

R = gas constant (8.314 x 10^7 ergs/°K mole) and,

T = °K.

Most pores in foods are in the 10 – 300 μm range. Assuming complete wetting (cos θ) and pure water (γ_s=72.3 dyne/cm) in the pores, the Kelvin equation predicts an A_w in the range of 0.989 – 0.999. Thus the A_w is lowered very little by capillarity. However, 5 – 7% of the pore volume in foods is of pores of 0.01 – 0.001 μm, which lowers the A_w above the vapour space to values of 0.899 – 0.34. Thus, smaller capillaries have a greater effect on lowering of A_w.

3. **Surface interaction**: Finally, water directly interacts with other chemical groups on molecules through dipole – dipole force, ionic bonds (H_3O^+ or OH^-), van der Walls forces (hydrophobic bond), and the hydrogen bond. These water molecules, so bound, require extra energy to be transferred from the liquid to the vapour state and thus are less free to the vapour, resulting in reduced A_w. This effect is more pronounced at low A_w. The point of critical importance is the monolayer. This is the moisture content at each polar and ionic group has a water molecule bound to it, to form the start of a liquid like phase. Reactions which depend on water as a reaction phase medium do not occur below this moisture content at appreciable rates.

2.5 ROLE OF WATER IN FOOD PRESERVATION AND SHELF LIFE OF FOODS

Control of the water level in foods is an important aspect of food quality. Foods may be more desirable either crispy or dry. Freezing and drying are common food preservation processes that are used to extend the shelf life of foods because they render water unavailable for pathogenic or spoilage bacteria.

2.6 WATER HARDNESS AND TREATMENTS

The hardness of water is measured in parts per million of calcium carbonate. Soft water contains 0-60 ppm and has no mineral salts. It contains some organic matter. Hard water contains more than 60 ppm dissolved salts. Water may exhibit temporary hardness due to iron, or calcium and magnesium bicarbonate ions [$Ca(HCO_3)_2$ and $Mg(HCO_3)_2$]. The water may be softened as it is boiled (soluble bicarbonates precipitate in boiling and leave deposits or scales) and insoluble carbonates may be removed from the water.

Permanent hardness of water cannot be removed by boiling as it contains either calcium or magnesium sulphates ($CaSO_4$ or $MgSO_4$) as well as other salts that are not precipitated by boiling. Permanent hardness is removed by the use of chemical softeners. Hard water exhibits less cleaning effectiveness than soft water due to the formation of insoluble calcium and magnesium salts with soap. The use of detergents rather than soap prevents this formation.

Water has a pH of 7 when it is neither acidic nor alkaline. Water is acidic if the pH is less than 7 and alkaline if the pH is more than 7. Tap water displays a variance on either side of neutral. It may be slightly alkaline or slightly acidic depending on the source. Hard water has a pH of upto 8.5. Chlorinated water is that which has had chlorine added to kill or inhibit the growth of microorganisms. Manufacturing or processing plants may require potable soft water of good quality to prevent turbidity, off-colour and off-flavour in food products. The use of tap water, which is not sufficiently soft, is not advisable for use in food products.

2.7 MOISTURE MEASUREMENT TECHNIQUES

There are several methods for determination of moisture content of food materials. The choice of method depends on many factors, such as (1) the form in which water is present in the product, (2) the relative amount of water present, (3) the rapidity of determination, (4) accuracy of method, (5) product's nature whether easily oxidized or decomposed, and (6) cost of equipment used.

Moisture content is determined mainly by two methods, (1) direct, also called primary and (2) indirect, also called as secondary methods. The accuracy of moisture content determination by direct methods is high, but time consuming. Indirect methods are faster and mostly employ the electrical properties of the grain.

2.7.1 Direct Methods

Air Oven Method

2-3 / 25-30 grams of ground / unground representative sample is placed in an air oven at a temperature of 130°C / 100°C for 2-3/72-96 hours. The moisture content of the samples is measured by the difference in initial and final weights of the sample. The selection of sample size, temperature and duration may be different for different materials.

Vacuum Oven Method

2-3 grams of representative sample of ground material is placed in a vacuum oven (25 mm vacuum) and dried at 100°C for 72-96 hours. Here also the moisture content is measured by the difference in initial and final weights of the sample.

Brown-Duvel Fractional Distillation Method

100 grams of the sample is mixed along with 150 ml of mineral oil and boiled. Moisture from the sample is evaporated, collected, condensed and measured in a graduated cylinder. The time required for moisture determination is about 30 minutes.

Infra-red Method

Moisture content is directly measured by evaporation of water from the sample with an infra red heating lamp. The infra red lamp evaporates the moisture of the product and the difference in initial and final weights gives a measure of the amount of moisture in the food.

2.7.2 Indirect Methods

Electrical Resistance Method

The electrical conductivity or resistance of a product depends upon its moisture content. This principle is employed in resistance measuring devices. The food sample is kept in a container at a particular compaction and temperature. The electrical resistance is then measured across it and the resistance is calibrated to give the moisture content.

Dielectric Method

Similar to the electrical resistance method, but here the capacitance of the sample is measured when a high frequency current is passed through the sample placed between the two plates of the condenser.

Chemical Method

The removal of water by strong desiccants ($CaCl_2$) is caused by the vapour pressure gradients. The moisture moves from the samples to the drying agent, due to vapour pressure gradient between the sample and the desiccant. The hydration of salt is accompanied by evolution of heat. The heat of evolution helps in driving the water out of the samples. Calcium chloride, when heated to redness reacts with superheated steam to form HCl and Calcium hydroxide.

$$CaCl_2 + H_2O \rightarrow Ca(OH)_2 + 2HCl \qquad (2.3)$$

2.8 EMC AND ITS RELEVANCE TO FOOD PRESERVATION

Most of the food products absorb or loose moisture from environment. When the ambient temperature rises and humidity of air decreases, the water present in foods vaporizes. Consequently the food loses moisture which results in desiccation / drying. In other words, if the vapour pressure of water present in the foods is more than the vapour pressure of moisture in air, the water present in food vaporizes and diffuses into the atmosphere. Alternatively, if the vapour pressure of water in the foods is less than the atmospheric vapour pressure, foods will absorb moisture from the atmosphere. This property of gaining or loosing of moisture as per the atmospheric conditions is known as hygroscopicity.

The moisture content attained by foods with respect to the set of atmospheric temperature and relative humidity is called the equilibrium moisture content (EMC) of the food. In such condition, the food moisture is in equilibrium with the surrounding air.

2.8.1 Importance of EMC

EMC is of particular importance for drying and storage of food materials. The usefulness of EMC are:

i) EMC gives an idea whether the food material will gain or lose moisture under a particular atmospheric condition.

ii) It gives an idea about rate of moisture removal.

iii) EMC helps to determine drying characteristics.

iv) With the knowledge of EMC, it can be predicted as to what final moisture level a product can be dried with the heated air.

2.8.2 Hysteresis Effect

When food products in the process of loosing moisture attains equilibrium moisture content with the surroundings, the EMC is known as desorption EMC. But when a dry product gains moisture from the surroundings and attains EMC, that value of EMC is said to be adsorption EMC. At some relative humidity and temperature level there is a meaningful difference between the desorption and adsorption EMC values. The desorption EMC values are higher than the adsorption EMC values. The differences between desorption and an adsorption curve is known as hysteresis effect (Figure 2.1). As seen from the figure, the differences between the adsorption and desorption values are more significant for the intermediate range of moisture contents.

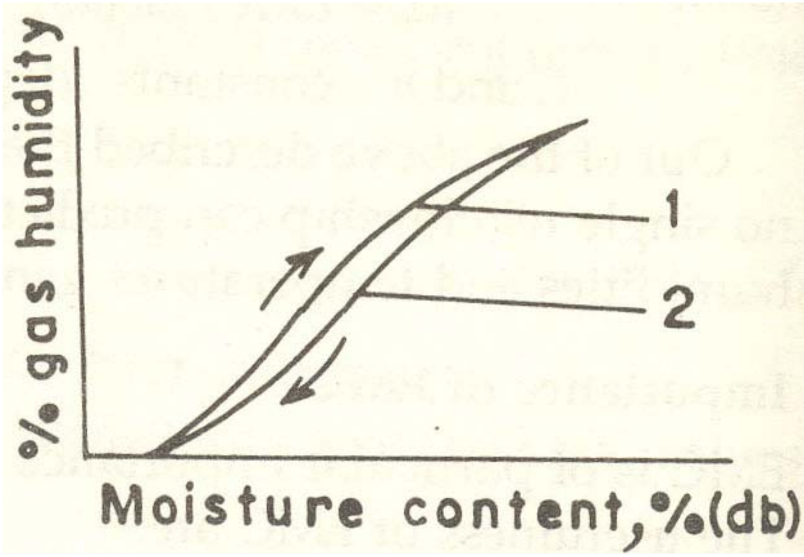

Figure 2.1: Hysteresis effect: 1) Adsorption EMC curve, 2) Desorption EMC curve

2.9 EMC DETERMINATION METHODS

The methods of determination of EMC of food materials can be categorized into two: (1) static method and (2) dynamic method. In the static method, food is left in the air with known temperature and humidity until it attains equilibrium, while in the dynamic method the conditioned air is agitated or moved by mechanical means and the food attains equilibrium condition further.

2.9.1 Static Method

In static methods, to bring the atmospheric air to desired relative humidity levels different concentrations of acids or salt solutions are used. Static methods are generally time consuming, and to bring the food to equilibrium condition, 3 – 4 weeks are required. Thus in case of high humidity and high temperature conditions, chances of attack of moulds are high. Decomposition and change in food structure is also possible. It is essential to maintain the required humidity and temperature conditions of air throughout the test period. Temperature is normally maintained using an incubator or oven whereas relative humidity is maintained using acid/salt solutions in desiccators.

2.9.2 Dynamic Method

Desorption Method

The property of dry air to absorb moisture from moist foods is employed. Most foods are put in an airtight container. When the air comes in equilibrium to food its relative humidity is measured by a hygrometer. Since the container has small quantity of air, it reaches equilibrium with the food within a short period.

Isotenoscopic Method

This method also employs absorption of moisture by dry air to determine EMC of the food material. But in this method arrangement is available to measure directly the vapour pressure exerted by the moist foods (Figure 2.2). The food sample is kept in a conical flask.

Isotenoscope is a U tube filled with the liquid of negligible vapour pressure. The arms of the tube has an enlarged section above the level of liquid to prevent drawing of liquid out of the tube while evacuating or readmitting air to the flask. The isotenoscope is connected to a vacuum pump through a vacuum storage jar. Atmospheric pressure can be brought back into this jar by means of a valve'V_1'. The 'V_2' is a shut off valve connecting closed while all air is evacuated from the flask, the vacuum storage jar, and from the system. Under this condition, vapour pressure builds up in the flask, which forces the liquid in the two arms of the isotenoscope to dissimilar level. Bleeding a small amout of air into the vacuum storage jar then equalizes the level of the liquid. This equalization pressure is continued until vapour pressure buildup in the flask has reached the maximum for the temperature of water bath. Valve 'V_2' is then closed and the absolute pressure indicated in the manometer is read. The isotenoscope is removed from the flask and a properly weighed stopper closes the flask. The weight of flask with sample is recorded to determine sample moisture content.

2.10 LET US SUM UP

Let us now recapitulate the information presented in this unit. Water is an important material in the food processing activities. It is necessary to take into account the behaviour and properties of water while planning for any food processing activity. Water in food products may be present in bound, entrapped and free forms. Water contained in a food material is expressed in terms of moisture content on either dry or wet weight basis. Another way to express the moisture content in a food material is to determine its water activity. Higher the free water content, higher is the water activity at a given temperature. Water activity and spoilage of a food material are positively correlated. Methods of moisture content determination could be direct as well as indirect. Oven method is one of the direct methods, which is accurate but time consuming. Measurement of electrical conductivity or dielectric constant of a food material is quick but indirect method of moisture content determination. A food material, when placed in the air of specific temperature and humidity, attains moisture content, which is called its equilibrium moisture content (EMC). Depending on whether the food material gained the moisture or lost it to attain the EMC, the two values may be different and this behaviour of food material is known as Hysteresis. EMC determined can be through either static or dynamic methods. Isotenoscope is an apparatus to determine EMC of food materials dynamically.

2.11 KEY WORDS

Moisture content : It indicates the amount of free moisture in any material.

Water activity : Water activity or A_w, is a ratio of the vapour pressure of water in a solution (P_s) as compared to the vapour pressure of pure water (P_w) at a given temperature.

Hygroscopicity : It is the property of gaining or loosing of moisture (due to vapour pressure difference) as per the atmospheric conditions.

Specific heat : Specific heat is the energy required to raise the temperature of unit quantity of water by unit temperature and is the same whether heating water or ice.

Latent heat of fusion : It is the energy required to convert unit quantity of ice to water at freezing point and the unit is J/g of ice at the freezing point.

Colloidal dispersion : Molecules that are too big to form true solutions can be dispersed in water, depending on their size and the mixture is called as colloidal dispersion.

Suspension : Particles that are larger than 100 nm are too large to form a colloidal dispersion. Those form a suspension when mixed with water. The suspended particles settles down if the suspension is left undisturbed.

Free water : Water that can be extracted easily from foods by squeezing, or cutting or pressing.

Bound water : Water that cannot be extracted easily is termed bound water.

Entrapped water : Water bound by food constituents so that they cannot be easily removed and they do not behave like liquid water.

EMC : The moisture content attained by foods with respect to the set of atmospheric temperature and relative humidity

Hysteresis : The difference between the adsorption and desorption EMC at any given temperature and relative humidity.

Isotenoscope : Equipment used for measuring dynamic EMC

2.12 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Foods are living systems where water is the basis of several biochemical processes including the growth of micro-organisms. Foods with high water content have, therefore, limited usable life. Water content in foods needs to be regulated to a manageable level for achieving the intended shelf-life.

2. a) Vapour pressure: Water in air normally exists in vapour form. As you know, air is composed of mainly oxygen, nitrogen, carbon di oxide, water vapour and other gases in small amounts. Each of these constituents of air contributes to the atmospheric pressure depending upon their relative magnitudes. Water vapour also contributes a small fraction to the pressure.

   b) Boiling point: Boiling point is the temperature at which water starts boiling. At mean sea level, the boiling point for pure water is 100°C or 373°K.

3. a) Ionic solutions have charged particles like anions and cations. Molecular solutions have the solutes in molecular form, which are not electrically charged.

   b) Colloid is a mixture of liquid and solid particles, which are so fine that they exhibit Brownian movement. The colloids remain in perpetual suspension. A true suspension retains its apparent homogeneity for a short time after stirring. The suspended particles then settle down.

   c) Free water is the water in a food material that can be extracted easily by squeezing, or cutting or pressing, whereas the water that cannot be extracted easily is termed bound water.

4. Water activity or A_w, is a ratio of the vapour pressure of water in a solution (P_s) as compared to the vapour pressure of pure water (P_w) at a given temperature.

$$A_w = \frac{P_s}{P_w}$$

5. The properties of food that control water activity are:

   a) Colligative effect
   b) Capillary effect
   c) Surface interaction

   Colligative effect: When a solid solute dissolves in water, it interacts with water in three dimensions through dipole – dipole, ionic and hydrogen bonds. These interactions affect the properties of water based on the amount of the added molecules relative to the amount of water molecules present. This interaction is called a colligative effect.

Check Your Progress Exercise 2

1. The hardness of water is measured in parts per million of calcium carbonate. The water may be softened as it is boiled (soluble bicarbonates

precipitate in boiling and leave deposits or scales) and insoluble carbonates may be removed from the water.

2. EMC: The moisture content attained by foods with respect to the set of atmospheric temperature and relative humidity is called the equilibrium moisture content (EMC) of the food.

   Hysteresis: At a relative humidity and temperature level there is a meaningful difference between the desorption and adsorption EMC values. The desorption EMC values are higher than the adsorption EMC values. The differences between desorption and an adsorption curve is known as hysteresis effect.

3. Different moisture measurement techniques are:

   Direct methods:

   a) Air oven method
   b) Vacuum oven method
   c) Brown-Duvel fractional distillation method
   d) Infra-red method

   Indirect methods:

   a) Electrical resistance method
   b) Dielectric method
   c) Chemical method

   Electrical resistance method: In this method, the food sample is kept in a container at a particular compaction and temperature. The electrical resistance is then measured across it and the resistance is calibrated to give the moisture content.

4. Different EMC measurement techniques are:

   i) Static method
   ii) Dynamic method

      a) Desorption method
      b) Isotenoscopic method

   Desorption method: Most foods are put in an airtight container. When the air comes in equilibrium to food its relative humidity is measured by a hygrometer.

UNIT 3 CLEANING AND GRADING

Structure

3.0 OBJECTIVES

By the time you have studied this unit, you should be able to:

- understand the importance of cleaning and grading in the food processing operations;
- know the cleaning and grading devices and their operating principles; and
- should be able to select a suitable cleaning and grading device for any given operation.

3.1 INTRODUCTION

Cleaning and grading are important post harvest operations undertaken to remove foreign and undesirable materials from the produce and to separate the produce into various fractions. The comparative commercial value of food products is dependent on their grade factors. These grade factors further depend upon (1) physical characteristics like size, shape, moisture content, colour, etc., (2) chemical characteristics like odour, and (3) biological factors like insect damage.

It is difficult to clearly differentiate between the processes of cleaning and grading because these are carried out simultaneously with the common procedures. The operation of cleaning and grading of the products are performed by exploiting the differences in engineering properties of the materials. These products may be used either for food or seed purposes.

3.2 DEFINITIONS AND OBJECTIVES OF CLEANING

Cleaning and grading both are the processes of separation. Cleaning generally means the removal of foreign and undesirable material from desired grains / products. The objective is to reduce the cost of further handling as unnecessary fraction would have been separated. Besides the clean material fetches higher prices. In this sense, cleaning is a value addition operation.

Grading refers to the classification of the cleaned product into various quality functions depending upon the commercial value and usage. For example, separating ripe tomatoes from unripe ones. This also is a value addition operation.

3.3 METHODS OF CLEANING

The undesirable material from the mixture could be removed by wet, dry or a combination of wet and dry methods.

3.3.1 Wet Method

The wet method of cleaning consists of spraying clean water over the mixture in a trough of water to remove the undesirables. Then the desirable washed material is appropriately dried to remove the adhering moisture. It is important in this process that the desirable material should not get affected by the washing treatment and that the water used for washing is clean so as not to leave any residue after washing and drying.

3.3.2 Dry Method

The dry methods of cleaning are based on the specific properties of the constituents of the mixture such as:

1. Size
2. Shape
3. Specific gravity or weight
4. Surface roughness
5. Aerodynamic properties
6. Ferro-magnetic properties
7. Colour
8. Electrical properties

Cleaners based upon size

Screen cleaners/graders: It performs the separation according to size alone. The mixture of grain and foreign matter is dropped on a screening surface, which is vibrated either manually or mechanically. A single screen can make the separation into two fractions. The screening unit may be composed of two or more screens as per the cleaning requirement.

A hand-operated screen cleaner (Figure 3.1) is made of mild steel. The separation takes place due to difference in size of grain and foreign matter. The cleaner is operated by hanging on an elevated point with the help of four ropes. Produce is fed on the screening surface in batches. The screens can be changed as per the grain to be handled. The cleaner is swung to and fro till all the grain is screened. The cleaned grain is retained by the bottom sieve which can be discharged by pulling a spring loaded shutter. Impurities of larger size, stubbles, chaff etc. are retained on the top sieve and can be removed easily. Down stream from the bottom sieve consists of dust, dirt, brokens, shrivelled produce etc. drop down during the operation.

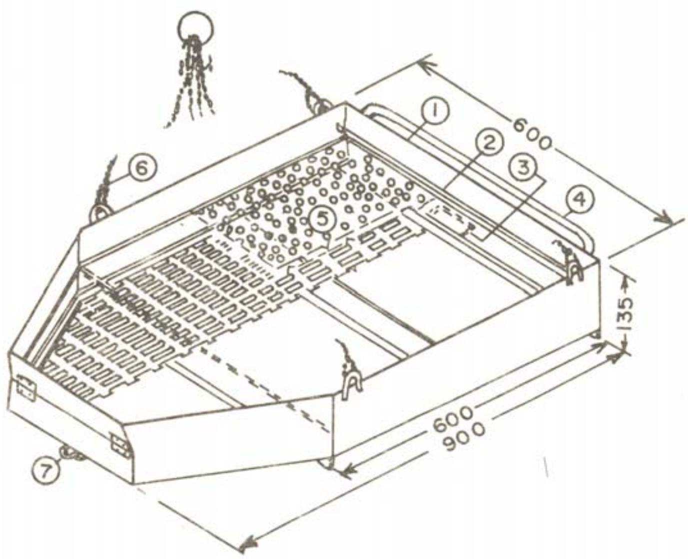

Figure 3.1: Hand operated double screen grain cleaner. 1) frame 2) draper rod 3) screen handle 4) handle 5) scalper and grader screens 6) rope attachment 7) shutter opening attachment

Air screen cleaners: The screens used in combination with air blast performs satisfactory cleaning and separation operations for most of the granular materials. The air-screen cleaner uses three cleaning systems: blowing or aspiration, scalping screens and grading lower screens. The air-screen grain cleaner can be classified in two distinct types: *(i)* vibratory screen, *(ii)* rotary screen, based on movement of the screening surface.

Vibratory air-screen cleaner: The screening unit is composed of double or multiple (up to 8 number) screens. These screens are tightened together and suspended by hangers in such a manner that these have horizontal oscillating motion and slightly vertical motion. These two motions in combination move the grain down the screen and at the same time toss sufficiently above the screen so that the bed of grain is properly stirred. The slope of the screen is adjustable to control the rate of downward travel of the grain. The screens are available in various shapes like; round, triangular or slotted holes as discussed earlier. Sometimes the holes of the screen are clogged when the machine makes fine degree of sorting. To avoid the clogging, the screens are generally fitted with a brush which moves under the screen and pushes the clogged material back through the screen. Other such devices can also be used for this purpose. A simple vibratory type air-screen cleaner is shown in Fig. 3.2.

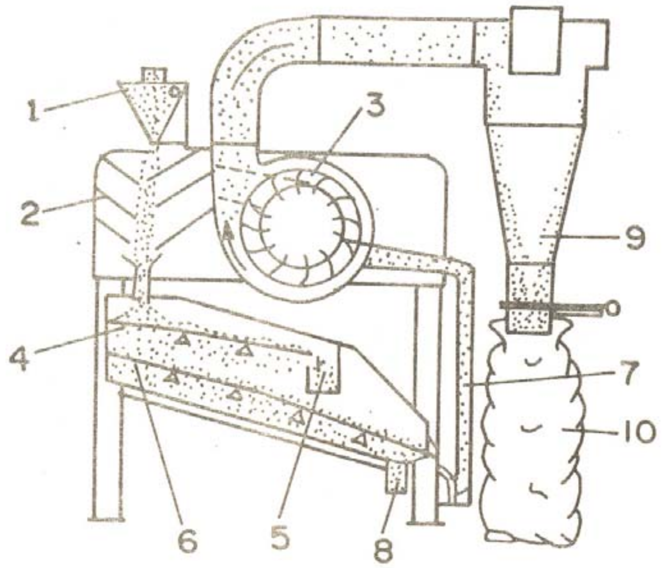

Figure 3.2: Schematic diagram of a vibratory air screen cleaner. 1) Feed Hopper, 2) Baffle plate, 3) Blower, 4) Upper screen, 5) Discharge channel, 6) Sand sifter, 7) Ascending separator, 8) Discharge funnel, 9) Centriclone, 10) Dust Bag

Rotary screen cleaner: The rotary screen cleaner has normally circular decks. Their motion is circular in horizontal plane. These have either single or double drum. A single drum rotary screen cleaner is shown in Figure 3.3. The machine consists of a rotary screen, aspirator and hopper and equipped with an electric motor, which gives drive to the rotary screen and the aspirator. The mixture is fed into the hopper. The sound grains pass through the screen perforation into the centre of the screen drum, whereas oversized material is retained above and pass out though an outlet. The sound grains come out at the centre side of the screen drum rotating at low speed and fall onto the vibratory screen which remove the dirt particles. The light particles like straw and dust are sucked away by the aspirator and discharged through the aspirator outlet. The cleaned grains are delivered through the discharge chute.

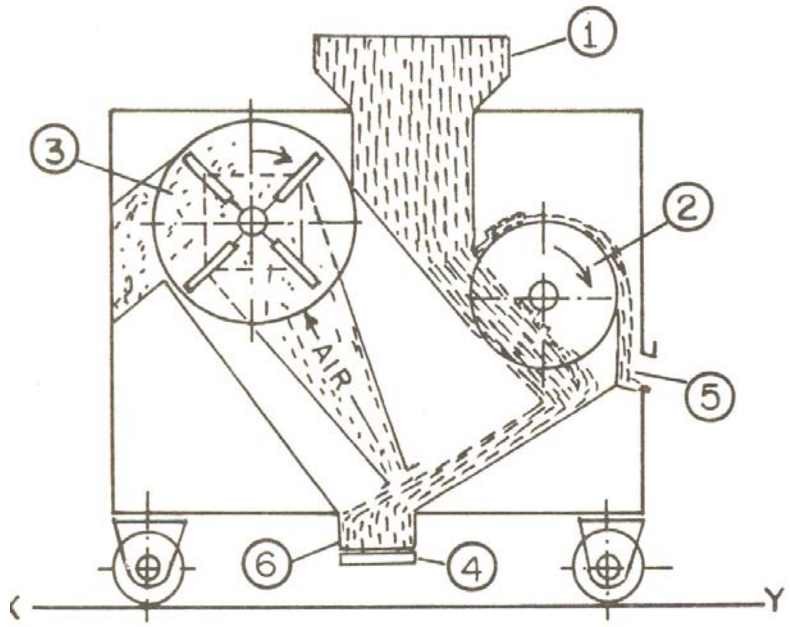

Figure 3.3: Diagram of a single drum rotary screen cleaner. 1) Feed hopper, 2) Rotary screen, 3) Aspirator, 4) Discharge chute, 5) Over size foreign matter outlet, 6) Vibratory screen

Specific gravity cleaners

The specific gravity separator makes the separation according to difference in density or specific gravity of the materials. This separator works on two principles, (1) the characteristics of grains to flow down over an inclined surface, (2) the floatation of the particle due to upward movement of air.

The main part of the device is a triangular-shaped perforated deck. The deck is properly baffled underneath to ensure uniform distribution of air over it. The pressure or terminal velocity of the air rising through the deck can be controlled very closely within a wide range (Figure 3.4).

The mixture of produce is fed into the feed box. The air is blown up through the porous deck surface and bed of the grain by a fan at such a rate that the material is partially lifted from contact with the deck surface. The lightest materials are lifted to the top of the stratified mass. The air does not lift the heavier particles. The stratified mass moves along the direction of conveyance due to oscillating motion of the deck and is discharged at the right edge of the deck.

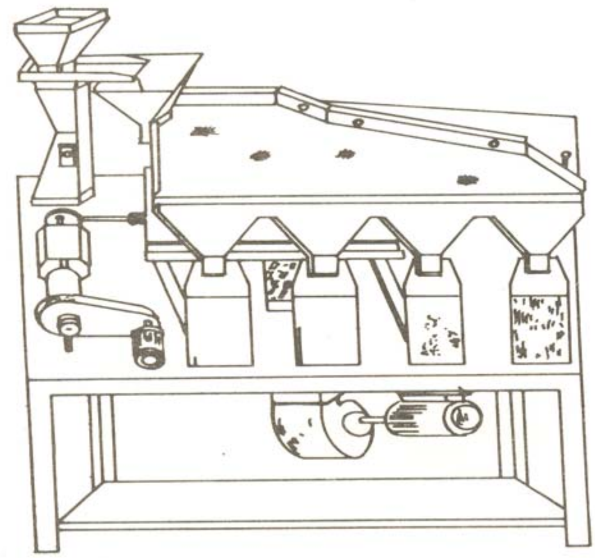

Figure 3.4: Specific gravity separator

Aerodynamic cleaners

The pneumatic separation is based on the difference in aerodynamic properties of various constituents of the mixture. The aerodynamic properties of a particle depend upon its shape, size, density, surface and orientation with respect to air current. Both the aspirator and the pneumatic separator use terminal velocity of the grain to separate different fractions. This refers to the velocity of air required to suspend particles in a rising air current.

In a pneumatic separator, the fan is placed at the intake end of the machine, which creates higher pressure than the atmospheric pressure. The high pressure air blast separates the materials. The mixture of products is introduced into a confined rising air stream; the air current lifts the particles with low terminal velocities whereas the particles with higher terminal velocities than air velocity fall down. The air velocity can be adjusted by altering the speed of fan or by changing the opening of air inlet (Figure 3.5).

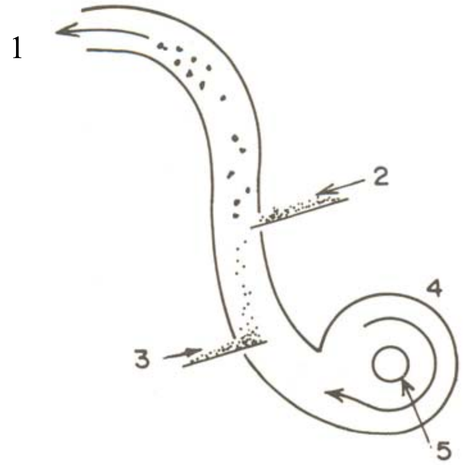

Figure 3.5: Diagram of a pneumatic separator. 1) Undersirable material removal, 2) Uniform feeder, 3) Clean grain outlet, 4) Centrifugal blower, 5) Control for air intake

3.4 METHODS OF SEPARATION

We often encounter mixtures of food materials, which need to be separated into different fractions for either subsequent marketing or processing. Fruits harvested from an orchard are normally of different sizes, which would fetch lower prices as compared to the graded fruits packed nicely. There are several similar situations where it is necessary to separate different fractions from a mixture. This separation could be achieved by utilizing one or more of the properties of the constituents of the mixture. The most common property is the size. The other properties normally utilized for separation are weight, specific gravity, surface roughness, optical properties and magnetic properties. The basic principles of the operation of different separators are being presented in the following sections.

3.4.1 Size Based Separators

The bulk food material such as a basket of fruits or vegetables is fed to a container from which the individual food items are segregated on the basis of their diameter or length or any other significant dimensions. In case of handy materials such as dry fruits and nuts, even oscillating sieves could be used for the separation. However, fresh fruits and vegetables get easily damaged, therefore, they need to be carefully handled. The relative motion between the food items and the separator is minimized. A grader for separating mangoes on size basis is shown in Figure 3.6. As you may note the fruits roll on the continuously diverging channel and, thus, the separation takes place.

Figure 3.6: Size based mango grader

3.4.2 Specific Gravity Separators

Some materials, when separated on size basis do not give the correct classification, for example, some groundnut pods may attain a particular size, the kernels in them remain immature. Obviously, such pods are not desirable and need to be separated from the pods that have bold kernels. This separation could be achieved by letting the mixture float in a fluid. Based on the specific gravity, the fractions will settle down differently. A cream separator in dairy processing is also categorized under specific gravity separators.

3.4.3 Colour Separators

The colour separator separates the fruits, vegetables or grains due to difference in colour or brightness. The colour separators are generally used for larger crop seeds like peas and beans. These seeds differ in colour because of varietal differences and also due to immaturity or disease. The mud balls and discoloured or defective seeds can be removed with the help of electronic separator. The material mixture is fed uniformly into the optical chamber of the separator.

Two photocells are fixed at a particular angle, which direct both beams to one point of the parabolic trajectory of the grains. A needle is placed on the other side, which is connected to a high voltage source (Figure 3.7). When a beam falls on a dark object through photoelectric cells, current is generated on the needle. The needle end receives a charge and imparts it to the dark seeds. The grains are then passed between two electrodes with a high potential difference between them. The seed is compared with a selected background or colour range, and is separated into two fractions according to difference in colour. Since this machine views each produce individually, the capacity is low.

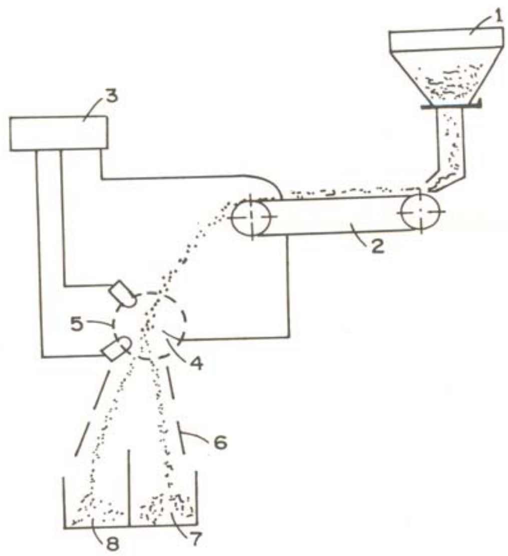

Figure 3.7: Schematic of a colour separator 1) hopper, 2) belt conveyor, 3) amplifier, 4) charging needle, 5) optical chamber, 6) deflecting electrodes, 7) foreign material, 8) desired material

3.4.4 Weight Based Separators

Certain food items are of regular shape or size. They are separated on weight basis. The food items are conveyed over a set of pan balances arranged in such a way that the lowest weight objects travels farthest. Heavier object tips the balances earlier and get collected in a trough. The lighter object passes on these balances and moves farther till the appropriate balance tips down and the object is picked up for separation into the correct class.

3.4.5 Magnetic Separators

The magnetic separator performs separation on the basis of surface texture and stickiness properties of the grain. Since the grains do not contain any free iron, therefore, are not attracted by the magnet. A selective pre-treatment of mixing finely ground iron powder to feed mass is given. The grain mixture is fed to a screw conveyor or other mixing device that tumbles and mixes the grain with a proportioned amount of water. Due to moisture, iron powder adheres to rough, cracked, broken and sticky seed coats. Moisture does not remain on smooth grains so no iron powder adheres to smooth surfaced grains.

The grain mixture is fed onto the top of a horizontal revolving magnetic drum, the smooth grains that are relatively free of powder fall along the drum simply by gravity. The materials with iron powder are attracted by the magnetic drum and stick to it and are removed by rotary brush or break in the magnetic field as shown in Figure 3.8.

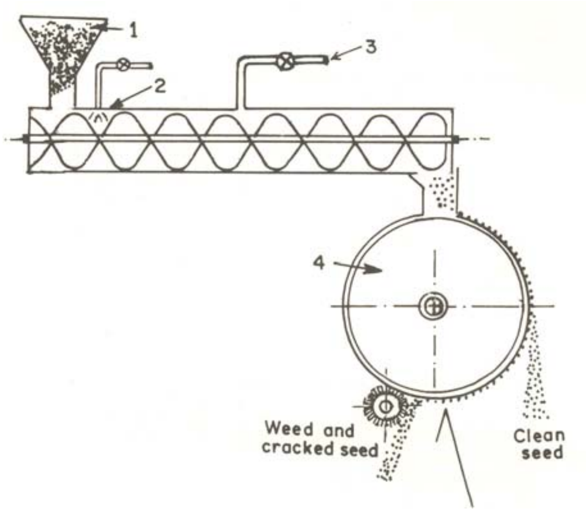

Figure 3.8: Magnetic Separator. 1) Feed hopper, 2) Water spray, 3) Iron powder mixing, 4) Magnetic drum.

3.4.6 Surface Texture/Roughness Separator

The mixture to be separated is fed over the centre of an inclined draper belt moving in upward direction. The round and smooth grains roll or slide down the draper at faster rate than the upward motion of the belt, and these are discharged in a hopper. The flat shape or rough surfaced particles are carried to the top of the inclined draper and dropped off into another hopper. (Figure 3.9). The belts of different degrees of roughness may be used as a draper for separate materials. If rolling tendencies of the grain are predominant, the rough canvas belt may be used. The smooth, plastic belt may be used in case sliding action is desired for the lower fraction. Feed rate, speed of draper and angle of inclination are other important variables for effective separation of dissimilar materials.

The feed rate is kept low enough to give opportunity to each grain for separation. The speed of the draper may be varied to simulate with the length of incline. The angle of inclination is adjusted to assure rolling or sliding of the desired lower fraction. To increase the capacity of the separator, number of belts may be used one above another in a single machine.

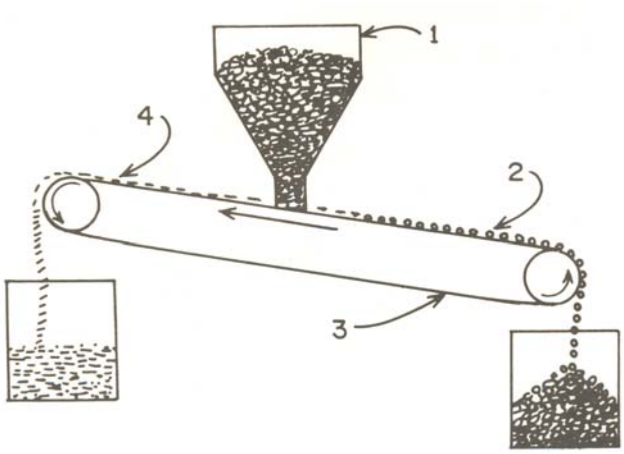

Figure 3.9: Inclined draper. 1) Feed hopper, 2) Round seed, 3) Canvas draper, 4) Flat seed/impurities.

3.5 SCREENS

The basic purpose of any screen is to separate a mixture of particles / items of different sizes into two distinct fractions. These fractions are, (1) the - underflow, the particles that pass through the screen, and (2) the overflow or oversize, the materials that are retained over the screen. A screen can be termed as **ideal** screen that separates the mixture in such a way that the largest particle of underflow is just smaller than screen opening, while the smallest particle of overflow is just larger than the screen opening. But in practice a given screen does not gives perfect separation as stated above, and is called **actual** screen. The underflow may contain material coarser than screen size, whereas the overflow may contain particles smaller than screen size as shown in Figure 3.10.

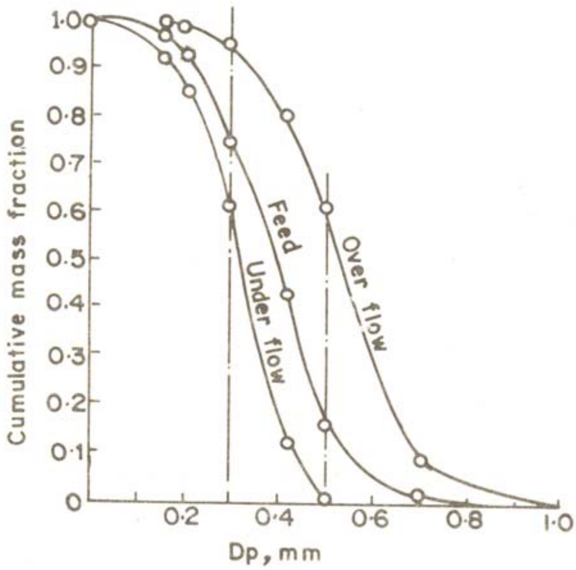

Figure 3.10: Graphical representation of various flows of a screen

In most screens the grain/ seed drops through the screen opening by gravity. Coarse grains drop quickly and easily through large opening in a stationary surface. With finer particles, the screening surface must be agitated in some way. The common ways are, (1) revolving a cylindrical screen about a horizontal axis and (2) shaking, gyrating or vibrating the flat screens.

3.5.1 Grizzly

The grizzly is a simple device consisting of a grid made up of metal bars, usually built on a slope, across which the material is passed. The path of material flow is parallel to the length of bars. The bars are usually so shaped that the top is wider than the bottom. The grizzly is often constructed in the form of a short endless belt so that the oversize is dumped over the end while the sized material passes through. In this case bar length is transverse to the path of materials. The grizzly is used for coarsest and rough separations.

3.5.2 Revolving Screen/Cylinder Sorter

Trommel or revolving screen is a cylinder that rotates about its longitudinal axis. The wall of the cylinder is made of perforated steel plate or sometime the cloth wire on a frame, through which the material falls as the screen rotates. The axis of cylinder is inclined along with the feed end to the discharge end. Sizing is achieved by having smallest opening screen at the feed end with progressively larger opening screens towards the discharge end. This type of sorter is simple and compact with no vibration problem. But the capacity of cylinder sorter is lesser than the vibrating screen of same size. Although it is an accurate sizer, it does not perform well with friable material or in cases where particle degradation is undesirable because tumbling produces some autogeneous grinding. The speed of rotation of the trommel is kept within the limit at which the material is carried from bottom to a distance equal to the radius of cylinder before it starts tumbling. The inclination of cylinder sorter for dry granular materials is kept up to 125 mm/m. Changing the speed of operation and the inclination of cylinder can change the capacity, bed depth and efficiency of these screens. Effective screening area (not the total surface of cylinder) is calculated by multiplying the length of cylinder by $\frac{1}{3}$ of the diameter.

3.5.3 Shaking Screen

Like the vibrating screen, shaker is a rectangular surface over which material moves down on an inclined plane. Motion of the screen is back and forth in a straight line. Although in some cases vibration is also given to the screen. Unlike the vibrating screen, the shaker does not tumble or turn material enroute except that some shaking screens have a step-off between surfaces having different size openings, so that there may be two or three tumbles over the full length of the screen. The shaker is widely used as combined screen and conveyor for many types of bulk material.

3.5.4 Rotary Screen

Rotary and gyratory screens are either circular or rectangular decked. Their motion is almost circular and affects sifting action. These are capable of accurate and complete separation of very fine sizes but their capacity is limited. These screens are further classified into two categories.

Gyratory Screens

This is generally a single decked machine. It has horizontal plane motion, which is circular at feed end and reciprocating at the discharge end. The drive mechanism is at the feed end and is either a V-belt or direct coupling. The shaft that imparts motion to the screen is a counter balanced eccentric. The shaft moves about a vertical axis. At the discharge end most rotary screens have linkage to the base frame, usually a self-aligning bearing. Gyratory screens operate with screening surface nearly horizontal.

Circular Screens

These are also rotary screens but their motion in horizontal plane is circular over the entire surface. Similar to the gyratory screens, the screening surface of circular screens is also little bit tilted for allowing the material to move over them.

3.5.5 Vibratory Screen

The vibratory screens are agitated by an eccentric unit. When materials to be separated are put on a vibratory screen, because of its vibration, materials are also agitated and separated during their transit over the screen. The eccentricity is usually of two types, (1) a shaft to which off centre weights are attached, and (2) a shaft that itself is eccentric or off centred. In the later case the eccentricity is balanced by a fly wheel for providing uniform vibration. Most vibrating screens are inclined downward from the feed end. Vibration is provided to the screen assembly only, and the body and other surrounding structure are isolated from vibration. Generally, upto three decks are used in vibrating screens. The capacity of vibrating screen is higher than any other similar sized screen and is very popular for cleaning and grading of granular agricultural products.

3.5.6 Horizontal Screen

Horizontal screens are special case of vibrating screen. These are designed for operation with low head room. They operate absolutely flat without the aid of gravity. All sorting, stratification and material transportation' take place on the strength of a sharp forward thrust which imparts motion to particles with a missile like trajectory, while the return stroke pulls the deck out from underneath the bed. Effectiveness of these screens is higher because material is kept on the screen for a longer period in comparison to inclined screens.

3.5.7 Other Screens

Various other types of screens used for cleaning and separation are listed below:

1. Rotex screens
2. Hummer screens
3. Circular vibrators
4. Symon's rod deck screens
5. Resonant vibrant screens
6. Centrifugal screens

3.5.8 Particle Motions in Separation Equipment

There are four different regime motions that can take place for the rigid particles placed on a moving trough depending upon the frequency of oscillation. The regimes are given below:

1. Particles stationary with respect to trough.

2. Particles slip during part of cycle and remain adherent to the trough during the rest of cycle.

3. As regime (2) with slip and gliding motion.

4. Particles purely in stick and slip motion.

Reciprocatory Motion

This can be either purely in horizontal plane or in an inclined plane. Depending upon the plane, the motion of particles is different as given below:

a) **Horizontal reciprocating motion:** This motion is obtained with an eccentric and a connecting rod and is usually in a path parallel to the horizontal projection of the path of material as it moves from inlet to outlet as shown in Figure 3.11. If the pitch (amplitude) is steep enough the motion has a substantial vertical component to the screen surface, which initiates sliding motion, and a large quantity of material can be moved.

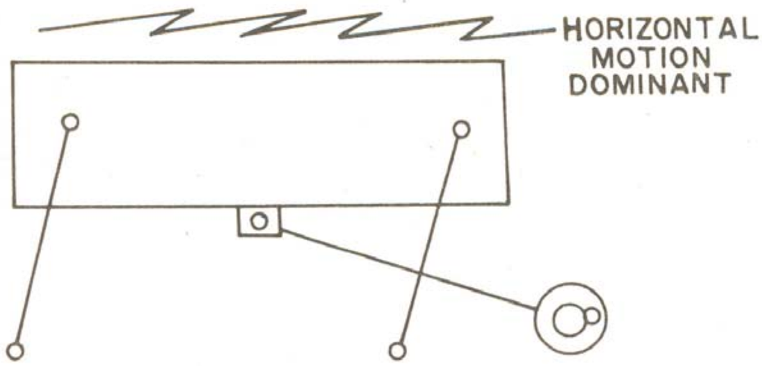

Figure 3.11: Horizontal reciprocating motion

b) **Inclined reciprocating motion:** The screen can be moved in an inclined plane reciprocatingly by eccentric and connecting rod unit (Figure 3.12). Such motion would have a vertical and horizontal components parallel to the horizontal projection of path of moving material. Combined horizontal and vertical motion can also be achieved by a rotary drive attached directly to the screen and operating in a vertical plane parallel to the path of the material flow. The horizontal motion is shown in Fig 3.13b and the vertical motion is shown in Fig 3.13a. The vertical component lifts the material from the screen surface for a fraction of time. The vertical motion can loosen the mass of material thus dislodging finer particles to settle at the bottom. The combined vertical and horizontal motion is also effective in moving large volume of material rapidly over the surface. This technique is useful in coarse sifting or where the screen openings are substantially larger than the particle size.

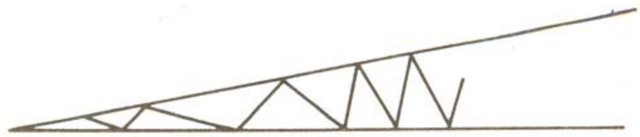

Figure 3.12: Inclined reciprocatory motion

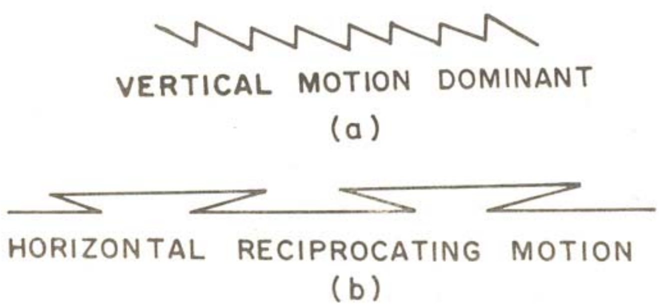

Figure 3.13: a) and b) Vertical and horizontal reciprocating motion

Combined Horizontal and Reciprocating Motion

In this, an eccentric drive is used to change the horizontal reciprocating motion into a rotary motion in a horizontal plane at inlet end, whereas the other end has reciprocating motion. In such arrangement there is a component of reciprocating motion both in parallel and perpendicular to the direction of material flow at inlet and this gradually changes into an elliptical motion at the central section of the screen and finally becomes a true reciprocating motion at the discharge end as shown in Figure 3.14. This section is effective in spreading the material to the sides of screen at the inlet end. The looping path of the material also presents more screen openings since particle moves not only back and forth but also from side to side across the screen surface.

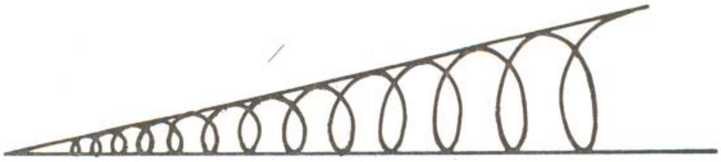

Figure 3.14: Combined horizontal and reciprocating motion

Horizontal Rotary Motion

If the screen surface is rotated in a horizontal plane the material will travel in the overlapping loop path during the passage from inlet to discharge end as shown in Figure 3.15. The multidirectional motion overcomes inter particle friction and maximum number of openings are available, thus screening can be accomplished on a relatively shorter distance. Rotary motion is provided by an off-centred weight attached to the screen through the frame and it is rotated at proper speed in horizontal plane. This imparts desired frequency and motion. The amplitude of movement is controlled by the magnitude and eccentricity of weight as well as the position, which affects its leverage on the screen. Sifters may also be driven by means of one or more directly connected eccentrics. The speed of eccentric and the amount of eccentricity control the frequency and amplitude of motion.

Figure 3.15: Horizontal rotary motion

3.5.9 Perforated Metal Screens

i) **Round openings:** The round openings in a perforated sheet metal screen are measured by the diameter (mm or in.) of the openings. For example, $\frac{1}{18}$ screen has round perforation of $\frac{1}{18}$ in. in diameter or 2 mm.

ii) **Oblong openings:** The oblong or slotted openings in a perforated sheet metal screen are designated by two dimensions; the width and length of the opening. While mentioning oblong openings the dimension of width is listed first then the length as 1.8 x 20 mm. Generally, the direction of the oblong opening is kept in the direction of the grain flow over the screen.

iii) **Triangular openings:** There are two different systems used to measure triangular perforations. The most commonly used system is to mention the length of each side of the triangle in mm, it means, 9 mm triangle has 3 equal sides each 9 mm long. The second system is to mention openings according to the diameter in mm that can be inscribed inside the triangle. This system is identified by the letter Vas 9V, l0V etc.

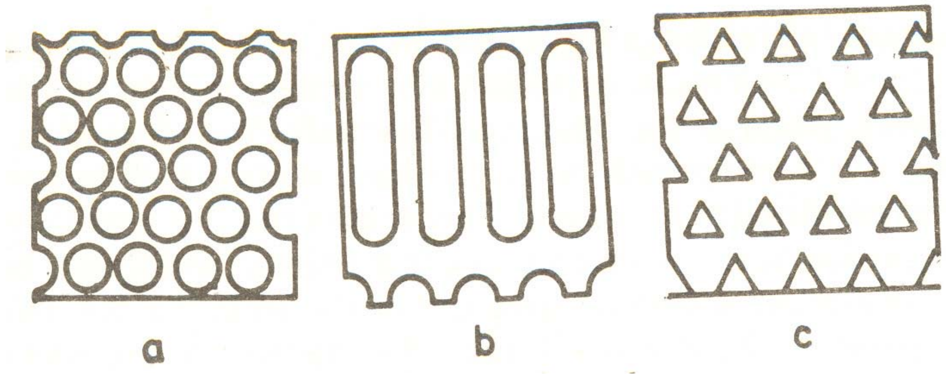

Figure 3.16: Perforated metal screens. a) Round holes, b) Oblong holes, c) Triangular holes

3.5.10 Wiremesh Screens

i) **Square mesh:** The square openings in wire mesh are measured by the number of openings per inch in each direction. A 9×9 screen has 9 openings per inch (Figure 3.17).

ii) **Rectangular mesh:** the rectangular openings in wire mesh screens are measured in the same way as square wire mesh screen. A 3×6 rectangular wire mesh screen will have 3 openings per inch in one direction and 6 openings per inch in the other direction. The rectangles formed by the wire mesh are parallel to the direction of grain flow (Figure 3.18).

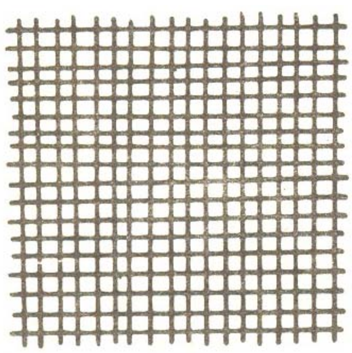

Figure 3.17: Wire mesh screen (square openings)

Figure 3.18: Wire mesh screen (rectangular openings)

3.6 EFFECTIVENESS AND EFFICIENCY OF SCREENS, CLEANERS, GRADERS AND SEPARATORS

The screen effectiveness may be defined as the ability of a screen in closely separating the feed into overflow and underflow according to its size. If the screen functions properly, all material 'O' would be in the overflow, while all the material 'U' would be in the underflow. The material balance in a screening operation can be derived as follows:

F = mass flow rate of feed, kg/hr.
O = mass flow rate of oversize, kg/hr.
U = mass flow rate of undersize, kg/hr.
m_f = mass fraction of material in feed.
m_o = mass fraction of material in overflow.
m_u = mass fraction of material in underflow.

The total quantity of feed is the sum of overflow and underflow

$$F = O + U$$

or,

$$Fm_f = Om_o + Um_u \tag{3.1}$$

Substituting $O = F - U$ and, $U = F - O$

$$\frac{O}{F} = \frac{m_f - m_u}{m_o - m_u} \tag{3.2}$$

and,
$$\frac{U}{F} = \frac{m_o - m_f}{m_o - m_u} \tag{3.3}$$

A common measure of screen effectiveness is the ratio of actual amount of oversize material in the overflow to the amount of oversize material entering with the feed.

Thus,

$$E_o = \frac{Om_o}{Fm_f} \tag{3.4}$$

and
$$E_u = \frac{U(1 - m_u)}{F(1 - m_f)} \tag{3.5}$$

Overall effectiveness $E = E_o x E_u = \dfrac{OUm_o(1 - m_u)}{F^2 m_f (1 - m_f)}$ (3.6)

Substituting the values of

$$\frac{O}{F} \text{ and } \frac{U}{F}, \; E = \frac{(m_f - m_u)(m_o - m_f)m_o(1 - m_u)}{(m_o - m_u)^2(1 - m_f)m_f} \tag{3.7}$$

The effectiveness of screening or cleaning efficiency for an air screen cleaner as suggested by Bureau of Indian Standards (BIS) is:

$$\text{Cleaning efficiency} = \frac{E(F - G)(E - F)(1 - G)}{F(E - G)^2(1 - F)} \tag{3.8}$$

where, E = fraction of clean seed at clean seed outlet

F = fraction of clean seed in feed

and G = fraction of clean seed at foreign matter outlet

3.7 LET US SUM UP

In this unit, we have learnt the basics of cleaning and grading operations as specialized forms of the separation process. The methods of cleaning and grading are based upon the properties of the materials. Various machines used for the cleaning and grading operations have been introduced. Screens are used very commonly in the separation processes and, therefore, various types of screens have been presented. The analysis of the screened material ultimately provides the basis of determining the cleaning and separation efficiency.

3.8 KEY WORDS

Cleaning : Generally means the removal of foreign and undesirable material from desired grains / products.

Grading : Refers to the classification of the cleaned product into various quality functions depending upon the commercial value and usage.

Cleaning efficiency : It is the ratio of the actual amount of impurities present in a mixture to the impurities obtained during the cleaning process.

Magnetic separator : Uses the magnetic properties of metallic contaminants to separate them from the produce.

Colour sorting : Uses the colour differences between the produce and the unwanted materials for sorting.

Pneumatic separation : Uses the property of terminal velocity to separate materials.

Screen effectiveness : It may be defined as the ability of a screen in closely separating the feed into overflow and underflow according to its size.

3.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Cleaning is defined as the method of removal of foreign or undesirable material from the foods whereas grading is defined as the classification of the cleaned produce into various fractions based on qualitative or quantitative parameters.

2. The five characteristics of foods that are used for its separation from unwanted materials include:

   i) Size
   ii) Shape
   iii) Specific gravity or weight
   iv) Surface roughness
   v) Aerodynamic properties

3. i) Air screen separator: Air blast in conjunction with screens is used to achieve the separation. Air blast helps to separate dust and lighter material before the remaining material is separated by screens.

   ii) Inclined draper: The mixture to be separated is fed over the centre of an inclined draper belt moving in upward direction. The round and smooth grains roll or slide down the draper at faster rate than the upward motion of the belt, and these are discharged in a hopper. The flat shape or rough surfaced particles are carried to the top of the inclined draper and dropped off into another hopper. The belts of different degrees of roughness may be used as a draper for separate materials.

   iii) Pneumatic separator: A blower is placed at the inlet of the separator. The mixture is suspended in the air and the different fractions get separated due to their differing terminal velocities.

   iv) Colour sortor: Colour or brightness is sensed by photocells. The photocell gives an output based on the colour/brightness variation and the product is separated if the output is below or above the threshold level.

Check Your Progress Exercise 2

1. Four types of screen that are available for cleaning and grading of foods are:

   a) Horizontal screen
   b) Rotary screen
   c) Grizzly screen
   d) Vibratory screen

Grizzly screen: Grizzly is made up of coarse grid of metal bars usually put on a slope. The path of material flow is parallel to the length of bars. The grizzly is used for rough and coarse separation like crushed stones, ores etc.

2. The screen effectiveness may be defined as the ability of a screen in closely separating the feed into overflow and underflow according to its size.

3. i) fraction of clean seed in feed = 100 - 6.5 = 93.5 or 0.935

ii) fraction of clean seed in clean grain outlet = 100 - 0.5 = 99.5 or 0.995

iii) fraction of clean seed in foreign matter outlets = $\frac{0.2}{100} + \frac{1}{100} + \frac{0.5}{100}$

$= 0.002 + 0.01 + 0.005$

$= 0.017.$

Then E = 0.0995, F = 0.935 and G = 0.017

$$\text{Therefore, Cleaning efficiency} = \frac{E(F-G)(E-F)(1-G)}{F(E-G)^2(1-F)}$$

$$= \frac{0.995(0.935-0.017)(0.995-0.935)(1-0.017)}{0.935(0.995-0.017)^2(1-0.935)}$$

$= 91.18\%$

4. i) Fraction of clean seed at clean seed out let, $E = \frac{246.5}{250.0} = 0.986$

ii) Fraction of clean seed in feed $F = \frac{231.25}{250.0} = 0.925$

iv) Fraction of clean seed in-foreign matter outlets $G = \frac{1.25}{250.0} + \frac{4.5}{250.0} + \frac{2.0}{250.0} = 0.031$

$$\text{Therefore, Cleaning efficiency} = \frac{E(F-G)(E-F)(1-G)}{F(E-G)^2(1-F)}$$

$$= \frac{0.986(0.925-0.031)(0.986-0.925)(1-0.031)}{0.925(0.986-0.031)^2(1-0.925)}$$

$= 82.34\%$

UNIT 4 STORAGE

Structure

4.0 OBJECTIVES

By the time you have studied this unit, you should be able to:

- explain the importance of storage;
- understand the type of damages take place during storage;
- identify the traditional and improved storage system being followed; and
- underline the types of losses take place.

4.1 INTRODUCTION

Horticultural crops not only provide us with nutritional and healthy foods, but also generate a cash income to growers. Appropriate production practices, careful harvesting and proper packaging, storage and transport contribute to the good produce quality. Once a crop is harvested it is impossible to improve its quality. The horticultural crops, because of their high moisture content are inherently more liable to deteriorate especially under tropical conditions. Moreover, they are biologically active and carry out transpiration, respiration, ripening and other biochemical activities, which deteriorate the quality of the produce.

Losses during post harvest operations due to improper storage and handling are enormous and can range from 10-40 percent. Post harvest losses can occur in the field, in packing areas, in storage, during transportation and in the wholesale and retail markets. Severe losses occur because of poor facilities, lack of know-how, poor management, market dysfunction or simply the carelessness of farmers. Losses can be reduced if proper storage process is adopted after harvesting.

Storage of fresh fruit and vegetable produce is an important economic aspect as it stabilizes prices, avoids glut in the market, and makes fruits and vegetables available in off season. Storage extends the usefulness and availability of vegetables and fruits since deterioration of the freshness is minimized. Storage also avoids wastage, relieves stress during main season and assures regular supply to the consumers with high quality fruits and vegetables. If not stored, the farmers have to sell the produce soon after harvest at throwaway prices in the market and they suffer great loss. Therefore, creation of storage facilities is essential for proper development of vegetable and fruit industries in the country.

4.2 STORAGE PARAMETERS FOR FRESH PRODUCE

Temperature and humidity management remains the most effective tool for extending the shelf life of fresh horticultural produce. The following table gives approximate storage life and recommended temperature and humidity levels for commercial storage.

Commodity	Temp (^{0}C)	Relative humidity (%)	Approximate storage life	Highest freezing point
Apples	-1 to 4	90-95	1-12 months	-1.5
Apricots	-0.5 to 0	90-95	1-3 weeks	-1.0
Bananas, green	13 to 14	90-95	-	-0.7
Blackberries	-0.5 to 0	90-95	2-3 days	-0.7
Blueberries	-0.5 to 0	90-95	2 weeks	-1.2
Cranberries	2 to 4	90-95	2-4 months	-0.8
Currants	-0.5 to 0	90-95	1-4 weeks	-1.0
Dewberries	-0.5 to 0	90-95	2-3 days	-1.2
Elderberries	-0.5 to 0	90-95	1-2 weeks	-

Turnip greens	0	95-100	10-14 days	-0.2

4.3 DAMAGES DURING STORAGE

Insect/ pests form one of the most important factors responsible for losses in agricultural production at various stages. Living organisms and the environment interact to bring about spoilage of stored products. Living organisms may be plants, insects, pests, man, animal, bacteria, fungi etc. High post-harvest losses are caused by the invasion of fungi, bacteria, insects and other organisms. Micro-organisms attack fresh produce easily and spread quickly, because the produce does not have much of a natural defence mechanism and has plenty of nutrients and moisture to support microbial growth. Control of Post harvest decay is becoming a more difficult task, because the number of pesticides available is falling rapidly as consumer concern for food safety increases.

It is estimated that 5 to 10% of the world food production is damaged by insects during storage. The estimated losses due to insects in India have been estimated to be around 3% of the country's production. Insects feed on the germ and endosperm causing loss in weight as well as nutrients. Besides, they cause contamination with their excreta and dead bodies. The damages can be grouped into, (1) direct damages, and (2) indirect damages.

4.4 DIRECT DAMAGES

i) Few insects consume germ as well as some endosperm and the others eat away both. It causes in loss of weight, loss of nutrients, loss of germination power, loss in gradation and consequently falls in market value.

ii) The contamination may be with the dead bodies, excreta, cast skin, odour.

iii) Structures and containers also get damaged by causing tunneling in wooden parts.

4.5 INDIRECT DAMAGES

i) It occurs when heat is created and migration of moisture takes place.

ii) It creates distribution of parasites to man. Few tape worms select stored grain insects as intermediate hosts.

4.6 SOURCES OF INFESTATION

Infestation sources are mainly five types, the field itself, infested bags, infested transport, infested godown and infested stocks.

Field: Insects may attack the crop in the field itself and same is brought to the storage centers where it continues attack. The infestation may be visible or invisible. Fumigation should be done immediately to check the growth of insects.

Infested bags: When new bags are used for packing the newly harvested produce, the insects hiding in the seams of the bags may attack the freshly harvested produce. The gunnies should be fumigated prior to packing the freshly harvested produced.

Infested transport: *DDVP* or Malathion should be sprayed on transport used for carrying the newly harvested produce. If the bullock cart or tractor trolley has been used as the transport for carrying infested stocks on the previous occasion, the left over insects may attack the fresh produce.

Infested godowns: The Godowns *should* be thoroughly cleaned and fumigated as insects present in the cracks and crevices of the wall or that hibernate in the structures, may emerge out and attack the produce.

Infested stocks: In case sound produce/stocks are brought to a storage unit godown where infested stocks are in storage, cross infestation may takes place.

4.7 STORAGE REQUIREMENTS

For successful storage the conditions needed is a better product, optimum required temperature, atmospheric humidity, right stage of maturity for the product to be stored, and freedom from diseases and other injury. There is rapid deterioration in injured or diseased products during storage, particularly under conditions favourable for the development of storage rots. The main storage principles are:

Relative Humidity

Transpiration rates (water loss from produce) are determine by the moisture content of the air, which is usually expressed as relative humidity. At high relative humidity, produce maintains saleable weight; appearance, nutritional quality and flavour, while wilting, softening and juiciness are reduced. Leafy vegetables with high surface-to-volume ratios; injured produce and immature fruits and vegetables have higher transpiration rates. High temperatures, low relative humidity and high air velocity increase transpiration rates.

Relative humidity needs to be monitored and controlled in storage. Control can be achieved by a variety of methods:

1. Operating a humidifier in the storage area.
2. Regulating air movement and ventilation in relation to storage room load.
3. Maintaining refrigeration coil temperature within the storage room.
4. Using moisture barriers in the insulation of the storage room or transport vehicle.
5. Wetting the storage room floor.
6. Using crushed ice to pack produce for shipment.
7. Sprinkling leafy vegetables, cool-season root vegetables and immature fruits and vegetables with water.

Temperature

Respiration and metabolic rates are directly related to room temperatures within a given range. The higher the rate of respiration, the faster the produce deteriorates. Lower temperatures reduce respiration rates and the ripening and senescence processes, which prolong the storage life of fruits and vegetables. Low temperatures also slow the growth of pathogenic fungi, which cause spoilage of fruits and vegetables in storage.

Producers should give special care and attention to proper storage conditions for produce with high to extremely high respiration rates, as these crops will deteriorate much more quickly.

It is impossible to make a single recommendation for cool storage of all fruits and vegetables. Climate of the area where the crop originated, the plant part, the season of harvest and crop maturity at harvest are important factors in determining the optimum temperature. A general rule for vegetables is that cool-season crops should be stored at cooler temperatures (0 to 1.7°C) and warm-season crops should be stored at warmer temperatures (7 to 13°C).

Freezing injury

Temperatures that are too low can be just as damaging as those too high. Freezing will occur in all commodities below 0^oC. Whether injury occurs depends on the commodity. Some can be repeatedly frozen and thawed without damage, while others are ruined by one freezing.

Injury from freezing temperatures can appear in plant tissues as loss of rigidity, softening and water soaking. Injury can be reduced if the produce is allowed to warm up slowly to optimum storage temperatures and if it is not handled during the thawing period. Injured produce should be marketed immediately, as freezing shortens its storage life.

Chilling injury

Fruits and vegetables that require warmer storage temperatures (4.5 to 13°C) can be damaged if they are subjected to near-freezing temperatures (0°C). Cooler temperatures interfere with normal metabolic processes. Injury symptoms are varied and often do not develop until the produce has been returned to warmer temperatures for several days. Besides physical damage, chilled produce is often more susceptible to disease infection.

Quality and condition of material

If the fruits are over ripe, they will rot and get spoilt early and quickly. If they are not ripe, the shrinkage can take place and make the product unfit for consumption. The flavour and aroma also changes leading to an appreciable reduction in sugar content and development of acidic (or off-flavour) flavours under storage or transit due to high content of acids. There is also a considerable change in original colour of skin, flesh, firmness, etc, and the product (fruit, root, etc.) becomes soft. The chemical changes continue to take place in immature product (fruits etc) after harvest. The starch content begins to decline and there is increase in sugar content. Also a slow inversion of sucrose to reducing sugars takes place.

Total nitrogen content almost remains the same, but the form of nitrogen is changed, that is, protein and nitrogen decrease compared to soluble nitrogen, fats, oils and waxes increase in storage but oil content increases faster compared to rest. Regarding enzymes the activity of oxidase remains almost constant while catalase activity becomes faster in storage. The mineral constituents also remain constant in the storage. The respiration rate is faster till the fruits are fully mature and finally over mature

Ethylene, a natural hormone produced by some fruits as they ripen, promotes additional ripening of produce exposed to it. The old age saying that one bad apple spoils the whole bushel is true. The damaged or diseased fruits produce high levels of ethylene and stimulate the other apples to ripen too quickly. As the fruits ripen, they become more susceptible to disease. Ethylene "producers" should not be stored with fruits, vegetables, or flowers that are sensitive to it. The result could be loss of quality, reduced shelf life and specific symptoms of injury. Ethylene producers include apples, apricots, avocados, ripening bananas, honeydew melons, papayas, peaches, pears, plums and tomatoes.

Advantages of storage

1. The wastage is avoided.
2. The stress during main season is relieved. It is easy to carry over the produce from periods of high production to periods of low production.
3. Distress selling during glut is offset which ensures remunerative price to the grower.
4. It assures regular supply to the consumer of high quality fresh fruit and vegetables throughout the year at reasonable prices.
5. It is easy to supply and hold regular trade of vegetables from the place of production to the place of consumption.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Why storage of fruit and vegetables are required?

....
....
....
....
....
....

2. What are the factors responsible for proper storage of fruits and vegetables?

....
....
....
....
....
....

3. What are the sources of Infestation in storage?

....
....
....
....
....

…………………………………………………………………………………

4. What are various injury occur to fruit and vegetables during storage?

4.8 STORAGE PROCESS

Most rapidly maturing tropical fruits, soft fruits of all kinds, and leafy vegetables with a large surface area tend to have high respiration rates and normally have short storage lives. In contrast, most temperate fruits, cured potatoes and onions, and vegetable root crops often have lower respiration rates and consequently longer storage lives. Respiration of all produce increases with temperature, which is why all storage techniques aim for a reduction in temperature of the produce.

- Lower storage temperature offers the additional advantage of greatly reduced water loss from the produce with reduced transpiration. High relative humidity slows down water loss and enhances storage life of the produce. Stores should ideally be maintained at the highest relative humidity (RH) that the crop could tolerate.

It is important to retain adequate circulation of the air within a store and around the produce to ensure efficient cooling. However, over-rapid air movement can drastically increase water loss by the produce. Therefore, the choice of the correct storage technique is governed by:

- the type of produce, its temperature from harvest and its respiration rate as well as produce quality;
- the storage temperature and humidity best suited to the produce and intended storage life, with implicating chill damage or unnecessary microbial spoilage;
- appropriateness to the market place and its requirements;
- and above all, the economics of the whole operation.

The different types of storages are (i) ground or pit storage; (ii) natural caves (iii) air-cooled storage; (iv) evaporative cooling (v) ventilated Storages (vi) improved Zero-energy Cool Chamber (vii) refrigerated storages; (viii) controlled atmosphere (CA), modified atmospheres (MA) or Hypo baric storage.

4.9 TRADITIONAL STORAGE STRUCTURES

Ground storage or pit storage

This method of storing vegetables is very commonly followed to the hills, especially in the snow-bound, arid dry template area, deep in the Himalayas. It is always available, simple, cheap, easily made and effective method practiced in some areas. The vegetables like potato, beetroot, carrot, radish, turnip, sweet potato and cabbage are piled in layers in the pit or trenches dug at a higher, well-drained place where water after snow melting does not accumulate. The pits may be pucca or kuchcha and lined with straw or leaves, the produce is then covered with straw followed by a thin layer of soil or prevents severe freezing injury. However, the trenches/ pits are also covered with wooden planks or tree branches and a small hole is kept for proper aeration at each corner.

Cellers and caves

The cellers are sophisticated type of below ground storage. These can be part of above ground buildings or underground rooms, where access is easy. The caves are also the natural shelters available under big rocks, which are used for storing vegetables. Good drainage, protection from rains or snowfall and natural hazards are essential. The performance of cellers is improved by providing controlled ventilation, openings for entrance of cold air and exit for warm air by conventional circulation whenever cooling is required. Though optimum temperatures generally cannot be retained. A good, cellar/cave will provide satisfactory storage for hard vegetables.

4.10 IMPROVED STORAGE STRUCTURES

Air-cooled storage

These are simply insulated structures, above ground and partly underground, which are cooled by circulation of colder monoxide air. When the temperature of the produce is of desired level and the temperature of the outside air is comparatively lower, air is circulated at the stock in the store mechanically through bottom inlet vents and top dampers. Fans if fitted are controlled manually or automatically. Air-cooled stores are cheap, easy to install and to operate, which are still widely used for the storage of potato and sweet potato, because both these products need relatively higher storage temperatures to avoid accumulation of sugar and chilling injury, respectively. Potatoes are commonly stored in bulk, piled in stores with air delivery even under the floor or at floor level and with sufficiently spaced air outlets.

Evaporative cooling

This utilizes the evaporation of water using heat of respiration of the vegetables. Water should be near or around the vegetables. Hot, dry air is thus cooled when it flows through a wet surface. The temperature may be reduced 1°-5°C and relative humidity increases by 20-30 percent depending on the prevailing temperature and relative humidity. The hotter and drier the surrounding microclimate, the greater the decrease in temperature and higher the increase in relative humidity. Evaporative cooling is very useful, especially in vegetables which easily wilt, shrivel, or soften because of low relative humidity. A few applications of evaporative cooling can be; (i) sprinkling fresh vegetables with water; (ii) keeping fresh vegetables in moist containers (earthen pots or jars); (iii) keeping vegetables inside drip coolers. There are locally developed structures with sides which could absorb water to be evaporated like jute sack or charcoal held on two sides by wire netting. Water is allowed to drip on the walls continuously

Ventilated Storages

Before the advent of refrigeration, ventilated storage was the only means available for storage of fresh produce and today is still in wide use all over the world for a variety of crops. Ventilated storage is ambient air storage, which makes use of controlled ventilation for cooling of the produce and maintenance of lower temperatures. It requires much lower capital investment and operating costs than refrigerated storage and is perfectly adequate for some crops and conditions where:

- Production is being stored for local use.
- The crops to be stored have a relatively long natural and storage life.
- Regular inspection is possible to remove spoilage centers.
- There is a significant difference between day and night temperatures, for example at altitudes above 1000 meters and most temperate latitudes.
- The need is for relatively short storage periods.
