A ventilated store may be used for onions, garlic, yams and sweet potato. However, ambient or ventilated storage for most other commodities is neither a practical nor an economic proposition because spoilage rates are simply too high. Some ventilated storage at the retail point may be an every day reality for small shopkeepers but larger ships and supermarkets, and most importers and wholesalers use refrigerated stores. Hanging onions and garlic are the simplest form of ventilated storage. In low temperature areas, storage houses for potatoes have air inlets at the sides near the floor level and outlets near the ceiling. These storage houses are found ventilated. The entry and exit of fresh air is mechanically controlled by thermostats, which also measure temperature inside and outside the room. Air is allowed to enter when it is cold and to leave when it is hot.

Improved Zero-energy Cool Chamber

A low cost zero-energy cool chamber, developed at IARI, New Delhi, recently is based on the principle of evaporating cooling. Raw material readily available is used for installing the short-term double-walled storage for fresh vegetables and fruits. The inside temperature of the chamber maintained is between 17-18°C (lower than outside) with relative humidity of about 90 percent during the peak summer months and also throughout the year. Such chambers are quite suitable for storage of fresh vegetables for short duration. Moreover, these are cheap, economical and within the reach of an average vegetable grower.

4.11 MODERN STORAGE STRUCTURES

Refrigerated Storage

Refrigerated storage is a well-established technology widely used for storing horticultural crops all over the world and is undoubtly the most effective method of prolonging the storage shelf life of fresh vegetables and reduces post-harvest losses by arresting metabolic breakdown of fungal deterioration of the commodity. Its application is limited only by cost and benefit considerations. Essentially, all crops can benefit by being stored at a suitable low temperature, which extends the storage life and preserves quality.

Many horticultural crops have storage life spans ranging from less than one month to several months when refrigerated. Therefore, refrigerated storage can be used continuously only if different crops with different harvesting seasons can share the facility. There are other important reasons why this method is not used in many tropical and sub-tropical countries, where refrigeration is needed most. The initial investment cost is too high and its energy consumption too large for many countries

When this method is to be used on a large-scale, the total value of the commodity should be considered. It may keep the commodity fresh for a long period but if it is not profitable to put in refrigerated store or even to rent a refrigerated room, then it is economical to use other methods of storage. Many tropical and subtropical fruit and vegetables are susceptible to low temperature injury. Due to the lack of money to erect and run cold storages by the individual farmer or farming community, the use of cold storages is limited. However, some well-to-do farmers and government agencies have created these facilities and are making use of them for storing high-priced vegetables. As the commodities have their optimum temperature and relative humidity at which they keep fresh for the longest possible time, therefore the cold room should have the desired temperature and relative humidity

The commodities should be cooled as soon as possible. Root and bulb vegetables should be properly cured before storing for better protection from micro-organisms. For better results, avoid mixing different commodities because most of the fruit & vegetables release ethylene on their ripening, thus leafy vegetables root and bulb vegetables and green fruit vegetables should not be mixed. Only good quality produce should be stored in different chambers. Storing of poor quality produce may not be economical in the long run. The faster the temperature of the vegetable is lowered down to the optimum, the longer is the shelf life of the commodity. Cooling vegetables and fruits immediately after harvesting before storage at the optimum temperature is an effective way to remove both field and product heat leading to slow deterioration. The fast cooling is called pre-cooling and is done by cooling in special pre-cooling chambers or equipment with air (room cooling)- with a much higher capacity to cool than a usual cold room. In lead water (hydro cooler), the vegetable is sprayed or immersed in ice water, here the cooling time is determined by the temperature difference between the water and the vegetable, the nature of the vegetable and type of container used.

4.12 CONTROLLED ATMOSPHERE (CA) AND MODIFIED ATMOSPHERE (MA) OR HYPERBOLIC STORAGE

The fresh horticultural produce consumes oxygen for respiration and releases carbon dioxide and ethylene. The ethylene further enhances ripening. Reducing oxygen and increasing carbon dioxide can increase the shelf life. In CA storage the levels of CO2, O2 and N2 in the storage room are monitored. CA storage combined with refrigeration reduces respiration and delays yellowing and quality changes. However the tolerance of individual varieties of horticultural crops needs to be considered.

Commercial application of CA storage is limited to only a few crops, apples and pears being the most popular ones. It is not used for other crops because the benefit is too slight to cover the cost. The technologies involved are complicated and sophisticated. The cost of building, facilities, and management for CA storage is considerably higher than for refrigerated storage. Therefore it should not be recommended for any crop without a thorough cost and benefit analysis.

While in modified atmosphere (MA), the respiration of the commodity is allowed to reach a desirable low level of O2 and high level of CO2 inside a closed chamber, container, plastic bag or plastic tent and the gases are maintained at those levels. Both the systems are best used with refrigerated storage involving manipulation of CO2, O2 and N2. Other gases such as ethylene, acetylene and propylene are also considered. MA differs from CA only in how precisely the addition of pressures is modified. CA storage is more precise than MA storage without basis or reducing the atmospheric gaseous pressure exerted on the stored valuable vegetables. The CA is seldom used commercially for vegetables, whereas the use of plastic bags to line containers or as retain packages is an example of modified atmosphere. For prevention of accumulation of too much CO2 and decrease of too much O2, a few holes can be made.

Danish cabbage has been reported to be kept better during four to five months at 0˚C in gas mixtures with 2.5 to 5% oxygen and carbon dioxide than it has in air. Mature green tomatoes may keep green for five to six weeks at 13˚C in an atmosphere at 3% oxygen with 97% nitrogen. After removal to air at 18˚ C, these tomatoes ripened normally with acceptable flavour. Mushroom in refrigerated storage has been kept better for short periods in atmosphere with 5 to 10% carbon dioxide than air.

All types of controlled atmosphere storage require frequent gas analysis to determine when aeration is required to add oxygen or to remove carbon dioxide

Therefore, the fresh fruit and vegetables storage can help in bringing lucrative returns to the vegetable growers and others dealing with the vegetable, trade, and supplying fresh, full of flavour, aroma and attractive vegetables from the different areas, in original state to the consumers. Thus, there is great potentiality of storing vegetables and fruits for both fresh and in processed form.

4.13 LOSSES IN STORAGE

Fruits, vegetables, root crops, ornamentals collectively called horticulture products are inherently perishable. Losses occur in the period between harvesting and consumption. The loss is generally a result of multiple causes and malpractices along the marketing chain.

About 20% of the damage to produce takes place during harvesting and field handling. The grower should ensure that the produce is harvested well, is kept in good condition till it is treated, kept in safe storage, consumed or sold.

If post harvest treatments are being used, they should start immediately after the produce has been harvested, to ensure that the essential freshness and nutritional values are maintained to the maximum.

Losses during post harvest operations due to improper storage and handling are enormous and can range from 10-40 percent. Post harvest losses can occur in the field, in packing areas, in storage, during transportation and in the wholesale and retail market. Severe losses occur because of poor facilities, lack of know-how, poor management, market dysfunction or simply the carelessness of farmers. Proper storage conditions, temperature and humidity are needed to lengthen the storage life and maintain quality once the crop has been cooled to the optimum storage temperature.

4.14 INDIAN STANDARDS

Various Indian standard are notified by Bureau of Indian Standards, New Delhi, these are given below.

Indian Standards on Storage and Marketing Structures for Agricultural Commodities

IS:

600-1955	Code of practice for construction of BUKHARI type rural food grain storage structure.
601-1955	Code of practice for construction of KOTHARI type food grain storage structure.

602-1955	Code of practice for construction for MORAI type rural food grain storage structure.
603-1960	Code of practice for construction of underground rural food grain storage structure.
607-1965	Code of practice for construction of bagged food grain storage structures suitable for trade and government purposes (revised).
609-1955	Code of practice for improvement of existing structures used oriented to be used for food grain storage.
631-1961	Aluminium food grain storage bins.
1497-1959	Layout for regulated market yards for agricultural commodities.
1787-1961	Layout for regulated market yards for fruits and vegetables.
1788-1961	Layout for regulated market yards for cattle.
2059-1962	Layout for regulated market yards for tobacco.
2821-1964	Thermo-sampler.
3453-1966	Code of practice for construction of hexagonal type concrete-cum-masonary bins for bulk storage of food grains.
5503(PartI)-1969	General requirements for silos for grain storage: Part I Constructional requirements.
5503(PartII)-1969	General requirements for silos for grain storage: Part II Grain handling equipment and accessories.
5606-1970	Steel bins for grain storage.
5826-1970	Constructional requirements for flat storage structures for grain (capacity above 200 tonnes).
6151 (Part I)-1971	Storage management code: Part I Terminology.
6151 (Part II)-1971	Storage management code: Part II General care in handling and storage of agricultural produce and inputs (superseding IS: 610-1955 and IS: 611-1955).
6201-1971	Constructional requirements for flat storage structures for grains (100-200 tonnes capacity).
6663-1972	Method for determination of angle of repose of grains.

Indian Standards on Storage Structures and Storage Management

IS:

607-1971	Code of practice for construction of bagged storage structures (second revision).

3453-1966	Code of practice for construction of hexagonal type concrete-cum-masonry bins bulk storage of food grains.
3503(Part I)-1969	General requirements for silos for grain storage: Part I Constructional requirements.
3503 (Part II)-1969	General requirements for silos for grain storage: Part II Grain handling equipment and accessories.
5606-1970	Steel bins for grain storage.
5826-1970	Constructional requirements for flat storage structures for grain (capacity above 200 tonnes).
6151 (Part I)-1971	Storage management code: Part I Terminology.
6151 (Part II)-1971	Storage management code: Part II General care in handling and storage of agricultural produce and inputs.
6151 (Part III)-1976	Storage management code: Part III Specific care in handling and storage of agriculture produce and inputs.
6201-1971	Constructional requirements for flat storage structures for grains (100 to 200 tonnes capacity).
6883-1972	Method for determination of angle of repose of grains.
7147 (Part I)-1973	Steel bins for domestic storage: Part I GHARELU KOTHI.
7247	Code of practice for fumigation of agricultural produce
7247 (Part I)-1973	Methyl bromide.
7247 (Part II)-1973	Ethylene dibromide.
7247 (Part III)-1973	Aluminium phosphate.
7247 (Part IV)-1975	Ethylene dichloride and carbon tetrachloride mixture.
7715-1975	Methods for testing suitability of bins for safe storage of food grains.
7716-1975	Method for testing efficacy of fumigation for disinfestations of grains in domestic bins.
8455-1977	Code of practice for construction of polyethylene embedded bins for bulk storage of food grains.

4.15 LET US SUM UP

Storage of fresh fruits and vegetables produced is an important economic aspect as it tends to stabilize prices to make use of higher production period to low production period, to avoid glut in the market, to make fruits and vegetables available in off season to earn better return. Due to improper storage, infestation takes place in the produce. Proper storage conditions should be maintained during storage. Various parameters such as relative humidity, temperature, etc. are important during storage. Storage can be made in various types of storage structures depending upon capacity and resources available. Important storage methods are Ground storage or pit storage, evaporating cooling, Ventilatated storage, Refrigerated storage, controlled and modified storage.

4.16 KEY WORDS

Temperature : It is the temperature of surroundings of fruits and vegetables stored.

Infestation : It refers to attack of insects and pests on stored product.

Refrigerated storage : In this condition storage temperature ranges from –1C to 10 C. Storage below –1 C is termed as freezer storage.

Airtight storage : Airtight storage refers to storage conditions in which air is minimum (.2% by volume) leading to arrest the insect infestation in dry grains.

4.17 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - Need for storage,
   - Storage conditions for optimum condition,
   - Suitable storage condition for various fruit and vegetables.

2. Your answer should include the following points:

   - various factors,
   - relative humidity,
   - temperature,
   - moisture content.

3. Your answer should include the following points:

   Various types of infestation takes places in storage, it include direct damages and indirect damages, all type of sources for infestation should be noted.

4. Your answer should include the following points:

   Various types of injury like freezing and chilling injury should be mentioned

Check Your Progress Exercise 2

1. Your answer should include the following points:

   - Ground storage or pit storage,
   - Cellers and caves.

2. Your answer should include the following points:

   - Air-cooled storage,
   - Evaporating cooling,
   - Ventilated storage,
   - Improved Zero-energy cool chamber.

Check Your Progress Exercise 3

1. Your answer should include the following points:

   Reasons for post harvest losses and factor effecting losses.

2. Your answer should include the following points:

   Percentage of losses taken place during post harvest operations.

UNIT 5 SIZE REDUCTION

Structure

5.0 OBJECTIVES

By the time you have studied this unit, you should be able to:

- understand the principles and methods of size reduction;
- describe various size reduction equipments and their efficiencies; and
- understand the importance of size reduction and able to decide the suitability of different machinery for various uses.

5.1 INTRODUCTION

The term *size reduction* is applied to all the ways in which particles of solids are cut or broken into smaller pieces. Throughout the process industries solids are reduced in size and shape by different methods for different purposes. Reduction in size is brought about by mechanical means without any change in chemical properties of the materials. During size reduction operation, chunks of large particles are crushed or reduced to workable size. In this process uniformity in size and shape of the individual particles of the resultant product is desirable, but difficult to attain. Size reduction sometimes leads to increased reactivity of solids, helps separation of unwanted ingredients and reduces the bulk of fibrous materials for easier handling.

5.2 PRINCIPLES OF SIZE REDUCTION

Crushers and grinders are the equipment mostly used for size reduction of agricultural products. An ideal size reducer should fulfil the following conditions, namely (1) large capacity, (2) should yield a pre-desired sized product or range of size, (3) small power input requirement per unit of product handled and (4) easy and trouble free operation. Usually the performance of any milling equipment is compared with respect to an ideal operation as standard. The characteristics of the actual equipment are compared with those of the ideal unit.

Size reduction results in the production of small particles which may be required either for larger surface area or because of their definite shape, size and number. Amount of power required to create smaller particles is one of the parameters of the efficiency of operation. Second parameter is the desired uniformity of size. The actual unit seldom yields a uniform sized product. Irrespective of uniformity of feed size the ground product consists of a mixture of various particle sizes. In some equipment there is a provision to control the magnitude of the largest particles like the hammer mill, but the fine size is beyond control. In some size reducing machine fines are minimized but they can not be eliminated altogether.

5.3 METHODS OF SIZE REDUCTION

Solids may be broken in many different ways, but only four of them are commonly used in size-reduction machines: (1) compression, (2) impact, (3) attrition or rubbing, and (4) cutting. A nutcracker, a hammer, a file, and a pair of scissors exemplify these four types of action. Sometimes size reduction results from the attrition of a particle by one or more other particles or from intense shear in the supporting fluid. In general, compression is used for coarse reduction of hard solids, to give relatively few fines; impact gives coarse, medium, or fine products; attrition yields very fine products from soft, nonabrasive materials. Cutting gives a definite particle size and sometimes a definite shape, with few or no fines.

Crushing: When an external force is applied on a material in excess of its strength, the material fails because of its rupture in many directions. The particles produced after crushing are irregular in shape and size. The type of material and method of force application affects the characteristics of new surfaces and particles. Food grain flour, grits and meal, ground feed for livestock are made by crushing process. Crushing is also used to extract oil from oilseeds and juice from sugarcane.

Impact: When a material is subjected to sudden blow of force in excess of its strength, it fails, like cracking of nut with the help of a hammer. Operation of hammer mill is an example of dynamic force application by impact method.

Shearing: It is a process of size reduction which combines cutting and crushing. The shearing units consist of a knife and a bar. If the edge of knife or shearing edge is thin enough and sharp, the size reduction process nears to that of cutting, whereas a thick and dull shearing edge performs like a crusher. In a good shearing unit the knife is usually thick enough to overcome the shock resulting from material hitting. In an ideal shearing unit the clearance between the bar and the knife should be as small as practicable and the knife as sharp and thin as possible.

Cutting: In this method, size reduction is accomplished by forcing a sharp and thin knife through the material. In the process minimum deformation and rupture of the material results and the new surface created is more or less undamaged. An ideal cutting device is a knife of excellent sharpness and it should be as thin as practicable. The size of vegetables and fruits are reduced by cutting.

5.4 SIZE REDUCTION EQUIPMENT

Size-reduction equipment is divided into crushers, grinders, ultrafine grinders, and cutting machines. *Crushers* do the heavy work of breaking large pieces of solid material into small lumps. A primary crusher operates on run-of-mine material, accepting anything that comes from the mine face and breaking it into 150 to 250 mm lumps. A secondary crusher reduces these lumps to particles perhaps 6 mm in size. *Grinders* reduce crushed feed to powder. The product from an intermediate grinder might pass a 4O mesh screen; most of the product from a fine grinder would pass a 200 mesh screen with a *74 μm* opening. An *ultrafine grinder* accepts feed particles no larger than 6 mm; the product size is typically 1 to 50 μm. *Cutters* give particles of definite size and shape, 2 to 10 mm in length.

The principal types of size-reduction machines are as follows:

A. Crushers (coarse and fine)

   1. Jaw crushers
   2. Gyratory crushers
   3. Crushing rolls

B. Grinders (intermediate and fine)

   1. Hammer mills; impactors
   2. Rolling-compression mills
      a) Bowl mills
      b) Roller mills
   3. Attrition mills
   4. Tumbling mills
      a) Rod mills
      b) Ball mills; pebble mills
      c) Tube mills; compartment mills

C. Ultrafine grinders

   1. Hammer mills with internal classification
   2. Fluid-energy mills
   3. Agitated mills
   4. Colloidal mills

D. Cutting machines

   1. Knife cutters; dicers; slitters

These machines do their work in distinctly different ways. Compression is the characteristic action of crushers. Grinders employ impact and attrition, sometimes combined with compression; ultrafine grinders operate principally by attrition. A cutting action is of course characteristic of cutters, dicers, and slitters.

5.4.1 Crushers

Crushers are slow-speed machines for coarse reduction of large quantities of solids. The main types are jaw crushers, gyratory crushers, smooth-roll crushers, and toothed-roll crushers. The first three operate by compression and can break large lumps of very hard materials, as in the primary and secondary reduction. Toothed-roll crushers tear the feed apart as well as crushing it; they handle softer feeds like coal, bone, and soft shale.

Jaw crushers: In a jaw crusher feed is admitted between two jaws, set to form a V open at the top. One jaw, the fixed, or anvil, jaw, is nearly vertical and does not move; the other, the swinging jaw, reciprocates in a horizontal plane. It makes an angle of 20° to 30° with the anvil jaw. An eccentric drives it so that it applies great compressive force to lumps caught between the jaws. The jaw faces are flat or slightly bulged; they may carry shallow horizontal grooves. Large lumps caught between the upper parts of the jaws are broken, drop into the narrower space below, and are recrushed the next time the jaws close. After sufficient reduction they drop out the bottom of the machine. The jaws open and close 250 to 400 times per minute.

The most common type of jaw crusher is illustrated in Figure 5.1. In this machine an eccentric drives a pitman connected to two toggle plates, one of which is pinned to the frame and the other to the swinging jaw. The pivot point is at the top of the movable jaw or above the top of the jaws on the centerline of the jaw opening. The greatest amount of motion is at the bottom of the V, which means that there is little tendency for a crusher of this kind to choke. Some machines with a 1.8 by 2 m feed opening can accept rocks 1.8 m in diameter and crush 1200 ton/h to a maximum product size of 250 mm. Smaller secondary crushers reduce the particle size of precrushed feed to 6 to 50 mm at much lower rates of throughput.

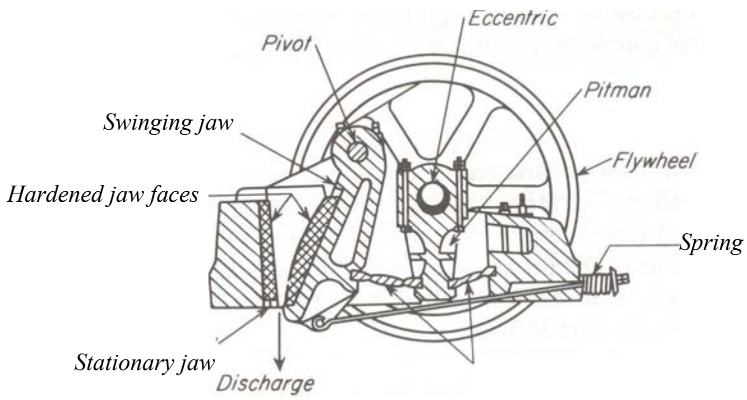

Figure 5.1: Jaw crusher

Gyratory crushers: A gyratory crusher may be looked upon as a jaw crusher with circular jaws, between which material is being crushed at some point at all times. A conical crushing head gyrates inside a funnel-shaped casing, open at the top. As shown in Figure 5.2, the crushing head is carried on a heavy shaft pivoted at the top of the machine. An eccentric drives the bottom end of the shaft. At any point on the periphery of the casing, therefore, the bottom of the crushing head moves toward, and then away from, the stationary wall. Solids caught in the V-shaped space between the head and the casing are broken and rebroken until they pass out the bottom. The crushing head is free to rotate on the shaft and turns slowly because of friction with the material being crushed.

The speed of the crushing head is typically 125 to 425 gyrations per minute. Because some part of the crushing head is working at all times, the discharge from a gyratory is continuous instead of intermittent as in a jaw crusher. The load on the motor is nearly uniform; less maintenance is required than with a jaw crusher; and the power requirement per ton of material crushed is smaller. The biggest gyratories handle up to 4500 ton/h. The capacity of a gyratory crusher varies with the jaw setting, the impact strength of the feed, and the speed of gyration of the machine. The capacity is almost independent of the compressive strength of the material being crushed.

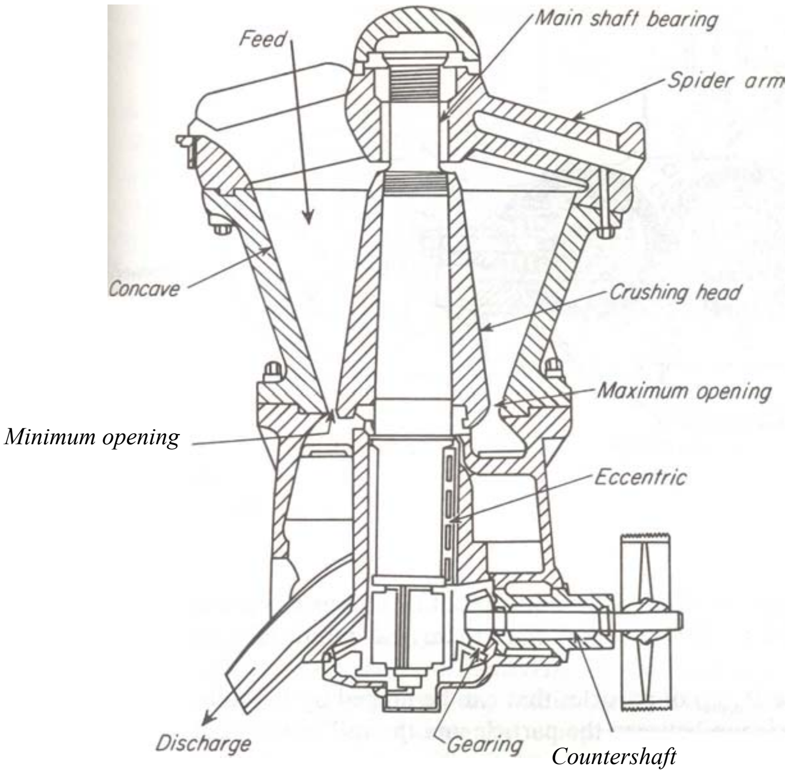

Figure 5.2: Gyratory crusher

Smooth-roll crushers: Two heavy smooth-faced metal rolls turning on parallel horizontal axes are the working elements of the smooth-roll crusher illustrated in Figure 5.3. Particles of feed caught between the rolls are broken in compression and drop out below. The rolls turn toward each other at the same speed. They have relatively narrow faces and are large in diameter so that they can "nip" moderately large lumps. Typical rolls are 600 mm in diameter with a 3OO mm face to 2000 mm in diameter with a 914 mm face. Roll speeds range from 50 to 300 r/min.

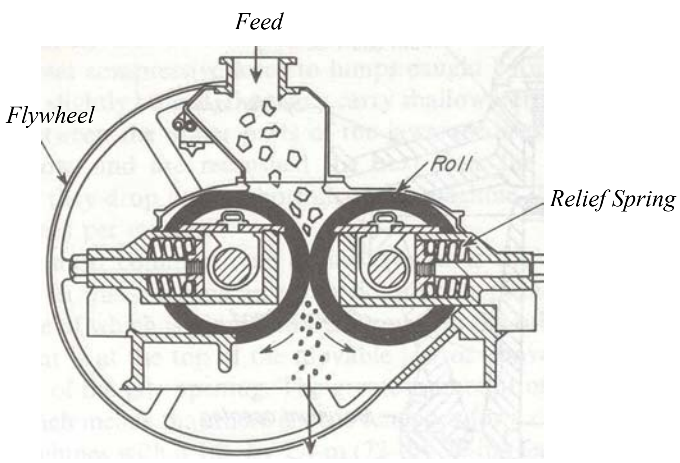

Figure 5.3: Smooth roll crusher

Smooth-roll crushers are secondary crushers, with feeds 12 to 75 mm in size and products 12 mm to about 1 mm. The limiting size $D_{p.max.}$ of particles that can be nipped by the rolls depends on the coefficient of friction between the particle and the roll surface, but in most cases it can be estimated from the simple relation.

$$D_{p.max.} = 0.04R + d5.1 \qquad (5.1)$$

where R = roll radius
d = half the width of the gap between the rolls.

The maximum size of the product is approximately equal to *2d.*

The particle size of the product depends on the spacing between the rolls, as does the capacity of a given machine. Smooth-roll crushers give few fines and virtually no oversize. They operate most effectively when set to give a reduction ratio of 3 or 4 to 1; that is, the maximum particle diameter of the product is one-third or one-fourth that of the feed. The forces exerted by the roll are very great, from 8700 to 70,000 N/cm of roll width. To allow unbreakable material to pass through without damaging the machine, at least one roll must be spring mounted.

Toothed-roll crushers: In many roll crushers the roll faces carry corrugations, breaker bars, or teeth. Such crushers may contain two rolls, as in smooth-roll crushers, or only one roll working against a stationary curved breaker plate. A single-roll toothed crusher is shown in Figure 5.4 Machines known as *disintegrators* contain two corrugated rolls turning at different speeds, which tear the feed apart, or a small high-speed roll with transverse breaker bars on its face turning toward a large slow-speed smooth roll. Some crushing rolls for coarse feeds carry heavy pyramidal teeth.

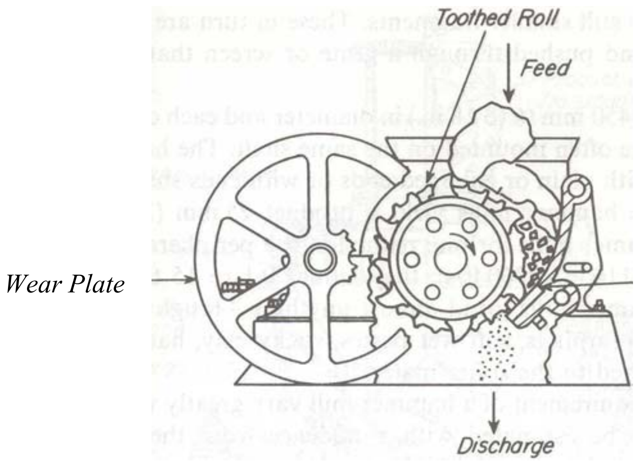

Figure 5.4: Single-roll tooth crusher

Other designs utilize a large number of thin-toothed disks that saw through slabs or sheets of material Toothed-roll crushers are much more versatile than smooth-roll crushers, within the limitation that they cannot handle very hard solids. They operate by compression, impact, and shear, not by compression alone, as do smooth-roll machines. They are not limited by the problem of nip inherent with smooth rolls and can therefore reduce much larger particles. Some heavy-duty toothed double-roll crushers are used for the primary reduction of coal and similar materials. The particle size of the feed to these machines may be as great as 500 mm; their capacity ranges up to 500 tons/h.

5.4.2 Grinders

The term *grinder* describes a variety of size-reduction machines for intermediate duty. The product from a crusher is often fed to a grinder, in which it is reduced to powder. The chief types of commercial grinders described in this section are hammer mills and impactors, rolling-compression machines, attrition mills, and tumbling mills.

Hammer mills and impactors: These mills all contain a high-speed rotor turning inside a cylindrical casing. The shaft is usually horizontal Feed dropped into the top of the casing is broken and falls out through a bottom opening. In a hammer mill the particles are broken by sets of swing hammers pinned to a rotor disk. A particle of feed entering the grinding zone cannot escape being struck by the hammers. It shatters into pieces, which fly against a stationary anvil plate inside the casing and break into still smaller fragments. These in turn are rubbed into powder by the hammers and pushed through a grate or screen that covers the discharge opening.

Several rotor disks, 150 to 450 mm in diameter and each carrying four to eight swing hammers, are often mounted on the same shaft. The hammers may be straight bars of metal with plain or enlarged ends or with ends sharpened to a cutting edge. Intermediate hammer mills yield a product 25 mm to 20-mesh in particle size. In hammer mills for fine reduction the peripheral speed of the hammer tips may reach 110 m/s; they reduce 0.1 to 15 ton/h to sizes finer than 200-mesh. Hammer mills grind almost anything tough fibrous solids like bark or leather, steel turnings, soft wet pastes, sticky clay, hard rock. For fine reduction they are limited to the softer materials.

The capacity and power requirement of a hammer mill vary greatly with the nature of the feed and cannot be estimated with confidence from theoretical considerations. They are best found from published information or better from small-scale or full-scale tests of the mill with a sample of the actual material to be ground. Commercial mills typically reduce 60 to 240 kg of solid per kilowatt hour of energy consumed.

An *impactor,* illustrated in Figure 5.5, resembles a heavy-duty hammer mill except that it contains no grate or screen. Particles are broken by impact alone, without the rubbing action characteristic of a hammer mill. Impactors are often primary-reduction machines, processing up to 600 ton/h. They give particles that are more nearly equidimensional (more "cubical") than the slab-shaped particles from a jaw crusher or gyratory crusher. The rotor in an impactor, as in many hammer mills, may be run in either direction to prolong the life of the hammers.

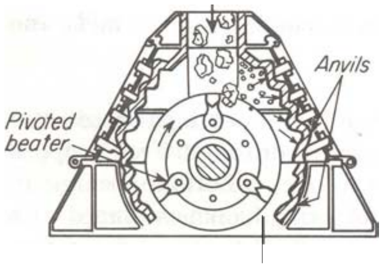

Figure 5.5: Impactor

Rolling-compression machines: In this kind of mill the solid particles are caught and crushed between a rolling member and the face of a ring or casing. The most common types are rolling-ring pulverizers, bowl mills, and roller mills. In the roller mill illustrated in Figure 5.6, vertical cylindrical rollers press outward with great force against a stationary anvil ring or bullring. They are driven at moderate speeds in a circular path. Plows lift the solid lumps from the floor of the mill and direct them between the ring and the rolls, where the reduction takes place. Product is swept out of the mill by a stream of air to a classifier separator, from which oversize particles are returned to the mill for further reduction. In a bowl mill and some roller mills the bowl or ring is driven; the rollers rotate on stationary axes, which may be vertical or horizontal. They pulverize up to 50 ton/h. When classification is used, the product may be as fine as 99 percent through a 200-mesh screen.

Attrition mills: In an attrition mill particles of soft solids are rubbed between the grooved flat faces of rotating circular disks. The axis of the disks is usually horizontal, sometimes vertical. In a single-runner mill one disk is stationary and one rotates; in a double-runner machine both disks are driven at high speed in opposite directions. Feed enters through an opening in the hub of one of the disks; it passes outward through the narrow gap between, the disks and discharges from the periphery into a stationary casing. The width of the gap, within limits, is adjustable. At least one grinding plate is spring mounted so that the disks can separate if unbreakable material gets into the mill. Mills with different patterns of grooves, corrugations, or teeth on the disks perform a variety of operations, including grinding, cracking, granulating, and shredding, and even some operations not related to size reduction at all, such as blending.

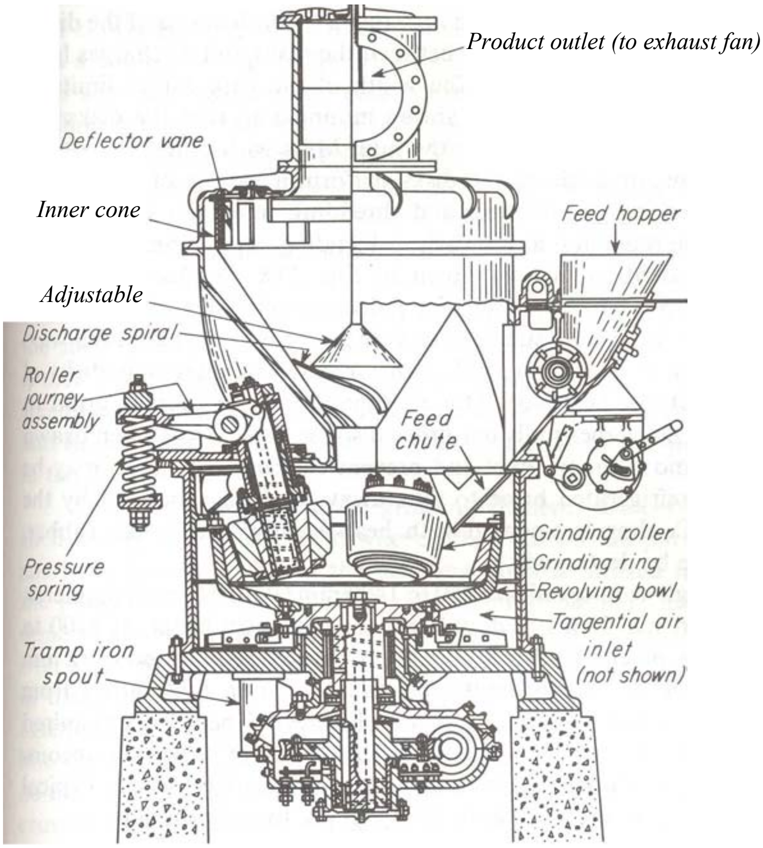

Figure 5.6: Roller mill

A single-runner attrition mill is shown in Figure 5.7. Single-runner mills contain disks of buhrstone or rock emery for reducing solids like spices, starch, insecticide powders, and carnauba wax. Metal disks are usually of white iron, although for corrosive materials disks of stainless steel are sometimes necessary. Double-runner mills, in general, grind to finer products than single-runner mills but process softer feeds. Air is often drawn through the mill to remove the product and prevent choking. The disks may be cooled with water or refrigerated brine to take away the heat generated by the reduction operation. Cooling is essential with heat-sensitive solids like spices, rubber which would otherwise be destroyed.

The disks of a single-runner mill are 250 to 1400 mm in diameter; turning at 350 to 700 r/min. Disks in double-runner mills turn faster, at 1200 to 7000 r/min. The feed is precrushed to a maximum particle size of about 12 mm and must enter at a uniform controlled rate. Attrition mills grind from 1 to 8 ton/h to products that will pass a 200-mesh screen. The energy required depends strongly on the nature of the feed and the degree of reduction accomplished and is much higher than in the mills and crushers described so far. Typical values are between 8 and 80 kWh (10 and 100 hp-h) per ton of product.

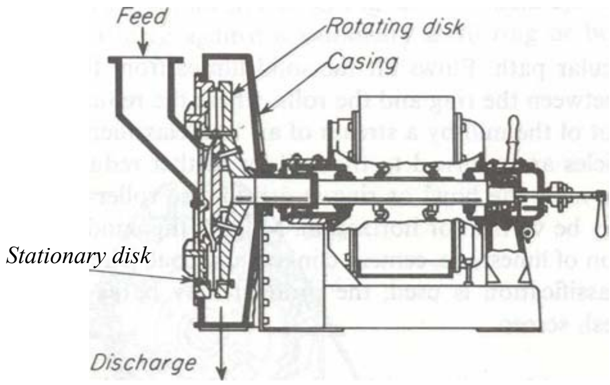

Figure 5.7: Attrition mill

Tumbling mills: A typical tumbling mill is shown in Figure 5.8. A cylindrical shell slowly turning about a horizontal axis and filled to about half its volume with a solid grinding medium forms a tumbling mill. The shell is usually steel, lined with high-carbon steel plate, porcelain, silica rock, or rubber. The grinding medium is metal rods in a rod mill, lengths of chain or balls of metal, rubber, or wood in a ball mill, flint pebbles or porcelain or zircon spheres in a pebble mill. For intermediate and fine reduction of abrasive materials tumbling mills are unequaled.

Unlike the mills previously discussed, all of which require continuous feed, tumbling mills may be continuous or batch. In a batch machine a measured quantity of the solid to be ground is loaded into the mill through an opening in the shell. The opening is then closed and the mill turned on for several hours; it is then stopped and the product is discharged. In a continuous mill the solid flows steadily through the revolving shell, entering at one end through a hollow trunnion and leaving at the other end through the trunnion or through peripheral openings in the shell.

In all tumbling mills, the grinding elements are carried up the side of the shell nearly to the top, from whence they fall on the particles underneath. The energy expended in lifting the grinding units is utilized in reducing the size of the particles. In some tumbling mills, as in a *rod mill,* much of the reduction is done by rolling compression and by attrition as the rods slide downward and roll over one another. The grinding rods are usually steel, 25 to 125 mm in diameter, with several sizes present at all times in any given mill. The rods extend the full length of the mill. They are sometimes kept from twisting out of line by conical ends on the shell. Rod mills are intermediate grinders, reducing a 20 mm feed to perhaps l0 mesh, often preparing the product from a crusher for final reduction in a ball mill. They yield a product with little oversize and a minimum of fines.

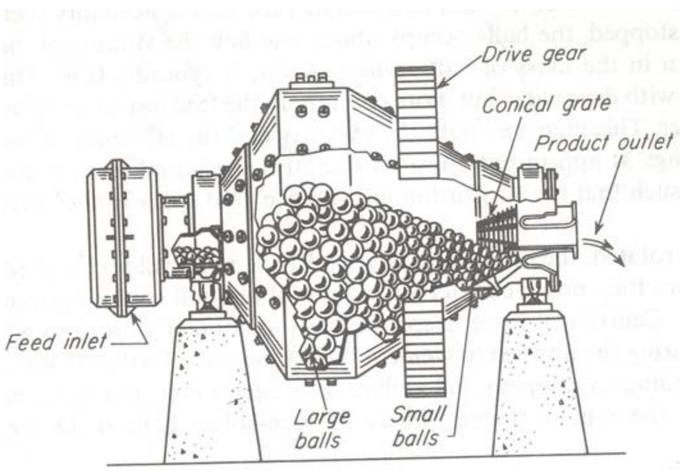

Figure 5.8: Conical ball mill

In a *ball mill* or *pebble mill* most of the reduction is done by impact as the balls or pebbles drop from near the top of the shell. In a large ball mill the shell might be 3 m in diameter and 4.25 m long. The balls are 25 to 125 mm in diameter; the pebbles in a pebble mill are 50 to 175 mm in size. A *tube mill* is a continuous mill with a long cylindrical shell, in which material is ground for 2 to 5 times as long as in the shorter ball mill. Tube mills are excellent for grinding to very fine powders in a single pass where the amount of energy consumed is not of primary importance. Putting slotted transverse partitions in a tube mill converts it into a *compartment mill.* One compartment may contain large balls, another small balls, and a third pebbles. This segregation of the grinding media into elements of different size and weight aids considerably in avoiding wasted work, for the large, heavy balls break only the large particles, without interference by the fines. The small, light balls fall only on small particles, not on large lumps they cannot break.

Segregation of the grinding units in a single chamber is a characteristic of the *conical ball mill* illustrated in Figure 5.8. Feed enters from the left through a 60° cone into the primary grinding zone, where the diameter of the shell is a maximum. Product leaves through the 30° cone to the right. A mill of this kind contains balls of different sizes, all of which wear and become smaller as the mill is operated. New large balls are added periodically. As the shell of such a mill rotates, the large balls move toward the point of maximum diameter, and the small balls migrate toward the discharge. The initial breaking of the feed particles, therefore, is done by the largest balls dropping the greatest distance; small particles are ground by small balls dropping a much smaller distance. The amount of energy expended is suited to the difficulty of the breaking operation, increasing the efficiency of the mill.

5.4.3 Ultrafine Grinders

Many commercial powders must contain particles averaging 1 to 20 μm in size, with substantially all particles passing a standard 325-mesh screen that has openings 44 μm wide. Mills that reduce solids to such fine particles are called *ultra fine grinders*. Ultrafine grinding of dry powder is done by grinders, such as high-speed hammer mills, provided with internal or external classification, and by fluid-energy or jet mills. Ultrafine wet grinding is done in agitated mills.

Classifying hammer mills: A set of swing hammers is held between two rotor disks, much as in a conventional hammer mill. In addition to the hammers the rotor shaft carries two fans, which draw air through the mill in the direction shown in the figure and discharge into ducts leading to collectors for the product. On the rotor disks are short radial vanes for separating oversize particles from those of acceptable size. In the grinding chamber the particles of solid are given a high rotational velocity. Coarse particles are concentrated along the wall of the chamber because of centrifugal force acting on them. The air stream carries finer particles inward from the grinding zone toward the shaft in the direction *AB*. The separator vanes tend to throw particles outward in the direction *BA*. Whether or not a given particle passes between the separator vanes and out to the discharge depends on which force predominates- the drag exerted by the air or the centrifugal force exerted by the vanes. Acceptably fine particles are carried through; particles that are too large are thrown back for further reduction in the grinding chamber. Changing the rotor speed or the size and number of the separator vanes varies the maximum particle size of the product. Mills of this kind reduce 1 or 2 ton/h to an average particle size of 1 to 20 μm, with an energy requirement of about 40 kWh/metric ton.

Fluid energy mills: In these mills the particles are suspended in a high - velocity gas stream. In some designs the gas flows in a circular or elliptical path; in others there are jets that oppose one another or vigorously agitate a fluidized bed. Some reduction occurs when the particles strike or rub against the walls of the confining chamber, but most of the reduction is believed to be caused by interparticle attrition. Internal classification keeps the larger particles in the mill until they are reduced to the desired size.

The suspending gas is usually compressed air or superheated steam, admitted at a pressure of 7 atm through energizing nozzles. The grinding chamber is an oval loop of pipe 25 to 200 mm in diameter and 1.2 to 2.4 m high. Feed enters near the bottom of the loop through a venturi injector. Classification of the ground particles takes place at the upper bend of the loop. As the gas stream flows around this bend at high speed, the coarser particles are thrown outward against the outer wall while the fines congregate at the inner wall. A discharge opening in the inner wall at this point leads to a cyclone separator and a bag collector for the product. The classification is aided by the complex pattern of swirl generated in the gas stream at the bend in the loop of pipe.2 Fluid-energy mills can accept feed particles as large as 12 mm but are more effective when the feed particles are no larger than 100-mesh. They reduce up to 1 ton/h of non sticky solid to particles averaging! to 10 11m in diameter, using 1 to 4 kg of steam or 6 to 9 kg of air per kilogram of product. Loop mills can process up to 6000 kg/h.

Agitated mills: For some ultrafine grinding operations, small batch non rotary mills containing a solid grinding medium are available. The medium consists of hard solid elements such as balls, pellets, or sand grains. These mills are vertical vessels 4 to 1200 L in capacity, filled with liquid in which the grinding medium is suspended. In some designs the charge is agitated with a multiarmed impeller; in others, used especially for grinding hard materials (such as silica or titanium dioxide), a reciprocating central column "vibrates" the vessel contents at about 20 Hz. A concentrated feed slurry is admitted at the top, and product (with some liquid) is withdrawn through a screen at the bottom. Agitated mills are especially useful in producing particles 1 */lm* in size or finer.

Colloid mills: In a colloid mill, intense fluid shear in a high-velocity stream is used to disperse particles or liquid droplets to form a stable suspension or emulsion. The final size of the particles or droplets is usually less than 5 */lm.* Often there is little actual size reduction in the mill; the principal action is the disruption of lightly bonded clusters or agglomerates. Syrups, milk, purees, ointments, paints, and greases are typical products processed in this way. Chemical additives are often useful for stablizing the dispersion.

In most colloid mills the feed liquid is pumped between closely spaced surfaces one of which is moving relative to the other at speeds of 50 m/s or *more.* In the mill shown schematically in Figure 5.9 the liquid passes through the narrow spaces between the disk-shaped rotor and the casing. The clearances are adjustable down to 25 */lm.* Often cooling is required to remove the heat generated. The capacities of colloid mills are relatively low, ranging from 2 or 3 L/min for small mills up to 440 L/min for the largest units.

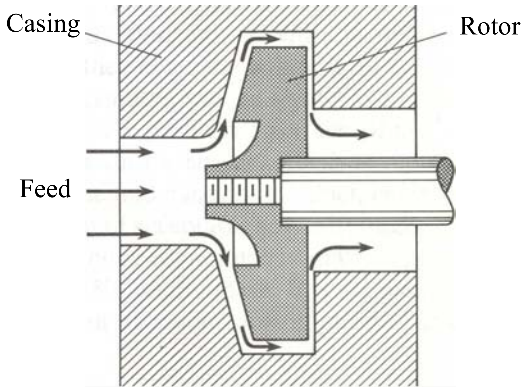

Figure 5.9: Schematic drawing of colloid mill

5.4.4 Cutting Machines

In some size-reduction problems the feed stocks are too tenacious or too resilient to be broken by compression, impact, or attrition. In other problems the feed must be reduced to particles of fixed dimensions. These requirements are met by devices that cut, chop, or tear the feed into a product with the desired characteristics. The sawtoothed crushers mentioned above do much of their work in this way. True cutting machines include rotary knife cutters and granulators. These devices find application in a variety of processes but are especially well adapted to size reduction problems in the manufacture of rubber and plastics.

Knife cutters: A rotary knife cutter, as shown in Figure 5.10, contains a horizontal rotor turning at 200 to 900 r/min in a cylindrical chamber. On the rotor are 2 to 12 flying knives with edges of tempered steel or stellite passing with close clearance over 1 to 7 stationary bed knives. Feed particles entering the chamber from above are cut several hundred times per minute and emerge at the bottom through a screen with 5 to 8 mm openings. Sometimes the flying knives are parallel with the bed knives; sometimes, depending on the properties of the feed, they cut at an angle. Rotary cutters and granulators are similar in design. A granulator yields more or less irregular pieces; a cutter may yield cubes, thin squares, or diamonds.

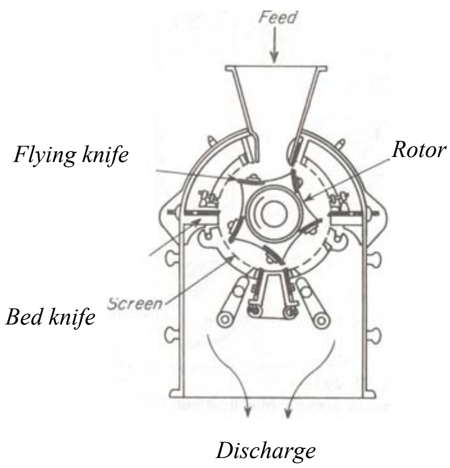

Figure 5.10: Rotary knife cutter

5.5 EFFICIENCY OF SIZE REDUCTION

The ratio of the surface energy created by crushing to the energy absorbed by the solid is the crushing efficiency, η_c . If e_s is the surface energy per unit area, in meter times kg force per square meter, and A_{wb} and A_{wa} are the areas per unit mass of product and feed, respectively, the energy absorbed by a unit mass of the material W_n is

$$W_n = \frac{e_s\left(A_{wb} - A_{wa}\right)}{\eta_c} \tag{5.2}$$

The surface energy created by fracture is small in comparison with the total mechanical energy stored in the material at the time of rupture, and most of the latter is converted into heat. Crushing efficiences are therefore low. Typical crushing efficiencies range between 0.06 and 1 percent.

The energy absorbed by the solid W_n is less than that fed to the machine. Part of the total energy input W is used to overcome friction in the bearings and other moving parts, and the rest is available for crushing. The ratio of the energy absorbed to the energy input is, η_m , the mechanical efficiency. Then, if W is the energy input,

$$W = \frac{W_n}{\eta_m} = \frac{e_s\left(A_{wb} - A_{wa}\right)}{\eta_m \eta_c} \tag{5.3}$$

5.6 ENERGY REQUIREMENT FOR SIZE REDUCTION

The cost of power is a major expense in crushing and grinding, so the factors that control this cost are important. During size reduction, the particles of feed material are first distorted and strained. The work necessary to strain them is stored temporarily in the solid as mechanical energy of stress, just as mechanical energy can be stored in a coiled spring. As additional force is applied to the stressed particles, they are distorted beyond their ultimate strength and suddenly rupture into fragments. New surface is generated. Since a unit area of solid has a definite amount of surface energy, the creation of new surface requires work, which is supplied by the release of energy of stress when the particle breaks. By conservation of energy, all energy of stress in excess of the new surface energy created must appear as heat.

If $\dot{m}$ is the feed rate, the power (P) required by the machine is

$$P = W\dot{m} = \frac{\dot{m}e_s\left(A_{wb} - A_{wa}\right)}{\eta_c \eta_m} \quad (5.4)$$

The average particle size of a mixture of particles is defined in several different ways. Probably the most used is the volume-surface mean diameter, $\overline{D}_s$, which is related to the specific surface area A_w. It is defined by the following equation

$$\overline{D}_s \equiv \frac{6}{\phi_s A_w \rho_p} \quad (5.5)$$

where ϕ_s, spehiricity of particle, and

ρ_p, density of particle, kg/m^3

Substituting A_{wb} and A_{wa} from equation 5.5 in 5.4 we get

$$P = \frac{6\dot{m}e_s}{\eta_c \eta_m \rho_p}\left(\frac{1}{\phi\overline{D}_{sb}} - \frac{1}{\phi\overline{D}_{sa}}\right) \quad (5.6)$$

where $\overline{D}_{sa}$ is mean diameter of feed, and

$\overline{D}_{sb}$ is mean diameter of product

5.6.1 Empirical Relationships

Rittinger's Law: A crushing law proposed by Rittinger in 1867 states that the work required in crushing is proportional to the new surface created. This "law," which is really no more than a hypothesis, is equivalent to the statement that the crushing efficiency, η_c, is constant and, for a given machine and feed material, is independent of the sizes of feed Md product. If the sphericities ϕ_a and ϕ_b are equal and the mechanical efficiency is constant, the various constants in equation (5.6) can be combined into a single constant K_r, known as Rittinger's constant and Rittinger's law written as

$$\frac{P}{\dot{m}} = K_r\left(\frac{1}{\overline{D}_{sb}} - \frac{1}{\overline{D}_{sa}}\right) \quad (5.7)$$

Kick's Law: In 1885 Kick proposed another "law," based on stress analysis of plastic deformation within the elastic limit, which states that the work required for crushing a given mass of material is constant for the same reduction ratio, that is, the ratio of the initial particle size to the final particle size. This leads to the relation

$$\frac{P}{\dot{m}} = K_k \ln\frac{\overline{D}_{sa}}{\overline{D}_{sb}} \quad (5.8)$$

where K_k is a constant.

A generalized relation for both cases is the differential equation

$$d\left(\frac{P}{\dot{m}}\right) = -\frac{Kd\overline{D}_s}{\left(\overline{D}_s\right)^n} \tag{5.9}$$

Solution of equation (5.9) for n = 1, 2 leads to Kick's law and Rittinger's law, respectively.

Both Kick's law and Rittinger's law have been shown to apply over limited ranges of particle size, provided K_k and K_r are determined experimentally by tests in a machine of the type to be used and with the material to be crushed. They thus have limited utility and are mainly of historical interest.

Bond Crushing Law and Work Index : A somewhat more realistic method of estimating ,the power required for crushing and grinding was proposed by Bond in 1952. Bond postulated that the work required to form particles of size D_p from very large feed is proportional to the square root of the surface-to-volume ratio of the product s_p/v_p and $s_p/v_p = 6/\phi_s D_p$, from which it follows that

$$\frac{P}{\dot{m}} = \frac{K_b}{\sqrt{D_p}} \tag{5.10}$$

where K_b is a constant that depends on the type of machine and on the material being crushed. This is equivalent to a solution of equation (5.9) with n = 1.5 and a feed of infinite size. To use equation (5.10), a work index W_i ; is defined as the gross energy requirement in kilowatt hours per ton of feed needed to reduce a very large feed to such a size that 80 percent of the product passes a $100\ \mu m$ screen. This definition leads to a relation between K_b and W_i . If D_p is in millimeters, P in kilowatts, and $\dot{m}$ in tons per hour,

$$K_b = \sqrt{100x10^{-3}}W_i = 0.3162W_i \tag{5.11}$$

If 80 percent of the feed passes a mesh size of D_{pa} millimeters and 80 percent of the product a mesh of D_{pb} millimeters, it follows from equations (5.10) and (5.11) that

$$\frac{P}{\dot{m}} = 0.3162W_i\left(\frac{1}{\sqrt{D_{pb}}} - \frac{1}{\sqrt{D_{pa}}}\right) \tag{5.12}$$

The work index includes the friction in the crusher, and the power given by equation (5.12) is gross power. For dry grinding, the power calculated from equation 5.12 is multiplied by 4/3.

5.7 SCREEN ANALYSIS

The most common method of classification of comminuted product is screening of the ground material through set of sieves, which is also called as ‘screen analysis.’ Bureau of Indian Standards has standardized mesh sizes for screen analysis. The size of openings of standard screens are given in Table 5.1

Table 5.1: Test sieves and their respective sizes

BSS	ASTM	BISS	Width of opening in inches	Width of opening in mm
	4	480	0.1870	4.750
5	6	340	0.1252	3.250

325	-	5	0.0017	0.044
350	325	-	-	0.044
400	-	4	0.0015	0.038

For determination of average particle size in ground food grains, a set of Bureau of Indian Standard Screens is arranged serially in a stack. For food grain flour analysis, a set of BIS sieves No. 100, 70, 50, 40, 30, 20 and 15 with pan and cover are taken. A sample of 250 g of ground product is dried in an oven to constant weight. The dried sample is placed in the topmost sieve and the set is placed on the sieve shaking machine and shaken for 5 minutes.

5.8 FINENESS MODULUS

The fineness modulus indicates the uniformity of grind in resultant product. It is determined by adding the weight fractions retained above each sieve and dividing the sum by 100. An example of determination of fineness modulus is presented below:

Determination of fineness modulus

BIS sieve No.	Weight of material retained	% material retained	Fineness modulus	Average particle size, mm
100	0.0	$7 \times 0.00 = 0.00$		
70	2.8	$6 \times 1.12 = 6.72$		
50	18.4	$5 \times 7.36 = 36.8$		
40	28.7	$4 \times 1.48 = 45.92$	$\frac{279.72}{100} = 2.7972$	$D = 0.135\,(1.366)^{F.M.} = 0.323$ mm
30	90.8	$3 \times 6.32 = 108.96$		
20	98.5	$2 \times 39.4 = 78.8$		
15	6.3	$1 \times 2.52 = 2.52$		
Pan	4.5	$0 \times 1.80 = 0.00$

5.9 LET US SUM UP

We will now recollect the major concepts presented in this unit. Size reduction is an important unit operation to facilitate the processing of food. The four methods of size reduction are crushing, impact, shearing and cutting. A large number of size reducing machines have been developed to meet the specific needs of the raw materials and the food processing. There are two basic parameters which are considered in the design or selection of a size reducing equipment. The first is the energy required for the size reduction. Finer the final particle size, larger will be the energy requirement. Rittinger, Kick, and Bond have proposed different empirical equations for estimating the energy requirement in size reduction. Effort should be made to use one or more of these equations to ensure that the size reduction operation is being carried out efficiently. The other basic parameter is the quality of the final product which is expressed in terms of particle size distribution. Fine mass modulus is computed from the particle size distribution obtained from screen analysis of the final product. It indicates the uniformity of the particle sizes in the final product.

5.10 KEY WORDS

Size reduction/ Comminution : The term *size reduction* is applied to all the ways in which particles of solids are cut or broken into smaller pieces.

Crushing : When an external force applied on a material excess of its strength, the material fails because of its rupture in many directions.

Impact : When a material is subjected to sudden blow of force in excess of its strength, it fails, like cracking of nut with the help of a hammer.

Shearing : It is a process of size reduction, which combines cutting and crushing. The shearing units consist of a knife and a bar.

Cutting : It is a method of size reduction accomplished by forcing a sharp and thin knife through the material.

Grinders : The term *grinder* describes a variety of size-reduction machines for intermediate duty. The product from a crusher is often fed to a grinder, in which it is reduced to powder.

Rittinger's law : A crushing law proposed by Rittinger in 1867 states that the work required in crushing is proportional to the new surface created.

Kick's law : It is based on stress analysis of plastic deformation within the elastic limit, which states that the work required for crushing a given mass of material is constant for the same reduction ratio, that is, the ratio of the initial particle size to the final particle size.

Crushing efficiency : It is the ratio of the actual and the theoretical energy requirement for crushing a material into a given size multiplied by 100.

Screen analysis : Is the most common method of classification of comminuted product obtained using screening of the ground material through set of sieves.

Fineness modulus : The fineness modulus indicates the uniformity of grind in resultant product. It is determined by adding the weight fractions retained above each sieve and dividing the sum by 100.

5.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. i) large capacity,
   ii) should yield a predesired sized product or range of size,
   iii) small power input requirement per unit of product handled, and
   iv) easy and trouble free operation.

2. Solids may be broken in many different ways, but only four of them are commonly used in size-reduction machines:

   i) *compression, e.g. a nutcracker:* Application of external force in excess of the material strength. The particles produced after crushing are irregular in shape and size.

   ii) *impact, e.g. a hammer:* Material is subjected to sudden blow of force in excess of its strength, which causes rupture.

   iii) *attrition, or rubbing, e.g. a file:* It combines cutting and crushing. The shearing units consist of a knife and a bar. If the edge of knife or shearing edge is thin enough and sharp, the size reduction process nears to that of cutting, whereas a thick and dull shearing edge performs like a crusher.

   iv) *cutting. e.g. a pair of scissors:* Accomplished by forcing a sharp and thin knife through the material. In the process minimum deformation and rupture of the material results and the new surface created is more or less undamaged.

3. Size-reduction equipment are: crushers, grinders, ultrafine grinders, and cutting machines.

   They work on the methods of compression, impact, attrition, or rubbing, and cutting. Compression is the characteristic action of crushers. Grinders employ impact and attrition, sometimes combined with compression; ultrafine grinders operate principally by attrition. A cutting action is of course characteristic of cutters, dicers, and slitters.

4. i) *Jaw crusher:* In a jaw crusher feed is admitted between two jaws, set to form a V open at the top. The jaws open and close 250 to 400 times per minute.

   ii) *Toothed roll crusher:* The particle size of the feed to these machines may be as great as 500 mm; their capacity ranges up to 500 tons/h.

   iii) *Hammer mill:* These mills all contain a high-speed rotor turning inside a cylindrical casing. The shaft is usually horizontal Feed dropped into the top of the casing is broken and falls out through a bottom opening.

   iv) *Attrition mill:* In an attrition mill particles of soft solids are rubbed between the grooved flat faces of rotating circular disks. The axis of the disks is usually horizontal, sometimes vertical.

   v) *Tumbling mill:* A cylindrical shell slowly turning about a horizontal axis and filled to about half its volume with a solid grinding medium forms a tumbling mill. For intermediate and fine reduction of abrasive materials tumbling mills are unequaled.

Check Your Progress Exercise 2

1. i) *Colloidal mill:* In a colloid mill, intense fluid shear in a high-velocity stream is used to disperse particles or liquid droplets to form a stable suspension or emulsion. The final size of the particles or droplets is usually less than 5 */lm.* The principal action is the disruption of lightly bonded clusters or agglomerates.

   ii) *Knife cutter:* A rotary knife cutter, as shown in Fig. 5.10, contains a horizontal rotor turning at 200 to 900 r/min in a cylindrical chamber. On the rotor are 2 to 12 flying knives with edges of tempered steel or stellite passing with close clearance over 1 to 7 stationary bed knives. Feed particles entering the chamber from above are cut several hundred times per minute and emerge at the bottom through a screen with 5 to 8 mm openings.

2. Crushing efficiency η_c is the ratio of the surface energy created by crushing to the energy absorbed by the solid whereas mechanical efficiency η_m is the ratio of the energy absorbed to the energy input to any size reduction machine.

3. 0.06 % and 1%.

4. Determination of flour sizes of two setting by sieve analysis:

i) Average particle size of product in I setting:

BIS sieve No.	Weight of material retained	% material retained	Fineness modulus	Average particle size, mm
100	0.0	$7 \times 0.00 = 0.00$	$\frac{295.08}{100} = 2.9508$	$D = 0.135\,(1.366)^{F.M.} = 0.338$ mm
70	10.1	$6 \times 4.04 = 24.24$		
50	16.7	$5 \times 6.68 = 33.40$		
40	36.0	$4 \times 14.40 = 57.60$		
30	83.2	$3 \times 33.28 = 99.84$		
20	96.0	$2 \times 38.40 = 76.80$		
15	8.0	$1 \times 3.20 = 3.20$		
Pan	0.0	$0 \times 0.00 = 0.00$		
		295.08		

ii) Average particle size of product in II setting:

BIS sieve No.	Weight of material retained	% material retained	Fineness modulus	Average particle size, mm
100	0.0	$7 \times 0.00 = 0.00$	$\frac{264.76}{100} = 2.6476$	$D = 0.135\,(1.366)^{F.M.} = 0.308$ mm
70	1.5	$6 \times 0.60 = 3.60$		
50	13.3	$5 \times 5.32 = 26.60$		
40	36.1	$4 \times 14.44 = 57.76$		
30	74.8	$3 \times 29.92 = 89.76$		
20	104.6	$2 \times 41.84 = 83.68$		
15	8.4	$1 \times 3.36 = 3.36$		
Pan	11.3	$0 \times 4.52 = 0.00$		
		264.76		

Determination of Power Requirements:

i) According to Rettinger's Law

$$\frac{P}{\dot{m}} = K_r\left(\frac{1}{\overline{D}_{sb}} - \frac{1}{\overline{D}_{sa}}\right)$$

or $$\frac{8.0}{0.2} = K_r\left(\frac{1}{0.338} - \frac{1}{4.33}\right)$$

or $40 = K_r \times 2.7276$

or $K_r = 14.6649$

Putting the value of K_r in II setting,

$$\frac{P}{0.2} = 14.6649\left(\frac{1}{0.308} - \frac{1}{4.33}\right)$$

or $\quad P = 0.2 \times 14.6649 \times 3.0157 = 8.85$ kW

ii) According to Kick's Law

$$\frac{P}{\dot{m}} = K_k \ln \frac{\overline{D}_{sa}}{\overline{D}_{sb}}$$

or $$\frac{8.0}{0.2} = K_k \ln \frac{4.33}{0.338}$$

or $\quad K_k = 15.6846$

Putting the value of K_k in II setting,

$$\frac{P}{0.2} = 15.6846 \ln \frac{4.33}{0.308}$$

or $\quad P = 8.2916$ kW

5. Screen analysis is a method of classification of comminuted product by screening of the ground material through set of standard sieves.

6. The fineness modulus is an indicator of the uniformity of grind in the resultant/final product. It is determined by adding the weight fractions retained above each sieve and dividing the sum by 100.

UNIT 6 MILLING

Structure

6.0 OBJECTIVES

By the time you have studied this unit, you should be able to:

- understand the principles and methods of milling;
- describe the various milling equipments, their efficiencies and relevant methods used for various products; and
- understand the importance of milling, their impact and utility and be able to decide the suitability of different machinery for various products.

6.1 INTRODUCTION

Milling is a general trade name, which normally means reduction of food material into various end products like meal, pulp, flour, splitted products etc. Milling includes cleaning, grading, separating, mixing, pearling, polishing, dehusking, size reduction etc. The meaning of the term milling varies with the commodity. For example, milling of wheat refers to a grinding operation to produce flour, whereas in rice industry, milling refers to overall operations in a rice mill i.e. cleaning, dehuskng, paddy separation, bran removal and grading of milled rice. Milling also refers to extraction of juice, oil or separation of fibre etc.

Most of the agricultural products are in solid form which is generally difficult to handle, compared to liquid and gases. In processing, solids appear in many forms as large irregular pieces or finely divided powders. These particles may be hard and abrasive, soft, brittle, dusty or sticky and plastic. According to the forms of solids, means are to be found to manipulate them into end products and possibly to improve their handling and processing characteristics.

6.2 METHODS OF MILLING

The methods of milling are similar to those discussed in the previous unit on size reduction. However, in case of fruits and vegetables, milling may refer to the juice extraction, cutting for different purposes, etc. For oilseeds it is the expression of oil by compression, solvent extraction etc. and for grains it will vary from one grain to another, for example rice milling would mean hulling, shelling, polishing etc. whereas for wheat it is simple grinding and separation into different fractions and for pulses the dehulling and splitting of the grains.

6.3 MILLING EQUIPMENT

6.3.1 Milling Equipment for Solid Foods

Size reduction of fibrous foods

Most fruits and vegetables fall into the general category of 'fibrous' foods. Fruits and vegetables have an inherently firmer texture and are cut at ambient or chill temperatures. There are five main types of size reduction equipment, classified in order of decreasing particle size, as follows.

1. Slicing equipment consists of rotating or reciprocating blades which cut the food as it passes beneath. In some designs food (Figure 6.1) is held against the blades by centrifugal force. In other (for slicing meats) the food is held on a carriage as it travels across the blade. Harder fruits such as apples are simultaneously sliced and de-cored as they are forced over stationary knives fitted inside a tube. In a similar design (the hydro cutter) foods are conveyed by water at high speed over fixed blades.

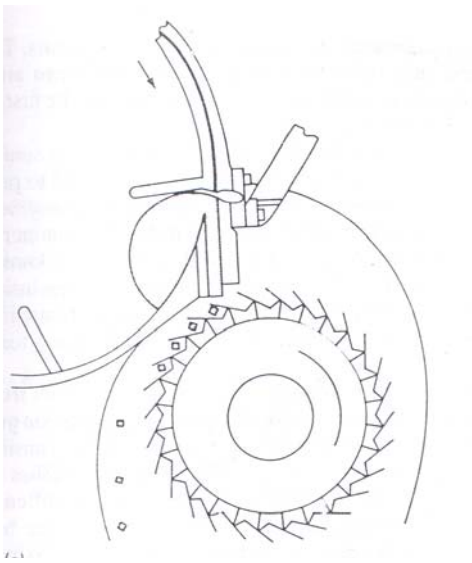

Figure 6.1: Slicing equipment

2. Dicing equipment is for vegetables, fruits and meats. The food is first sliced and then cut into strips by rotating blades. The strips are fed to a second set a rotating knives which operate at right angles to the first set and cut the strips into cubes (Figure 6.2).

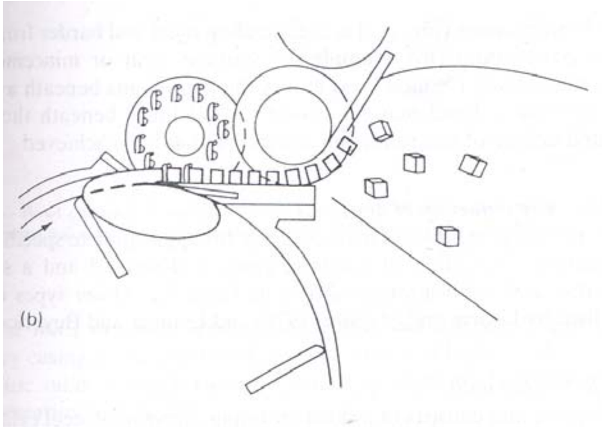

Figure 6.2: Dicing equipment

3. *Flaking equipment* for flaked nuts, fish or meat is similar to slicing equipment. Adjustment of the blade type and spacing is used to produce the flakes.

4. *Shredding equipment.* Typical equipment is a modified hammer mill in which knives are used instead of hammers to produce a flailing or cutting action. A second type of shredder is known as the *squirrel cage disintegrator.* Here two concentric cylindrical cages inside a casing are fitted with knife blades along their length. The two cages rotate in opposite directions and food is subjected to powerful shearing and cutting forces as it passes between them.

5. *Pulping equipment* is used for juice extraction from fruits or vegetables and for pureed and pulped meats. A combination of compression and shearing forces is used in each type of equipment. A rotary grape crusher consists of a cylindrical metal screen fitted internally with high-speed rotating brushes or paddles. Grapes are heated if necessary to soften the tissues, and pulp is forced through the perforations of the screen by the brushes. The size of the perforations determines the fineness of the pulp. Skins, stalks and seeds discarded from the end of the screen. Other types of pulper, including roller presses and screw presses are used for juice expression.

   A *bowl chopper* (Figure 6.3) is used to chop meat and harder fruits and vegetabes into a coarse pulp (for example for sausage meat or mincemeat preserve). A horizontal, slowly rotating bowl moves the ingredients beneath a set of high-speed rotating blades. Food may be passed several times beneath the knives until required degree of size reduction and mixing has been achieved.

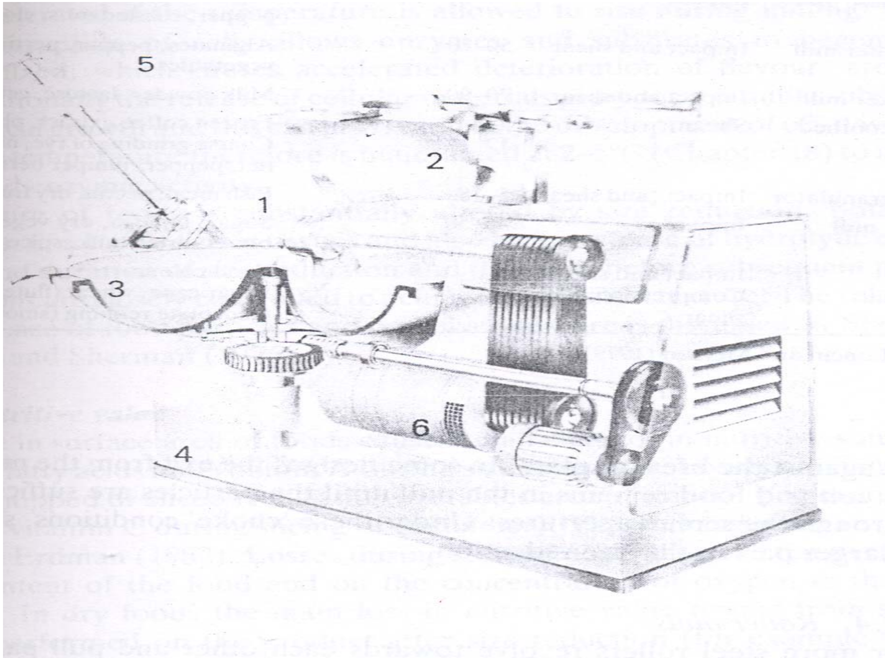

Figure 6.3: Bowl chopper: 1) Cutting blades, 2) Cover, 3) Rotating cutter bowl, 4) Casings; 5) Rotating unloader disc; 6) Main motor drive

Size reduction of dry foods

There are a large number of mills available for application to specific types of food.

Ball mills

This type of mill consists of a slowly rotating, horizontal steel cylinder which is half filled with steel balls 2.5-15cm in diameter. At low speeds or when small balls are used, shearing forces predominate. With larger balls or at higher speeds, impact forces become more important. A modification of the ball mill named the *rod mill* has rod instead of balls to overcome problems associated with the balls sticking in adhesive foods.

Disc mills

There are a large number of designs of disc mill. Each type employs shearing forces for fine grinding or shearing and impact forces for coarser grinding. For example,

1. single-disc mills in which food passes through an adjustable gap between a stationary casing and a grooved disc which rotates at high speed,

2. double-disc mills in which two discs rotate in opposite directions to produce greater shearing forces, and

3. pin-and-disc mills which have intermeshing pins fixed either to the single disc and casing or to double discs. (Figure 6.4)

These improve the effectiveness of milling by creating additional impact and shearing forces.

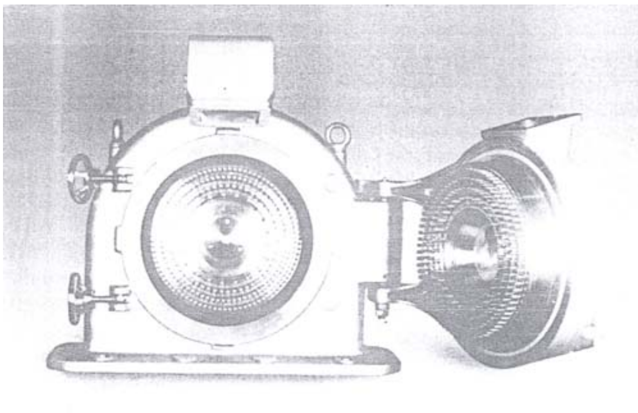

Figure 6.4: Pin and disc mill

Hammer mills

A horizontal cylindrical chamber is lined with a toughened steel breaker plate. A high-speed rotor inside the chamber is fitted with hammers along its length (Figure 6.5). In operation, food is disintegrated mainly by impact as the hammers drive it against the breaker plate. In some designs the exit from the mill is restricted by a screen and food remains in the mill until the particles are sufficiently small do pass through the screen apertures. Under these ‘choke’ conditions; shearing forces play a larger part in the size reduction.

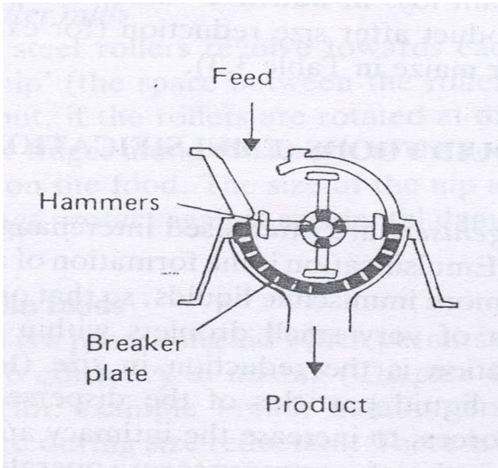

Figure 6.5: Hammer mill

Roller mills

Two or more steel rollers revolve towards each other and pull particles of food through the ‘nip’ (the space between the rollers) (Figure 6.6). The main force is compression but, if the rollers are rotated at different speeds, or if the rollers are fluted (shallow ridges along the length of the roller), there is an additional shearing force exerted on the food. The size of the nip is adjustable for different foods and overload springs protect against accidental damage from metal or stones.

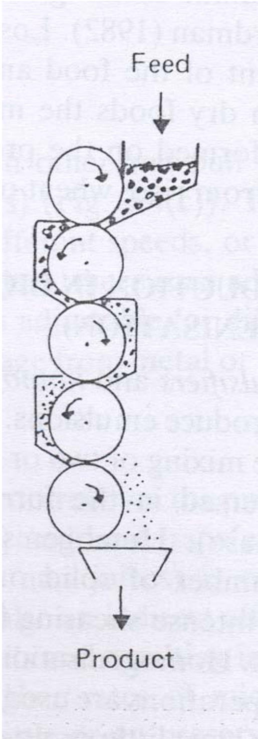

Figure 6.6: Roller mill

6.3.2 Milling Equipment for Liquid Foods (Emulsification and Homogenisation)

The terms emulsifiers and homogenisers are often used interchangeably for equipment used to produce emulsions. Emulsification is the formation of a stable emulsion by the intimate mixing of two or more immiscible liquids, so that one (the dispersed phase) is dispersed in the form of very small droplets within the second (the continuous phase). Homogenisation is the reduction in size (to 0.5-3µm) and increase in number of solid or liquid particles of the dispersed phase, by the application of intense shearing forces, to increase the intimacy and stability of the two substances. Homogenisation is therefore a more severe operation than emulsification. Both operations are used to change the functional properties or eating quality of foods. They have little or no effect on nutritional value or shelf life.

The four main types of homogenizer are as follows:

1. high-speed mixers;
2. pressure homogenisers;
3. colloid mills;
4. ultrasonic homogenisers.

High-speed mixers

Turbine or propeller-type high-speed mixers are used to pre-mix emulsions of low-viscosity liquids. They operate by shearing action on the food at the edges and tips of the blades.

Pressure homogenisers

These consist of a high-pressure pump, operating at 10,000-70,000kPa, which is fitted with a homogenizing valve on the discharge side. An example of one of the many different designs of valve is shown in Figure 6.7. When liquid is pumped through the small, adjustable gap (300μm) between the valve and the valve seat, the high pressure results in a high liquid velocity (8400 ms^{-1}). There is then an almost instantaneous drop in velocity as the liquid emerges from the valve. These extreme conditions of turbulence produce powerful shearing force. The collapse of an air bubbles (termed *cavitation)* and impact forces created in some valves by placing a hard surface (a *breaker ring)* in the path of the liquid further reduce the globule size. In some foods (for example milk products) there may be inadequate distribution of the emulsifying agent over the newly formed surfaces, which causes fat globules to clump together. A second similar valve is then used to break up the clusters of globules. Pressure homogenisers are widely used before pasteurisation and ultrahigh-temperature sterilisation of milk, and in the production of salad creams, ice cream and some sauces.

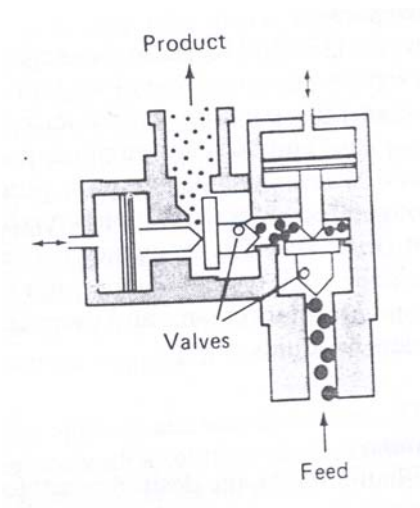

Figure 6.7: Hydraulic two-stage pressure homogenizing valve

Colloidal mills

These homogenisers are essentially disc mills. The small (0.05-1.3 mm) gap between a vertical disc which rotates at 3000-15000 rev min^{-1}, and a similar-sized stationary disc creates high shearing forces. They are more effective than pressure homogenisers for high-viscosity liquids, but with intermediate-viscosity liquids they tend to produce larger droplet sizes than pressure homagenisers do. Numerous designs of disc, including flat, corrugated and conical shapes, are available for different applications. Modifications of this design include the use of two counter-rotating discs or intermeshing pegs on the surface of the discs to increase the shearing action. For highly viscous foods (for example peanut butter, meat or fish pastes) the discs may be mounted horizontally (the *paste mill).* The greater friction created in viscous foods may require these mills to be cooled by recirculating water.

Ultrasonic homogenisers

High-frequency sound waves (18-30 kHz) cause alternate cycles of comprssion and tension in low-viscosity liquids and cavitation of air bubbles, to form an emulsion with droplet sizes of 1-2μm. In. operation, the dispersed phase of an emulsion is added to the continuous phase and both are pumped through the homogenisers at pressures of 340-1400kPa. The ultrasonic energy is produced by a metal blade, which vibrates at its resonant frequency. Vibration is produced either electrically or by the liquid movement (Figure 6.8). The frequency is controlled by adjusting the clamping position of the blade. This type of homogeniser is used for the production of salad creams, ice cream, synthetic creams and essential oil emulsions. It is also used for dispersing powders in liquids.

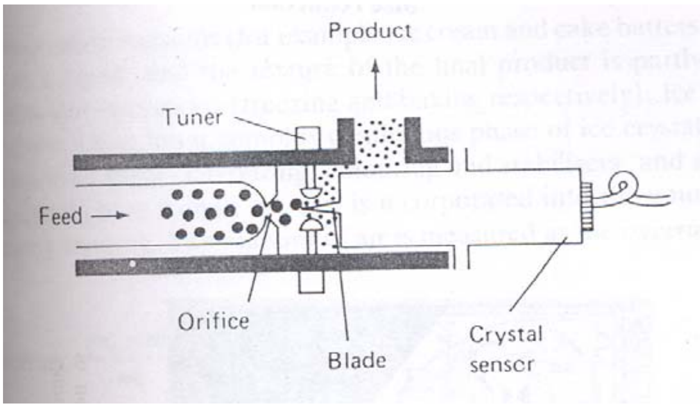

Figure 6.8: Ultrasonic homogenizer

6.4 EFFICIENCY OF MILLING

To achieve good results from any milling machine the followings should be given due care, (1) feed should be *of* proper size and feeding rate should be uniform, (2) hard or unbreakable material is not-allowed to enter the mill, (3) after grinding the product is removed as soon as possible, and (4) there should be some arrangement to remove the heat generated during milling operation.

Determination of power requirement for a particular grinding job is difficult. The exact amount of power requirement depends on type of material, moisture content of feed, material feed rate, type and condition of mill, product particle size requirement, nature of abrasive surface etc.

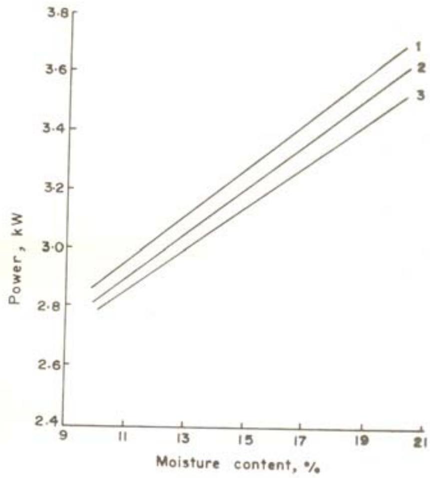

Figure 6.9: Effect of moisture content on power requirement: 1) 2800 rpm, 2) 2680 rpm, 3) 2560 rpm.

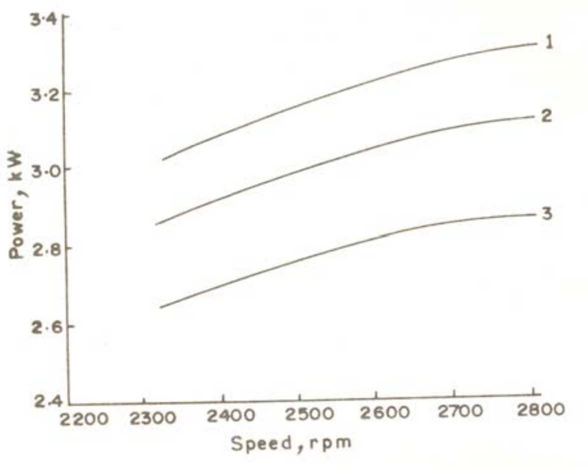

Figure 6.10: Effect of speed of operation on power requirement: 1) 17.9% moisture content, 2) 15% moisture content, 3) 11.8% moisture content.

Grains at higher moisture content are more difficult to grind than dry grains. The effect of moisture upon the power requirement for grinding of wheat with swinging hammer mill is shown in Figure 6.9. It was also found that fibrous materials require more power for grinding than non-fibrous material. At increased rotational speed the power requirement also increases (Figure 6.10).

Energy consumption: In size reduction of solids, bulk of the energy input is dissipated as heat energy. This energy raises the temperature of milled product, the mill and the air. Some of the energy is lost during vaporization of grain moisture. Comparatively small fraction of energy input is utilized for creation of new surfaces. During grinding of grains the temperature rise is observed to be 20°C or more in emery burr mills. This temperature rise may partially decompose some materials. Therefore, there should be some arrangement to remove this heat. In some abrasive mills provision is made to draw ambient air for cooling purposes.

6.5 METHODS OF SEPARATION

The unit operation of separation can involve separating a solid from a solid, as in the peeling of potatoes or the shelling of nuts; separating a solid from a liquid, as in the many types of filtration; or a liquid from a solid, as in pressing juice from a fruit. It might involve the separation of a liquid from a liquid, as in centrifuging oil from water, or removing a gas from a solid or a liquid, as in vacuum removal of air from canned food in vacuum exhausting.

One of the commonest forms of separating in the food industry is the hand sorting and grading of individual units as in the case of vegetables and fruit. However, because of the high cost of labour, mechanical and electronic sorting devices have been developed. Difference in colour can be detected with a photocell and off-colour products rejected. This can be done at enormous speeds with automatic rejection of discoloured or mouldy nuts or kernels of grain that flow past the photocell. In the case of peanuts to be made into peanut butter, each peanut individually passes through a light beam that activates a jet of air to blow the discoloured peanuts from the main stream when an off-colour changes the amount of reflected light. Light shining through eggs can detect blood spots and automatically reject such eggs. Automatic separation according to size is, easily accomplished by passing fruits or vegetables over different size screens, holes, or slits.

The skins of fruits and vegetables may be separated using a lye peeler (Figure 6.11). Peaches, apricots, and the like are passed through a heated lye solution. The lye or caustic softens the skin to where it can be easily slipped from the fruit by gentle action of mechanical fingers or by jets of water. Differences in the density of the fruit and skin can then be used to float away the removed skin.

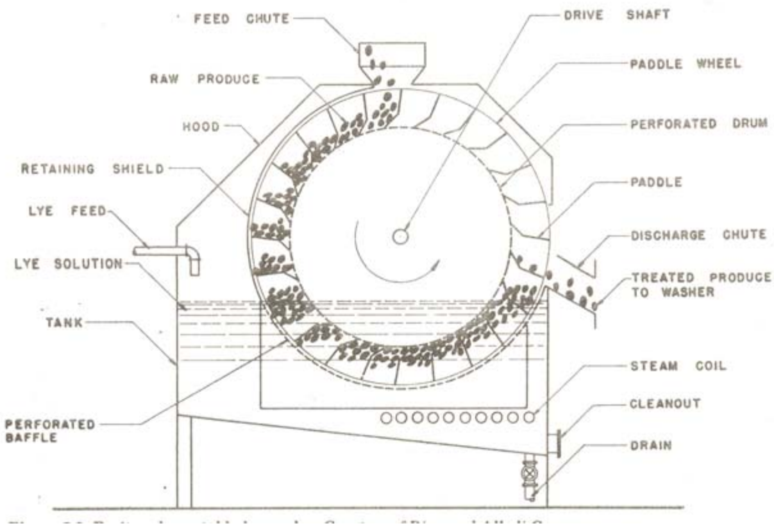

Figure 6.11: Lye peeler

To separate corn oil from corn kernels, the germ portion of the corn first is separated from the rest of the kernel by milling; then the oil is separated from the germ by applying high pressure to the germ in an oil press. Similarly, pressure is used to squeeze oil out of peanuts, soybeans, and cottonseeds. The traces of oil can be removed from the pressed cake by the use of fat solvents. There then remains the separation of the oil from the solvent.

Crystallization is used to separate salt from seawater, or sugar from sugar cane juice. Here, evaporation of some of the water causes super saturation, and crystals form. Since crystals are quite pure, this is also considered a purification process. The crystals are then separated from the suspending liquid by centrifugation.

Newer methods of separation include several techniques involving manufactured membranes with porosities or permeabilities capable of separations and fractionations at the colloidal and macromolecular size level. Ultrafiltration uses membranes of such porosity that water and low-molecular-weight salts, acids, and bases pass through the membrane but larger protein and sugar molecules are retained. This selective separation process, carried out at ambient temperatures, avoids the heat damage to sensitive food constituents that is often associated with water evaporation at high temperatures. Further, removal of acids and salts with the water prevents their concentration, which would otherwise be detrimental to sensitive retained solids.

6.6 RELEVANT STANDARDS

There are many relevant standards developed by the Bureau of Indian Standards, Codex Alimentarieus, etc. which needs to be followed for different methods and processes. These can be obtained from respective organizations.

6.7 LET US SUM UP

Milling is one of the important unit operations in fruit and vegetable processing industry. A suitable and adequate milling would prove to be a boon for any food industry because a proper selection would reduce the energy consumption and enhance the quality and profitability of a food processing industry.

6.8 KEY WORDS

Slicing equipment : It consists of rotating or reciprocating blades which cut the food as it passes beneath.

Dicing equipment : Dicing equipment is for vegetables, fruits and meats. The food is first sliced and then cut into strips by rotating blades. The strips are fed to a second set of rotating knives which operate at right angles to the first set and cut the strips into cubes.

Flaking equipment : *Flaking equipment* for flaked fish, nuts or meat is similar to slicing equipment. Adjustment of the blade type and spacing is used to produce the flakes.

Pulping equipment : *Pulping equipment* is used for juice extraction from fruits or vegetables and for pureed and pulped meats. A combination of compression and shearing forces is used in each type of equipment.

UNIT 7 MATERIAL HANDLING

Structure

7.0 OBJECTIVES

By the time you have studied this unit, you should be able to:

- understand the principles and concepts of material handling;
- know various available material handling devices and their drive mechanisms; and
- understand the importance of material handling and decide the suitability of different machinery for various uses.

7.1 INTRODUCTION

Material handling is an activity that uses the right method to provide the right amount of the right material at the right place, at the right time, in the right sequence, in the right position and at the right cost. Material handling includes a number of operations that can be executed either by hand (manual) or by mechanical means or devices to convey material and to reduce the human drudgery. Mechanical handling devices aim to lighten the work of human labour. After harvesting, crops are moved, transported or conveyed from place to place. In earlier periods all these operations were manual. The crops were primary processed and bagged/boxed by human labour. Foods were transported several times through storage and processing plants, and the processed food products were conveyed manually to consumers. Thus, foods were handled too much involving increased costs and human drudgery. But in modem times, some of the mechanical devices have replaced human labour, other supplement it or in some case make possible to handle larger quantities of grains per unit human labour.

7.1.1 Material Handling Principles

Various principles involved in material handling are:

1. Thorough study the problem and identification of problem areas, constraints and goals.
2. Develop plans, which meets our basic requirements, is flexible and includes desirable features.
3. Integrate various activities such as receiving, shipping, production assembly, etc.
4. Make the unit load size as large as possible.
5. Use the cubic space as effectively as possible.
6. Where possible standardize equipment and procedures.
7. Design equipment and methods that allow effective interaction between humans and machines.
8. When evaluating handling equipment, examine energy requirement and costs.
9. To the extent possible, use methods and equipment that minimize adverse effects on the environment.
10. Where possible mechanize methods to achieve efficiency.
11. Use methods and equipments that provides the maximum flexibility.
12. Simplify, combine or if possible eliminate unnecessary moves or equipment.
13. Use gravity as much as possible to transfer material keeping in mind safety and product damage.
14. Use safe handling equipment and methods.
15. To the extent possible computerize, so as to achieve better material and information control.
16. Integrate material and information flows.
17. Evaluate each alternate layout and select the most effective and efficient one.
18. Evaluate each alternate solution and select one based on cost per unit handled.
19. Perform preventive maintenance.
20. Develop equipment replacement plan based on after-tax life cycle costs.

7.1.2 Systems Approach to Materials Handling

When establishing methods of materials handling, a systems approach covering raw materials, materials in process and finished products is needed, in order to optimize flow rates in the correct sequence throughout the production process and to avoid bottlenecks or shortages. Additionally the flow of foods through a factory should be as simple as possible to reduce costs, to avoid confusion, which could lead to the contamination of processed foods by raw foods, to improve working conditions and to attain the benefits.

7.2 MATERIAL HANDLING DEVICES

7.2.1 Conveyors

Conveyors are widely used in all food processing industries for the movement of solid materials, both within unit operations and between operations (Table 7.1). There are a large number of conveyor designs, produced to meet specific applications. Common types include the following.

1. **Belt conveyor:** This is an endless belt, which is held under tension between two rollers, one of which is driven. The belts may be stainless steel mesh or wire, synthetic rubber, or a composite of canvass, steel and polyurethane or polyester. Flat belts are used to carry packed foods, and trough-shaped belts are used for bulk materials. Belts may be inclined up to 45°, if they are fitted with cross slats to prevent the product from slipping. Metal or wooden slatted conveyors are used instead of belts for greater load bearing and a reduced risk of damage to the conveyor.

2. **Roller conveyor** and skate wheel conveyor. Free-running (unpowered) rollers or wheels are either horizontal, to allow packed foods to be pushed along, or slightly inclined for transport under gravity. Rollers are heavier and stronger than wheels and therefore able to carry heavier loads. However, they are more difficult to start and stop, and more difficult to use around corners. Steeper inclines produce greater acceleration of packages, and a fall of approximately 10 cm in 3 m is sufficient for most purposes. Powered conveyors are used horizontally, or at a maximum inclination of 10-12°.

3. **Chain conveyor:** This is used to move churns, barrels, crates and similar bulk containers by placing them directly over a driven chain, with protruding lugs, located at floor level. A similar monorail conveyor is used for moving meat carcasses on an overhead track.

4. **Screw conveyor:** This consists of a rotating helical screw inside a metal trough. It is used to move bulk foods (for example flour and sugar) and small-particulate foods (for example peas or grains). The main advantages are the uniform, easily controlled discharge, the compact cross-section (without a return conveyor) and total enclosure to protect the product and to prevent contamination. They may be horizontal or vertically inclined but are generally limited to a maximum length of 6 m as, above this, high friction forces result in excessive power consumption.

5. **Vibratory conveyors:** These impart a vertical movement to food, to raise it a few millimetres off the conveyor, and a forward movement, to move the food along the conveyor. The amplitude of vibration is adjusted to control the speed and direction of movement. This precise control makes vibratory conveyors useful as feed mechanisms for processing equipment. They are also useful, for moving sticky or friable foods (snack foods).

6. **Flight conveyors:** Here, bulk material (for example grain or flour) is dragged through an enclosed channel by an endless chain fitted with hooks or flights. Chain speeds are low (6-10m min^{-1}) and the inclination is limited to 30°, above which the material slips back.

7.2.2 Elevators

Four common types of elevator are as follows:

1. **Bucket elevators:** consist of metal or plastic buckets fixed between two endless chains. They have a high capacity for free-flowing powders and particulate foods. The shape and spacing of the buckets, the method of discharge and the speed of the conveyor (15-100 m min^{-1}) control the flow rate of materials.

2. **Magnetic elevators:** are used for conveying cans within canneries. They have a positive action in being able to hold the cans in place and are thus able to invert empty cans for cleaning and operate at high speeds with minimal noise.

3. **Flight elevators**: are essentially inclined flight conveyors. They have flexibility in use for a wide range of free-flowing bulk foods, high capacity and good space utilization.

4. **Pneumatic elevators:** Powders or small-particulate foods are suspended in air, which is re-circulated at 1000-1700 m min^{-1} inside a system of pipes. The air velocity is critical; if it is too low, the solids settle out whereas, if it

is too high, there is abrasion damage to the pipe surfaces. Similar equipment is used to classify foods and to dry foods. A build-up of static electricity is prevented by control over the moisture content of the food and earthing the equipment. This is necessary when conveying powders to minimize the risk of dust explosions. This type of equipment has a smooth operation and cannot be overloaded. It has few moving parts; low maintenance costs and only requires a supply of compressed air at 700 kPa.

7.3 PRINCIPAL DRIVE MECHANISMS, SUITABILITY OF USE AND ENERGY REQUIREMENT FOR MATERIAL HANDLING

7.3.1 Belt Conveyors

A belt conveyor is an endless belt operating between two pulleys with its load supported on idlers. The belt may be flat for transporting bagged material or V-shaped or some other enclosed shape for moving bulk grains. The belt conveyor consists of a belt, drive mechanism and end pulleys, idlers and loading and discharge devices (Figure 7.1). Belt conveyors have antifriction bearing, therefore, these have a high mechanical efficiency. Material carried by belt conveyor lie still on the surface of belt or there is no relative motion between the product and belt. This results in generally no damage to material. Belt can be run at higher speeds, so, large carrying capacities are possible. Horizontally the material can be transported to longer distance but there is a limit to carry the material on elevation. A properly designed and maintained belt conveyor has long service life and low operating costs. Compared to other types of horizontal conveying system, the initial cost of belt conveyor is high for short distances. But for longer distances, the initial cost of belt conveying system is competitive or low.

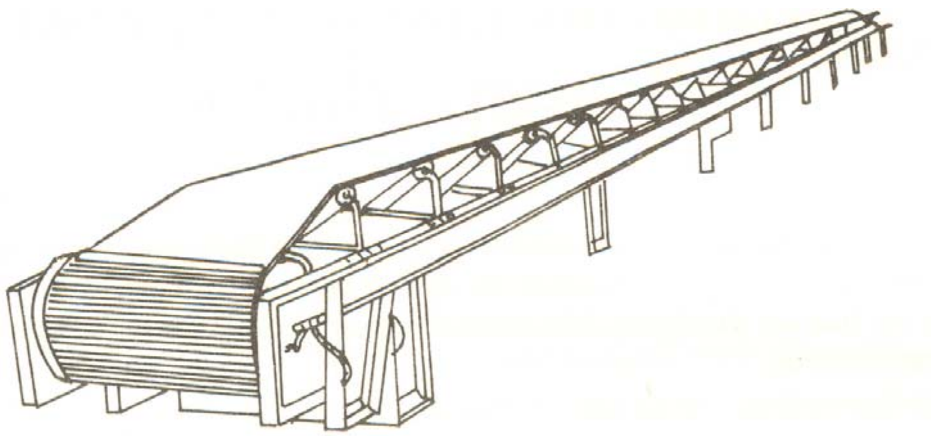

Figure 7.1: Belt conveyor

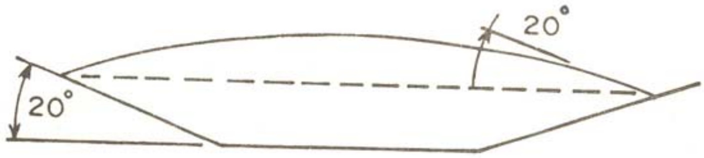
The design of belt conveyor system is based on available space, horizontal conveying length and conveying lift, characteristics of the material to be conveyed and capacity requirement. On the basis of overall requirement and information, the following will be determined to design a belt conveyor, belt width, belt speed, required horsepower, maximum belt tension and breaking strength of the belt, diameter of the pulleys and idlers and quality of belt (thickness).

The first step in the design of a belt conveyor with a specified conveying capacity is to determine the speed and width of the belt. The belt speed should be selected to minimize product spillage. The selection of belt width will depend upon the capacity requirement, speed of operation, angle of inclination of belt conveyor, trough angle and depth. The capacity of belt conveyor can be given by;

$$\text{Capacity, m}^2\text{/hr} = (\text{area of cross-section, m}^2) \times (\text{belt-speed, m/min}) \times 60 \quad (7.1)$$

The load cross sections of troughed belt is shown in Figure 7.2.



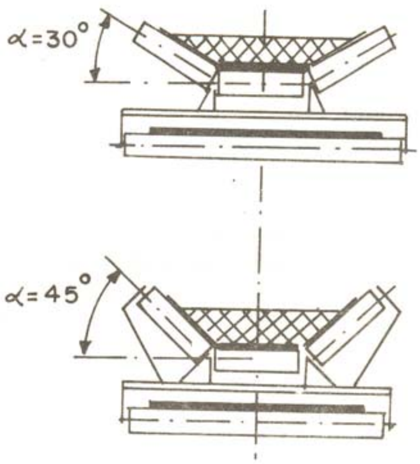


Figure 7.2: Various troughing configurations

The horsepower required for operation of belt conveyor for conveying grains can be calculated by the following equations. These equations are based on lift, friction resistance of the belt and pulleys and trippers. The values of constants are given in Table 7.2.

$$HP_1 = \frac{\text{Beltspeed, m/min.}}{0.3048} \text{x} \frac{(A+B)(3.281L)}{100} \quad (7.2)$$

$$HP_2 = \text{Capacity, t/hr} X \frac{0.48 + 0.01L}{100} \quad (7.3)$$

$$HP_3 = \frac{\text{Lift, m}}{0.3048} \text{x} 1.015 \text{x} \frac{\text{Capacity, t/hr}}{1000} \quad (7.4)$$

where, L = length of belt, m
A & B are constants.

Table 7.2: Values of constants A and B

Belt width, cm	Constants		Additional horsepower for tripper
	A	B	
36	0.20	0.00140	0.70
41	0.25	0.00140	0.85
46	0.30	0.00162	1.00
50	0.30	0.00187	1.40
60	0.36	0.00224	1.70
76	0.48	0.00298	2.50

The majority of belt conveyors for transporting bulk material use some type of rubberised conveyor belt made up of carcass. The pull of load is taken by the longitudinal strength of belt while the transverse strength supports the load. The belt is protected from damage by a rubber cover. The thickness of top rubber cover varies with thickness and wear resistance requirements.

7.3.2 Screw Conveyors

The screw conveyor consists of a tubular or U-shaped trough in which a shaft with spiral screw revolves. The screw shaft is supported by end and hanger bearings. The rotation of screw pushes the grain along the trough. A typical screw conveyor is shown in Figures 7.3a and b. The screw conveyor is used for conveying of products generally for short distances. Screw conveyor requires relatively high power and is more susceptible to wear than other types of conveyors. The pitch of a standard screw, which is the distance from the center of one thread to the center of the next thread, is equal to its diameter.

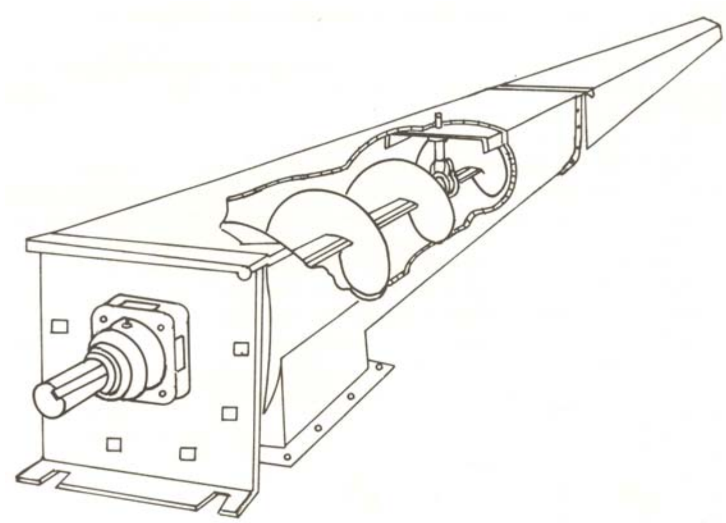

Figure 7.3a: Screw conveyor

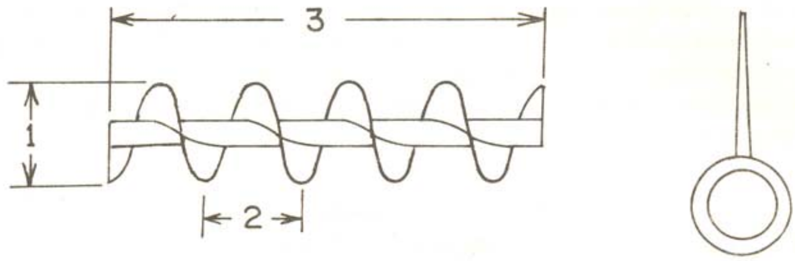

Figure 7.3b: Screw conveyor-details: 1) Screw diameter, 2) Pitch of screw, 3) Screw length

As the screw conveyor's driving mechanism is simpler, and no tensioning device is required, the initial cost of the conveyor is lower than any other conveyor with the same length and capacity. The main parts of a screw conveyor are, screw blade, screw shaft, coupling, trough, cover, inlet and outlet gates, bearings and drive mechanism.

The screw conveyor is generally used to move grains horizontally. However, it can also be used at any angle up to *90°* from the horizontal, but the capacity correspondingly reduced as *per* the inclination of conveyance.

The screw basically consists of a shaft and the screw blade or flight. The flight is a continuous one-piece helix, shaped from a flat strip of steel welded onto the shaft. The screw shaft is usually a joint less tube with thick sides and a high tensile strength to reduce the weight. The thickness of the steel strip helix decreases from the inner edge to the outer edge. Troughs of screw conveyor have different shapes. Most common is U shaped trough. In an enlarged or *flared* trough the sidewalls become wider at the top (Figure 7..4). This type of trough is usually used *for* conveying non-easy flowing materials, which may have lumps. The tubular trough is completely closed with circular cross-section and mostly used *for* conveying materials at inclination or *for* vertical lift.

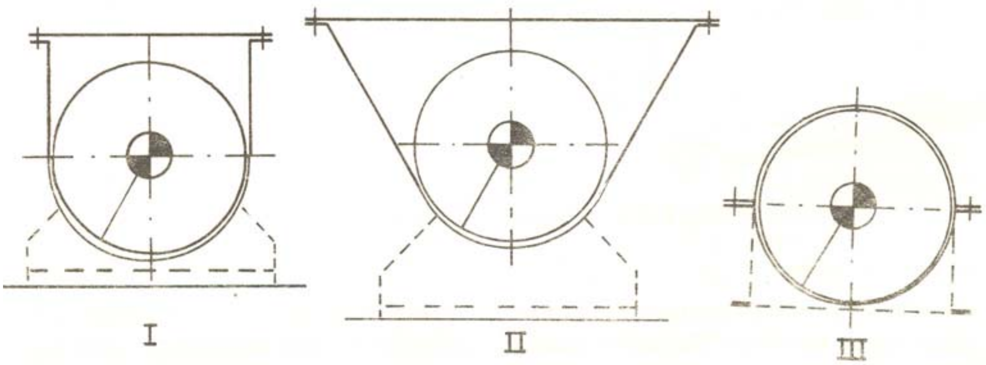

Figure 7.4: Various shapes of screw conveyor trough I) U-trough, II) Flared trough, III) Tubular trough.

For operational reasons, some gap is provided between the edge of the screw blade and the trough walls. Due to this gap it is not possible to completely empty the trough of a horizontal screw conveyor. If the screw conveyor is used to convey different materials, mixing of products is possible. Also when the food particles are pressed between the screw edge and trough walls, they can be damaged. During conveyance the kernels are also subjected to continuous friction with the trough walls. Screw conveyor may be designed for clockwise or counterclockwise rotation. The change in direction of rotation does not affect the capacity.

The capacity of screw conveyor is influenced by the screw diameter, inclination of the screw blade, speed of the blade, shaft diameter and cross-section of loading. The theoretical conveyance capacity of the screw conveyor can be given by the following equation.

$$\text{Capacity Q, m}^3\text{/hr} = 47.2\ (D^2 - d^2) \times p \times n \qquad (7.5)$$

where, D = screw diameter, m
d = shaft diameter, m
p = pitch, m
n = rpm

The theoretical capacity is more than the actual capacity because of screw housing clearance and the loading factor (Figure 7.5).

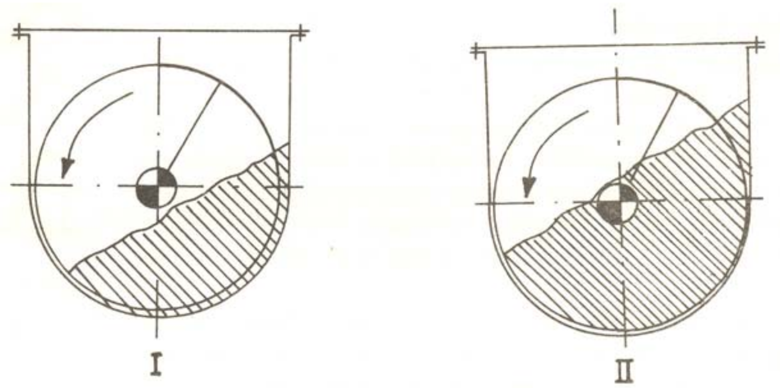

Figure 7.5: Screw conveyor loading factor I) 30% loading, II) 55% loading

The power requirement of screw conveyors for horizontal operation may be determined by the following equation:

$$\text{HorsePower} = \frac{QLWF}{4500} \qquad (7.6)$$

where, Q = conveyor capacity, m^3/min.
L = conveyor length, m
W = bulk material weight, kg/m3
F = material factor (for paddy 0.4)

If the calculated horsepower is less than 1.0, double the value.

Horsepower	=	1 to 2	multiply the value by 1.5
Horsepower	=	2 to 4	multiply the value by 1.25
Horsepower	=	4 to 5	multiply the value by 1.1

For horsepower values of more than 5, no correction is required.

Screw conveyors can be operated in an inclined position. In this case, the material will be conveyed upward. The capacity of inclined screw conveyor decreases than the horizontal operation. A screw conveyor inclined 15 degrees will carry about 75% of the rated horizontal capacity. At an inclination of 25 degrees, it will carry about 50% of the rated horizontal capacity.

7.3.3 Pneumatic Elevator

The pneumatic conveyor moves granular materials in a closed duct by a high velocity air stream. Pneumatic conveying is a continuous and flexible transportation method. The material is carried in pipelines either by suction or blowing pressure of air stream. The granular materials because of high air pressure are conveyed in dispersed condition. For dispersion of bulk material, air velocities in the range of 15-30 m/s is necessary. The pneumatic conveying system needs a source of air blowing or suction, means of feeding the product into the conveyor, and a cyclone or receiving hopper for collection of products. There are three basic systems of pneumatic conveying. These are pressure or blowing system, suction or vacuum system, and combined push-pull or suck-blow system.

In blowing or positive pressure systems, the product is conveyed by using air pressures greater than the atmospheric pressure. This system consists of a fan or blower, an air-lock feeder for introducing the product into the system, ducts and suitable air and product separating device. The product is fed into the pneumatic conveying system from the bottom of a hopper.

The feeder should be able to feed product at a specified rate in a pneumatic conveying system from the supply hopper at one pressure to the conveying pipeline at another pressure. The most common type of feeder is rotary feeder (Figure 7.6). It consists of a bladed rotor with pockets at the inlet port. When the rotor moves, the products are dropped to outlet port and to the conveying pipeline. The advantage of rotary feeder is that it meters the supply of products into the conveying pipeline. It also affects the air lock, which is necessary for the operation of the system.

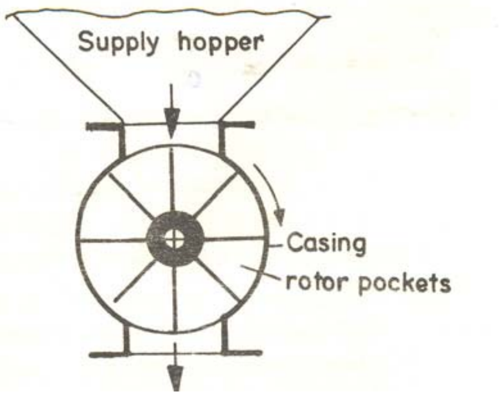

Figure 7.6: Rotary feeder for pneumatic conveyor

The selection of air mover is the most important aspect of the design of a pneumatic conveying system. In design, the two factors, (1) supply air pressure and (2) the volumetric flow rate of air should be considered. .

The supply pressure's value depends upon the working pressure drop required for the length of conveying line and across the filter. The magnitude of air pressure depends on the conveying length and the properties of the product to be conveyed. The volumetric flow rate of air depends on the necessary air velocity and pipe or duct size used in the system. In pneumatic conveying systems, fans and blowers with high volumetric flow rates and low pressures to positive displacement compressors producing high pressures are used. .

For separation of product particles from air, air-product separators are used. Cyclones are mostly used to collect the particles. Cyclone is a device, which removes the bulk of the product particle from the conveying air stream by centrifugal force. In some cyclone, a fabric filter is attached to remove residual dust and fine product particles from the air stream (Fig. 7.7). The conveying air is first passed through the cyclone and then it goes to the fabric filter for secondary separation of finer particles.

Limitations of Pneumatic Conveying

1. Erosion of solid surfaces and equipment surfaces by solid particles with conveying air stream. The rate of erosion of solid surfaces increased remarkably with conveying of abrasive products.

2. In case of bends or misaligned sections, the erosion problem becomes severe. In industrial installations, the erosion of duct system poses major problem in the operation of pneumatic conveying system.

3. In a pneumatic conveying system, chances of repeated impacts between the particles and the solid surfaces are high. Due to such impacts, product degradation results, because of this changes take place in the product size distribution and consequently the market value diminishes.

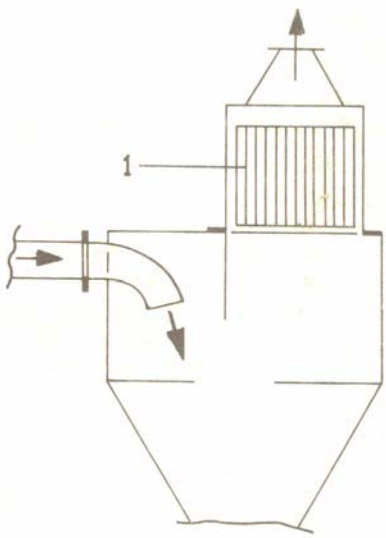

Figure 7.7: Separation of product particles from air by means of fabric filter

7.3.4 Bucket Elevator

A bucket elevator consists of buckets attached to a chain or belt that revolves around two pulleys one at top and the other at bottom. The vertical lift of the elevator may range between few meters to more than 50 m. Capacities of bucket elevators may vary from 2 to 1000 t/hr. Bucket elevators are broadly classified into two general types, 1) spaced bucket elevators and 2) continuous bucket elevators. The above two types are further subdivided into various classes.

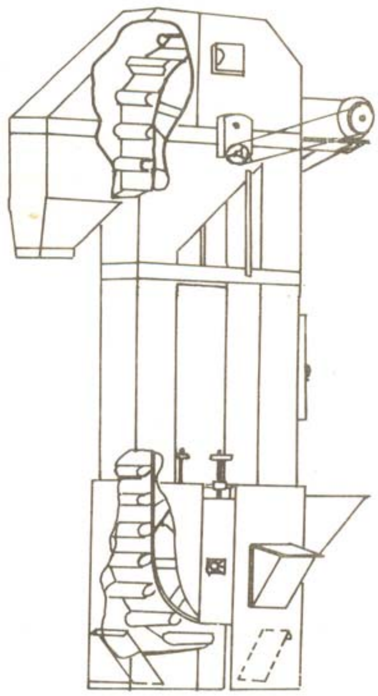

Figure 7.8: Bucket elevator

The spaced bucket elevators are further classified as, 1) centrifugal discharge elevators, 2) positive-discharge elevators, 3) marine leg elevators and 4) high-speed elevators. The continuous bucket elevators are classified as 1) super capacity bucket elevators, and 2) internal-discharge bucket elevators.

The spaced-bucket centrifugal discharge type is most commonly used for elevating the grains. A centrifugal discharge bucket elevator is shown is Figure 7.8. The bucket elevator is a very efficient device for the vertical conveyance of bulk grains. Bucket elevators with belts are employed in food industries for vertical conveyance of grains, derivatives and flours. Bucket elevators are usually mounted at a fixed location, but they can also be mounted in a mobile frame. Bucket elevators have high capacities and it is a fairly cheap means of vertical conveyance.

It requires limited horizontal space and the operation of conveying is enclosed in housing, thus it is dust free and fairly quite. The bucket elevator has limited wear problem since the product is enclosed in buckets. In a bucket elevator, the conveyor belt with buckets runs over pulleys at the upper and lower ends. The top pulley is driven pulley while the lower pulley is return and tension pulley. Buckets are usually made of steel or plastic and are bolted onto the belt. The buckets may be enclosed in a single housing called leg, or two legs may be used. The return leg may be located at some distance from the elevator leg. The houSing or legs are also made of steel, are welded or bolted together, and are dust tight. The curved hood is designed for proper centrifugal discharge of the grains. The boot can be loaded from the front or back or both (Figure 7.9). The various discharge types of bucket elevators are shown in Figure 7.10. The product flow is discharged either by means of gravity or centrifugal force.

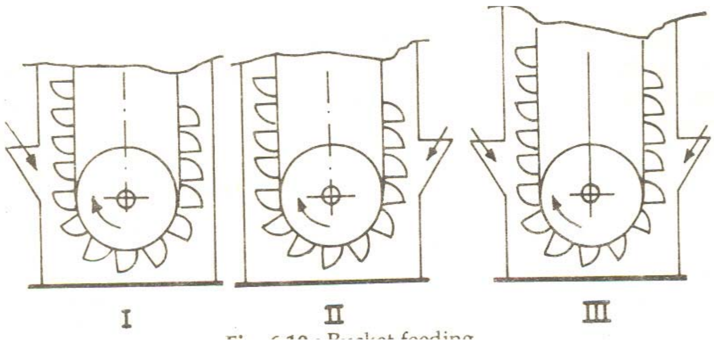

Figure 7.9: Bucket feeding I) Front feed, II) Back feed, III) Combined feed.

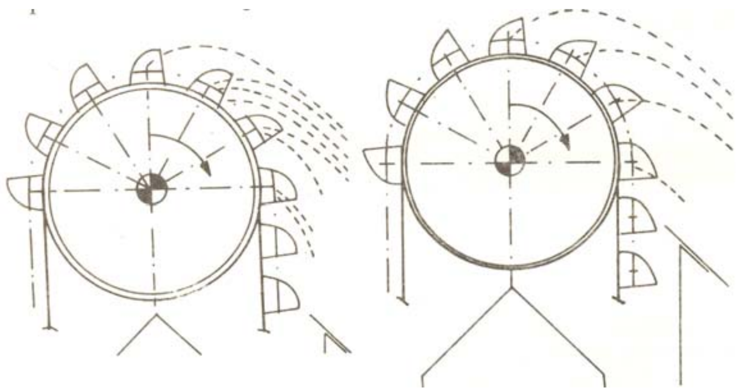

Figure 7.10: Bucket elevator's discharge methods: 1) Low speed gravitational discharge, 2) high speed centrifugal discharge.

The bucket elevator's capacity mainly depends on bucket size, conveying speed, bucket design and spacing, the way of loading and unloading, the bucket and the characteristic of bulk material. Belt speed is the first critical factor to consider. Bucket elevators with a belt carrier can be used at fairly high speeds of 2.5 to 4 m/ s. The speed of the belt depends on the head pulley speed. If the belt speed is too low, the discharge of the grains becomes more difficult, with too high speed the buckets are not fed well. A properly designed bucket elevator driven at the correct speed will make a clean discharge.

The gravitational discharge occurs with non-adhesive bulk material elevated at low speed and by means of buckets mounted closely together. In such discharge, the contents of a bucket flow over the rear side of the previous bucket. With purely centrifugal discharge, complete contents of a bucket are projected towards the discharge chute. Such type of discharge is obtainable with high belt speeds and smaller diameter drive pulleys. In elevating of grains the discharge from bucket elevators is a combination of centrifugal and gravitational discharge. Part of the bucket contents is projected by the centrifugal force, the rest flows out by gravity.

When a product mass turns around a pulley, it is influenced by two forces, (1) gravitational force, which is oriented downwards and (2) centrifugal force. The magnitude of the centrifugal force which is oriented outward can be given by

$$c_f = \frac{WV^2}{gr} \tag{7.7}$$

where, W = weight of grain
V = velocity of product mass
g = acceleration due to gravity .
r = radius of the wheel plus one-half of the projection of the bucket

For optimum centrifugal discharge, and calculation of the speed of head pulley, the resultant force is zero, it means that the centrifugal force is equal to the force of gravity, or, $c_f = W$

Hence, $W = \dfrac{WV^2}{gr}$ or, $V = \sqrt{gr}$

Since velocity, $V = \dfrac{2\pi nr}{60}$ (n = rpm) (7.8)

$$\frac{2\pi nr}{60} = \sqrt{gr} \quad \text{or,} \quad n = \frac{60\sqrt{g}\sqrt{r}}{2\pi\sqrt{r}\sqrt{r}} = \frac{29.9}{\sqrt{r}} \qquad (7.9)$$

The bucket elevator's capacity may be calculated by the following equation.

Elevator capacity, *m^3/hr* = bucket capacity, *m^3* x number of bucket per meter of belt x belt speed, m/min. × 60 (7.10)

$$Capacity, t/hr = \frac{Capacity, m^3/hr \times material density, kg/m^3}{1000} \qquad (7.11)$$

Drive mechanism

The drive mechanism of a bucket elevator is located near the elevator head. At the elevator head, the belt is turned around the drive pulley. Drive motor with gearbox and couplings are mounted on a rigid and separate frame. For serving the elevator head section, the drive mechanism, a working platform is provided. Usually a ladder is provided for access to this platform.

The theoretical horsepower requirement for the bucket elevator can be calculated by the following equation.

$$hp = \frac{QHF}{4500} \qquad (7.12)$$

where, Q = capacity of bucket elevator, kg/min
H = lift of elevator, m
F = factor; 1.5 for elevators loaded on the up side and 1.2 for elevators loaded on the bottom side

The theoretical horsepower should be increased 10-15% to provide for friction and power requirements for loading, power transmission and drive losses.

7.4 INTERACTION BETWEEN MATERIAL AND HANDLING DEVICES

Interaction between the material and the handling device is one of the important considerations for the selection of a suitable material handling device. The suitability of the different material handling devices for food products have been already discussed in section 7.2 and 7.3.

7.5 SELECTION OF MATERIAL HANDLING DEVICES

The selection of proper conveying system is important for ease in operation and getting desired capacity for a particular product. Before selecting a conveying system, the following principles should be taken into account.

1. The conveying device has to be selected according to the characteristics of the products being conveyed
2. The stability of the conveyor must be ensured under all normal working and climatic conditions.
3. The capacity of conveying and speed rating should be maintained at specified limits.
4. The dead load of the conveyor should be low in relation to the weight of transported product.
5. In a conveying system possibility of use of gravity should be taken into consideration.
6. The capacity of handling/conveying equipment should match with the capacity of processing unit or units.
7. Spillage of conveyed products should be avoided. Pollution of the environment due to noise or dust by the conveying system should also be avoided.

The four basic issues (Figure 7.11) relating to integration of material handling (MH) equipment into a manufacturing environment are (1) extraction to extract information about individual material handling tasks, (2) filtering and matching of individual tasks with individual resources, without regard to system performance and economy, (3) aggregation of tasks into sets that are then matched with technologies and (4) system selection and specification.

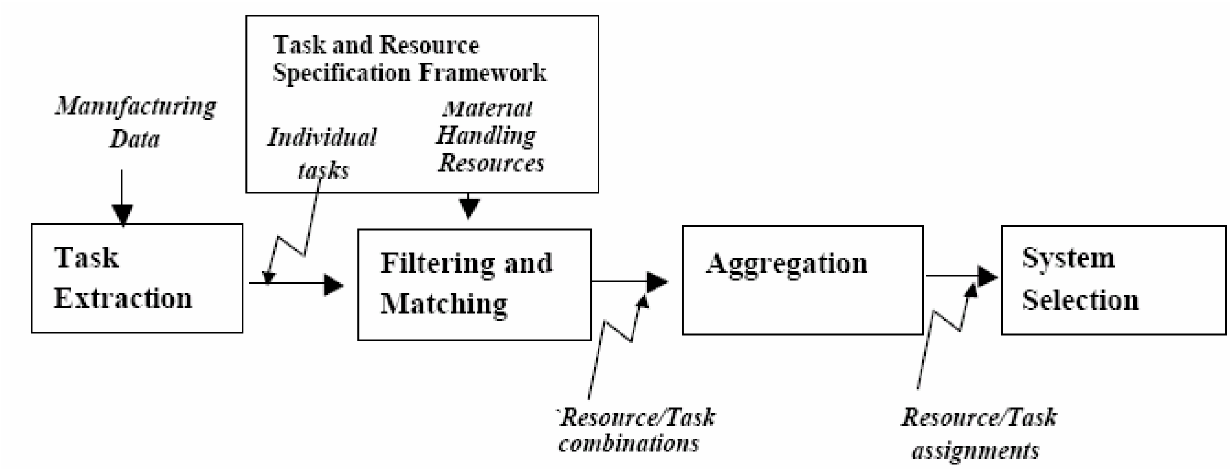

Figure 7.11: Major steps of procedure for selecting and specifying material handling equipment for manufacturing.

7.6 COST OF MATERIAL HANDLING

The cost of material handling will depend on (i) material to be carried, (ii) distance over which the material is to be carried, (iii) height of material elevation, (iv) efficiency of the material handling device, (v) maintenance cost of the material handling device, (vi) cost of the device, (vii) life span of the material handling device, (viii) method of loading and unloading of the material onto and from the device, etc.

There is no thumb rule as to which material handling device would be economical for a particular operation. It has to be therefore, decided keeping in mind the actual activity to be undertaken.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.
c) Use separate sheets where no space is provided.

1. Write a short note on the importance of material handling in food industry.

7.7 LET US SUM UP

Conveyors and elevators are the two much important classes of material handling equipment. Once we know the characteristics of the material to be handled and other critical requirements, one could select an appropriate conveyor/elevator. These conveyors/elevators could be chain, belt, bucket, screw, pneumatic, magnetic, vibratory types. Proper selection and design of capacity and power units leads to the minimization of the cost of material handling.

7.8 KEY WORDS

Material handling : It is a method of carrying the material from one place to another either horizontally or vertically.

Selection of material handling equipment : It is a method of adoption of the most appropriate handling device to suite ones own requirement.

Elevators : Used for transfer of materials in horizontal direction where the angle of lift is very steep.

Power requirement : It is the amount of energy required per unit time to operate any system.

Capacity : It is the total material that any given system can carry for a given time and energy utilized.

7.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Importance of material handling in food industry:
2. Five principles of material handling are:
   - Thoroughly study the problem and identify problem areas, constraints and goals.
   - Develop plans, which meets our basic requirement, is flexible and includes desirable features.
   - Integrate various activities such as receiving, shipping, production assembly, etc.
   - Make the unit load size as large as possible.
   - Use the cubic space as effectively as possible.
3. i) A belt conveyor is an endless belt operating between two pulleys with its load supported on idlers. The belt may be flat for transporting bagged material or V-shaped or some other enclosed shape for moving bulk grains.

   ii) The screw conveyor consists of a tubular or U-shaped trough in which a shaft with spiral screw revolves. The screw shaft is supported by end and hanger bearings. The rotation of screw pushes the grain along the trough.

iii) A bucket elevator consists of buckets attached to a chain or belt that revolves around two pulleys one at top and the other at bottom. The vertical lift of the elevator may range between few meters to more than 50 m. Capacities of bucket elevators may vary from 2 to 1000 t/hr.

4. Conveyors are mainly used for horizontal or inclined transmission of materials. The inclination is limited to the material transported, whereas, elevators can be used to lift materials vertically irrespective of the material they carry.

5. i) Calculate capacity by using equation 7.1.
   ii) Hp = Hp1 (Equation 7.2) + Hp2 (Equation 7.3) + Hp required for tripper (Table 7.2)

6. i) Calculate capacity by using equation 7.5.
   ii) Calculate horse power by using equation 7.6.

7. i) Calculate capacity by using equation 7.11.
   ii) Calculate horse power by using equation 7.12.

UNIT 8 TRANSPORTATION AND PACKAGING

Structure

8.0 OBJECTIVES

By the time you have studied this unit, you should be able to:

- understand the principles and methods of transportation;
- describe the various types of packaging material and their selection for food packaging; and
- decide the suitability of different types of packaging material.

8.1 INTRODUCTION

The prevention of food losses is of vital concern to growers as well as processors, and various measures can be applied at all stages between the grower and the consumer in order to reduce wastage, improve food security and generate income and profit.

The use of appropriate packaging and transportation is one of these measures and when properly applied can have a dramatic effect, reducing losses and ensuring that products reach the customer in the best possible condition. Appropriate packaging and transportation can range from the proper use of containers in which to transport produce to local markets, through to sophisticated systems that can extend the shelf-life of a processed foodstuff for a year or more.

Essentially, packaging:

- Aims to provide protection from all types of external damaging effects;
- Is an integral part of the food processing chain and helps both producers and consumers to transport, store, sell, purchase and use foods more efficiently;
- Is a means of ensuring that the product is delivered to the user in known quantities and in the expected condition for a specified shelf-life;
- Is a means of making the food more attractive in order to promote its use and increase sales;
- Conveys information to customers about the type of food they are buying, how to prepare it, its shelf-life, and that it conforms to relevant food legislation.

Thus, at its simplest level, packaging contains and protects, while at its most sophisticated it takes on additional roles such as preserving, selling, information and enhancing the convenience element of the product.

The type of packaging required depends mainly on the nature of the product, the length of time and conditions under which it will be transported and stored before use, the final market for which it is intended and local food laws. If the food is to be consumed near to where it is produced and eaten quickly after processing, little or no packaging may be required. However, if the product is aimed, for example, at a distant export market, the packaging requirements can become extremely complicated. At the point of sale, good packaging and presentation helps to attract customers, and may provide extra convenience in use.

8.2 METHODS OF TRANSPORTATION AND THEIR SUITABILITY WITH RESPECT TO PRODUCT

Damage in transit is one of the oldest problems in packaging. The hazard that packages meet cannot be anticipated and are mostly accidents. Protection is required against the average hazard encountered and not against the most severe one. The distribution system of a consumer good in its simplest form is shown below.

PRODUCTION

Figure 8.1: Distribution system for a consumer good

The distribution hazards encountered in any system which needs to be taken care of to decide the packaging material depends on the mode of transportation, method of handling and storage. The transportation modes and hazards there in are:

8.2.1 Bullock or Horse Drawn Cart

- Used for short distance transport.
- Stacking height upto 5 feet.
- Drop height upto 5 feet.
- Bumping due to rough road surface.
- Directional placements of packages may not be possible.

8.2.2 Road-Trucks

- Used for long and short distances.
- Package dimensions should suit the body dimensions for maximum space utilization.
- Door to door service.
- Delays in journey during rainy season.
- Freight rates generally higher than that of rail.
- Lower standard packages accepted than in rail.

Hazards

- Stacking height upto 7 feet.
- Drop height upto 4 feet.
- Puncturing of fibreboard boxes by protruding bolts etc. of the sides.
- Bumping due to irregular road surfaces.

8.2.3 Rail-Goods Trains

- Tran-shipment necessary.
- Pilferage is a major problem.
- Proper handling instructions essential.
- Packages can be sent on railways risk.
- Packages are to conform to rules and regulations of the railways.
- Door to door delivery possible only by container service.
- No problem for inter-state transport.
- Less interruption of journey even in rainy season.

Hazards

- Stacking height upto 8 feet.
- Vibration due to rail joints and track conditions.
- Shunting shock.
- Very high temperature (upto 70°C) in steel wagons in summer.

8.2.4 Sea-Ship

- Packages are carried in ship holds and decks.
- Normally the journey is preceeded and followed by other modes of transport. Hence packages should conform to the regulation of other modes also.
- Require proper handling instructions in different languages and figures.
- Freight rates by Cubic volume.

Hazards

- Stacking height upto 10-15 feet.
- Manual or machine handling.
- Very high relative humidity in the holds.
- Salt spray water on the decks or on the docks.
- Vibration due to engine propeller
- Swaying due to waves.

8.2.5 Air-Cargo

- High freight charges and hence lighter packages to be used.
- Limitations on size & weight of packages.
- Less journey time.
- Better handling.
- No cooling facility available.

Hazard

- High frequency vibration due to engine.
- Low temperature and pressure when flying at high altitudes.

8.3 SPECIAL REQUIREMENTS FOR TRANSPORATION OF AGRICULTURAL MATERIALS

Agricultural materials are living and continue all the physiological functions even after harvest. Therefore, it requires special care during its handling, packaging and transportation. Fresh as well as processed products meant for human consumption are of utmost importance keeping in view the seriousness of different health hazards associated with the contamination of foods during transportation. Most of the requirements with respect to the advantages, hazards and precautions are discussed in section 8.2 and 8.7.

8.4 TRANSPORATION COSTS

Transportation costs would depend on many factors like methods of transportation, efficiency of transportation, input costs for transportation, allowable time limit for transportation, losses during transportation, cost of the produce that is being transported and other associated costs. All these must be taken into consideration before deciding the method of transportation so as to minimize losses and optimize the profits.

8.5 ROLE OF PACKAGING OF AGRICULTURAL AND FOOD MATERIALS

Packaging is an integral part of food processing. It performs two main functions: to advertise foods at the point of sale, and to protect foods to a pre-determined degree for the expected shelf life. The main factors that cause deterioration of foods during storage are:

- mechanical forces (impact, vibration, compression or abrasion),
- climatic influences that cause physical or chemical changes (UV light, moisture, oxygen, temperature changes),
- contamination (by micro-organisms, insects or soils) and
- pilferage, tampering or adulteration.

In addition the package should not influence the product (for example by migration of toxic compounds, by reactions between the pack and the food or by selection of harmful micro-organisms in the packaged food). Other requirements of packaging are smooth efficient and economical operation on the production line, resistance to breakage (for example fractures, tears or dents caused by filling and closing equipment, loading/unloading or transportation) and minimum total cost.

The main marketing considerations are:

- the brand image and style of presentation required for the food,
- flexibility to change the size and design of the containers, and
- compatibility with the method of handling distribution, and the requirements of retailer.

In summary, the package should be aesthetically pleasing, have a functional size and shape, retain the food in a convenient form, possibly act as a dispenser and be suitable for easy disposal or re-use. The package design should also meet any legislative requirements concerning labelling of foods.

8.5.1 Packaging Functions

The functions of packaging are numerous and include such purposes as protecting *raw* or processed foods against spoilage and contamination by an array of external hazards. Packaging serves as a barrier in controlling oxygen and water levels, facilitates ease of use, offers adequate storage, conveys information and provides evidence of possible product tampering. It achieves these goals by assisting in the following manners:

- Preserving against spoilage of colour, flavour, odour, texture, and other food qualities.
- Preventing contamination by biological, chemical, or physical hazards.
- Controlling absorption and losses of O_2, water vapour and other volatile substances.
- Facilitating ease of using product contents-such as packaging that incorporates the components of a metal together in meal "kits" (e.g. tacos).
- Offering adequate storage before use-such as stockable, resealable, pourable.
- Preventing/indicating tampering with contents by tamper-evident labels.
- Communicating information regarding ingredients, nutrition facts, manufacturer name and address, weight, bar code information, and so forth via package labelling.
- Marketing-standards of packaging, including worldwide acceptability of certain colours and picture symbols vary and should be known by the processor; packages also carry such information as merchandising messages, health messages, recipes, and coupons.

8.6 PACKAGING OF LOW AND HIGH MOISTURE FOODS

Packaging containers of foods both low and high moisture are classified as primary, secondary, and tertiary. A ***primary*** container is the bottle, can, drink box, and so forth that contains food. It is a direct-food-contact surface and is, therefore, subject to approval by competent authority, which tests for the possible migration of packaging materials into food.

Several primary containers are held together in ***secondary*** containers, such as corrugated fiberboard boxes (commonly, but not correctly, referred to as cardboard), and do not have direct food contact. In turn, several secondary containers are bundled into ***tertiary*** containers such as corrugated boxes or overwraps that prepare the food product for distribution or palletizing. They offer additional food protection during storage and distribution where errors, such as dropping and denting or crushing cartons, may occur. They prevent the brunt of the impact from falling on the individual food container.

8.6.1 Packaging Materials

In choosing the appropriate packaging for their product, packers must consider many variables. For example, *canners* must make packaging choices based on cost, product compatibility, shelf life, flexibility of size, handling systems, production line filling and closing speeds, processing reaction, impermeability, dent and tamper resistance, and consumer convenience and preference. Processors who use films for their product must select film material based on its "barrier" properties that prevent oxygen, water vapour, or light from negatively affecting the food.

The most common food packaging materials include metals, glass, paper, and plastic. Some examples of these leading materials appear in the following text.

Metal

Metals such as steel and aluminum are used in cans and trays. A metal can forms a hermetic seal, which is a complete seal against gases and vapor entry or escape, and it offers protection to the contents. The trays may be reusable, or disposable recyclable trays, and either steamtab1e or No. 10 can size. Metal is also used for bottle closures and wraps.

1) **Steel** has a non-corrosive coating of tin inside, thus the name "tin can," where as **tin-free steel** (TFS) relies on the inclusion of chromium or aluminum in place of tin. Steel is manufactured into the traditional three-piece construction can, which includes a base, cylinder, and lid, and also a two-piece can, consisting of a base and cylinder in one piece without a seam, and a lid. The latter are lightweight and stackable. The five primary types of steel vacuum closures include side seal caps, lug caps, press-twist caps, snap-on caps, and composite caps.

2) **Aluminum** is easily formed into cans with hermetic seals. It is also used in trays and for wraps such as aluminum foil, which provide an oxygen and light barrier. It is lighter in weight than steel and resists corrosion.

Glass

It is derived from metal oxides such as silicon dioxide (sand). It is used in forming bottles or jars (which receive hermetic seals) and thus protects against water vapour or oxygen loss. The thickness of glass must be sufficient to prevent breakage from internal pressure, external impact, or thermal stress. Glass coatings, similar to eyeglass coatings of silicones and waxes, may be applied to glass containers in order to minimize damage-causing nicks and scratches.

Paper

It is derived from the pulp of wood and may contain additives such as aluminium particle laminates, plastic coating, resins, or waxes. These additives provide burst strength (strength against bursting), wet strength (leak protection), and grease and tear resistance, as well as barrier properties that assure freshness, protect the packaged food against vapour loss and environmental contaminants, and increase shelf life.

Varying thicknesses of paper may be used to achieve thicker and more rigid packaging.

- Paper is thin (one layer) and flexible, typically used in bags and wrappers. Kraft (or strong" in German) paper is the strongest paper. It may be bleached and used as butcher wrap or may remain unbleached and used in grocery bags.
- Paperboard is thicker (although still one layer) and more rigid. Ovenable paperboard is made for use in either conventional or microwave ovens by coating paperboard with PET polyester.
- Multilayers of paper form *fiberboard,* which is recognized as "cardboard".

Plastic

It has shrink, nonshrink, flexible, semirigid, and rigid applications, and varies in its degree of thickness. Important properties of the many types of plastics that make them good choices for packaging material include the following:

- Flexible and stretchable.
- Lightweight.
- Low-temperature formability.
- Resistant to breakage, with high burst strength.
- Strong heat sealability.
- Versatile in its barrier properties to O_2, moisture, and light.

8.7 PACKAGING FOR PHYSICAL DISTRIBUTION AND TRANSPORATION

Any package is functionally incomplete if the goods received at the distribution is unacceptable. Hence, the secondary and tertiary packaging, which can withstand the physical abuses during handling, transportation and storage, is also very important. The most commonly used conventional transport containers for fresh and processed food includes wooden boxes, corrugated fibreboard boxes, plastic crates, high-density polyethylene drums, steel drums and pails. Sacks are also generally used to bring fresh produce to the processing centres from the fields. The selection of a transport container is based on the characteristics of the product, the kind of handling and transportation hazards likely to be encountered at various stages of the distribution system.

8.7.1 Transportation Containers

The primary function is to contain the article. It may need to be designed to prevent pilferage during the journey between manufacturer and ultimate consumer. A third and the most important property of the shipping container is its compatibility with the product contained within it. The other important aspect of a shipping container is labelling regarding what it contains, how much it contains and when it is packed and possibly sales promotion.

Wooden Containers

Wooden containers are one of the earliest shipping container since wood was then available in plenty. But presently, use of wood is discouraged as our forests are depleting year by year. There is a stiff competition from fibreboard containers both in terms of cost and performance. Still the wood container is widely used for perishables in the domestic market. The requirement for such a purpose include:

- Aeration required for the dissipation of heat and exchange of gases.
- High stacking strength and stability.
- There should be no fungus and mould growth when stored at high relative humidity.
- Dimensional stability.

Corrugated Fibre Board Boxes (CFB)

The corrugated fibreboard is made of paperboard liners and corrugating medium. The structure of corrugated fibreboard consists of a fluting medium running in a sinusoidal wave form between the two liners, thus separate the liners by a distance to obtain good stiffness.

Unbleached virgin coniferous craft is most appropriate for liner materials. It has a high tearing resistance and stiffness and a low rate of moisture absorption from air. Other materials like straw, bagasse, bamboo etc. have lower performance particularly when exposed to higher relative humidities. In case these materials are used, their substance has to be increased at least by 50% to get the satisfactory performance.

In case of packaging for fruits and vegetables, ventilation holes for the dissipation of heat and exchange of gases are very much essential. Careful attention must be given to the number, size. shape and position of these holes without sacrificing the strength of the box.

Inserts and cushioning materials are generally used for packing glass bottles. Pouches and fresh produce. There are various types of inserts and cushioning materials that are being used.

- **'Cell pack'** – Traditional partitioning method contribute to the stacking strength of the box.

- **'Paper honey comb'** – Can be adopted to different produce size and shape.

- **'Moulded pulp trays'** – Generally used for eggs and fruit and vegetables.

- **'Expanded polystyrene inserts'** – Can be produced in short runs at reasonable costs.

- **'Thermoformed PVC trays'** – Generally used for packaging produce in single layers only.

- **'Paper wool or wood wool'** – In combination with paper tissue, gives good protection if tightly packed.

- **'Plastic foam net'** – Generally used for glass bottles and large size fruits.

Barrels and Drums

Metal and wooden barrels are commonly in use. The metal barrels include steel and aluminium. Aluminium barrels are used for storing beer. Wooden barrels are made of staves bound together with hoops and may be 'tight' or 'slack'. The tight ones are used for storing heavy solids. semisolids and liquids. The wooden barrels are also used for storage and ageing of alcoholic liquors.

A drum is a cylindrical shipping container differing from barrels in having straight sides and flat or bumped ends designed for storage and shipments as an unsupported outer package that may be shipped without boxing or crating. Drums can be either metal drums (usually from Aluminium or Steel) fibre drums, ply wood drums and plastic drums. Metal drums are single wall, with either double head, partial opening, with convex or flat head or flat full removable head construction. The capacity usually ranges from 12-110 gallons. The inner surfaces of the metal drums are coated with lacquers. The commercially used lacquers are oleoresinous types. phenolic resins, vinyls, and epoxy resins.

Fibre drums are made by fibreboard of plies not less than 0.3 mm thick. The capacity of these drums varies between 0.5 to 100 gallons. The advantages of fibre drums are they are not returnable and has good stackability, low tare weight and easy opening and closing features. Printing can improve their appearance. Care should be taken not to expose these drums at high relative humidities.

The basic types of fibre drums are;

- Plain drums – No moisture proofness.
- Liquid tight drums – has rubber or plastic gaskets.
- Water vapour proof drums – Inside laminated with asphalt paper or polyethylene.
- Lined and coated drums – Prevents direct contact between content and fibreboard.

Fibre drums are generally used for shipping semisolids having a minimum viscosity of 5000 cps. It is also used for liquid insecticides fruit juices and other food stuffs. Plywood drums are made of 3 ply veneer which laps and joined with staples. The ply wood drums are primarily used to pack dry products and have an excellent weight to strength ratio.

The polyethylene drums are rigid and self supporting. They are available between 5-55 gallons capacity. The advantages of these drums are its flexibility, non toxicity, light weight, durability, high chemical resistance. The polythene drums have good resistance to breakage.

Sacks

Sacks are generally made from flexible low cost materials like jute, textiles, papers and plastics. Paper sacks are made of two or more plies of sack krafts, which is pure sulphate paper having a substance of 70 gsm or more.

Plastic sacks are generally made from polyvinyl chloride, polyethylene and polypropylene. The advantages of plastic sacks are, it weighs only 2/3 of multiwall paper sack and has better weather and impact resistance. These sacks are made by extrusion and blowing. The closures are made by sticking or heat sealing.

Sacks made from a combination of plastic and jute are also commercially available. Fresh fruit and vegetables are generally packed in sacks for transportation from harvesting fields to packing houses and/or retail markets. Sacks do not provide support for the product against superimposed loads and also offers less resistance to impact loads. Possibilities of sifting and spilling are common.

Bag-in-Box

In this system, the bag is supported on the outside by a rigid container made of paper board or corrugated board carton. It is generally used to fill a variety of liquid and dry products like tea, instant coffee, milk foods, baby foods, glucose powder, biscuits, spices, aseptic and non-aseptic fruit juices, edible oil, ghee etc. This system is tamperproof and offers cost effectiveness. Depending on the product, wide range of plastic films, laminates, coextruded barrier films, metallised film and aluminium foil can be used for the inner construction.

There are two methods of producing bag-in-box packages:

- Lined carton system,
- Coated and laminated carton system.

In the case of lined carton system, the inner liner is made from a suitable laminate such as LDPE/Paper/HDPE, paper/foil/LDPE and polyester to give the required shelf-life protection to the product. The outer carton is made of duplex board for protection against damages.

The second method combines the carton forming/gluing operation with a lining feed mechanism. Products considered for bag-in-box packaging should be tested for compatibility with the package and performance under handling shipping conditions.

Palletisation

A pallet is a platform made to hold one or more boxes, bags, cartons etc. in a group. The pallet is one of the simplest single devices for material handling. The other advantages of palletisation are:

- Reduced labeling requirements.
- Better utilization of storage space because of higher stacking strength.
- A reduction in mechanical strains and damages.
- A reduction of the total distribution time.
- A better maintenance of produce quality.

A pallet can be made of wood, corrugated and honey comb paperboard, plastic, reinforced plastic or metal. The choice is based on the service conditions, such as weight of load, climatic environment, durability requirement, local availability and costs.

8.8 QUALITY TESTING OF PACKAGES AND PACKAGING MATERIALS

An essential part of any packaging programme is the testing and evaluation of the complete packaged unit, as well as the various components. It is good economics to determine the optimum design in the beginning to maintain uniform performance throughout the life of the package. A good test programme will indicate the results to be expected in the field and it will yield dividends far in excess of its original cost and good management demands an objective evaluation of every step in the packaging operation.

To predict the performance of a package, there is a necessity to use a wide array of test procedures in package performance analysis with the following aspects:

- Identification of various materials used in packaging.
- Suitability of the materials for the intended use.
- Knowledge of materials properties both when used alone and when used in combination with other packaging materials.
- Ability to evaluate the material performance in the final package form in contact with packaged product.
- Determining the durability of materials through normal or even abnormal handling and abuse (including shipping).

8.8.1 What is Testing?

A test can generally be defined as an act of determining a given property or characteristics of a product (packaging material or package) by taking one or more measurements qualitatively or quantitatively according to prescribed procedure.

8.8.2 Why Testing?

Tests on packaging materials and packages are performed mainly for the following purposes:

- Comparison with competitive material to compare the offers.
- Current checks over the uniformity of new supplies of packaging materials, i.e., to check for change in quality if any from batch to batch.
- Quality checks during the production of packaging materials or packaged commodities.
- Evaluation of the suitability of packaging materials for certain factors like protection against mechanical or climatic hazards.

8.8.3 Steps in Test Methods

- Scope: The purpose and limitations of the methods are to be elaborated to avoid ambiguity.
- Significance: Relevance, the test has with respect to actual or intended performance.
- Terminology: The technical terms and abbreviations used should be fully defined or explained when they are not in common use
- Apparatus: All the various equipments necessary should be fully described in all the details, including dimensions range and accuracies etc.
- Materials: All reagents etc. are to be given in detail.
- Sampling: Enough attention has to be paid to proper sampling since a test can be only as informative as the sample permits

- Test specimen: The test sample consists of a minimum number of specimens and these specimens are to be prepared as required for the measurement of property and to suit the requirement. Preparation of the specimens is very important for the reliability of the test results.

- Conditioning: Time, temperature and relative humidity, to which the specimen are to be preconditioned and also conditions during testing.

- Test procedure: Method of actual measurement when there are more than one procedure. The procedure to be followed is described in detail.

- Method of evaluation: This gives the method (calculations) employed to arrive at the test property from the observations (readings) taken.

- Report: This tells how the results are to be reported and includes the method of presentation, its form (tables, graphs, diagrams etc.). Some times the precision of the test is also included in the report.

8.8.4 Package Functions and Characteristics

Mostly the evaluation of packaging materials is based on package functions and the characteristics of package.

Product Protection

1. Storage life of food products: Mainly depends upon the barrier properties of the packaging materials for:

   - Humidity: Water vapour transmission.
   - Gases: Oxygen/Carbon dioxide/Nitrogen/Sulphur dioxide.
   - Aroma: Specific organic vapour and transmission rate.

2. Product damage and integrity:

   In terms of resistance to stresses in distribution.

   - Impact resistance.
   - Dart impact and Spencers impact value for the film.
   - Compression resistance for finished packages.

   In terms of resistance to bursting:

   - Bursting strength.

   In terms of resistance to repeated stresses as in vibrations:

   - Gelboflex crack resistance for films/laminates/coextruded films.

3. Product packaging compatibility:

   Chemical resistance:

   - Grease resistance.
   - Tainting.
   - Migration of constituents from packaging materials into foods.

4. Pilferage and adulteration:

   Good closure and joints required.

   - Heat seal in plastic pouches.

Machinability

1. Easy sliding on machine:
   - Reduced friction.
   - Slip of packaging material surface (kinetic coefficient of friction).
2. Resistance to stresses in packaging operations:
   - Tensile strength and elongation.
   - Resistance to tear propagation.
   - Heat seal range and hot tack

Consumer and Marketing Functions

1. Ease of opening and reclosures:
   - For flexible pouches a 'V' – notch to start tear (good with foil laminates and cellophanes) may not be suitable for polythene and Nylon films.
   - Fold retention for closures of laminate pouches
2. Ease of dispensing:
   - Wide mouth for solids and pasty foods.
   - Clean squeeze out from flexible pouches (Non stickiness to the package wall).
   - Ease of disposal – problems for the future, particularly for non-recyclable multilayer plastic packs.

8.8.5 General Common Tests for Films, Foils, Laminates and Paper and Paper Board

Thickness

Thickness is the perpendicular distance between the two outer surfaces of the material and is normally expressed in units of length. Many physical properties of packaging materials are dependent upon the thickness, e.g. WVTR and GTR of films are inversely proportional to thickness and decreases with increase in thickness. For paper board, thickness is reported in points or in mm. (1 point = 1/1000") for papers, it is in mm or inches. For films, thickness is reported in micron, mils. or in gauges (25 micron (μm) = 1 mil = 1/1000" = 100 gauge = 0.025 mm.

The Basis Weight (for paper and paper boards)

The basis weight is the average weight of an arbitrarily selected area of the paper (weight per unit area i.e. gms/ sq.metre or lbs/1000 sq.ft for paper boards). As the packaging papers are sold and purchased only in terms of weight the basis weight assumes special significance. Most of the physical properties such as burst strength; thickness and bulk are evaluated and specified in accordance with the particular basis weight involved.

Tensile Strength Test

The tensile strength of paper is defined as the force applied parallel to the plane of the specimen of specified width and length under specified condition of loading (K gms/15 mm or lbs/inch width). The test indicates the durability and serviceability of papers in many packaging operations such as wrapping, bagging. printing etc. Usually tensile strength is more in machine direction than in transverse direction and extension is less in machine direction than in transverse direction. Plastic films are normally tested at higher speeds because of higher extensibility. The stress strain curve helps in locating yield point and knowing the yield strength etc.

The Bursting Strength Test

This test measures the ability of a paper or paper board to withstand pneumatic or hydraulic pressure build up. For films, foils, laminates and papers the pneumatic type test is used. Heavy papers and paper boards are tested on hydraulic type of testers (lbs/sq.in or kg/sq. cm). The test gives a sort of combined tear and tensile properties. In many cases it serves as good index of the quality of fabrication of packaging materials. Another Associated property is Burst factor. The burst factor = Bursting strength (in gm/sq.cm)/Basis weight (in gm/sq.mt).

Water Vapour Transmission Rate

The water vapour transmission rate (WVTR) is measured as the quantity of water vapour in gms that will permeate from one side to the other side of the film of an area of one square metre in 24 hours, when the relative humidity difference between the two sides is maintained at 90% gradient at 37.8°C. The property is important to estimate the efficiency of the packaging material or a package for resistance to the flow of water vapour and is helpful in considering the selection of barrier materials for hygroscopic foods.

Gas Transmission Rate

The gas transmission rate (GTR) is normally determined by measuring the change in volume at constant pressure (atmospheric), or the change in pressure at constant volume and the quantity of gas flowing across the film is compiled as volume at NTP.

$$\text{GTR} = \frac{\text{V.(76)x24}}{\text{At(P1} - \text{P2)}} \text{ cc/ m}^2\text{/ 24 hrs.atm} \qquad (8.1)$$

where ‘V’ is the volume (at NTP) of gas transmission through 'A' sq. metres of the test material in time 'f, when the average pressure difference between the two sides is maintained at (P1-P2) cm of Hg. The temperature of the test can be changed as per the requirement. GTR is an important property to estimate the efficiency of the packaging material or a package for resistance to the flow of gases and helps in selection of barrier materials for oxygen sensitive foods.

Grease Resistance

Grease resistance is measured by exposing one side of the test specimen creased or uncreased to a grease containing red dye. The time required for the red stain to show on the unexposed side is taken as a measure of this property. For plastic films, the test can be performed directly in pouches using groundnut oil coloured with red sudan dye.

Tearing Resistance for Papers

The papers are tested for their tearing resistance properties in two ways:

i) Internal tearing: The energy required to propagate an initial tear is measured (More followed in practice).
ii) Edge tearing: The energy required to initiate a tear is measured. The test is done on both the directions of paper. The work done in tearing is measured by the loss in the potential energy of the pendulum of the instrument. Tear Factor: is a term similar to Burst Factor, one finds in use.

$$\text{Tear factor} = \frac{\text{Tearing resistance in gms.}}{\text{Basis weight in GSM}} \times 100 \qquad (8.2)$$

Impact Tests for Plastics

These tests are designed to measure the ability of the films to withstand fracture by shock. The test is a measure of toughness of the material. It is a combination of deformation and breaking properties.

The Abrasion Resistance

This test is designed to measure the ability to withstand surface wear and rubbing. It is a measure of some mechanical properties like hard resillience. The procedure consists in abrading the sample with a wheel of standard abradent for a definite number of revolutions and finding the weight loss of the sample.

Heat Seal Strength

The test is used for heat sealable plastic packaging materials. The heat seal strength may be expressed as percentage of the tensile strength of the base material (gm/ cm width). The strength of heat seal depends upon temperature, dwell time, pressure and the type of heat sealing surfaces and each material has optimum values under these conditions.

Environmental Stress Cracking

The purpose of the test is to study the influence of some reagents like soaps, wetting agents, oils or detergents on plastics, determined by exposing the specimens for a specific time to those environments and observing the cracks. The test report consists of the percentage of failures.

Identification of Plastic Films

Different types of plastics used in packaging differ in their properties. It becomes necessary to identify them for their proper selection. Though there is no systematic method for identifying packaging films, based on some characteristics of various films, such as appearance, odour, feel and drape, they can be identified by a few simple tests like specific gravity, solubility, burning and copper wire test etc. For laminates and coextruded films, it is difficult to identify by such simple tests. Nowadays IR spectroscopy and NMR are used to identify qualitatively as well as quantitatively.

Specific Tests

Apart from these common tests, there are some specific tests for different packaging materials which are enlisted in various standards developed by the Bureau of Indian Standards and other organizations.

8.9 STANDARDS FOR SAFE PACKAGING

The packaging laws and regulations affecting food products are mainly covered under:

- The Standards of Weights and Measures Act, 1976, and the Standards of Weights and Measures (Packaged Commodities) Rules, 1977 (SWMA).
- The Prevention of Food Adulteration Act, 1954, and the Prevention of Food Adulteration Rules, 1955 (PFA).
- The Fruit Products Order, 1955 (FPO)
- The Agmark Rules

8.10 DISPOSAL OF PACKAGING MATERIALS

Indiscriminate use of different packaging materials for packaging of food products has caused a serious problem of pollution and ecological imbalance due to the problem of their disposal. Packaging waste contributes in great proportion to the increase in the volume of waste and to the saturation of landfills. The packaging sector, especially the plastics industry, is currently under some attack from the environmental point of view due to problems in waste disposal, pollution by litter and waste of resources.

At present, the following different principal methods are used to control solid waste disposal.

i) Land in-fill
ii) Incineration
iii) Composting
iv) Direct constructional use (unsorted) (v) Reuse (sorted)
v) Pyrolysis
vi) Chemical treatment

In the case of land in-fill method, the waste is reduced in particle size and then deposited in a special location, which may be excavated and covered with a minimum level. The process is hygienic and can reclaim wasteland. Incineration comprises the burning of waste till all combustible matter is fully oxidized. Composting involves biodegradation leading to a bland product, which is useful in agriculture. In direct constructional use, the waste is treated to compact, compressed with binders like bitumen and the resulting blocks are used for construction of roads, artificial islands, causeways, airfields, etc.

Packaging materials like metal, paper and glass can be segregated and reused or recycled. Pyrolysis is a method of heating material in the absence or presence of a limited amount of oxygen and the components can be separated for reuse. The chemical treatment is oriented towards a specific component of waste like hydrolysis of polyurethanes in scrap automobiles and degradation of paper to sugars or alcohols.

When the product is removed from the packed container, it becomes litter, which is harmful, polluting and expensive and this has to be disposed off quickly.

8.10.1 Recycling of Packaging Materials

Recycling of packaging materials play a very important role in saving the raw material, energy and to minimize the environmental pollution.

Recycling of tin-plate is a cumbersome process, since the lacquers / lithography and tin has to be separated from the base steel. Then the base steel can be sent to the steel-producing plant for remelting to produce fresh steel plate for reuse. The separation of steel from tin in two-piece cans and lids is easier and more economical. Similarly, chromium can be separated from the tin-free steel and the base steel can be reused for production of fresh base plate.

By recycling aluminium, more than 90 per cent of the energy can be saved by melting and reprocessing the metal. It is also claimed that the quality of recycled aluminium is better. About 50-60 per cent of the aluminium cans are recycled.

With respect to plastic packaging materials, PET can be reprocessed and used for stuffings, plates, piping, fibres, etc. Used PET bottles are not suitable for production of fresh PET bottles. Plastic-wastes are also used for recovery of energy by incineration.

8.10.2 Biodegradable Plastics

Plastics used in food packaging at present are non-biodegradable. The overflowing landfills cannot absorb the large quantity of plastic trash created in many countries. To reduce the waste, the best solution is a combination of biodegradable plastics, plastics recycling and composting. Biodegradable plastics are biodisintegratable plastics, which disintegrate into polymer chains and break down into water and carbon dioxide.

The first generation biodegradable plastics are made of polymers containing about 6 per cent starch (normally, corn starch), which biodegrades and a pro-oxidant, which enhances the reaction of the polymer with oxygen in the air. New biodegradable plastics contains up to 97 per cent starch.

Biodegradable plastics have the same strength and flexibility as commonly used petroleum-based plastics and can be melted, moulded and shaped as required. However, they are not suitable for applications requiring high-temperature resistance or impact. The same production techniques like injection moulding, extrusion blow-moulding, melt casting or spinning used for plastic-based plastics can be used without retooling the manufacturing plant. Biodegradable plastics are viable alternatives and are gradually becoming popular commercially.

Other than biodegradable plastics, chemical and photodegradable plastics have also been developed. They are chemical plastic, for which a natural catalyst like metal salt is added and the photodegradable plastic for which a light-sensitive chemical is added to or sprayed on the plastic to make it disintegrate in ultraviolet light.

8.11 SPECIAL PACKAGING

Other than the traditional packaging materials, there are some special ones, which can be selectively used for packaging of foods. Some of them are discussed in the following paragraphs:

8.11.1 Edible Films

Natural edible films extend shelf life, although for shortest time periods than synthetic non-edible packaging materials. Examples of edible films include casings, such as in sausage, and edible waxes, such as those applied to fruits and vegetables, the waxes function to improve or maintain appearance, prevent mold, and contain moisture while still allowing respiration. Food may be coated with a thin layer of polysaccharides such as cellulose, pectin, starch and vegetable gums, or proteins, such as casein and gelatin. Cut dried, fruit pieces are often sprayed with an edible film prior to their inclusion into items such as breakfast cereal.

8.11.2 Foil

These may be used in snack bags (chips, etc.) or as a laminate in aseptic packaging. It is used as a wrapping for dry, refrigerator, or freezer storage. It provides a moisture-proof and vapour-proof barrier,

8.11.3 Laminates

These are multilayers of foil, paper, or plastics which may be utilized selectively according to the specific food packaging need, In combination, the various laminates may provide more strength and barrier protection than the individual laminate material. Laminates provide barriers useful in controlling O_2, water vapor, and light transmission, and they provide good burst strength. The laminates may resist pinholes and flex cracking. Retort pouches are examples or laminates used in packaging and contain polyester film, aluminum foil, and polypropylene.

8.11.4 Vacuum Packaging

Vacuum packaging modifies the atmosphere surrounding the food by removing oxygen, and it extends shelf life. Vacuum-packaging machines are available for small-, medium-, or large-scale production capacity and may be used to successfully package a variety of food sizes and forms such as small cheese blocks, large primal cuts of meat, or liquids. The procedure used for vacuum packaging is to place the food in a flexible-film, barrier pouch, and put it inside a vacuum-packaging chamber, where oxygen is removed. This creates a skintight package wall and protects against the entry of escape of gases such as air and CO_2, or water vapor. It assures inhibition of microbial growth, which would alter microbial and organoleptic properties such as appearance and odor. Water weight loss and freezer burn are also inhibited with this packaging method.

8.11.5 Modified Atmosphere Packaging (Map) Or Gas Flush Packaging

Modified atmosphere packaging modifies the internal package atmosphere of food. It is primarily applied to fresh or minimally processed foods that are still undergoing respiration, and it is used for the packaging of baked goods, coffees and teas, dairy products, dry and dehydrated foods, lunch kits, and processed meats in order to keep the meat pigment looking desirable. It is also used for nuts and snack food applications. MAP is one of the most widely used packaging technologies.

Modified atmosphere packaging contains the food under a gaseous environment that differs from air, in order to control normal product respiration (ethylene, CO_2, water vapor, and O_2) and growth of aerobic microorganisms. Nitrogen gas, which is odorless, tasteless, colorless, nontoxic, and nonflammable, is introduced into the food package after all atmosphere has been removed from the pouch and vacuum chamber and just prior to hermetic sealing of the package. This modification offers protection from spoilage, oxidation, dehydration, weight loss and freezer burn, and extends shelf life.

Unlike vacuum packaging, the film used for MAP remains loose-fitting, This avoids the crushing effects of skintight vacuum packaging, When used in combination with aseptic packaging, which reduces the microbial load, MAP becomes a more effective technology, Most new and minimally processed foods use MAP in combination with aseptic technology and reduced temperature.

8.11.6 Controlled Atmosphere Packaging

Both controlled atmosphere (CA) in storage environments and controlled atmosphere packaging (CAP) permit controlled oxygen and carbon dioxide exchange. Today, CAP containers control O_2, CO_2, water vapor, and ethylene concentration and, worldwide distribution of produce depends on CAP for high-quality food.

Clostridium botulinum is an anaerobic bacteria that grows in the absence of available oxygen. Therefore, it may grow in anaerobic packaging environments. To retard its growth in CAP food products, foods must have short storage times and be held at cold temperatures. Control of water activity (Aw) and salt is also necessary to prevent growth as sodium competes with the bacteria for water absorption

8.11.7 Active Packaging Technologies

Typically, packaging serves in a passive role by protecting food products from the external environment. It provides a physical barrier to external spoilage, contamination, and physical abuse in storage and distribution. Today, packaging more actively contributes to the product development, controls maturation and ripening, helps in achieving the proper color development in meats, and extends shelf life. It plays an active role in protecting foods. Examples of active packaging technologies are listed in the following:

Active packaging for fresh and minimally processed foods provide the following:

- Edible moisture or oxygen barrier (to control loss of moisture and enzymatic oxidative browning in fresh cut fruits and vegetables and to provide controlled permeability rates matched to the respiration rate of the fruit).
- Edible antimicrobial (biocidal) polymer films and coatings (which release controlled amounts of chlorine dioxide into the food, depending on temperature and humidity; or destroy E. coli 0157:H7 in meats, and prevent mold growth in fruits).
- Films that are scavengers of off-odours.
- Oxygen scavengers for low oxygen packaging.

Active packaging for processed foods provides the following

- Edible moisture barrier.
- O_2, CO_2, and odour scavenger.

Other active packaging technologies include the following:

- Microwave doneness integrators (indicators).
- Microwave susceptor films to allow browning and crispness (french fries, baked products, popcorn).
- Steam release films.
- Time-temperature indicators (TTI) which are unable to reverse their colour when the product has been subject to time-temperature abuse for frozen products.

8.11.8 Aseptic Packaging

In order to destroy any *Cl. botulinum* spores and extend the shelf life of low-acid foods, *aseptic packaging* may be utilized. Independent sterilization of both the foods and packaging material, with assembly under sterile environmental conditions, is the rule for aseptic packaging.

The container is filled with a sterile (no pathogens or spores) or commercially sterile (no pathogens, but some spores) liquid food product, and sealed in a closed, sterile chamber. Once packed, the product requires no refrigeration. Liquids such as creamers, milk, or juices may be packed in this manner. Triple or multiple packs of flavoured milk and juice, with attached straws, are available on grocery shelves. The market leaders of aseptic packages have introduced easy-open, easy-pour features into their canons. The plastic devices are injection moulded and adhere to the package tops.

8.11.9 Flexible Packaging

It is available for packaging use in the foodservice industry and is finding more applications at the retail level, including packaging for bagged cereals and sliced deli meat. Non-rigid packaging containers such as stand-up pouches or tubes and zippered bags are examples of flexible packaging used for peanuts, peanut butter, or produce such as fresh-cut lettuce and peeled baby carrots. (The packaging must also be resealable to meet consumer demands and may have zipper handles or spouts with screw-off tops.)

Flexible packaging is adequate for the plethora of low-fat/no-fat food products such as salty snack foods that are available in the marketplace. It keeps these products fresh by providing flavour and aroma barriers, which keep outside doors out and flavours in. It is used for fresh fruits and vegetables and matches respiration rate as closely as possible.

Manufacturers are offering more food products in flexible packaging and find that "cost savings and environmental concerns are two of the driving forces behind the switch to flexible packaging". "Faster, better, stronger, cheaper… the packaging industry continually tries to improve the process. Nowhere is this more apparent than in flexible packaging".

8.12 LET US SUM UP

After studying the contents of this unit, you can appreciate that there are several options for transportation and packaging of food materials. Depending upon the location and the commodity, a rigid combinations of mode of transportation and packaging with minimum losses and at least cost.

While manual and animal drawn carts have their relevance for small distances, motorized transport is required to haul the food material over long distances. The tractor, truck, rail, sea and air transport modes have their useful mass based on the perishability, urgency, cost and benefit attributes.

The role of packaging is to facilitate handling and marketing and to ensure the minimum spoilage during storage, handling and transport. The packaging also has a criterion of consumer appeal. Besides food quality, the issue of food and environmental safety have also become important. The disposal of used packaging material so as not to cause pollution needs to be given due considerations.

8.13 KEY WORDS

Transport	:	It refers to the transfer of material from one place to another be it the transport of raw materials to the processing industry or the finished product from the industry to the market place.
Transmission rate of packages	:	It refers to the transfer of a particular component like water vapour, oxygen, etc. across the packaging material per unit area per unit time.
MAP	:	Modified atmosphere packaging contains the food under a gaseous environment that differs from air, in order to control normal product respiration (ethylene, CO_2, water vapour, and O_2) and growth of aerobic microorganisms.
CAP	:	Controlled atmosphere packaging (CAP) permit controlled oxygen and carbon dioxide exchange.
Active packaging	:	Packaging more actively contributes to the product development, controls maturation and ripening, helps in achieving the proper colour development in meats, and extends shelf life. It plays an active role in protecting foods.
Vacuum packaging	:	Vacuum packaging modifies the atmosphere surrounding the food by removing oxygen, and it extends shelf life.
Aseptic packaging	:	It is packaging of the food material in a sterile environment.
Biodegradable Plastics	:	Biodegradable plastics are biodisintegratable plastics, which disintegrate into polymer chains and break down into water and carbon dioxide.
Transportation cost	:	Involves all costs involved and each must be taken care to optimize profits.
CFB	:	The corrugated fibreboard is made of paperboard liners and corrugating medium. The structure of corrugated fibreboard consists of a fluting medium running in a sinusoidal wave form between the two liners, thus separate the liners by a distance to obtain good stiffness.
Bag-in-box	:	In this system, the bag is supported on the outside by a rigid container made of paper board or corrugated board carton.
Palletization	:	A pallet is a platform made to hold one or more boxes, bags, cartons etc. in a group.

8.14 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Appropriate packaging and transportation is one of these measures applied at all stages between the grower and the consumer in order to reduce wastage, improve food security and generate income and profit. When properly applied it can have a dramatic effect, towards reduction of losses and ensuring quality product for the customer. Appropriate packaging and transportation ranges from the proper use of containers in which to transport produce to local markets, through to sophisticated systems that can extend the shelf-life of a processed foodstuff for a year or more.

2. i) Suitability

   - Tran-shipment necessary.
   - Pilferage is a major problem.
   - Proper handling instructions essential.
   - Packages can be sent on railways risk.
   - Packages are to conform to rules and regulations of the Railways.
   - Door to door delivery possible only by container service.
   - No problem for inter-state transport.
   - Less interruption of journey even in rainy season.

   Hazards:

   - Stacking height upto 8 feet.
   - Vibration due to rail joints and track conditions.
   - Shunting shock.
   - Very high temperature (upto 70°C) in steel wagons in summer.

   ii) Suitability

   - High freight charges and hence lighter packages to be used.
   - Limitations on size & weight of packages.
   - Less journey time.
   - Better handling.
   - No cooling facility available.

   Hazards:

   - High frequency vibration due to engine.
   - Low temperature and pressure when flying at high altitudes.

3. Three factors that cause deterioration of foods during storage are:

   - mechanical forces (impact, vibration, compression or abrasion),
   - climatic influences that cause physical or chemical changes (UV light, moisture, oxygen, temperature changes),
   - contamination (by micro-organisms, insects or soils).

4. Four packaging functions are as follows:

   - Preserving against spoilage of colour, flavour, odour, texture, and other food qualities.
   - Controlling absorption and losses of O_2 and water vapour.

- Offering adequate storage before use-such as stockable, resealable, pourable.
- Preventing/indicating tampering with contents by tamper-evident labels.

Check Your Progress Exercise 2

1. A ***primary*** container is the bottle, can, drink box, and so forth that contains food. It is a direct-food-contact surface. Several primary containers are held together in ***secondary*** containers, such as corrugated fiberboard boxes (commonly, but not correctly, referred to as cardboard), and do not have direct food contact. In turn, several secondary containers are bundled into ***tertiary*** containers such as corrugated boxes or overwraps that prepare the food product for distribution or palletizing.

2. a) Different types of plastics available for food packaging.
   b) Their suitability for packaging of food materials.
   c) Their relative advantages and disadvantages.

3. a) Describe wooden containers and CFB box.
   b) The type of foods that can be packed using wooden containers and CFB box.
   c) Their advantages and disadvantages if any, over other packaging materials.

Check Your Progress Exercise 3

1. A test can generally be defined as an act of determining a given property or characteristics of a product (packaging material or package) by taking one or more measurements qualitatively or quantitatively according to prescribed procedure. Three reasons for testing of packages include the following:

   - Comparison with competitive material to compare the offers.
   - Current checks over the uniformity of new supplies of packaging materials, i.e., to check for change in quality if any from batch to batch.
   - Quality checks during the production of packaging materials or packaged commodities.

2. i) Tensile strength and tearing strength tests

   ii) Water vapour transission rate and bursting strength tests

Check Your Progress Exercise 4

1. The three packaging laws and regulations affecting food products are:

   - The Standards of Weights and Measures Act, 1976, and the Standards of Weights and Measures (Packaged Commodities) Rules, 1977 (SWMA).
   - The Prevention of Food Adulteration Act, 1954, and the Prevention of Food Adulteration Rules, 1955 (PFA).
   - The Fruit Products Order, 1955 (FPO)

2. The principal methods used to control solid waste disposal are:

   i) Land in-fill.
   ii) Incineration.
   iii) Composting.
   iv) Direct constructional use (unsorted).
   v) Reuse (sorted).
   vi) Pyrolysis.
   vii) Chemical treatment.

3. In all the short notes the following points needs to be covered:

   i) The definition.
   ii) Use and principle.
   iii) Foods suitable for the method.
   iv) Advantages and disadvantages of the method.

UNIT 9 JUICE AND BEVERAGES

Structure

9.0 OBJECTIVES

By the time you have studied this unit, you should be able to:

- prepare various fruit beverages;
- learn principles of various preservation techniques;
- know equipment used in the processing of fruit beverages;
- explain quality aspects and standards of product; and
- describe packaging requirements and types of packaging material.

9.1 INTRODUCTION

Fruit beverages are easily digestible, highly refreshing, thirst- quenching, appetizing and nutritionally far superior to synthetic and aerated drinks. The fruit beverage include natural and sweetened juices, squash, syrup, fruit juice concentrate and fruit juice powder.

In this unit we will study the various steps in the preparation of fruit beverages, and their preservation methods for extending their shelf life. Measures taken to improve the quality of the final product by Fruit Products Order (FPO) is also given in this unit. Apart from this, you will learn the importance of packaging and different packaging materials used in the processing industry.

9.2 FRUIT JUICE

The concept of fruit juices has gained immense consumer popularity. Fruit juices are products for direct consumption and are obtained by the extraction of cellular juice from fruit, this operation can be done by pressing or by diffusion. The fruit juice processing technology employed for different fruits and the various equipments required during different stages of processing has been covered here.

9.2.1 Preparation of Fruit Juice

Fruit juices must be prepared from sound, mature fruits only. Soft fruit varieties such as grapes, tomatoes and peaches should only be transported in clean boxes, which are free from mould and bits of rotten fruit. The flow chart for fruit juice production is given in Figure 9.1.

Labelling and Storage

Figure 9.1: Flow chart for fruit juice production

Washing: Fruit must be thoroughly washed. Generally, fruits are submitted to pre-washing before sorting and a washing step just after sorting. Washing can be done either by water or by dilute hydrochloric acid (1 part acid : 20 part water).

Sorting: Removal of partially or completely decayed fruit is the most important operation in the preparation of fruit for production of first quality fruit juices; sorting is carried out on moving inspection belts or sorting tables.

Crushing/Grinding/Disintegration: This is applied in different ways and depends on fruit types: Crushing for grapes and berries; Grinding for apples, pears; Disintegration for tomatoes, peaches, mangoes, apricots etc. This processing step will need specific equipments, which differs from one type of operation to another.

Enzyme treatment: The enzyme treatment of crushed fruit mass is applied to some fruits by adding 0.2-0.8% pectolitic enzymes at about 50° C for 30 minutes. This optional step has the following advantages: extraction yield will be improved, the juice colour is better fixed and taste of finished product is improved.

Expression/extraction*:* Generally juice is expressed from the crushed/disintegrated fruit pulp. During expression, juices should not be unnecessarily exposed to air as it will spoil the colour, taste and aroma and also reduce the vitamin content.

The equipments used for the juice extraction are screw type juice extractors, basket presses or fruit pulpers (shown in figure). All equipments used in the preparation of fruit juices and squashes should be rust and acid proof. Copper and iron vessels should be strictly avoided as these metals react with fruit acids and cause blackening of the product. Machines and equipments made of aluminium, stainless steel, etc can be used.

Straining/Filtration*:* The extracted juice contain some amount of suspended matter. The suspended matter consists of broken fruit tissue, seed, skin, gums, pectic substances and protein in colloidal suspension. These materials can be removed by straining through a thick cloth or sieve. Removal of all suspended matter improves the appearance but often results in disappearance of fruity character and flavour. The present practice is to let fruit juices and beverages retain a cloudy or pulpy appearance to some extend (Figure 9.2).

Clarification: It is the process of complete removal of all suspended material from the juice**.** This can be performed by many methods viz. centrifugation, enzyme treatment, settling, filtration, freezing(-18^{o}C), use of high temperature (nearly 82^{o}C) and low temperature(-2 to –3 ^{o}C). The chemical treatments like addition of gelatin, albumin, casein, or a mixture of tannin and gelatin are also used for the removal of suspended particles.

Centrifugation is carried out in centrifugal separators with a speed of 6000 to 6500 rpm. Enzyme clarifying is based on pectic substance hydrolysis; this will decrease the viscosity of juice and facilitate their filtration. The treatment is the addition of pectolitic enzyme preparations in a quantity of 0.5 to 2 g/l. This will last for 2 to 6 hours at room temperature, or less than 2 hours at 50° C, a temperature that must not be exceeded.

De-tartarisation is applied only to raisin juice and is aimed to eliminate potassium bi-tartrate from solution. This step can be performed by the addition of 1% calcium lactate or 0.4% calcium carbonate.

9.2.2 Preservation of Fruit Juices

Fruit juice is preserved to prevent the decay/spoilage and to extend the shelf life of the juice in a good condition for future use. This is generally done by the use of high temperature (pasteurization and flash pasteurization), use of low temperature (refrigeration and freezing), preservation with chemicals (sulphur dioxide and benzoic acid), drying, filtration, carbonation, and by using sugar. The methods used for the preservation are follows:

Pasteurization

Preservation by heat is the most common method. It is the process of heating fruit juice at boiling temperature or slightly below it for a sufficient length of time to kill the microorganisms that cause spoilage. The juice is hermetically sealed in containers before being pasteurized. Usually the fruit juices are pasteurized at about 85°C for 25 to 30 minutes according to the nature of the juice and size of the container.

Flash Pasteurization

In this method, fruit juice is heated for a short time at a temperature higher than the pasteurization temperature and held at that temperature for about a minute and then filled into containers which are sealed air tight under cover of steam to sterilize the seal and then, cooled. For the maintenance of the product quality, the rate of heat transfer in these pasteurizers are kept high. The heat transfer depends on the viscosity of the juice, specific heat of the juice and temperature difference. This method has many advantages viz., minimum loss of flavour, preservation of vitamins, economy of time and space, uniformity in body of juice, and minimum cooked flavour.

Preservation by Chemicals

Microbial spoilage of fruit beverages is also controlled by using chemical preservatives. The inhibitory action of preservative is due to their interfering with the mechanism of cell division, permeability of cell membrane and activity of enzymes. Pasteurized fruit beverages undergo spoilage once opened. To avoid this it is necessary to use chemical preservatives. Chemically preserved beverages can be kept for a fairly long time even after opening the seal of the bottle. The two important chemical preservatives permitted in our country by FPO are sulphur dioxide (including sulphites) and benzoic acid (include benzoates).

Sulfur dioxide: It is widely used throughout the world in the preservation of fruit juice and other beverages. It has good preserving action against bacteria, moulds and inhibits enzymes. In addition, it acts as an antioxidant and bleaching agent. It is generally used in the form of it’s salts such as sulphite, bisulphite and metabisulphite.

The advantages of using sulphur dioxide are:

1. It has better preserving action against bacterial fermentation
2. It helps to retain colour
3. It ensures better mixing and hence their preservation

4. It helps in preserving the surface layer of juices.
5. Excess amount can be removed by heating or by vacuum

The limitations of sulphur dioxide are:

1. It can't be used in some coloured juices like those of jamun, strawberry etc on account of its bleaching action.
2. It corrodes the tin containers.
3. Some consumers may be sensitive to sulphur dioxide.

Benzoic acid: It is only partially soluble in water and hence it's salt, namely sodium benzoate is used as preservative. Pure sodium benzoate is tasteless and odourless. The antibacterial action of benzoic acid is increased in the presence of CO_2 and acid. Benzoic acid is more effective against yeast than against moulds. The quantity of benzoic acid depends on the acidity of the products. In case of fruit juices with pH of 3.5-4, addition of 0.06% of sodium benzoate is recommended.

By Addition of Sugar

Syrups containing 66 % or more of sugar do not ferment. Sugar absorbs most of the available water with the result that there is very little water for the growth of microorganisms. This reduction in water will inhibit the multiplication of microorganisms and gradually they die out from the product.

By Freezing

Microbial growth and enzymatic reactions are retarded in juice stored at low temperatures. The lower the storage temperature the slower will be the rate of a chemical or enzyme reaction. Freezing is the process in which the temperature of a food is reduced below the freezing point, and a proportion of the water undergoes a change in state to form ice crystals. Under the usual condition of storage of frozen foods, microbial growth is prevented completely and the action of food enzymes greatly retarded. The best way of preserving pure fruit juice is by freezing. Properly frozen juice retains its freshness, colour and aroma for a long time. This method is particularly useful in case of juices whose flavour is adversely affected by heating. Preservation by freezing is carried out at about −30° C, after a preliminary de-aeration. Then storage is done at −15 to −20° C.

By Drying

Drying is the processes of removal of moisture to a pre determined level. You know that the growth of microorganisms is directly dependent upon the concentration of water present in the food. So a reduction in moisture will reduce the growth of microorganisms. Moisture can be removed by the application of heat. The details regarding the methods of drying are given in the Unit 4.

By Carbonation

It is the process of dissolving sufficient carbon dioxide in fruit juice so that the product when served gives off the gas as fine bubbles and has characteristic taste. Carbonation is done at a concentration of 1.5% CO_2 under a pressure of 7 kg/cm². Another advantage of carbonation is the removal of air from the fruit juice, which reduces the oxidation of ascorbic acid, prevents browning and microbial growth. High carbonation should be avoided as it usually destroys the delicate flavour of the juice. The keeping quality of carbonated fruit beverages is enhanced by adding about 0.005 % of sodium benzoate.

By Filtration

In this method, the juice is first clarified through ordinary filters and then passed through special filters. These special filters retain yeast and bacteria. Various types of germ-proof filters are used for this purpose. This requires elaborate precautions to ensure complete sterility in the bottled product.

By Irradiation

The irradiation process involves passing of fruit juice through a radiation field allowing the juice to absorb desired amount of radiation energy. The juice itself never comes in contact with radioactive material. The gamma radiations from the radioactive material will disinfest, sterilize and preserve the fruit juice. The dose required to provide stability is partly determined by the solid content of the juice. Generally irradiation lightens the colour of the juice. On storage, however, darkening occurres and stored irradiated apple juice shows little difference from the original colour. Flavour changes caused by the irradiation are less. The dose required to obtain stability may be reduced by heating the juice to a higher temperature (50^{o}C) prior to irradiation. In this way, a dose of 3 kilo Grey is adequate to secure stability at ambient temperature for more than a year.

9.2.3 Bottling

Bottles are thoroughly washed with hot water and drained before filling. A 1.5 to 2.5 cm head space is left during filling. They are then sealed either with crown corks (by crown corking machine) or with caps (by capping machine).A typical corking machine is shown in Figure 9.2.

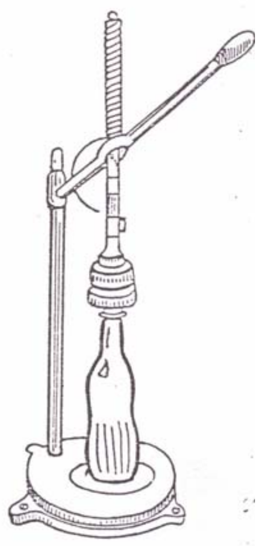

Figure 9.2: Crown corking machine

9.3 EQUIPMENTS FOR THE PRODUCTION OF JUICE AND PULPS

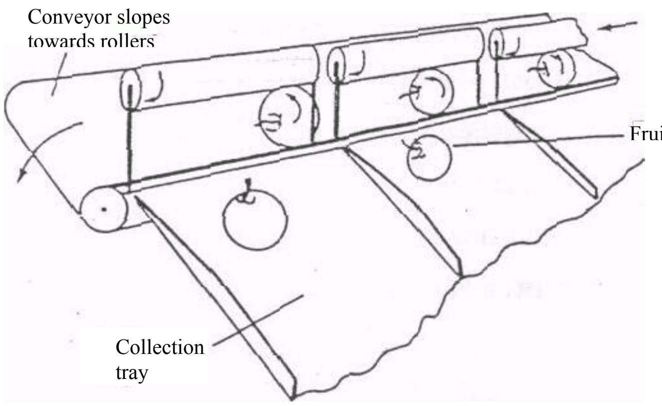
Different types of equipments are used in the juice processing plant, starting from equipments for washing, sorting, extracting to pasteurizers. While selecting an equipment the material of construction is very important. Glass-lined equipment, or equipment made of metals like stainless steel, monel metal, nickel, aluminium or bronze should be used because such equipment is not readily acted upon the fruit or vegetable juices. A unit of machinery made of different metals should also be avoided because is similar metals in the system or unit will lead to the setting up of small electrical couples and consequently corrosion will take place. Use of rubber in the equipments should be avoided as far as possible.

9.3.1 Washing Equipments

Different types of equipments are available for washing of fruits and vegetables. Tender fruits are usually washed with a fine overhead spray of water, while the fruits travel on a continuous woven wire belt. On small scale processing plants washing is carried out in cement or galvanized iron tanks.

9.3.2 Sorting Equipments

In large factories, a continuous broad belt, made of woven metal, is generally employed for sorting the fruits. In smaller factories, however, batch sorting will be sufficient. A schematic diagram of belt and roller sorter and screen sorter are shown in Figure 9.3a and 9.3b.



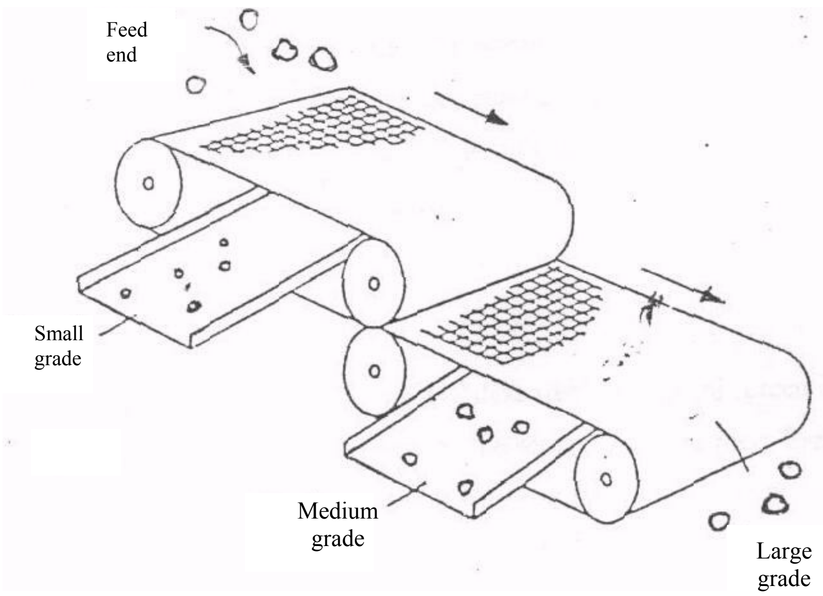


Figure 9.3: Sorting machines: a) Belt and roller sorter; b) Screen grader

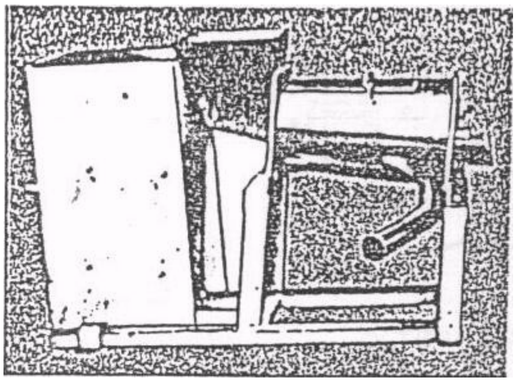
9.3.3 Pulping/Grinding Equipments

There are two types of extractions. In the first case, the fruits are crushed and pressed continuously in one operation (Figure 9.4). In the second case, the fruits are crushed or cut into small pieces or comminuted in a mill, and these are subsequently pressed in a suitable press. Some of the crushing/ extraction equipments are discussed here.



Pulper

Figure 9.4: Fruit pulper

Hammer mills: These are devices to pulp/crush the whole fruit in preparation for extraction. Hammer mills consist of heavy stainless steel bars spinning from a common axis under a high speed of rotation. The fruit is disintegrated until it will pass out through a screen of specific size mounted in the bottom of the mill (Figure 9.5). The mash will be of finer particle size and the smaller particle size will allow greater yields in case of firm fruits. Softer fruit presses with more difficulty, and a larger particle size in the mash will enhance ease of pressing.

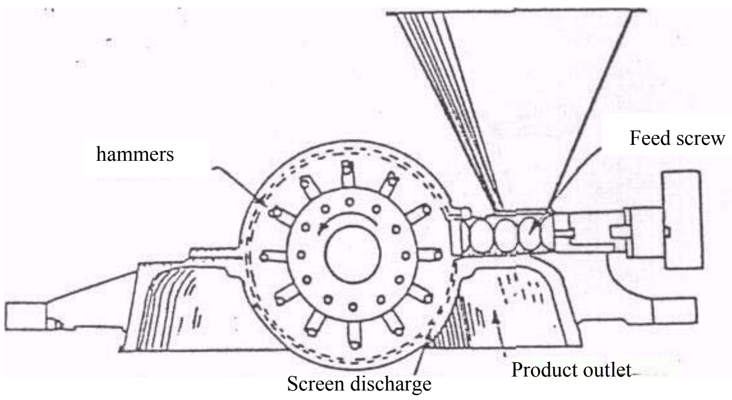


Figure 9.5: Sectional view of hammer mill

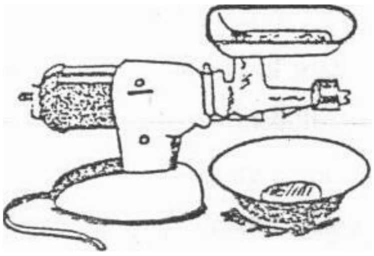
Grating mills: These offer an alternative method for disintegrating fruits. In grating mill, the fruit is drawn past fixed knifes mounted on a cylinder. Control of the grind is accomplished by adjusting the depth of the knifes and thus the size of cut from the fruit

Crusher: In grape juice processing, a stemmer/crusher removes residual stems, leaves, and petioles from the grapes and does the initial crush of the fruit after arrival at the plant. This unit is designed around a rotating drum perforated with holes of approximately 2.5 cm diameter. In the process of traversing the rotating drum, grapes are caught by the perforated drum and knocked from the stems. The individual grapes are broken open or crushed in the process and drop through the drum.

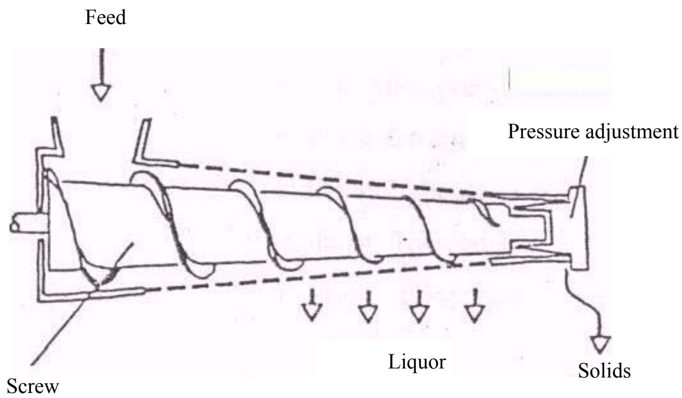
9.3.4 Screw Press

A typical screw press consists of a reinforced stainless steel cylindrical screen enclosing a large bore screw with narrow clearance between the screw and the screen. Breaker bars are located between the screw intervals in order to disrupt the compressing mash. Working principle of a typical screw extractor is shown in Figure 9.6a and Figure 9.6b. Back pressure is provided at the end of the chamber and is usually adjustable. The segments of the fruit are fed through a hopper at one end of a feeding screw, revolving inside the perforated screen. The juice flows out through the perforations and the pomace comes out through the other end. Capacities for screw press with a 30.5 cm and 41 cm diameter are 5,080 kg and 15,240 kg per hour.

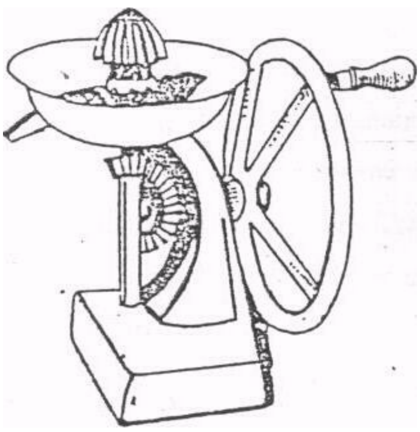


Screw Type Juice Extractor

(a)



(b)



Lime Juice Extractor

(c)

Figure 9.6: a) Screw extractor; b) Working principle of screw press; and c) Lime juice extractor

9.3.5 Basket Press

These are of various designs and capacities and are worked manually by hydraulic pressure. The manually operated press consists of a strong cylindrical basket which is made of wooden slates. It rests on a wooden or metallic base. There is strong screw at the top of this frame. The mash is folded in a strong cloth and placed inside the basket. By turning the screw by hand or with a hydraulic pump, the juice is pressed out. A schematic diagram of basket press shown in Figure 9.7.

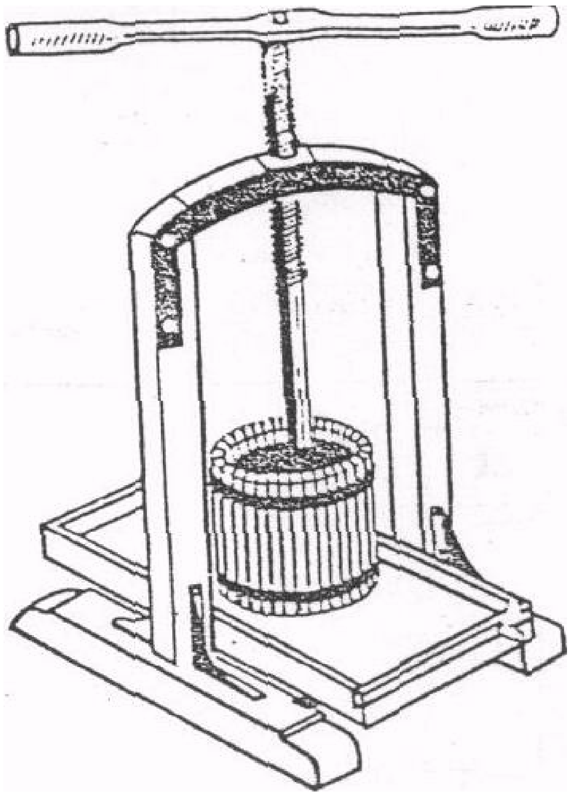


Figure 9.7: A typical basket press

9.3.6 Rack and Frame Hydraulic Press

The hydraulic rack and frame press is a very common press system found in small juice operations. It was the primary method of fruit juice pressing operations for many years. Heavy cotton or nylon cloths are filled with a set amount of mash and then folded to produce what is called a cheese. The individual cheese is stacked and separated by a wooden, stainless steel, or plastic spacer platen. The combined stack is then compressed using a hydraulic ram, during which the juice is expressed. A typical hydraulic juice press is shown in Figure 9.8.

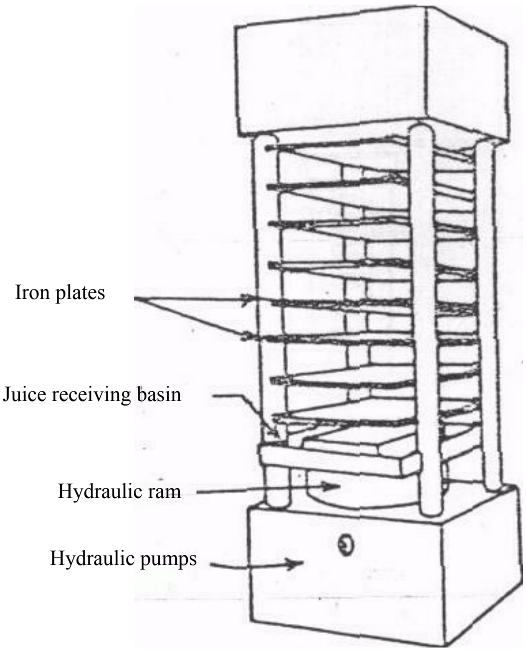

Figure 9.8: Schematic diagram of a hydraulic juice press

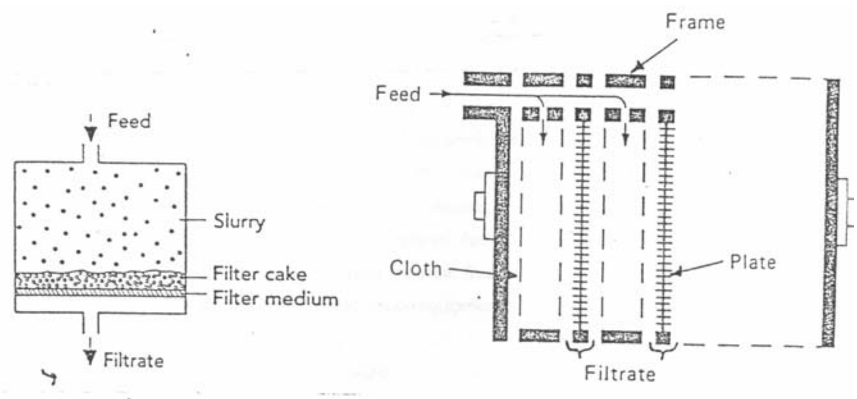
9.3.7 Decanter

A high solid stream can be partially clarified using decanters and finishers. Both pieces of equipment operate on the principle of a spinning central cone, drum, or set of paddles pushing the juice through a screen of some type. The unit is typically mounted horizontally, and throughput is relatively high. Total suspended solids may be reduced to 1% or less during operation, depending upon characteristics of the feed stream and operating conditions of the separator.

9.3.8 Filtration Equipment

Finely suspended particles in the juice are removed with a special equipment known as filter press. Filter presses are available with various designs and capacities. The filtering media may be finely woven cloth, canvas, fibre, asbestos pads, cotton or wood pulp discs, porous porcelain wares etc. The frame and filter press is highly effective for clarification of lime juice required for the preparation of lime juice cordial. A schematic diagram, explaining the working principle of frame and filter press is shown in Figure 9.9a and Figure 9.9b.



(a) **(b)**

Figure 9.9: Filters: a) Schematic representation of filtration; b) Plate and frame filter press

9.3.9 Deaerator

Freshly extracted and screened juice contain large amount of oxygen, which should be removed before packing. Most of the air is present on the surface of the juice and some is dissolved in it. The air as well as other gases are removed by subjecting the fresh juice to a high vacuum. This method is highly expensive due to the vacuum creation. The equipment used for the removal of oxygen from the fruit juice is called deaerator. The deaerated juice is heated in a flash pasteurization equipment.

9.3.10 Flash pasteurizer/Rapid Pasteurizer

In this equipment, the juice is heated rapidly to a temperature of about 5.5°C higher than the pasteurization temperature and kept at this temperature for about 10-60 second. By this technique, the loss of flavour and vitamin destruction is minimum and the juice keep a uniformly cloudy appearance. A schematic diagram of flash pasteurization equipment is shown in Figure 9.10.

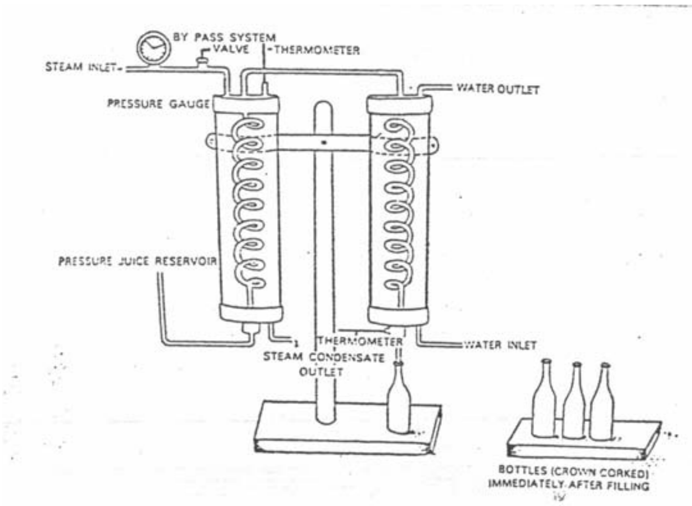


Figure 9.10: Schematic representation of a flash pasteurizer

9.4 SQUASHES

Squash essentially consists of juice containing moderate quantity of fruit pulp to which cane sugar is added for sweetening. According to FPO this type of fruit beverage should contain at least 25% fruit juice or pulp and 40-50 % total soluble solids on weight basis. It also contains about 1.0 % acid and 350-ppm sulphur dioxide or 600 ppm sodium benzoate. It is diluted before serving.

Juice or pulp of fruits is extracted in different ways as discussed earlier. This juice is used for the preparation of squash. Sugar, citric acid, flavouring materials, colour and preservatives are added to the juice in correct proportion. Sugar, citric acid and water are mixed and heated. The dirt is skimmed-off. The clean syrup is blended with the juice. After mixing all the ingredients, a calculated amount of chemical preservative, namely, sodium benzoate or potassium metabisulphite (KMS) is added. Colour and essence can be added to the squash, but should be fairly resistant to the action of preservatives.

The bottles should be cleaned and well sterilized before filling. There should be about 1.2-2.5 cm of head-space in bottles. Bottles are closed with pilfer proof closures, which should be dipped in 1% potassium metabisuphite solution. The bottles are washed, dried and labelled. The product keeps well for more than one year without much change in colour, taste and flavour.

9.5 CORDIAL

This is a sparkling, clear sweetened fruit juice from which pulp and other suspended materials have been completely removed. It contains at least 25% juice and 30% total soluble solids. It also contains about 1.5% acid and 350ppm sulphur dioxide. This is very suitable for blending with wines.

Juice is stored in barrels which are lined with microcrystalline wax. KMS is added as preservative during storage. During storage, the sediment settles and forms a compact layer at the bottom and clear juice remains at the top. Clarification process takes 2-3 months. The clear juice is siphoned off. This method is slow. To make it fast, gelatin and tannin can be added. In clear juice, sugar, water, colour and preservatives are added and the mixture is filtered by means of a filter press. The clear cordial is then bottled.

9.6 SYRUPS

This type of fruit beverage contains at least 25% fruit juice or pulp and 65% total soluble solids. Since the syrup strength is very high, to avoid crystallization, sugar is inverted by adding a small quantity of citric acid and heating in water. It also contains 1.3-1.5% acids and is diluted before serving. Syrups with 65 ^{o}Brix TSS can retain their fresh flavour for over four years. The condition required for this is that a juice should be filtered to a brilliant condition for making the syrup.

9.7 CARBONATED BEVERAGES

The use of fruit juices in the preparation of carbonated drinks is practically unknown in our country. Mostly, artificially flavoured drinks which have no nutritive value are prepared by this method. The use of fruit juices would increase the nutritive value of carbonated beverages.

One of the most important factors that relates to the taste of the bottled fruit juice beverage is carbon dioxide gas content or degree of carbonation. Carbonation is the process of dissolving or incorporating carbon dioxide in a beverage so that when served, it gives off the gas in fine bubbles and has the characteristic pungent taste suitable to the carbonated beverage.

In beverage manufacture, CO_2 not only provides the distinctive taste of carbonated drinks but also inhibits the growth of certain microorganisms. Fruit juices can be carbonated directly or preserved in the form of concentrates for subsequent carbonation. Clarification of such juice is essential prior to carbonation. Carbonated beverage can keep well for about a week without addition of any preservative. For longer storage of carbonated drink, use of preservative (0.05 % sodium benzoate) is necessary.

9.8 FRUIT JUICE CONCENTRATES

Fruit juice concentration offers significant advantages to the processor. Juices obtained by removal of a major part of their water by vacuum evaporation or fractional freezing is termed as “concentrated juices”. By concentrating the juice, the processor reduces the bulk of the juice, thereby reducing storage volume requirement and transportation costs. The process starts with pressing fruits and obtaining pure fruit juice. This is then stabilized by heat treatment which inactivates enzymes and micro-organisms. The next processing step is concentration under vacuum up to 40-65° Brix or 4-7 fold. The concentrates are then blended for standardisation and stored. Many methods are adopted for concentrating fruit juice. They are discussed below:

Evaporation: Evaporation is the most important process for concentration of fruit juices. Production of concentrated juices by evaporation is performed under vacuum (less than 100 mm Hg residual pressure) up to a concentration of 65-70% total sugar which assures preservation without further pasteurization. Modern evaporation installations recover flavours from juices which are then reincorporated in concentrated juices.

Evaporator generally consists of a heat transfer surface, a feed distribution device, a liquid vapour separator and a condenser. A schematic diagram of an evaporator is shown in Figure 9.11. With most of the juices, it is desirable to heat the juice for as short time as possible and rapidly cool the product. This minimizes the effect on flavour, aroma, and sugar components.

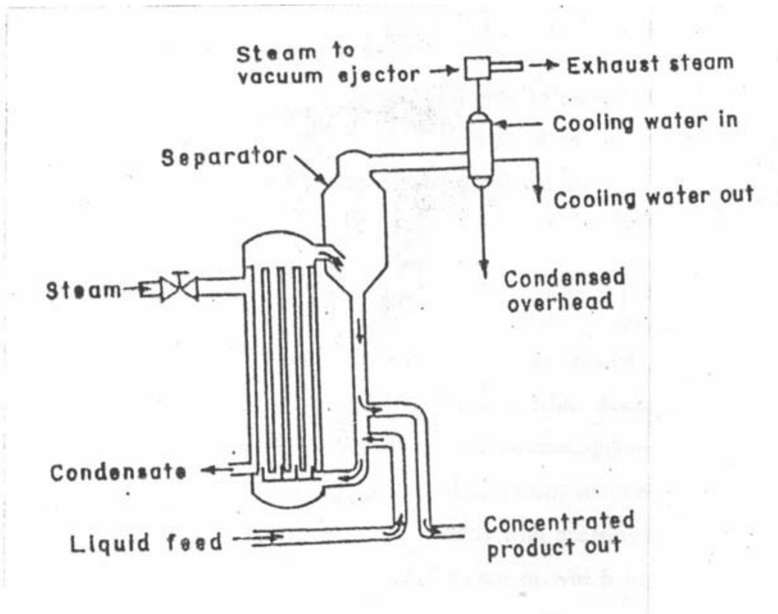

Figure 9.11: Diagram of a typical evaporator

Membrane concentration: Membranes are available that can effectively separate water molecules from other food constituents. Concentration of juice is also possible by using combination of reverse osmosis and evaporation. Specific membranes are used for this purpose. The principle involved is the interposition of a membrane between the feed stream and a transfer stream, and the establishment of conditions providing a driving force for the transport of water across the membrane from the feed to the transfer stream. A schematic diagram explaining the working principle of membrane concentration is shown in Figure 9.12.

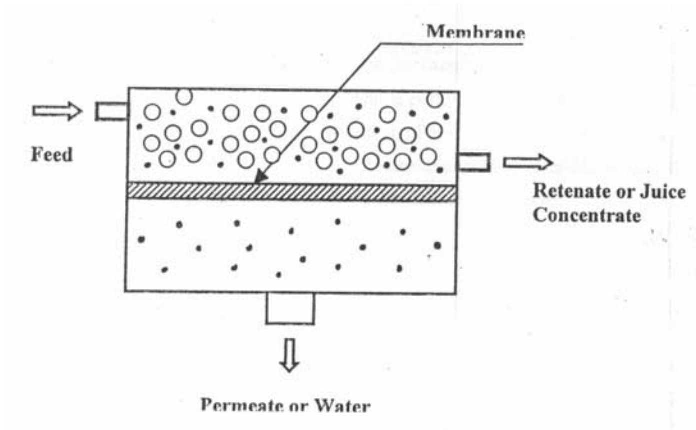

Figure 9.12: Schematic representation of ultrafiltration process

The reverse osmosis technology is effective in concentrating a low solid juice (7-8 ^{o}Brix) two or three fold. From there, use of evaporation technology would be appropriate. Recently, a new reverse osmosis design has claimed effectiveness in achieving a 50-60 ^{o}Brix concentrate. These fruit juice concentrates are often further stabilised by the addition of sodium benzoate and potassium sorbate and are usually stored away from light and are refrigerated or frozen.

Membrane concentration has many advantages over the other concentration techniques. Since the temperature of the processing is less, product quality is maintained. Lower energy requirements, lower labour costs, lower floor space, and wide flexibility are other advantages.

Freeze concentration: This process is based on freezing point depression. Pure water freezes at a temperature of 0^oC. However, if dry solid is dissolved, freezing take place at further low temperatures. In this process a freezer is used to produce ice crystals out of fresh juice and a device is used for separating these ice crystals. The separation of ice crystals from the juice slurry is done by using a centrifuge or filter press.

Freeze concentration avoids the problems associated with evaporation methods that depend upon the heat. It is capable of concentrating most juices to 50^oBrix without appreciable loss of taste, aroma, colour or nutritive value.

9.9 FRUIT JUICE POWDERS

In this method juices are preserved in the form of powder. The juice is sprayed as mist into an evaporating chamber and the flow of air is so regulated that dried juice falls to the floor of the chamber in the form of dry powder. The powder is then separated and packed air tightly. The powder, when dissolved in water makes a fruit drink almost similar to its original fresh juice.

Many fruit juices can be dehydrated to powders or crystals for reconstituting into beverages and are available at prices comparable with quality frozen concentrates. These powdered products are available in several sizes of package. Additives which are permitted by FDA are usually included. These powdered products are also considered as "sports drink", which requires mixing by the individuals and avoids the inconvenience of transporting large volume of liquid.

These powders are highly hygroscopic in nature and hence require proper packaging. Fruit juice powder from fruits like oranges, mangoes, jackfruit, guava etc. are prepared from strained fruit juices either by spray drying or puff drying and pulp can be used as the base material for baby foods. The powders can be made by vacuum drying, spray drying, freeze drying, drum drying or by foam-mat drying. The moisture content of powdered juice varies from 3-5%. The methods and principles of these drying processes are explained in unit 4 (Section 4.9).

9.10 QUALITY

The term 'quality' is one of the most defined terms in use in the food industry today. Quality may be defined as 'The totality of features and characteristics of a product that bear on its ability to satisfy a given need'. The first part, 'The totality of features and characteristics of a product…..'concerns objective factors related to the product. The second part, '……to satisfy a given need', concerns subjective factors related to the user or the consumer of the goods.

9.10.1 Factors Influencing Product Quality

To produce high-quality products, the processor needs to be aware of the quality attributes which the consumer discerns as most important and which are most relevant in determining acceptability. Most consumers would initially judge the acceptability of products on their appearance, flavour, texture and perceived nutritional benefits. Each of these attributes is a function of the bio-chemical and physico-chemical composition of the fruit or vegetable. This is influenced by various factors viz:

1. The quality and composition of the raw materials,
2. The effects of processing,
3. The effects of environmental factors, such as temperature, oxygen, light and moisture, encountered during storage and distribution,
4. Customer handling and use, and
5. The barriers to these factors provided by the packaging.

9.10.2 Measurement of Product Quality

One obvious way of measuring product quality is to monitor sales and customer complaints; the higher the sales and the fewer the complaints, the more likely one is to be satisfying the consumer requirements. However, no responsible food manufacturer would rely on this as their only method of quality control. Various methods used for the evaluation are:

1. Instrumental,
2. Immunoassay,
3. Near infrared spectroscopy, and
4. Sensory evaluation.

9.10.3 Quality Control Measures

Some of the important points to be considered for maintaining good quality products are as follows:

1. Only sound fruits or vegetables of sufficient maturity are to be used for processing.
2. Adequate hygienic practices should be followed during the processing of the product.
3. The inspector must be aware of the pesticides and other chemicals used in the production of the raw materials. Necessary laboratory analyses can then be arranged to ensure residue levels in the final product.
4. At the commencement of and during processing, the inspector should pay attention to the state of raw materials, the preparation of raw materials for processing (peeling, slicing, dicing, blanching, etc.), preparation and density of packing medium (sugar syrup, salt brine, etc.), the state of containers to be used (cleanliness and strength), the pasteurization or freezing process (time/temperature relationship), bottle filling and capping and bottle/container storage.
5. The people who work in the processing plant must maintain a high degree of personal cleanliness and conform to hygienic practices while on duty.
6. Persons who are monitoring the sanitation programs must have the education and/or experience to demonstrate that they are qualified.

7. Plant construction and design shall provide enough space for sanitary arrangement of equipments. The equipments must be self-cleanable as far as possible. Cleaning operations must be conducted in a manner that will minimize the possibility of contaminating foods or equipment surfaces that contact food.
8. Check the final product to ensure the vacuum and headspace, packing medium strength and container conditions. Statistically based sampling plans should be adopted for the examination of final product to ensure that it meets the requirements of the export regulations.
9. Each processing unit should have its own sufficiently equipped laboratory and staff to carry out physical, chemical and microbiological quality examinations of the goods.
10. Practice proper sanitary handling procedures. Cleaning operations must be conducted in a manner that will minimize the possibility of contaminating foods or equipment surfaces that contact food

9.10.4 Labelling

Customers and consumers expect the labelling on food to be a true description of what they are buying. Misleading or fraudulent labelling is an unfair trade practice that cannot be tolerated. The important requirements of a label are as follows:

1. A statement of identity,
2. A declaration of net contents (weight or volume),
3. The name and address of the manufacturer, packer, and
4. A list of ingredients (in descending order of volume or weight).

In addition, labels may also be required to include, amongst other things, the country of origin, date of manufacture or packing, a use-by or expiry date, nutritional qualities or values of the food, storage directions, a quality grade and directions for consumption.

9.11 STANDARDS

Government of India has made statutory provision for the control of quality. This has been made to maintain the quality of food, to prevent exploitation of the consumer by the sellers, to safeguard the health of consumers and to establish a criteria for the quality of food products. By this provision we can easily identify the quality of the processed products.

Fruit Products Order (FPO) – 1955, promulgated under Section 3 of the Essential Commodities Act – 1955, aims at regulating sanitary and hygienic conditions during the manufacture of fruit products. It is mandatory for all manufacturers of fruit and vegetable products to obtain a license under this Order. This act regulates the manufacture, storage and sale of fruit and vegetable products.

The FPO 1955 was issued by the Department of Food, Ministry of Food Processing Industries under the powers vested in the government under the Essential Commodities Act to ensure the quality of fruit and vegetable products. This order controls the production, distribution and quality of the fruits and vegetable products manufactured in the country as well as registration, licensing and operation of manufacturing units.

The FPO mark is given to the processor after the grant of license for manufacturing fruit or vegetable product, after the inspection of factory for hygiene and sanitation. FPO mark and license number is required by law to be exhibited on labels of each processed item along with the other information as laid down in the FPO rules.

The FPO specifications includes methods of preservation, permissible colours in the preparations and also the minimum quality requirements of the final products. Fruit and vegetable products which do not conform to the FPO specifications are considered adulterated.

FPO specifications for fruit beverages are as follows:

Sl. No.	Particulars	Specifications	
		Minimum % of TSS in final product	Minimum % of fruit juice or prepared fruit in final product
1.	Fruit Syrup	65	25
2.	Squash	40	25
3.	Cordial	30	25
4.	Unsweetened Juice	Natural	100
5.	Sweetened Juice	10	85
6.	Fruit Juice concentrate	32	100

Permissible limits of preservatives in fruit beverages:

Sl. No.	Fruit beverage	Preservative	Maximum level permitted (mlp)
1.	Fruit juice concentrate	Sulfur dioxide	1500
2.	Squashes, fruit syrups, cordials, fruit juices	Sulfur dioxide or Benzoic acid	350 600

9.12 PACKAGING

Packaging is an integral part of food processing. It performs two main functions: to protect the processed product from surroundings and to advertise the product at the point of sale. The main factors that cause deterioration of product during storage are as follows.

1. Mechanical forces (Impact, vibration, compression etc.),
2. Climatic influences that cause physical or chemical changes (UV light, moisture, oxygen, temperature changes),
3. Contamination (by microorganism, insects, or soil), and
4. Pilferage, tampering or adulteration.

9.12.1 Requirements and Functions of Packaging Materials

The following are among the more important general requirements and functions of food packaging materials/ containers:

1. They must be non-toxic and compatible with the specific foods.
2. Sanitary protection and light protection.
3. Moisture, gas, odour and fat protection.
4. Resistance to impact or other external forces.
5. Transparency.
6. Ease of opening and ease of disposal.
7. Pouring features and reseal features.
8. Size, shape, weight limitations.
9. Appearance and printability.
10. Low cost and other special features.
11. Eco-friendly.

9.12.2 Types of Packaging Materials

There are two main groups of containers: i) Shipping containers, and ii) Retail containers. Shipping containers are containers which contain and protect the contents during transport and distribution (e.g. Wooden, metal or fibreboard cases, crates, barrels, drums and sacks). Where as the retail containers are consumer units which protect and advertise the food in convenient quantities for retail sale and home storage.(e.g.: metal cans, glass bottles, jars, rigid and semi-rigid plastic tubs, collapsible tubes, paperboard cartons and flexible plastic bags).

Wooden containers: Wood offers good mechanical protection and good stacking characteristics. The bottles of fruit beverages are transported by the use of wooden crates. Boxes, crates, casks, kegs, pallets, and few other types of containers made of wood are used on a limited scale to package food products.

Textiles: Cotton bags, sacks and bales are also used in the shipping of food products. They have limited use in the packaging of larger quantities of some products. Open mesh bags are frequently used to pack products such as fresh vegetables, which require complete ventilation in transport and storage.

Metal Can: Metal cans have a number of advantages over other types of containers. These includes protection, convenience for ambient storage and tamper proof. However the cost and weight of metal containers are relatively high. The usual metal cans used are three piece cans, two-piece cans, aerosol cans and aluminum cans.

Tinplate is the common material used for metal cans. It is a rigid and impervious material, consisting of a thin sheet of low carbon steel coated with a very thin layer of tin. Tin is not completely resistant to corrosion but its rate of reaction with many food materials is considerably slower than that of steel. Some organic coatings are provided to protect the tin surface. The FDA approved coating used for the fruit beverage is known as "Beverage can enamel" The coatings not only protect the metal from corrosion by food constituents but also protect the foods from metal contamination.

Glass: There is more use of glass in food industry. Glass containers are chemically inert and do not react with or migrate into food products. They are resealable, recyclable, reusable and are transparent to microwaves. They are transparent to display the contents and impervious to moisture, gases, odours and microorganisms. The principal limitation of glass is its susceptibility to breakage, which may be from internal pressure, impact, or thermal shock, all of which can be greatly minimised by proper matching of the container to its intended use and intelligent handling practices. Main classes of glass receptacles are:

1. Jars which are resistant to heat treatments,
2. Jars, glasses, etc. for products not submitted to heat treatment (marmalades, acidified vegetables, etc.),
3. Glass bottles for pasteurized products (tomato juice, fruit juices, etc.) or not pasteurized (syrups), and
4. Receptacles with higher capacity.

Flexible Films: Flexible packaging describes any type of material that is not rigid. In general they are heat sealable, suitable for high speed filling, suitable for printing and add little weight to the product. They fit closely to the shape of the food, thereby wastage of space is less during transportation and storage. In most cases, such films are used in the construction of inner containers. Since they are non-rigid, their main functions are to contain the product and protect it from contact with air or water vapour. Their capacity to protect against mechanical damage is limited, particularly when thin films are considered.

Flexible films includes single films (e.g.: poly ethylene, poly ester, etc.), coated films (e.g.: films coated with aluminium), laminated films (lamination of two or more films) and co-extruded films.

Paper and paper board: Paper and paper board are used in a variety of package types and forms. Paper from wood pulp and reprocessed waste paper will be bleached and coated or impregnated with such materials as waxes, resins, lacquers, plastics, and laminations of aluminium. This is to improve water vapour and gas impermeability, flexibility, tear resistance, burst strength, wet strength, grease resistance, sealability, appearance, printability, etc.

9.13 LET US SUM UP

The fruit beverage industry is gaining popularity because of nutritional superiority of these beverages to synthetic and aerated drinks. We have discussed in detail about the preparation of a variety of fruit beverages viz., juices, squash, syrup, fruit juice concentrate and fruit juice powder.

The various methodologies adopted in preservation and the working principles of different equipments used in processing of fruit beverages are briefly described in this unit. In addition, the packaging requirements, types of packaging materials, quality aspects and standards of fruit beverages are explained in detail.

9.14 KEY WORDS

Disintegration : Size reduction of fruit

Enzyme : Enzymes are organic biocatalysts which govern, initiates and control biological reactions important for life processes.

Expression : Separation of liquids from solids by applying pressure.

Filtration : Separation of solids from liquids by passing the mixture through a bed of porous material.

Brix : Unit for the measurement of Total Soluble Solids present in fruit beverage.

TSS	:	Total Soluble Solids is the amount of sugars and water soluble substances present in fruit and vegetables.
Clarification	:	It is the process of complete removal of all suspended material from the juice
Centrifugation	:	The separation of immiscible liquids, or solids from liquids by the application of centrifugal force.
De-tartarisation	:	Elimination of potassium bi-tartrate from fruit beverage.
Pasteurization	:	It is the process of heat treatment used to reduce the total microflora, especially pathogenic bacteria.
Flash pasteurization	:	It is the process of heating fruit juice for a short time at a temperature higher than the pasteurization temperature and held at that temperature for about one minute.
Carbonation	:	It is the process of dissolving sufficient carbon dioxide in fruit juice
Decanter	:	It is the process of removal of suspended material from the juice.
Deaerator	:	The equipment used for the removal of oxygen from the fruit juice.
Squash	:	Fruit beverage which contain at least 25% fruit juice or pulp and 40-50 % TSS.
Cordial	:	Fruit beverage which contain at least 25% juice and 30% TSS.
Syrups	:	Fruit beverage which contains at least 25% fruit juice or pulp and 65% TSS.
Evaporation	:	It is the partial removal of water from liquid foods by boiling.

9.15 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Clarification is the process of complete removal of all suspended material from the juice**.** This can be performed by many methods viz. centrifugation, enzyme treatment, settling, filtration, freezing(-18°C), use of high temperature (nearly 82°C) and low temperature(-2 to –3 °C). The chemical treatments like addition of gelatin, albumin, casein, or a mixture of tannin and gelatin is also used for the removal of suspended particles.

2. The enzyme treatments during crushing process will enhance the extraction yield, the juice colour is better fixed and finished product taste is improved.

3. Pasteurization is the process of heating fruit juice at boiling temperature or slightly below it for a sufficient length of time to kill the microorganisms which cause spoilage. Whereas flash pasteurization is the process of heating fruit juice for a short time at a temperature higher than the pasteurization temperature and held at that temperature for about one minute.

4. Preservation of fruit juice can be done by addition of sugar, pasteurization, flash pasteurization, freezing, drying, carbonation, filtration, irradiation and by adding chemicals like sulfur dioxide or Benzoic acid.

Check Your Progress Exercise 2

1. Fresh fruit juice contain 100 % fruit juice, where as fruit beverage which contain at least 25% fruit juice or pulp and 40-50 % TSS is known as squash.

2. Cordial is a fruit beverage which contain at least 25% juice and 30% TSS, where as syrups contains at least 25% fruit juice or pulp and 65% TSS.

3. Various methods used for fruit juice concentration are: Evaporation, Freeze concentration and Membrane concentration.

4. Fruit juice powders are prepared from strained fruit juices by spray drying, vacuum drying, freeze drying, drum drying or by foam-mat drying. However spray drying is the most common method. The juice is sprayed as mist into an evaporating chamber and the flow of air is so regulated that dried juice falls to the floor of the chamber in the form of dry powder.

UNIT 10 JAMS, JELLIES, MARMALADE AND OTHER SUGAR-BASED PRODUCTS

Structure

10.0 OBJECTIVES

By the time you have studied this unit, you should be able to describe:

- importance of sugar, sweeteners, confections and sugar substitutes;
- types and sources of sugar and its role in food systems;

- methods of preparation of fruit jam, jelly, marmalade and other sugar-based products; and
- special care to be taken during the preparation of these sugar based products.

10.1 INTRODUCTION

Though India ranks first in the total production of fruits and vegetables, an appreciable amount of the produce is culled or of inferior quality. These culled fruits can be effectively utilised for the preparation of value added products like jam, jelly, marmalade, preserves, candies and other sugar based products.

The preparation of such sugar based products is one of the most important aspects of home scale preservation as well as industrial level processing of fruits. This method of preservation with high sugar concentration is principally based on the reduction in moisture content so as to arrest the microbial spoilage.

In this unit, first we'll learn about the various types of sugars, sweeteners, and their sources. The role of sugar in food system is dealt with. The preparation of the sugar based products and the special care taken during processing is described in detail. The quality aspects and packaging are also briefed in this section.

10.2 SUGAR

Sugars are carbohydrates, an important source of energy for the body. When we talk about sugar we usually refer to table sugar or sucrose, from cane or beet. There are many other types of sugars. Some occur naturally in fruits, vegetables and milk.

All sugars provide the same amount of calories (approximately 4 kilo calories or 16 kilo Joules per gram) and impart sweetness. There are two general classes of sweeteners – nutritive and non-nutritive. Nutritive sweeteners contain calories and provide energy, while non-nutritive sweeteners have no calories and provide no energy. Sucrose is the major nutritive sweetener; other sweeteners of this group are starch hydrolysates HFCS, glucose, fructose, lactose, polyols, maple syrup and honey. Examples of non-nutritive sweeteners are saccharin, acesulfame K, aspartame, etc.

10.2.1 Sources of Sugar

Sucrose is available in a variety of plant sources. However, the two most important sources of sugar for commercial production include sugarcane and sugar beet. In India, sugar is manufactured from sugarcane in the form of jaggery, open pan sugar, and vacuum pan sugar.

Sugar from Sugarcane

Jaggery: It is obtained mostly from sugarcane and also from palmyra, date palm and coconut. The harvested sugarcane is crushed to obtain juice. The sugarcane juice so obtained is freed from coarse suspended impurities and boiled in open pans. Jaggery has a light colour, good flavour, hardness and crystalline structure with good keeping quality. It contains about 65-85% sucrose, 10-15% invert sugar and 2.5% ash. Jaggery finds use in the preparation of non -crystalline candies and a variety of sweets.

Khandasari sugar: This is obtained by boiling the clarified sugarcane juice quickly to a required consistency to introduce the crystallization of sugar. The crystals are recovered by centrifugation and dried.

Sugar: It is manufactured from sugarcane juice in three different form, raw sugar, refined sugar and white sugar. The juice obtained by pressing the sugarcane is dark green in colour and turbid. It is mildly acidic with a pH of 5-5.4 and the sucrose content is 10-18%. This juice on filtration, evaporation and centrifugation will give raw sugar, which contain 96-97% sucrose. This raw sugar on refining will give refined and white sugar. The recovery of sugar is about 10-11%weight of sugarcane.

Sugar from Sugar Beet

Beet sugar is obtained from sugar beet. The clear liquid extracted from sugar beet on evaporation with controlled temperature yields a thick syrup. Raw sugar crystals are obtained from this thick syrup. The raw sugar on purification gives white sugar. Powdered sugar for icing of confectionary, cake and bakery products is made by pulverizing granulated sugar with or without edible starch.

10.2.2 Sweeteners

They are manufactured mainly from any starch source such as wheat, maize or corn, and are liquefied in the presence of enzymes. The liquid then undergoes saccharification after it is cooled to about 60^{o}C or so. Various types of sweeteners of this group are discussed below.

Starch hydrolysates: Starch syrup (glucose or maltose syrup), dried starch syrup, glucose and high fructose syrup are some of the sweeteners derived from starch degradation. Starch saccharification is carried out by either acidic or enzymatic hydrolysis under controlled processing conditions to yield starch hydrolysates with different composition to suit the diversified requirements. Their industrial uses include manufacture of soft caramel candies, alcoholic beverages and soft drinks, canning and processing of fruits and vegetables.

High fructose corn syrup: The commercial value of high fructose corn syrup (HFCS) is based on their increased sweetness as compared to the starting material, glucose, obtained from starch. The manufacturing process of HFCS include the use of specific enzymes for the liquefaction of starch, saccharification and isomerisation. The refined dextrose liquor is concentrated or blended to a dry solid level of 40-50%.

Glucose (Dextrose): Starch from corn, potatoes or wheat is saccharified enzymatically by α-amylase and /or microbial amyloglucosidase. After starch hydrolysis the product will contain 95% glucose. The syrup is purified and evaporated to crystallize glucose as α-D-glucose mono hydrate. Drying or crystallization gives the anhydrous form. Glucose is used as invigorating and strengthening agent in many nourishing formulations.

Fructose: Fructose is obtained by acid hydrolysis of inulin, a natural polymer of fructose found in tubers. Fructose is 1.5 times sweeter than sucrose and is used as sugar substitute for diabetics.

Lactose: Lactose is prepared from whey concentrates. The concentrate is heated, filtered, and evaporates to yield a yellow lactose. This raw lactose on filtration and crystallization will give α-D lactose monohydrate. β-lactose which is more soluble and easily digestible compared to α-lactose is also obtained by heating lactose solution.

Sugar alcohols: Polyols are so-called sugar alcohols. They do occur naturally but most are made commercially by the transformation of sugars. Isomalt is the most commonly used polyol and is derived from sucrose. Polyols are sweet and can be used in foods in a similar way to sugars although they can have a laxative effect when eaten in large quantities. Sugar alcohols are slightly lower in calories than sugar and do not cause a sudden increase in blood glucose. They include sorbitol, xylitol, lactitol, mannitol, and maltitol and are used mainly to sweeten sugar-free candies, cookies, and chewing gums.

Maple syrup: Maple syrup with sugar content of about 65% is obtained by evaporating the sap of maple tree. The sap from the tree has no flavour but develops a special flavour during evaporation. Maple syrup is used as a sweetener and as a flavouring agent.

Honey: Honey is produced by honeybees which suck up the nectar and honey due from flowers and other sweet saps of plants and store the nectar in their honey sac or pouch. Based on its end use, honey is classified as honey for domestic use of highest purity and bakery honey of less purity. Honey is marketed as liquid or as semisolid creamed honey and contains about 38% fructose, 31% glucose and 2% sucrose.

10.2.3 Confections

Chocolate confectionery: Chocolate is made from non-alkalized cocoa liquor by mixing with sucrose, cocoa butter and aroma substances including milk solids, nuts, coffee paste etc.. The ingredients are processed through several steps to yield a final product. The various processing steps include mixing, refining, ripening, conching, tempering and molding. The finished chocolate contains at least 40% cocoa liquor or a blend of liquor and cocoa butter and up to 60% sugar. Cocoa and chocolate products require careful storage condition of dry (55-65% humidity), cool (10-12^{o}C), well aerated space protected from light and odourous substances.

Sugar confectionery: Sugar confectionery includes both crystalline and amorphous types made from boiled sugar syrup. The temperature of boiling sugar solution and ingredients used will determine the nature of the end product. Crystalline confectionery or candies have a smooth texture, amenable for cutting with knife and easily chewable. Amorphous candies have a heterogeneous soft structure and break into pieces rather than be cut with knife.

Crystalline confectionery is made by adding ingredients such as invert sugar, glucose or corn syrup, which aid the formation of fine sugar crystals from sugar syrup. Amorphous confectionery is made by preventing crystallization of the sugar either by cooking the sugar solution at high temperature and allowing the product to harden quickly or by adding large amounts of ingredients, which inhibit crystallization.

10.2.4 Role of Sugar in Food Systems

Sugar (glucose) is the primary energy source. Sugar is used to improve the palatability of many foods and can thereby encourage a more varied diet. Using sugars can improve the texture and colour of baked goods. Sugars produce the moistness, attractive colour and crispy texture to food products. The various functional properties of sugar in food system include:

- Source of energy
- Nutritional aspects
- Flavour and colour production
- Sweetening
- Texturing
- Plasticizing action and
- Humectancy

10.2.5 Types of Sugar

Because of its diverse functional characteristics, sugar is used in many types of food preparation. Although this handbook focuses on the functions of "regular" sugar, the most common type used in the home, sugar is available in many other forms.

Granulated Sugar

There are many types of granulated sugar. Most of them are used only by food processors and professional bakers and are not available in the market. The types of granulated sugars differ in crystal size. Each crystal size provides unique functional characteristics that make the sugar appropriate for the food processors' special need.

Regular sugar, extra fine or fine sugar: "Regular" sugar, as you know, is the sugar found in every home's sugar bowl and most commonly used in home food preparation. It is the white sugar called for in most cookbook recipes. The food processing industry describes "regular" sugar as extra fine or fine sugar. It is the sugar most used by food processors because of its fine crystals that are ideal for bulk handling and are not susceptible to caking.

Fruit sugar: Fruit sugar is slightly finer than "regular" sugar and is used in dry mixes such as gelatin desserts, pudding mixes and drink mixes. Fruit sugar has a more uniform crystal size than "regular" sugar. The uniformity of crystal size prevents separation or settling of smaller crystals to the bottom of the box, an important quality in dry mixes and drink mixes.

Bakers special: Bakers Special's crystal size is even finer than that of fruit sugar. As its name suggests, it was developed specially for the baking industry. Bakers Special is used for sugaring doughnuts and cookies as well as in some commercial cakes to produce fine crumb texture.

Superfine, ultra-fine, or bar sugar: This sugar's crystal size is the finest of all the types of granulated sugar. It is ideal for extra fine textured cakes and meringues, as well as for sweetening fruits and iced-drinks since it dissolves easily.

Confectioners/powdered sugar: This sugar is granulated sugar ground to a smooth powder and then sifted. It contains about 3% cornstarch to prevent caking. Confectioners sugar is available in three grades ground to different degrees of fineness. The confectioners sugar available in supermarkets is the finest of the three and is used in icings, confections and whipping cream. Industrial bakers use the other two types of powdered sugar.

Coarse sugar: The crystal size of coarse sugar is larger than that of "regular" sugar. Coarse sugar is normally processed from the purest sugar liquor. This processing method makes coarse sugar highly resistant to colour change or inversion (natural breakdown to fructose and glucose) at high temperatures. These characteristics are important in making fondants, confections and liquors.

Sanding sugar: Another large crystal sugar, sanding sugar, is used mainly in the baking and confectionery industries to sprinkle on top of baked goods. The large crystals reflect light and give the product a sparkling appearance.

Jaggery

Brown sugars come in many different styles but are essentially one of the two types: sticky browns and free-flowing browns. The sticky browns were originally the sort of mixture that comes out of a cane sugar crystallizing pan. The extreme of this, still made in India today, is "jaggery" or "gur" which is essentially such a mixture boiled until dry. Brown sugar consists of sugar crystals coated in a molasses syrup with natural flavour and colour. Dark brown sugar has more colour and a stronger molasses flavour than light brown sugar. Lighter types are generally used in baking and making butterscotch, condiments and glazes. Dark brown sugar has a rich flavour that is good for gingerbread, mincemeat, baked beans, plum pudding and other full flavoured foods.

Free flowing brown sugars: These sugars are fine, powder-like brown sugars that are less moist than "regular" brown sugar. Since it is less moist it does not lump and is free-flowing like granulated white sugar.

Burnt sugar / caramelized sugar: Sugar caramelized by cooking at high temperature. Prepared in specialty items requiring a special flavour and colour. Not available for purchase, but can be made at home.

Liquid Sugars

Liquid sugar syrup: There are several types of liquid sugar. Liquid sucrose (sugar) is essentially liquid granulated sugar and can be used in products wherever dissolved granulated sugar might be used. Amber liquid sucrose is darker in colour and can be used where the cane sugar flavour is desirable and the non-sugars' are not a problem in the product. Granulated white sugar dissolves in water. They are used in beverages, jams, candy, ice cream, syrups, and cooked fondants.

Invert sugar: Inversion or chemical breakdown of sucrose results in invert sugar, an equal mixture of glucose and fructose. Available commercially only in liquid form, invert sugar is sweeter than granulated sugar. One form of liquid invert was specially developed for the carbonated beverage industry and can be used only in liquid products. It is used mainly in food products to retard crystallization of sugar and retain moisture. This can also be used in confectionery, canning and baking

10.2.6 Sugar Substitutes

Artificial sweeteners are non-nutritive (zero calories per serving), high intensity sugar substitutes. These are sweet synthetic substances, often used in place of other sugars in food manufacturing and cooking. One packet of these sweeteners is equivalent to the sweetness of 2 tones of table sugar. No low calorie sweetener is perfect for all uses. They provide products with increased stability, improved taste, lower production costs and more choices for the consumer. They have very long shelf lives and can be stored in original packaging in a dry location at room temperature. Some of the non-nutritive sweeteners used in food are saccharin, acesulfame K, aspartame, sucralose, Alitame, Cyclamate and stevia.

Saccharin is 300 times sweeter than sugar, but has a slightly bitter or metallic aftertaste. Saccharin is available under the trade name "*Sweet'N Low*". It is currently produced from a purified compound found in coal tar. It is not metabolized in the digestive tract and is excreted rapidly in the urine. As a result, saccharin does not contribute calories to the diet. Saccharin continues to be important for a wide range of low-calorie and sugar-free beverage applications. Saccharin also is used in cosmetic products, vitamins and pharmaceuticals.

Acesulfame K: Acesulfame K Acesulfame potassium) is 200 times sweeter than table sugar. Its trade name is *Sunette*. The chemical structure is similar to saccharin. This is used in baked goods, frozen desserts, beverages, and candies. It has excellent shelf life and does not break down when cooked or baked. It does not provide calories since the body does not metabolize it and it is excreted in the urine without being changed. Acesulfame-K is usually used in combination with aspartame or other sweeteners because it enhances and sustains the sweet taste of foods and beverages and helps to extend the shelf life of the food product.

Aspartame: It is produced from two amino acids aspartic acid and *phenylalanine* and is 180 times sweeter than sucrose. The trade name of Aspartame is *"NutraSweet"* and *"Equal*". During digestion, aspartame is broken down into these two individual amino acids. It is also broken down when exposed to heat, resulting in a loss of its sweet taste.

Sucralose: It is known by its trade name, "*Splenda*". It is 600 times sweeter than sugar and is used in baked goods, beverages, gelatin, and frozen dairy desserts. Sucralose is derived from sucrose (table sugar). It closely resembles table sugar in taste, is highly water-soluble, and is exceptionally stable at high temperatures. Sucralose is not absorbed from the digestive tract, so it adds no calories to consumed food. In addition, sucralose does not increase blood sugar levels. Because sucralose is so much sweeter than sugar, it is bulked up with malto-dextrin, a starchy powder, so it will measure more like sugar. It has good shelf life and doesn't degrade when exposed to heat.

Alitame: Like aspartame, alitame is made from amino acids, D-alanine and L-aspartic acid. Alitame is 2,000 times sweeter than sugar. It is currently approved for use in Australia, New Zealand, Mexico, and China.

Cyclamate: It was initially marketed as tablets that were recommended for use as a tabletop sweetener for people with diabetes and others who had to restrict their intake of sugar. Although it is approved for use in many countries, cyclamate is banned in the United States due to concerns over potential carcinogenicity.

Stevia: This is derived from a shrub. The cultivation of this plant in our country has increased in recent years. Though it can impart a sweet taste to foods, it cannot be sold as a sweetener because it is an unapproved food additive. However, stevia can be sold as a "dietary supplement", though it cannot be promoted as a sweetener.

10.2.7 Role of Sugar in Jams, Jellies and Other Sugar-based Fruit Products

Recipes use just about one part fruit to one part sugar in jams, jellies, and preserves. In these foods, sugar helps to retain the original flavour, aroma, colour and other quality attributes of the fruit. Fruit flavours are condensed and strengthened, resulting in the distinctive texture and pleasant appearance of jellies and preserves.

During gel formation, pectin, a natural component of fruits, forms a gel only in the presence of sugar and acid. Sugar prevents spoilage of jams, jellies, and preserves after the container is opened. Once the jam jar is opened, sugar attracts all water and water is transferred from the microorganisms into the concentrated sugar syrup. The micro flora is dehydrated and laid up, and cannot multiply further.

10.3 FRUIT JAM

Jam is a product with reasonably thick consistency, firm enough to hold the fruit tissues in position and is made by boiling fruit pulp with sufficient sugar. Jams contain 0.5-0.6% acid and invert sugar should not be more than 40%. FPO specifications for jam are given in section no. 2.14.

10.3.1 Preparation of Jam

Jam can be prepared from one kind of fruit or from two or more kinds. It may be made from practically all varieties of fruit. Apple, papaya, carrot, strawberry, mango, grapes, pineapple, etc. are used for the preparation of jams. Various combinations of different varieties of fruit can be often made to advantage, pineapple being one of the best for blending purposes because of its pronounced flavour and acidity.

Preparation of fruit pulp: Sound fruit is sorted, washed in running water or, preferably, brush-washed and prepared. The mode of preparation varies with the nature of the fruit. For example, mangoes are peeled, steamed and pulped; apples are peeled, cored, sliced, heated with water and pulped; plums are scalded and pulped; peaches are peeled and pulped; apricots are halved, steamed and pulped; berries are heated with water and pulped or cooked as such.

Addition of sugar: To make jams and jellies, up to a maximum of 25% of corn syrup for sweetness can be utilized. Generally, cane sugar of good quality is used in the preparation of jams. The proportion of sugar to fruit varies with type and variety of fruit, its stage of ripeness and acidity. A fruit pulp to sugar ratio of 1:1 is generally followed. This ratio is usually suited to fruits viz., berries, currants, plums, apricots, pineapple and other tart fruits.

Addition of acid: Citric, malic or tartaric acids are present naturally in different fruits. These acids are also added to supplement the acidity of the fruits deficient in natural acids during jam making. Addition of acid becomes necessary as adequate proportion of sugar- pectin- acid is required to give good set to the jam. The recommended pH for the mixture of fruit juice and pectin is 3.1. The acidity of finished jam varies between 0.5 to 0.7 % depending on the type of the jam. It is often advisable to add acid at the end of cooking which leads to more inversion of sugar. When acid is added in the beginning, it will result in poor set.

Processing/boiling: Fruit pulp is cooked with the requisite quantities of sugar and pectin, and finished to 69% Total Soluble Solids (TSS). Permitted food colours, requisite amount of citric acid and flavourings are added at this stage. The boiling process, in addition to excess water removal, also partially inverts the sugar, develops the flavour and texture. During jam boiling, all micro-organisms are destroyed within the product. When this is filled hot into clean receptacles which are subsequently sealed, and then inverted the hot jam contacts the lid surface, thus prevents the spoilage by micro-organisms during storage.

10.3.2 Judging of End Point

Concentration of jam is finished at an optimum point avoiding over cooking which leads to economic losses due to less yield. But under cooking will result in the spoilage of jam during storage due to fermentation. The finishing or end point of jam can be determined by the following methods.

Drop test: This method is the simplest way to determine the finishing point of jam, commonly used by housewives where no other facilities are available. In this method, a little quantity of jam is taken from the boiling pan in a tea spoon and allowed to air cool before putting a drop of it in a glass filled with water. Settling down of the drop without disintegration denotes the end point (Figure 10.1).

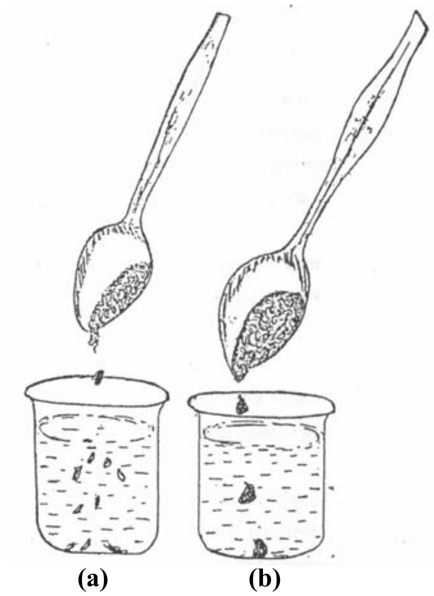

Figure 10.1: Determination of end point of jam/jelly drop test. a) Unfinished; b) End point

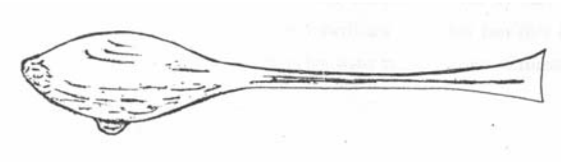
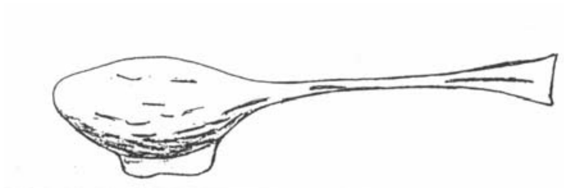
By sheet test: In this test, a small portion of jam is taken with a large spoon or wooden ladle, cooled slightly and then allow to drop off keeping the spoon or ladle in horizontally inclined position. If the jam drops like syrup, further concentration is needed. If it is in the form of flake or forms a sheet, the finishing point is attained (Figure 10.2).



(a)



(b)

Figure 10.2: Determination of end point of jam/jelly sheet test. a) Unfinished; b) End point

Refractometer method: This is the most common method used by small and large scale fruit processing industries for jam making (Figure 10.3). The cooking is stopped when the refractometer shows 69 ^{o}Brix.

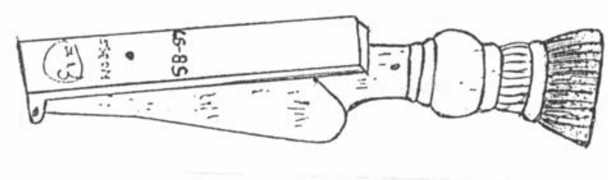


Figure 10.3: Refractometer

Boiling point method: Jam containing 69% TSS boils at 106 ^{o}C at sea level. This method is simplest and best to determine the finishing point of jam.

By weighing method: Weighing method is more laborious and time consuming. Here the boiling pan is weighed before and again after transferring the extract and sugar in to it. The end point is attained when the net jam weight is one and a half times of the quantity of sugar added.

10.3.3 Packaging

The product is packed in cans or glass jars, and cooled, followed by labelling and packaging. Containers including can or jar gets sterilized when hot jam (not less than 85^{o}C) is poured in them. Boiling the containers in hot water can also effect sterilization.

10.3.4 Special Care/ Problems in Jam Production

Crystallization: The final product should contain 30–40% invert sugar. If the percentage is less than 30, cane sugar may crystallize out on storage and if it is more than 50 the jam will become a honey-like mass due to high inversion of sugar into glucose. Corn syrup or glucose may be added along with cane sugar to avoid crystallization.

Sticky or gummy jam: Because of high percentage of total soluble solids, jams tend to become gummy or sticky. This problem can be solved by addition of pectin or citric acid, or both.

Premature setting: This is due to low total soluble solids and high pectin content in the jam and can be prevented by adding more sugar. If this cannot be done a small quantity of sodium bicarbonate is added to reduce the acidity and thus prevent pre-coagulation.

Surface graining and shrinkage: This is caused by evaporation of moisture during storage of jam. Storing in a cool place can reduce it.

Microbial spoilage: The mould attack on jam can be eliminated by storing them at less than 90% RH (Preferably at 80% RH). It is also advisable to add 40 ppm sulphur dioxide in the form of KMS. In the case of cans, sulphur dioxide should not be added to the jam as it causes blackening of the internal surface of the can.

10.4 FRUIT JELLY

A jelly is a semisolid product prepared by boiling a clear, strained solution of pectin containing fruit extract, free from pulp, after addition of sugar and acid. A perfect jelly should be transparent, well set, but not too stiff, and should have the original flavour of the fruit. It should be of attractive colour and keep its shape when removed from the mould. It should be firm enough to retain a sharp edge but tender enough to quiver when pressed. It should not be gummy, sticky, or syrupy or have crystallized sugar. The product should be free from dullness with little or no syneresis, and neither tough nor rubbery.

10.4.1 Preparation of Jelly

Jellies are gellified products obtained by boiling fruit juices with sugar, with or without the addition of pectin and food acids. Jellies are usually manufactured from juices obtained from a single fruit species only, obtained by boiling in order to extract as much soluble pectin as possible.
Selection of fruits: Guava, sour apple, plum, papaya, certain varieties of banana and gooseberry are generally used for preparation of jelly. Other fruits can also be used but only after addition of pectin powder, since these fruits are low in pectin content. Fruits can be divided into four groups according to their pectin contents. This classification is highly useful in preparation of jelly, because pectin is the important component, which is responsible for the texture of the jelly. The classification is as follows.

- Rich in pectin and acid: sour apple, grape, lemon, sour oranges, jamun, sour plum.
- Rich in pectin but low in acid: apple, unripe banana, pear, ripe guava, etc.
- Low in pectin but rich in acid: sour apricot, sweet cherry, sour peach, pineapple and strawberry.

- Low in pectin and acid: ripe apricot, peach, pomegranate, strawberry and any other overripe fruit.

Extraction of pectin/boiling: After selection, the fruits are washed thoroughly as with jam preparation discussed earlier. Most of the fruits are boiled for extraction of the juice in order to obtain maximum yield of juice and pectin. Boiling converts protopectin into pectin and softens fruit tissues. Very juicy fruits do not require the addition of water and are crushed and heated to boiling only for 5 min. Firm fruits are cut or crushed and boiled with water for 5 min. The length of boiling will vary according to the type and texture of fruit. The amount of water added to the fruit must be sufficient to give a high yield of pectin e.g. apples require one half to an equal volume of water, where as citrus fruits require 2-3 volumes of water for each volume of sliced fruits.

Straining and clarification: Pectin extract is obtained by straining the boiled fruit mass through bags made of linen, flannel, or cheese cloth folded several times. For large scale production, the fruit extract is made to pass through filter presses for clarity.

Analysis of extract: Clarified extract is analysed for pH, acidity, soluble solids and pectin content by common laboratory methods. For determining pectin content the easiest way adopted is precipitating the pectin with alcohol. A rapid test for evaluation of juice pectin content is by mixing a small sample of juice with an equal volume of 96% alcohol in a tube. The mixture from the tube is then emptied on a plate. The appearance of a compact gelatinous precipitate indicates a sufficient pectin content for jellification (Figure 10.4). Insufficient pectin will remain in numerous small granular lumps.

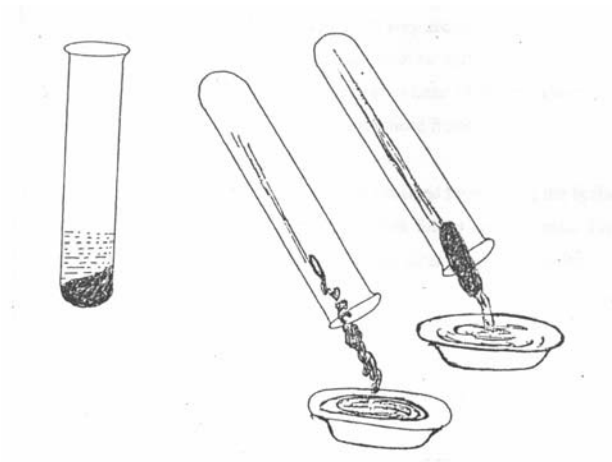

Figure 10.4: Pectin test for jelly extract. a) Low pectin extract; b) High pectin extract

Addition of sugar and pectin: Based on the pectin test of the fruit extract, quantity of sugar to be added is worked out. For the extract rich in pectin, sugar equal to the quantity of the extract is added. To the extract with moderate pectin 650 – 750 g of sugar should be added to each kg of extract. For juices rich in pectin, jellification will occur without pectin addition. If pectin content is less, 1-2% powder pectin will be added to the juice.

Addition of acid: Jelly strength increases with increasing hydrogen ion concentration until an optimum pH is reached which is generally 3.2 at 65%

sugar concentration. Jellying strength depends on the quantity of pectin and the acid present in the original fruit extract.

Processing/boiling: The juice is boiled up to remove about half of the water that has to be evaporated. Then the calculated sugar quantity is added gradually. The remainder of the water is evaporated until a TSS (refractometric extract) of 65% is reached. During boiling it is necessary to remove foam / scum formed. Product acidity must be brought to about 1% (malic acid) corresponding to pH > 3. Any acid addition is performed always at the end of boiling. Boiling of jellies is performed in small batches (25-75 kg) in order to avoid excessively long boiling time which brings about pectin degradation.

10.4.2 Judging of End Point

Boiling of jelly should not be prolonged, because excessive boiling results in greater inversion of sugar and destruction of pectin. The end point can be judged by sheet test, drop test, refractometry, thermometer, and by weighing the boiling mass. Methods like sheet test, drop test, and weighing of the boiling mass can be done in the similar way as in the case of jam preparation.

Refractometer method: This is the most common method used in fruit processing industries for jelly making. The cooking is stopped when the refractometer shows 65^o Brix.

Temperature test: A solution containing 65% TSS boils at 105^oC. Heating of the jelly to this temperature would automatically bring the concentration of solids to 65%. Endpoint of finishing jelly should be 4.5-5^oC higher than that of the boiling point of water at that place.

10.4.3 Packaging

After jelly is ready, it is skimmed to remove foam. It is cooled slightly before pouring into dry and hot glass jars. Cooling is optional and is carried out up to 85^oC, in double wall baths with water circulation. Filling is performed at a temperature not below 85^oC in receptacles (glass jars, etc.), which must be maintained still for about 24 hours to allow cooling and product jellification.

10.4.4 Important Considerations in Jelly Making

Pectin, acid, sugar (65%), and water are the four essential ingredients in jelly. Pectin test and determination of end point of jelly formation are very important for the quality of jelly.

Pectin: Pectin is the most important constituent of jelly. Stiffness of the gel increases with increasing concentration of pectin up to a certain point beyond which the addition of more pectin has little effect. Too little pectin gives a soft syrup instead of gel. Pectin tends to keep the sugar from crystallizing by acting as a protective colloid, but is not effective when the concentration of sugar is 70% or more. The amount of pectin extracted varies with the method of extraction, the ripeness of the fruit, the quantity of the water added for extracting the juice and the kind of fruit. Usually about 0.5-1.0 % of pectin in the extract is sufficient to produce good jelly. If the pectin content is higher a firm and tough jelly is formed and if it is less the jelly may fail to set.

Acid: The jellying of extract depends on the amount of acid and pectin present in the fruit. Tartaric acid gives a better result compared to citric and malic acid. The final jelly should contain at least 0.5% but not more than 1% total acid. Higher percentage of acid may cause syneresis of jelly.

Sugar: This is an essential constituent of jelly, which imparts to it sweetness as well as body. If the concentration of the sugar is high, the jelly retains less water resulting in a stiff jelly. When sugar is boiled with an acid it is hydrolysed into dextrose and fructose. Because of this partial inversion of the sucrose, a mixture of sucrose, glucose and fructose are found in the jelly. This mixture is more soluble in water than sucrose alone and hence the jelly can hold more sugar in solution without crystallization.

10.4.5 Problems in Jelly Making

The most important difficulties that are experienced are as follows:

- ***Failure to set:*** This may be due to the addition of too much sugar, lack of acid or pectin, cooking below/ beyond the end-point.
- ***Colour changes:*** Darkening at the top of the jars can be caused by storing them in too warm place or by an imperfect jar seal.
- ***Gummy jelly:*** It is the result of prolonged or over cooking in which more than desired inversion of sugar occurs
- ***Stiff jelly:*** Over cooking or using too much pectin makes too tough jelly which fails to spread when applied on bread.
- ***Cloudy or foggy jellies:*** It is due to the use of non-clarified juice or extract, use of immature fruits, over-cooking, over-cooling, non-removal of scum, faulty pouring, and premature gelation.
- ***Formation of crystals:*** It is due to addition of excess sugar and also due to the over-concentration of jelly. This excess sugar comes from over cooking, too little acid or from under cooking.
- ***Syneresis or weeping of jelly:*** The phenomenon of exudation of fluid from a gel is called syneresis or weeping and is caused by several factors. The factors include; excess of acid, too low concentration of sugar, insufficient pectin, premature gelation, and fermentation
- ***Presence of mold:*** Due to imperfect sealing and insufficient sugar.
- ***Colour fading:*** This is due to high temperature and bright light in storage room. Another possible cause could be the insufficient processing to destroy the enzymes affecting colour or the elevated processing temperature, which might cause colour fading. Trapped air bubbles can also contribute to the chemical changes by oxidation.

10.5 MARMALADE

This is fruit jelly in which slices of the fruit or its peel are suspended. The term is generally used for products made from citrus fruits like oranges and lemons in which shredded peel is used as the suspended material. In the preparation of marmalade, pectin and acid contents are kept on higher side than jelly. Bitterness is regarded as desirable characteristic of product. Marmalades are classified into two: jelly marmalade and jam marmalade.

10.5.1 Jelly Marmalade

Good quality jelly marmalade can be prepared from a combination of Sweet orange/ Mandarin orange and sour orange in a 2:1 proportion. Shreds of sweet orange (Malta) peel are used in the preparation.

10.5.2 Preparation of Jelly Marmalade

Sound, ripened fruit is sorted, washed, and prepared. The mode of preparation varies with the nature of the fruit. The fruits are then cut in to slices and are boiled for the preparation of extract.

Preparation of extract: The extraction of pectin, filtration/ straining of the extract and analysis of the extract is carried out in the same way as that of jelly preparation. This is explained under the headings 2.4.1.

Preparation of peel shreds: The outer layer of yellow portion of citrus fruits is peeled off carefully. The stripped-off peel is cut into slices of about 2-2.5 cm long and 1-1.2 mm thick. Boiling in water with 0.25% sodium bicarbonate or 0.1% ammonia solution can soften the shreds. Before addition to the jelly, the shreds may be kept in heavy syrup for some time to increase their bulk density to avoid floating on the surface when it is mixed with jelly.

Boiling: The fruit extract is boiled before the addition of sugar. During boiling, the impurities in the form of scum, are occasionally removed. When the temperature of the mixture reaches 103°C, the prepared shreds of peel are mixed in it at the rate of 5-7% of the original extract. Boiling is continued till the end point is reached. The end point is judged in the same way as in the case of jelly. Like jelly, marmalade also contains 65% TSS at 105°C. Boiling should not prolong for more than 20 min, after the addition of sugar to get bright and sparkling marmalade.

Cooling: The marmalade is cooled to permit the absorption of sugar by the shreds from the surrounding syrup. If the marmalade is filled in hot, the shreds may come to the surface instead of remaining in suspension. During cooling, the product is gently stirred occasionally for uniform distribution of shreds. When marmalade temperature reaches around 85°C, viscosity of syrup increases and a thin film begins to form on surface, which prevents shreds from coming to surface.

Flavouring: This is done by adding some flavour or orange oil to the product near the end of boiling to supplement the flavour lost during boiling. Generally, a few drops of orange oil are mixed in marmalade before filling into containers.

Packaging and Storage: Like jams and jellies, marmalade is also filled into jars and cans at a temperature around 85°C. Storage of marmalade must be done in dry rooms (relative humidity at about 75%), well ventilated, medium cool places (temperature 10-20°C), disinfected and away from direct sunlight and heat. These measures are necessary because marmalade is a hydroscopic product and, by water absorption, favourable conditions for mould development are created.

10.5.3 Jam Marmalade

Jam marmalade is practically made by the method used for preparation of jelly marmalade except that the pectin extract is not clarified. The orange peel after removing albedo portion is sliced into 0.3 cm thick pieces and treated in the same way as recommended for jelly marmalade. The sliced fruit of orange, lemon, or grape fruit after removing peel is mixed with little quantity of water and boiled to soften. The boiled mixture is pressed through coarse pulper to remove seed and to get thick pulp. The pulp is mixed with equal quantity of sugar and cooked to a consistency of 65° Brix or consistency of jam. The treated shreds are mixed in the jam when it is slightly cool. Some orange oil is also mixed in the marmalade before filling into containers. Filling and packaging is done in the similar way as adopted for packaging of jelly and jelly marmalade.

10.5.4 Problems in Marmalade Making

Browning during storage is very common which can be prevented by the addition of 0.09g of potassium metabisulphite (KMS) per kg of marmalade and not using tin containers. KMS dissolved in a small quantity of water is added to the marmalade while it is cooling. KMS also eliminates the possibility of spoilage due to moulds.

10.6 PRESERVES

A mature fruit/ vegetable or its piece impregnated with heavy sugar syrup till it becomes tender and transparent is known as preserve. When fruits are placed in a concentrated sugar syrup, the water moves out of the fruit and sugar moves into it until equilibrium is reached by osmosis. Apple, Cherry, anola, pineapple, pear, mango, papaya, strawberry, etc., can be used for making preserves. FPO specifications for preserves are given in Quality section (2.14).

10.6.1 Preparation Methods

Preparation involves primary operations like, selection of fruits, peeling, puncturing (to promote sugar penetration) and blanching. Blanching may be done with or without addictives to inactivate natural enzymes and to reduce the oxidative discolourisation. The blanched fruits are then treated for firming the texture of product. Now, sugar is added concentrated, and packed after the addition of preservatives. Different processes employed for the preparation of preserves from fruits and vegetables at commercial level are explained below.

Rapid process: Fruits are cooked in a low sugar syrup. Boiling is continued with gentle heating until the syrup becomes sufficiently thick. Rapid boiling should be avoided as it makes the fruit tough. The final concentration of sugar should not be less than 68 % which corresponds to a boiling point of 106 ^{o}C. This is simple and cheap process but the flavour and colour of the product are lost considerably during boiling.

Slow process: In this method, the fruits are blanched until it becomes tender. Sugar, equal to the weight of fruit, is then added to the fruit in alternate layers and the mixture allowed to stand for 24 hours. Then by boiling on second, third, and 4th day consecutively the strength of syrup is raised to 70 % TSS. A small quantity of citric or tartaric acid is also added to invert a portion of the cane sugar and thus prevent crystallization. The prepared preserve is then packed in containers.

Vacuum process: The fruit is first softened by boiling and then placed in the syrup which should have 30-35% TSS. The fruit syrup blend is then transferred to a vacuum pan and concentrated under reduced pressure to 70 % TSS. Preserves made by this process retain the flavour and colour of fruit better than by the other two methods.

Packaging of preserve: The preserve is cooled quickly, drained free of syrup and then filled in dry containers. Freshly prepared boiling syrup containing 68% TSS is then poured into the jars/containers which are then sealed air tight. In commercial scale production, however, it is better to sterilize the cans to eliminate any possibility of spoilage of product during storage.

10.7 CANDIED FRUIT/ VEGETABLE

A fruit or vegetable impregnated with cane sugar or glucose syrup, and subsequently drained free of syrup and dried, is known as candied fruit/vegetable. The most suitable fruits for candying are pineapple, cherry, anola, karonda, papaya, apple, peach, peels of orange, ginger etc.

Preparation: The process for making candied fruit is practically similar to that for preserves. The only difference is that the fruit is impregnated with syrup having a higher percentage of sugar or glucose. A certain amount (25-30 %) of invert sugar or glucose is substituted for cane sugar. The total sugar content of the impregnated fruit is kept at about 75% to prevent fermentation. It is desirable that cane sugar and invert sugar in the final syrup should be in equal proportion approximately. The syrup left over from the candying process can be used for candying another batch of the same kind of fruit.

Draining and drying: The fruit removed from the syrup is drained for about half an hour and unwanted pieces are removed. The fruit or peel is then wiped with a wet sponge or dipped for a moment in boiling water to remove adhering syrup. Then it is dried in shade or in a dryer at about 66^{o}C for 8 to 10 hours until the fruit is no longer sticky to handle.

10.8 GLAZED FRUIT/ VEGETABLE

Covering of candied fruits /vegetables with a thin transparent coating of sugar, which imparts them a glossy appearance is known as glazing. The FPO specifications for glazed fruits are given in quality section.

Preparation: Glazed fruits are prepared by passing the dried candid fruit through a sugar syrup. The sugar syrup is prepared by boiling a mixture of cane sugar and water (2:1) in a steam pan at 113 to 114 ^{o}C and skimming the impurities as they come up. Heating is then stopped and syrup is cooled to 93^{o}C. Granulation of sugar is achieved by rubbing the syrup with a wooden ladle on the side of the pan. Granulated candies are then placed on trays in warm dry room. To hasten the process, fruits may be dried in a dryer at 49^{o}C for 2 to 3 hours till they become crisp. These are then packed in air tight containers for storage.

10.9 CRYSTALLIZED FRUITS/ VEGETABLES

Candied fruits/ vegetables when covered or coated with crystals of sugar, either by rolling in finely powdered sugar or by allowing sugar crystals to deposit on them from a dense syrup are called crystallized fruits.

Preparation: The candied fruits are placed on a wire mesh tray which is placed in a deep vessel. Cooled syrup (70% TSS) is gently poured over the fruit so as to cover it entirely. The whole mass is left undisturbed for 12 to 18 hours during which time a thin coating of crystallized sugar is formed. The tray is then taken out carefully from the vessel and the surplus syrup drained off. The fruits are then placed in a single layer on a wire mesh trays and dried at room temperature or at about 49 ^oC in dryers.

10.10 FRUITS BAR/LEATHER

Fruit bar or leather can be prepared from different fruit pulps like mango, peach, plum, apricot, papaya, etc. The fruit pulp is taken and its TSS is raised to 30 ^{o} Brix by adding sugar. This pulp is then spread on stainless steel trays smeared with glycerol which are dried in a mechanical dehydrator at 60 $\pm$ 5 ^oC for 2 hours. Usually five layers are dried one above the other and the final product is packed in polythene bags.

10.11 FRUIT TOFFEES

This is made by mixing fruit pulp with other ingredients like glucose, milk powder and edible fat. The fruit pulp is first concentrated to half its volume. Generally, for one kilo gram of concentrated pulp, 160 g of glucose, 320 g of milk powder and 200 g of edible fat is added. This mixture is further heated to a thick consistency (75- 80 ^{o}Brix) followed by spreading it as a sheet of one cm thickness on a glycerol smeared flat tray and allowed to cool. Then these are cut into pieces (called as toffees) of desired size, wrap and store it in cool dry place.

10.12 PACKAGING OF THE FINISHED PRODUCT

Since candied and crystallized fruits are hygroscopic, they require waterproof packaging. These are packed in paper cellophane cartons. But with the development of packaging technology various types of flexible films are used, which are cheaper and highly effective in controlling moisture absorption and entry of other undesirable material from outside atmosphere into the food.

10.13 PROBLEMS IN PREPARATION OF PRESERVES/ CANDID FRUITS

- **Fermentation**: It is due to the low concentration of sugar used in the initial stages of preparation.
- **Floating of fruits in jar**: It is due to filling of the preserve without cooling.
- **Toughening of fruit skin or peel**: This is due to inadequate blanching or cooking.
- **Fruit shrinkage**: This is due to cooking of fruits in heavy syrup.
- **Stickiness**: It is due to insufficient consistency of the syrup, poor quality packaging and damp storage conditions.

10.14 QUALITY PARAMETERS

Quality is a measure of the degree of excellence or degree of acceptability by the consumer. The quality characteristics of a product may be due to sensory (colour, texture and flavour), hidden (nutritive value, toxicity, etc.), and quantitative characteristics (yield of jam, jelly etc.). Food quality control is generally defined as the regulation by law of food manufacture, distribution and sale, in order to prevent health hazards and fraud to the consumer. FPO act regulates the manufacture, storage and sale of fruit and vegetable products. The details of FPO and other aspects of quality are detailed in Unit 1.

The FPO specifications includes: methods of preservation, permissible colours in the preparations and also the minimum quality requirements of the final products. FPO specifications for jam jelly, marmalade, preserve, candy and other sugar based products are as follows:

Product		**Specifications**	
		Minimum % of TSS in final product	**Minimum % of prepared fruit in final product**
1.	Fruit jam	68	45 (25% in case of strawberry jam)
2.	Fruit jelly	65	45
3.	Marmalade	65	45
4.	Fruit preserve	68	55
	Product	**Specifications**	
		Total Sugar (%)	**Reducing sugar as % of total sugar**
1.	Candied and crystallized or glazed fruit and peel	Not less than 70	Not less than 25

Permissible limits of preservatives in fruit beverages

Sl. No.	**Product**	**Preservative**	**Parts per million (ppm)**
1.	Fruit jam, jelly, marmalade and preserve	Sulfur dioxide	150
2.	Crystallized, glazed fruits (including peel)	Sulfur dioxide	150

Some important quality considerations

- Jelly made from sugar and chemical pectin shall be clearly declared as synthetic jelly.
- When dry fruit is used for making jam it shall be clearly declared on the label.
- When preserves are packed in sanitary top cans, the contents shall not be less than 85% of the total space of the can.

10.15 LET US SUM UP

You must have now well understood that the basic principle behind the preparation of sugar based products is the addition of sugar and concentrating them by evaporation to a point where microbial spoilage is arrested.

We have also seen the importance of sugar and various sweeteners and their role in processed foods like jam, jelly etc. The methods for preparation of jam, jelly, marmalade and other sugar based products are detailed in this unit. The special care taken during their preparation are also traced out. A brief note of quality standards and packaging is also included.

10.16 KEY WORDS

Artificial sweeteners	:	They are synthetic, calorie free, high intensity sugar substitutes, sometimes used in place of other sugars in food manufacturing and cooking.
Glazing	:	Coating candied fruit with a thin transparent layer of sugar, which imparts them a glossy appearance, is known as glazing.
Crystallized fruit	:	These are candied fruits covered or coated with crystals of sugar.
Jam	:	Jam is a product with reasonably thick consistency, firm enough to hold the fruit tissues in position, and is made by boiling fruit pulp with sufficient sugar.
Jelly	:	Jelly is a semi solid product prepared by boiling a clear, strained solution of pectin containing fruit extract, free from pulp, after addition of sugar and acid.
Humectancy	:	Ability to retain water.
Inversion of sugar	:	Inversion is a chemical process in which sucrose breaks down to its constituent sugars: glucose and fructose.
Marmalade	:	Marmalade is a fruit jelly in which slices of the fruit or its peel are suspended.
Preserve	:	A mature fruit or its piece impregnated with heavy sugar syrup till it becomes tender and transparent is known as preserve.

10.17 SELF TEST FOR THE COMPLETE UNIT/ ASSIGNMENT

1. List out the various types of sugars.

2. How is marmalade different from jelly?

3. What is preserve? Why vacuum process is better compared to rapid and slow process?

4. What is a glazing? How it is different from crystallized fruit?

10.18 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. The various functional properties of sugar in food system include: source of energy, nutritional aspects, flavour and colour production, sweetening, texturing, plasticizing action and humectancy. Sugars provide readily accessible fuel for physical performance.

2. Sugar alcohols or polyols are slightly lower in calories than sugar and do not cause a sudden increase in blood glucose. Polyols are sweet and can be used in foods in a similar way to sugars although they can have a laxative effect when eaten in large quantities. Commercially they are made by the transforming sugars and are used mainly to sweeten sugar-free candies, cookies, and chewing gums. Eg: sorbitol, and mannitol.

3. Artificial sweeteners are non-nutritive or calorie free, high intensity sugar substitutes. These are sweet synthetic substances, often used in place of other sugars in food manufacturing and cooking. Eg: aspartame and saccharin.

Check Your Progress Exercise 2

1. The various problems encountered in the production of jam includes: Crystallization: due to the lower percentage of invert sugar(<30 %), Sticky or gummy jam: due to high percentage of TSS, Premature setting: due to low TSS and high pectin content, Surface graining and shrinkage: caused by evaporation of moisture and microbial spoilage during storage.

2. The end point of jelly can be judged by sheet test, drop test, refractometry, thermometer, and by weighing the boiling mass. Refractometer method is the most common method used in fruit processing industries for jelly making. The cooking is stopped when the refractometer shows 65 ^{o}Brix.

Answers to Assignments

1. Various types of sugars are available for different food preparations. They are Granulated Sugar, Brown Sugars and Liquid Sugars. Granulated sugar includes: Regular sugar, Fruit Sugar, Bakers Special, Superfine, Ultra -fine, Bar Sugar, Confectioners Sugar, Coarse Sugar, Sanding Sugar, where as Brown Sugars includes: Free Flowing Brown Sugars and Caramelized Sugar. The Liquid Sugars includes Liquid Sugar syrup and invert Sugar.

2. Marmalade is a fruit jelly in which slices of the fruit or its peel are suspended. The term is generally used for products made from citrus fruits like oranges and lemons in which shredded peel is used as the suspended

material. In the preparation of marmalade, pectin and acid contents are kept on higher side than jelly.

3. A mature fruit/ vegetable or its piece impregnated with heavy sugar syrup till it becomes tender and transparent is known as preserve. Since the concentration process is done under vacuum, i.e., at low temperature, the flavour and colour retention will be more in vacuum process. Where as the same will be lost at higher operating temperature in rapid and slow process.

4. Covering of candied fruits /vegetables with a thin transparent coating of sugar, which imparts them a glossy appearance is known as glazing. Where as crystallized fruits are candied fruits/ vegetables covered or coated with crystals of sugar, either by rolling in finely powdered sugar or by allowing sugar crystals to deposit on them from a dense syrup.

UNIT 11 PICKLES, CHUTNEYS, SAUCES AND TOMATO PRODUCTS

Structure

11.0 OBJECTIVES

By the time you have studied this unit, you should be able to describe:

- various methods of pickling and their keeping quality;
- preparation of chutney and sauces;

- preparation of various tomato products viz., Tomato Juice, Tomato Puree, Tomato Paste, Tomato Cocktail, Tomato Ketchup, Tomato Sauce, Tomato Soup; and
- quality standards, packaging and storage aspects of finished products.

11.1 INTRODUCTION

In the previous unit, you have learnt about the sugar based products from fruits and vegetables. Now we will see the preservation technique using salt, vinegar, spices, oil etc. Pickles, chutney and sauces are pleasant preserves of mainly fruits and vegetables and are good accompaniment of Indian as well as continental foods. These products improve the taste of food, stimulate the appetite and enhance digestion. Besides providing the diet with a variety, these products also make a nutritional contribution to the food and save time in a busy household schedule.

In this unit, we will study the pickling by different methods, their shelf life and causes of spoilage. An attempt has also been made to illustrate the different processing methods of chutney and sauces. Detailed processing steps of various tomato products and the quality aspects of the finished products are also included.

11.2 PICKLES

Pickle is an edible product preserved in a solution of common salt and vinegar. It is one of the most ancient method of preserving fruits and vegetables. Pickles are good appetizers and add to the palatability of meal. They stimulate the flow of gastric juice and thus help in digestion. Several kinds of pickles are sold in Indian market. Mango pickle ranks first. Pickles can also be prepared from fruits and vegetables like lemon, amla, onion, cauliflower, cabbage, beans, cucumber, bitter gourd, jackfruit, turnip etc. These are commonly made in homes as well as commercially prepared and exported. Fruits are generally preserved in sweetened and spiced vinegar, while vegetables in salt.

11.2.1 Pickling Process

The preservation of food in common salt or in vinegar is called pickling. Pickling may also be the result of fermentation by lactic acid forming bacteria, which are naturally present in large numbers on the surface of fresh vegetables and fruits. These bacteria can grow in acid medium and in the presence of 8-10% salt solution, whereas the growth of majority of undesirable organisms is inhibited. Lactic acid bacteria are most active at 30^{o}C, so this temperature should be maintained, as far as possible, in the process of pickling. Pickling is done in two stages.

Stage I can be done by any of the three following methods:

i) Fermentation with dry salting,
ii) Fermentation in brine, or
iii) Salting without fermentation.

Stage II is finishing and packing.

11.2.2 Fermentation with Dry Salting

In this method, the vegetable is treated with dry salt. The salt extracts the juice from the vegetables and forms the brine, which is fermented by lactic acid bacteria. The method of dry salting in general is as follows:

The vegetable is washed, drained, weighed for preparing pickles. Several alternate layers of the prepared vegetable and salt (20-30 g of dry salt/ kg vegetables) are kept in a vessel which is covered with a cloth and a wooden board and allowed to stand for 24 hrs. During this period brine is formed by osmosis. As soon as the brine is formed, the fermentation process starts and the CO_2 begins to evolve. When fermentation is over, gas formation stops. Under favourable conditions fermentation is completed in 8-10 days, however in cold weather it may take 2 to 4 weeks. When sufficient lactic acid has been formed, lactic acid bacteria stops to grow and no further change takes place in vegetables. However, precaution should be taken against spoilage by aerobic microbes, because in the presence of air "pickles scum", a kind of wild yeast, is formed which brings about putrefaction and destroys the lactic acid. Therefore the product may be preserved and kept by excluding air.

11.2.3 Fermentation in Brine

Steeping of the vegetables in a salt solution of pre determined concentration for a certain length of time is called brining. When vegetables are placed in brine, it penetrates in the tissues of the vegetables and soluble material present in vegetable diffuses into the brine by osmosis. The soluble material includes fermentable sugars and minerals. The sugars serve as food for lactic acid bacteria, which convert them into lactic and other acids. The acid brine thus formed acts upon vegetable tissues to produce characteristic taste and aroma of pickle.

The amount of brine required is usually half the volume of vegetables. Brining is the most important step in pickling. The growth of the majority of spoilage organisms is inhibited by brine containing 15% salt. Lactic acid bacteria, which are salt-tolerant, can thrive in brine of 8-10% strength though fermentation takes place fairly well even in 5 % brine. In a brine containing 10 % salt, fermentation proceeds somewhat slowly. Fermentation takes place to some extent up to 15 % but stops at 20% brine strength. It is, therefore, advisable to place the vegetables in 10 % salt solution for vigorous lactic acid fermentation. After fermentation process, the salt content is now increased gradually, so that by the time pickle is ready, salt concentration reaches 15%.

11.2.4 Salting Without Fermentation

Vegetables are washed, prepared and is mixed with salt (250 g/kg of prepared material). This high salt concentration will inhibit the fermentation. Vegetables packed with large amount of salt get cured. Then, they are drained and excess of salt is removed by soaking them in cold or warm water. Thereafter, the vegetables are stored in plain vinegar of 10% strength for several weeks. Vegetables can also be stored in sweetened and spiced vinegar. The spices can be added in the ground form or essential oil of spices may be added to impart the spice flavour.

11.3 VARIOUS PICKLES

At present, pickles are prepared with salt, vinegar, oil or with a combination of above ingredients with spices. These methods are discussed below:

11.3.1 Preservation with Salt

Salt improves the taste and flavour and hardens the tissue of vegetables and controls fermentation. Salt content of 15% or above prevents microbial spoilage. This method of preservation is generally used only for vegetables, which contains very little sugar. Since the sugar content is less, sufficient lactic acid cannot be formed by fermentation to act as preservative. However, some fruits viz., mango, lemon, etc. are also preserved with salt. An example for pickle preparation with salt is shown in Figure 11.1.

11.3.2 Preservation with Vinegar

This technology is based on the addition of food grade vinegar which has a bacteriostatic action in concentrations up to 4% acetic acid and bactericidal action in higher concentrations. Vegetables preserved in vinegar need to reach a final concentration of 2-3% acetic acid in order to assure their preservation. To achieve this final concentration, a 6-9% acetic acid vinegar is used, as related to the specific ratio of vinegar: vegetable. This higher concentration treatment helps to expel the gases present in the intercellular spaces of vegetable tissue.

In vinegar pickles, salt (2-3%) and sometimes sugar (2-5%) are also added. If the vinegar concentration is lower than 2%, vinegar pickles need to be submitted to a pasteurization in order to assure their preservation. Mango, garlic, chilies, etc. are preserved as such in vinegar. Vinegar pickles are the most important pickles consumed in other countries. Figure 11.2 shows the schematic flow chart of onion pickle by using vinegar as preservative.

11.3.3 Preservation with Oil

Oil pickles are highly popular in India. They are highly spiced. In India, mustard oil, rapeseed oil, sesame oil are generally used. The fruits or vegetables should be completely immersed in the edible oil. Cauliflower, lime, mango and turnip pickles are the most important oil pickles. The pickle remains in good condition for one to two years if handled properly. A schematic flow chart of lemon pickle by using oil as preservative is shown in Figure 11.3.

11.3.4 Preservation with Salt, Vinegar, Oil and Spices

This method combines the advantages of fermentation action of salt and the preservation action of both vinegar and oil. The flavouring property of spices is also made use of. The spices are usually fried in oil and mixed to the prepared fruit/ vegetable before the addition of vinegar. The spices can be added separately or in the form of spice vinegar. A schematic flow chart of tomato pickle by using salt, vinegar, oil and spices as preservative is shown in Figure 11.4.

11.4 CONTAINERS USED FOR PICKLING

Metallic vessels should be non corrodible. Usually, wide mouthed jars are used as they are easy to clean. The container should not impart any colour, taste, and flavour of its own to the pickle. Glass vessels, stainless steel, monel metal and aluminum containers are generally used as cooking utensils. The ladles, spoons and measuring vessels should also be of non corrosive materials.

11.5 KEEPING QUALITY

Properly brined vegetables will keep well in vinegar for a long time. The duration of brining is of utmost importance. If the vegetables are soaked for a short time of about 12 hrs only, the curing of the vegetable tissues will be incomplete with the result that the pickle will not have proper texture and taste. Brining has, therefore, to be controlled properly. On curing, the vegetables becomes semi translucent, and their colour changes from green to dark olive green or yellowish green. This is an indication of correct curing. This usually takes 4-5 weeks. By this method the vegetables can be kept more or less for an indefinite period, provided the right storage conditions are maintained. If the vegetable is kept in brine of 10% or less, all air should be excluded from the containers. During curing, the vegetables lose their 'raw' flavour and become firm and crisp.

Shelf life of fermented products: Some vegetables can be stored for years in high concentration of salt solution without a serious loss in quality though they are not stored for more than a year normally. The brine fermented products can be further processed with or without mild heat processing. During fermentation in bulk containers, microbial action influences the shelf stability. Complete conversion of fermentable carbohydrate to lactic acid and other end products renders the packaged products stable to subsequent fermentation. This is due to the presence of residual sugar, which leads to gas pressure and brine turbidity in the final package as a result of yeast and lactic acid bacterial growth. Preservatives like sodium benzoate, benzoic acid, sorbic acid and potassium bi-sulphate may be added to the product to enhance the keeping quality. Microorganisms (e.g. mould) producing softening enzymes should be excluded as they are active at pH values at which the packaged products are held.

11.6 CAUSES OF SPOILAGE

Different kinds of spoilage occur in pickles. They are as follows:

Bitterness: Use of strong vinegar or excess spice or prolonged cooking of spices imparts a bitter taste to the pickle.

Blackening: This is caused by iron which enters through the brine or from the equipment. Some times specific organisms also cause blackening.

Blemishes in pickled onions: Blemishes may sometime occur in the pickles and especially in onion pickles in vinegar. In the case of onions, white blotch is sometimes seen under the first layer of the skin. This appears to be owing either to some kind of fermentation or non removal of all the brine prior to the final pickling of the cured onion in the vinegar.

Cloudiness: When vegetables are placed in vinegar, it is generally presumed that the products will not spoil. In the case of onion and some other vegetables, however, sometimes the vinegar become cloudy turbid, there by spoiling the appearance of the pack. These raw materials being of a very solid structure, the acetic acid in the vinegar may not penetrate deep enough to prevent the activity of bacteria or other microbes that may be present in them . Hence the fermentation stars from inside rendering the vinegar cloudy. This activity of microbes can only be checked by proper brining. Cloudiness may also be caused by the use of a vinegar of inferior quality or imitation vinegar, or possibly by chemical action between the vinegar and the impurities such as calcium, magnesium and iron compounds that may be present in the salt used. This may also be caused by the reaction between the vinegar and minerals naturally present in the vegetable itself.

Dull and faded product: This is due to use of inferior quality materials or insufficient curing.

Scum formation: When vegetables are placed in the brine for curing a white scum is invariably formed on the surface owing to the growth of wild yeast. This scum may be thin or thick in appearance, varying from an almost imperceptible film to a thick wrinkled layer. It retards the formation of lactic acid. As this action may help in the growth of putrefactive bacteria, which causes the vegetable to become soft and slippery, it is essential to remove the scum as soon as it is formed. Addition of about 1% acetic acid helps to prevent the growth of wild yeast on the brine, without in any way hindering the formation of lactic acid. For this reason some manufacturers add a small amount of vinegar to the brine in the initial stage.

Shrivelling: This occurs when vegetables (e.g. cucumber) are placed directly in a very strong solution of salt or sugar or vinegar, Hence, a dilute solution should be used initially and its strength gradually increased.

Softness and slipperiness: This is the most common form of spoilage and caused by the action of bacteria. It is invariably owing to inadequate covering with brine or owing to the use of a week brine. By using a brine of proper strength and by keeping the pickle well below the surface of the brine, this kind of spoilage can be eliminated.

11.7 CHUTNEYS

A chutney is basically a mixture containing fruit or vegetable, spices, salt and/ or sugar, vinegar, etc. The method of preparation is similar to that adopted in the case of jams except that spices and vinegar are added. Chutney of good quality should be reasonably smooth, palatable, appetizing and have the true single flavour of the fruit or the vegetable used for the preparation.

11.7.1 Preparation of Chutney

Ripe fruit or vegetable is selected, cut into slices or pieces of suitable size and are softened by boiling in water. These are then, slowly cooked at a temperature below boiling point. Onion and garlic are added at the start to mellow their strong flavours. Spices are coarsely powdered before they are added to the product. Whole spices, if used, are bruised and tide loosely in muslin cloth before adding to the mixture and removed before bottling. Vinegar, sugar, and spices are added just a little before the final stage of boiling. This prevents the loss of some essential oils of spices and vinegar due to volatilization.

Long cooking of sugar darkens the colour of the chutney. For the preparation of dark colour chutney brown sugar is usually preferred, where as, white sugar is preferred for white colour chutneys. Spiced vinegar gives high quality product. Chutneys usually get thickened on cooling. The chutneys are bottled, while hot, in clean and warm jars which are then, adequately sealed and sterilized. A schematic flow chart of chutney production is shown in Figure 11.5.

11.8 SAUCES

Sauces and chutneys are usually made from the same raw materials, spices and flavours, however, difference is that, all sauces are sieved and as a result, are thinner and of smoother consistency than chutneys. The sieving is done to remove the skin, seeds and stalks of fruits, vegetables, and spices and to give a smooth consistency. Here the cooking process is longer compared to the chutney due the use of fine pulp or juice.

Sauces are generally of two kinds, and they are the thin sauces and the thick sauces. A good sauce whether thin or thick, have a continuous flow with no skin, seeds and stalks of the fruit and/ or vegetables and spices used for its preparation, and possesses pleasant taste and aroma. The details of thin and thick sauces are given below:

11.8.1 Thin Sauces

Thin sauces mainly consist of vinegar extract of various flavouring materials like, spices and herbs. Their quality depends mostly on the piquancy of the material used. Some sauces are matured by storing them in wooden barrel or casks. During storage they develop flavour and aroma. Freshly prepared products have often a raw and strong taste and they should, therefore, be matured by storage.

Preparation: For the preparation of thin sauces of high quality, the spices, herbs, fruits, and vegetables are macerated in cold vinegar. Some times, they are also prepared by boiling them in vinegar. The sauce is filtered through a fine or coarse mesh sieve of non corrodible metal, according to the quality desired. The skin, seeds and stalks of fruits, vegetables and spices used, should not be allowed to pass through the sieve as they spoil the appearance of the sauce. The usual commercial practice is to prepare vinegar extracts of each kind of spice and fruit separately, either by maceration or by boiling in vinegar and then blending these extracts suitably before filling the sauce into barrels for subsequent maturation.

Soya sauce made from soybeans and Worcestershire sauce made from tamarind are examples of thin sauces. The Worcestershire sauce is utilized in the preparation of cocktail also. Figure:6 shows a schematic flow chart of thin sauce production.

11.8.2 Thick Sauces

A sauce which does not flow freely and which is highly viscous is called a thick sauce. On the other hand thin sauces are less viscous in consistency. Thick sauces also contain more of sugar and less of acid. Generally spices and colouring added are practically similar to those in the case of thick ketchups and sauces. It should contain at least 3% acetic acid to ensure its keeping quality. The acidity should not however, exceed 3.4% as otherwise the sauce would taste sharp. The sugar content may usually varied from 15-30% according to the kind of sauce made. Usually malt vinegar is used. In addition to contributing to acidity of the sauce, it also improves its flavour. The sweetness is derived partly from dates, raisin, apple and tomato and partly from the sugar added. The colour of the sauces varies with the raw material use. Some times a little caramel is added.

Preparation: The manufacturing process is the same as for chutneys. Thickening agents are also added to prevent or retard sedimentation of solid particle in suspension in the sauce. In this country apple pulp is often used for this purpose. The starch obtained from maize, potato, arrow root, sago and rye are also used as thickening agents. Indian gum, gelatin, Irish moss, pectin and other similar substances can also be used subject to the food laws of our country. Tomato sauce and apple sauce are some of the examples for thick sauce. Preparation of tomato sauce is explained under the section 3.10.5.

11.9 SOUPS AND OTHER MIXES

Ready to serve soups such as tomato soup, mushroom soup, mixed vegetable soups, especially dried vegetable mixtures for quick preparation of soups at home, are gaining popularity in these days. Liquid soups are generally canned. They are warmed at the time of serving. The preparation and bottling of tomato soup is explained under tomato processing (3.10.8).

Check Your Progress Exercise 2

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Differentiate between thin sauce and thick sauce.

11.10 TOMATO PRODUCTS

Tomato is grown in our country in abundance, in all seasons. The farmer will get a very low profit during the peak-harvesting season and nearly 25% of the produce is spoiled due to improper post harvest practices. Such losses can be avoided by converting tomatoes into delicious products. Tomato can be processed to a variety of products like; canned tomato, paste, puree, juice, ketchup and sauce. In India tomato sauce and ketchup are very popular and are being manufactured on an increasingly large scale.

11.10.1 Tomato Juice

This product is characterised not only by its organoleptical properties (taste, colour, flavour) but also by its vitamin content close to those of fresh tomatoes. Modern technology is oriented to a maximum maintenance of organoleptic properties and of vitamin content.

At same time, it is important to assure juice uniformity by avoiding cellulosic particle sedimentation. A good quality juice should contain about 0.4 % acid (in terms of citric acid), 0.5% salt, and 1 % sugar. Juice stability is assured by a flash pasteurization, which assures the destruction of natural micro-flora, while keeping the initial properties. The modern technological flow sheet covers the following main operations:

Preparation of Tomato Juice

Pre-washing and washing: Pre-washing is carried out by immersion in water, cold or heated up to 50°C (possibly with detergents to eliminate traces of pesticides). Then washing is performed with water sprays.

Sorting: Only sound ripe red coloured tomatoes are used for the juice preparation. This is done on rolling sorting tables. This enables the removal of non-standard tomatoes – with green parts, yellow coloured, etc.

Crushing and pulping: Crushing is carried out in a special equipment. Fluted wooden roller crushers are utilized for this purpose. The crushed tomatoes can be pulped by the hot process or by the cold process. In hot pulping, crushed tomatoes are boiled in their own juice in steam jacketed stainless steel pans or in aluminium pans for 3 to 5 minutes. This process facilitates the extraction, dissolves pectic substances and contributes to the maintaining of vitamins and natural pigments. In some modern installations, this step is carried out under vacuum at 630-680 mm Hg and in very short time. Whereas in cold pulping, the tomatoes are crushed in cold and as such passed through a pulper. Here the extraction of juice is difficult and yield will be less compared to hot process.

Extraction: Extraction of juice and part of pulp (maximum 80%) is performed in special equipment / tomato extractors with the care to avoid excessive air incorporation. In some installations, as an additional special care, a part of pulp is removed with continuous centrifugal separators.

Deaeration and Homogenization: The air from the extracted juice is removed by using a deaerator under high vacuum. Homogenization is done for mincing of pulp particles and is mandatory in order to avoid future potential product "separation" in two layers.

Filling and bottling: After flash pasteurization at 130-150°C for 8-12 second, the juice is cooled at 90°C. This cooled juice is filled in receptacles (cans or bottles) at the same temperature (90^0C). The receptacles are then closed followed by their inversion for about 5 to 7 minutes. Cooling has to be carried out intensely. Full cans do not need further pasteurization because the bacteria that have potentially contaminated the tomato juice during filling are easily destroyed at 90°C due to natural juice acidity.

For bottles, it may be possible to avoid further sterilization if the following conditions can be strictly adhered: washing and sterilizing of receptacles, cap sterilization (with formic acid), filling and capping under aseptic conditions, in a space with UV lamps. Since this is quite difficult to achieve, it may be necessary to subject the bottles for pasteurization in water baths.

11.10.2 Tomato Puree

Tomato pulp without skin or seeds, with or without added salt, and containing not less than 9.0% of salt free tomato solids is known as "Medium tomato puree". It can be concentrated further to 'heavy tomato puree', which contains not less than 12% solids.

Preparation of tomato puree: Manufacturing steps fall into three successive categories: (i) obtaining tomato juice from the raw materials; (ii) juice concentration and (iii) tomato puree pasteurization. Tomato pulp and juice extraction is done from ripe tomatoes in the same manner as tomato juice preparation.

Concentration of the pulp is carried out either in an open cooker or in a vacuum pan. In open cooking, most of the vitamins are destroyed and the product becomes brown. On the other hand, use of vacuum pans, nutritive value is preserved and browning is also reduced. However this method is quite expensive. Ordinarily tomato juice can be concentrated to lower range in an open cooker, but for obtaining higher concentrations a vacuum pan is required. The end point is judged by determining the TSS. This is done by using either a specific gravity hydrometer or by a refractometer.

Tomato puree pasteurization assures the microbiological stability of the product. For this purpose, the puree coming out from concentration equipment is passed continuously and in a "forced" mode through a tubular pasteurizer from which it emerge, at a temperature of 90-92° C. The pasteurized puree is then filled hot in to cans or in glass receptacles.

11.10.3 Tomato Paste

The product with highest production volumes among concentrated products is tomato paste, which is manufactured in a various range of concentrations, with a minimum of 25% and up to 44% refractometric extract. The product is very similar to tomato puree except that the solid concentration is more. Tomato paste is the product obtained by removal of peel and seeds from tomatoes, followed by concentration of juice by evaporation under vacuum. Good quality tomato paste is a homogenous mass, with a high density, without foreign bodies (seeds, peel, etc.), with a red colour, and an agreeable taste and smell, close to those of fresh tomatoes.

Preparation procedure is also similar to that of tomato puree. Here the tomato juice obtained is further concentrated so that it contains not less than 25% tomato solids. This is known as tomato paste. On further concentration to 33% or more of solids, it is called concentrated tomato paste. Paste of good quality must have a volatile acidity of maximum 0.15% as lactic acid. An 8% salt addition is accepted. The end point is judged by using a refractometer. The product with required TSS is then pasteurized and filled into receptacles in the same way as explained under tomato puree.

11.10.4 Canned Tomato

The process of sealing tomatoes hermetically in containers and sterilizing them by heat for long storage is known as canning. The principle of canning is the destruction of spoilage microbes within the sealed container by thermal processing, i.e., by means of heat. Schematic representations of the unit operations are shown in Figure 11.7.

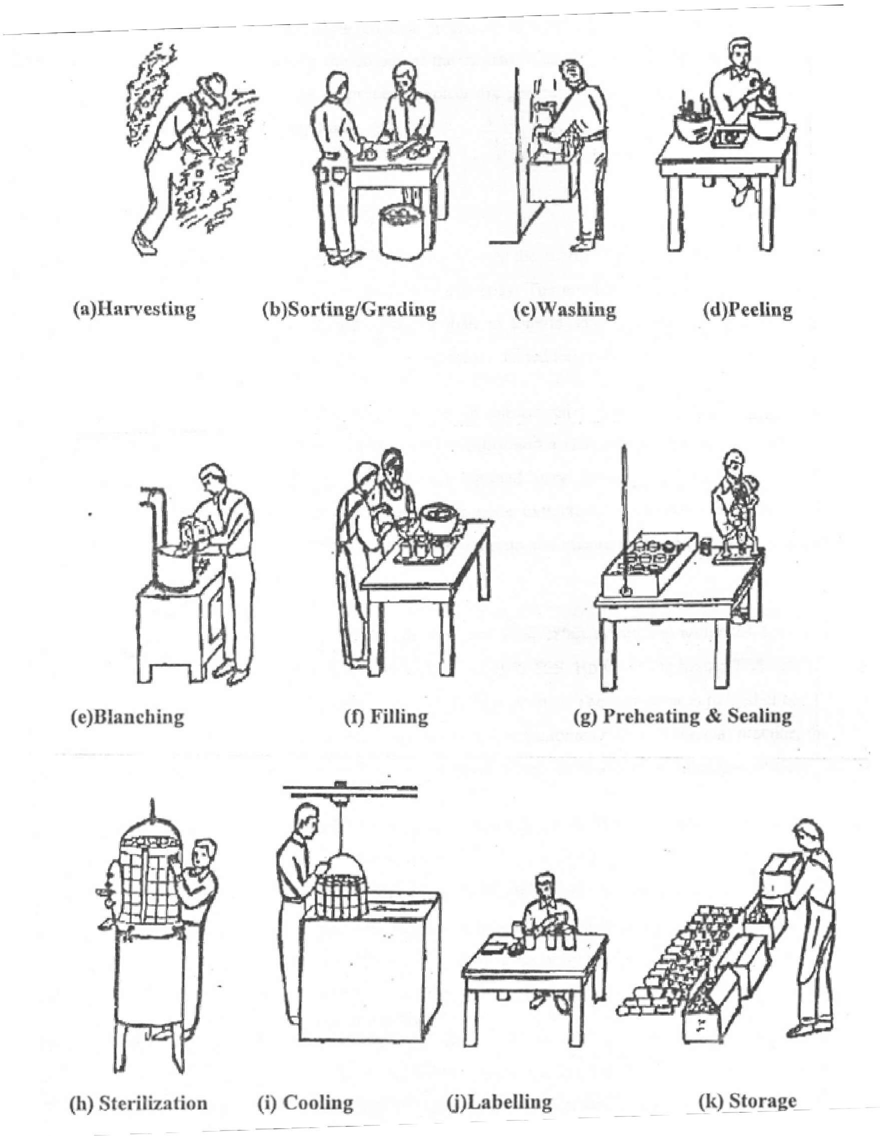

Figure 11.7: Schematic representation of fruit canning unit operations

Canning process: Canning involves the pre-treatments like selection of sound fruits and vegetables, grading, washing, peeling, cutting, blanching and cooling .The blanched tomato pieces are filled in plain cans and tomato juice is used as covering liquid. The filled cans are now subjected to exhausting for the removal of air and are then sealed immediately. The sealed cans are then thermally processed at high temperature (100°C) for about 25-30 minutes. After thermal processing, the cans are cooled rapidly to about 39°C to stop the cooking process and stored after labelling.

11.10.5 Tomato Sauce

Tomato sauce is the concentrated product prepared from the liquid extract from mature, sound, whole tomatoes to which is added salt, spices, sugar, vinegar, with or with out onion, garlic, or other vegetable flavouring ingredients. The final concentrated product contains not less than 12% tomato solids and 25% TSS. FPO specifications are given under quality standards.

Sauces can be obtained from fresh tomatoes or from concentrated products (tomato paste or concentrated tomato juice), those from fresh tomatoes being of superior quality. Technological processing covers the following steps: concentrated juice processing, addition of flavour/taste ingredients (salt, sugar, vinegar, spices, etc.), boiling, fine sieving, filling of receptacles, closing and pasteurization (45 min at 85°C).

Special care: About one third of the sugar required is added at the time of commencement of boiling to intensify and fix the red tomato colour. If the whole quantity of sugar is added initially, the cooking time will be longer and the quality of pulp will be adversely affected. Generally the sugar content in sauces/ ketchups varies from 10- 26 %. On the other hand, salt bleaches the colour of the tomato product. It is therefore desirable to add towards the end of cooking process. Spices are generally added in powdered form to the product by spice bag method.

11.10.6 Tomato Ketchup

Tomato ketchup is a popular condiment all over the world. Tomato ketchup is similar to tomato sauce except that it is thick in consistency. The amount of spices added in case of tomato ketchup is considerably higher than in tomato sauce. Thick sauces made from fruits and vegetables other than tomatoes are not called ketchups.

Preparation: Clean, wholesome tomatoes of intense red colour and of meaty, not watery texture are used for sauce making. High acidity and a rich tomato flavour are additional desirable qualities. Sound tomatoes are washed very thoroughly, cored, sliced, heat crushed and pulped (through a pulper or juice extractor) to remove seeds and skins. Tomato pulp or paste is then cooked with the requisite quantities of spices, onions, garlic, sugar, salt and vinegar.

The whole mass is concentrated to the required TSS (28%). A ketchup with a 28-30% TSS has a better flavour than those with more than 30% TSS. However the higher TSS ketchup generally keep for a long time, once the bottle is opened. The end point is judged either by means of a specific gravity hydrometer or by a refractometer. In commercial practice, the juice is concentrated to one third of its original volume as determined with a gauge stick.

Bottling: The mass is finally passed through the finisher, fitted with a very fine sieve, to remove any tomato fibre, and other impurities. The sieved ketchup is filled into clean, dry bottles. The ketchup should be filled hot (88^{o}C) to prevent browning and loss of vitamins during subsequent storage. Bottles are cleaned, labelled and packaged for marketing. Preservation is assured either by use of preservatives or by pasteurization.

11.10.7 Dried Tomato/Tomato Powder

Dried tomato is used for the production of flakes and tomato powder. For the preparation of dried product, tomatoes should be ripe, of good red colour and should be firm. Tomato pigments are stable because they are rich in carotene; therefore, pre-processing, such as blanching and sulphiting, is not necessary. Alternatively the slices may be dipped for 3 min in a solution containing 0.7% $K_2S_2O_5$ (KMS) plus 10% salt.

Washing and sorting are followed by cutting in halves lengthwise to eliminate the liquid and the seeds. Empty the tomatoes and then cut them lengthwise into slices of 6 to 8 mm thickness and place them in dryers. The tomatoes are dry when the raw material / dry product ratio is about 25:1. On an average, 40 g of dried products are obtained from I Kg of fresh tomatoes. The yield depends on the dry tomato residue and the degree of drying.

The dried slices may be reduced to flakes by rubbing through a sieve of about 10 mm mesh. This gives a better-looking product, which is easy to handle. The product may also be ground into powder but this will tend to cake and the colour is less appealing than the flakes. The product is then cooled (half an hour at room temperature), bagged and labelled for storage. The product must be kept in a dark place to reduce infestation by photophilic insects.

11.10.8 Tomato Soup

Soup is becoming very popular in India. Stored soup is warmed at the time of serving. The main constituents of the soup are tomato juice, butter or cream, spices, flour or starch (for thickening), onion, etc.

Preparation: In its preparation the first step is the preparation of tomato pulp just as in the case of tomato juice. Neutralize about $1/6^{th}$ of the acidity of the juice by adding a thin paste of sodium bicarbonate in water. The juice is then concentrated in a boiling pan. While it is being concentrated, add the spices in a cloth bag as in the case of tomato ketchup. In the meantime, mix the flour/ starch and butter/cream with one portion of juice (usually 10 to 15% of the total juice) to form a smooth paste. When the juice in the pan has been sufficiently concentrated, add this paste to it. Continue boiling to the desired consistency. Stirring is done continuously to prevent clotting of the starch. At the end, add sugar and salt and boil the mixture for about two minutes to dissolve them.

Bottling: The tomato soup is filled into cans and closed them properly for sterilization. Sterilization is carried out at 115^0C for 40- 45 minutes. The sterilized cans are cooled and stored in ambient temperature in a cool and dry place.

11.10.9 Chilly Sauce

It is highly spiced product made from ripe, peeled and crushed tomatoes and salt, sugar, spices, vinegar, with or without onion and garlic. The method of preparation is similar to that for tomato sauce except that the total unstrained pulp is used and the seeds are not removed. Hot product is filled in bottles or cans and processed in water at 85-90^{o}C for 30 minutes.

11.10.10 Tomato Pickle

Tomato pickles can be produced by using a combination of preservatives like salt, oil, spices and vinegar. The detailed method of the pickling process and flow chart for the same is explained under the section 3.3.4.

11.10.11 Tomato Chutney

Tomato chutney is produced from tomato pulp, and other ingredients like sugar, salt, vinegar, spices, onion, ginger, garlic, etc. The preparation of tomato chutney is similar to that of the chutney produced from other fruits and vegetables. The method of preparation is explained under the section 3.7.1.

11.10.12 Tomato Cocktail

Tomato cocktail is gaining popularity in many of the high-class hotels and restaurants. It is prepared just before serving and some times is also served from stock. In the later case, the cocktail is preserved by pasteurization in bottles. Although the recipes vary, the main constituent is tomato juice to which common salt, vinegar, Worcestershire sauce (Sauce from tamarind), lemon juice, etc. are added in different proportions to suit the palate.

The preparation of tomato juice is done in the similar way as explained in earlier products. Fresh or canned juice can be used for the cocktail production. Boil the tomato juice with the spices loosely tied in a cloth bag for about 20 minutes in a covered vessel. Then add the limejuice, vinegar and common salt. Only crystal clear limejuice should be used, because any sediment in it will impart an undesirable flavour.

Bottling: When all the ingredients have been mixed and the cocktail is ready for bottling, heat the cocktail to 82°C to 88°C and fill it into bottles, which have been sterilized and kept hot for filling. Close the bottles and keep them immersed in boiling water (100°C) for 30 minutes and then cool them.

11.11 MICROBIOLOGY OF RAW & FINISHED PRODUCTS

When tomatoes of poor quality are used in the preparation of tomato products, excessive amount of moulds, yeast, bacteria and fragments of insects lower the quality of the product. There are some prescribed limits for the mould, yeast and bacteria count permitted in the tomato products. Of these, mould count is the most important as it is the sure and positive indication of the condition of the tomatoes used. The insect fragment count is also highly indicative of gross contamination of the fruit and unhygienic conditions during handling and preparation of the raw material and finished products.

A minimum of 10 minutes heating of the sauce with 0.5% acetic acid could ensure the destruction of spore formers and addition of 750 ppm of sodium benzoate to the sauce would prevent microbial spoilage during storage.

11.12 PROBLEMS IN TOMATO PROCESSING AND MEANS TO AVOID THEM

11.12.1 Tomato Juice

- "Separation" in layers is due to not enough homogenisation or low / insufficient viscosity. In the first case it is necessary to intensify homogenisation; and in second to increase the pre-heating temperature to 60° C in order to obtain protopectine hydrolysis and pectolytic enzymes inactivation.
- Moulding of the juice is brought about by significant infection of raw materials, inadequate washing and control or by use of contaminated packages. The preventive measures should be decided after cause analysis. Good pasteurization can destroy all moulds but the bad juice taste remains.
- Fermentation of juice is manifested by a significant development of gases. Prevention methods are the same as for moulding.
- Tomato juice turns sour, without the formation of gases; this defect is initiated by thermophyl and thermo-resistant bacteria; the juice acquires a vinegary taste. Prevention: maintenance of flash pasteurization temperature at 130-135°C.
- Excessive vitamin C losses are due to a simultaneous action of heating and oxygen from air. It can be prevented by blocking air going into crusher and extractor, close receptacles in vacuum and assure an intensive de-aeration (vacuum degree 700 mm Hg) at a temperature of at least 35-40°C.
- Weak colour of tomato juice can be avoided by the utilisation of mature tomatoes and with a pulp of as red a colour as possible.

11.12.2 Tomato Paste and Puree

- Presence of sand is caused by inadequate washing or by a significant contamination of raw material; this can be prevented by a more intensive pre-washing and washing of tomatoes.
- There may be mould especially at the surface of tomato paste packed in drums. This can be prevented by accurate pre-washing and washing, following pasteurization instructions, packing in clean drums or receptacles, and closing receptacles immediately after filling.
- Fermentation is manifested by a weak alcohol smell or by a weak vinegar taste; when the fermentation is more advanced there is gas production in the product mass. Prevention: as for moulding prevention.

11.12.3 Tomato Sauces

Surface of the product turns black at the contact zone with air; this is due to the action of iron on the tannins from spices, tomato seeds, etc. Prevention is by avoiding iron equipments, avoiding crushing of tomato seeds and by sealing the receptacles under vacuum.

11.13 QUALITY STANDARDS

The importance of quality and its considerations has been discussed in detailed in Unit 1. Now we will see the FPO specifications for the products discussed in the present unit. FPO specifications for tomato products, pickles, chutneys and sauces are as follows:

Sl. No.	Product	Minimum TSS (%)	Mould count
1. 2.	Tomato juice Tomato soup	5.00 7.00	Not in excess of 30% of the field examined.
3. 4.	Tomato puree Tomato paste	9.00 25.00	Not in excess of 60% of the field examined
5.	Tomato ketchup/ sauce	25 .00(minimum acidity as acetic acid 1%)	Not in excess of 40% of the field examined
6.	Sauces other than tomato and soybean	15 .00(minimum acidity as acetic acid 1.2%)	Not in excess of 40% of the field examined

Permissible limits of preservatives in fruit beverages

Sl. No.	Food product	Preservative	Parts per million (ppm)
1.	Pickles and chutneys made from fruits and vegetables	Benzoic acid or Sulfur dioxide	250 100
2.	Tomato and other sauces	Benzoic acid	750
3.	Dehydrated vegetables	Sulfur dioxide	2000
4.	Tomato puree and paste	Benzoic acid	250

Some important considerations:

- In case of oil pickles the name of the fruit or vegetable used shall be declared on the label.
- When more than one vegetable is used in vinegar pickle the product shall be labeled as 'mixed pickles'.
- In case of sauces other than tomato and soybean, the names of fruits, vegetables or dried fruits used shall be declared on the label.
- In case of fruit chutney, the names of fruits may not be declared on the label, However, in case of mango chutney or other chutneys the content shall be declared on the label.

- Permissible limit of Copper (a toxic element) in tomato ketchup is 50 ppm, where as the same can be up to 100 ppm in tomato puree, paste, juice powder and cocktails.

11.14 LET US SUM UP

Chutney, sauce and pickle are various processed products from fruits and vegetables prepared by using preservatives like salt, vinegar, oil, spies etc. In making such products, the major objective is to provide consumer with more variety among the processed foods and to provide convenience to have fast food. Apart from extending the shelf life of fruits and vegetables, these products enhance sensory properties and nutritive value of food

You must now be well versed with the methods of pickling and chutney and sauce preparation. We have also seen how to obtain diversified products from tomato fruit. Finally, the keeping quality, standards, packaging and storage aspects of the finished products are also explained in this section.

11.15 KEY WORDS

Brine	:	Solution of common salt.
Brining	:	Steeping of the vegetables in a salt solution of pre determined concentration for a certain length of time.
Vinegar	:	It is a liquid obtained by alcoholic and acetic fermentation of material containing sugar. It contains about 4% acetic acid.
Chutney	:	It is an unstrained, concentrated product, which contains a mixture of fruit or vegetable, spices, salt and/ or sugar, vinegar.
Sauce	:	It is a strained, concentrated product, which contains a mixture of fruit or vegetable, spices, salt and/ or sugar, vinegar. These are thinner and smoother in consistency than chutneys.
Tomato paste	:	It is a concentrated and strained tomato product and contains not less than 25% tomato solids.
Tomato puree	:	It is a concentrated and strained tomato product but thinner than the paste and containing not less than 9.0 % of salt free tomato solids.
Spice bag	:	Bruised spices tide loosely in muslin cloth
Ketchup	:	Thick sauces made from tomato

11.16 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. The preservation of fruit or vegetable in common salt or in vinegar is called pickling. Pickling is the result of fermentation by lactic acid forming bacteria, which are generally present in large numbers on the surface of fresh vegetables and fruits. These bacteria can grow in acid medium and in

the presence of 8-10% salt solution, whereas the growth of a majority of undesirable organisms is inhibited.

2. Vegetables preserved in vinegar need to reach a final concentration of 2-3% acetic acid in order to assure their preservation. To achieve this final concentration, a 6-9% acetic acid vinegar is used, as related to the specific ratios vinegar: vegetables. This higher concentration treatment also helps to expel the gases present in the intercellular spaces of vegetable tissue.

3. Different kinds of spoilage occur in pickles. They includes: bitterness, blackening, blemishes in case of onion pickles, cloudiness, dull and faded product, scum formation, shrivelling and the most common one is, softness and slipperiness.

Check Your Progress Exercise 2

1. Thin sauces mainly consist of vinegar extract of various flavouring materials like, spices and herbs. Their quality depends mostly on the piquancy of the material used. Where as thick sauce does not flow freely and is highly viscous. Thin sauces are less viscous in consistency. Thick sauces also contain more of sugar and less of acid.

2. Thick sauces made from tomato are known as ketchup. It is similar to sauce except that it is thick in consistency. The amount of spices added in case of ketchup is considerably higher than in sauce. Thick sauces made from fruits and vegetables other than tomatoes are not called ketchups.

3. Generally the sugar content in sauces/ ketchups varies from 10- 26%. If the whole quantity of sugar is added initially, the cooking time will be longer and the quality of pulp will be adversely affected. About one third of the sugar required is added at the time of commencement of boiling to intensify and fix the red tomato colour.

Check Your Progress Exercise 3

1. The various unit operations in tomato juice production include: Pre-washing, washing, sorting, crushing, pulping, extraction of the juice, de-aeration, homogenization, filling and bottling. The filled juice is subjected to flash pasteurization and intensively cooled to ambient temperature for storage.

2. The various problems in the production of tomato juice are as follows: i) Separation in layers due to improper homogenization, ii) Moulding of the juice, iii) Fermentation of juice, iv) Souring of tomato juice, v) Excessive vitamin C losses, and vi) Weak colour of tomato juice.

3. A minimum of 10 minutes heating of the sauce with 0.5% acetic acid could ensure the destruction of spore formers and addition of 750 ppm of sodium benzoate to the sauce would prevent microbial spoilage during storage.

4. The major manufacturing steps of tomato puree and paste fall into three, which includes: i) obtaining tomato juice from the raw materials, ii) juice concentration, and iii) tomato puree preservation by pasteurization.

UNIT 12 DEHYDRATED PRODUCTS FROM FRUITS AND VEGETABLES

Structure

12.0 OBJECTIVES

The various points to be understood from this section are as follows:

- purpose of drying/ dehydration of drying of fruits and vegetables;
- procedure for dehydration of fruits and vegetables;
- methods and principles of different dehydration techniques; and
- packaging, storage and quality aspects of the dried products.

12.1 INTRODUCTION

Drying is the oldest known method of preserving food. Drying or dehydration is the removal of the majority of water contained in the fruit or vegetable. Although preservation is the primary reason for dehydration, it also lowers the cost of packaging, storing and transportation by reducing both the weight and volume of the final product. In addition, dried foods add variety to our diets. In the process of drying sufficient moisture is removed to protect the product from spoilage. The processing should be done in such a way that the food value, natural flavour and characteristic cooking quality of the fresh material are retained after drying

In this unit, we will examine the various steps in the preparation of dehydrated fruits and vegetables. The importance of water activity and the effect of drying on product quality are also discussed in this section. We'll see the working principles of various methods of drying and the comparative merits and demerits of these techniques. You can also learn about the packaging, storage and the special care to be adopted during drying process.

12.2 DEFINITION

Drying or dehydration means the process of removal of moisture by the application of artificial heat under controlled conditions of temperature, humidity and air flow. In this process a single layer of fruits or vegetables, as a whole or as pieces/slices are spread on trays which are placed inside the dehydrator. The initial temperature of the dehydrator is usually high which is gradually reduced.

12.3 USE OF DRIED FRUITS AND VEGETABLES

Of all food preservation methods, drying has received the most widespread and enthusiastic publicity in recent years. The use of dehydrated product has increased due to its advantages over other preservation techniques. The advantages are:

- The weight of a product is reduced to $1/4^{th}$ to $1/9^{th}$ of its original or fresh weight and thus the cost of transport is reduced.
- Due to reduction in bulk of the product, it requires less storage space.
- No preservative is added for its preservation.
- Nutrient concentration is very high per unit weight of dried product.
- Cost of processing is very low, as there is less labour and no sugar requirement.

Dried Fruits tend to be chewy and make delicious snacks. Pieces of dried fruits are good in cookies, muffins, cakes and breads. They can also be reconstituted and used in sauces, pies or added to gelatin salads, cooked cereals and ice cream. In addition to dried fruits, fruit leathers may also be used as snack foods.

Dried Vegetables can be used as chips or reconstituted for a cooked side dish. These are also used in soups, stews, casseroles and stuffings or made into powders. Campers and hikers value dried foods for their light weight, keeping qualities and ease of preparation.

12.4 STATE OF WATER IN FOODS

We know that the micro-organisms can grow very well at high moisture contents (above 80%). They get this water from the food in which they grow. If the water is removed from the food, water will transfer out from the bacterial cell too. This will stop multiplication of bacterial cells. In dehydration, it is important to understand the behaviour of water so that it can be removed most effectively and still leave a high quality product. Partial drying will be less effective than total drying, though for some micro-organisms partial drying may be quite sufficient to arrest bacterial growth and multiplication. Bacteria and yeasts generally require more moisture than moulds. Moulds can grow even on semi-dry foods on which bacteria and yeasts are difficult to survive. Example: moulds growing on partially dried fruits.

Water activity (a_w)

Food technologists often use a measure of "water activity" to describe how water interacts in food products. Water activity determines the lower limit of available water for microbial growth. It is defined as the ratio of the vapour pressure on the aqueous solution to that of pure water at the same temperature. Quantitatively, water activity is a measure of unbound, free water in a system available to support biological and chemical reactions. Water activity, and not absolute water content, is what bacteria, enzymes and chemical reactants encounter and are affected by, at the micro-environmental level in food materials. At the usual temperatures permitting microbial growth, most bacteria require a water activity in the range of about 0.90 to 1.00. Some yeasts and moulds grow slowly at a water activity down to as low as about 0.65.

The a_w has a major role to play on microbial spoilage and chemical changes produced in the food. The water activity of solutions containing solutes such as sugar, salts etc. will be less than 1. For food products, the a_w is generally less than 1. a_w is related to the moisture content of food, the types and concentration of different solutes, and the structure of the food. Two foods with the same water content can have different a_w values depending upon the degree to which water is free or otherwise bound to food constituents.

Free water and Bound water

The state of water in food is denoted by two types viz.; "free water and bound water". The working definition for these terms is "free water is that which gives water activity of one. Bound water gives water activity less than one. In drying process free water is relatively easy to remove from the food products, while bound water takes more energy to release from the food. This is because the bound water is bonded to the cell solutes. Thus the energy required to remove a molecule of water from a food increases as the water activity decreases. This is important to those who design drying operations, since energy is required to provide sufficient driving force for drying.

As a food product dries out and the water molecules becomes less mobile, physical changes also occur in the food. As water is removed, the product becomes more viscous, until a solid state is achieved on complete removal of the water. Thus the state of water present in the food or water activity plays an important role in determining the product quality.

12.5 FACTORS INFLUENCING DEHYDRATION

The drying operation of fruits and vegetables is a complex one since it involves simultaneous exchange of moisture and heat. Drying time in conventional ovens or dehydrators vary considerably depending on the amount of food dried, its moisture content, and temperature and humidity. Some foods require several hours and others may take more than a day. Prolonging drying time (by using lower temperatures) or interrupting drying time may result in spoilage.

Various factors that effect the rate of drying of horticulture produce include the following:

1. Composition of raw material.
2. Size, shape and arrangement of stacking of the produce.
3. Temperature, relative humidity and velocity of air.
4. Pressure.
5. Heat transfer to surface.

It is important to control the air temperature and circulation during the drying process. If the temperature is too low or the humidity too high (resulting in poor circulation of moist air) the food will dry more slowly than it should and microbial growth can occur. Watch temperature closely at the beginning and at the end of the drying period. If the temperature is too high in the initial phase, a hard shell may develop on the surface. This will prevent the removal of moisture from the interior portion and the moisture is trapped inside the food material. This is known as *case hardening*. Temperature, if too high at the end of the drying period may cause food to scorch. Temperature between 49^{o}C to 60^{o}C are recommended for drying fruits and vegetables. Temperature up to 65^{o}C may be used at the beginning, but should be lowered as food begins to dry. However during the last hour of the drying period, the temperature should not exceed 55^{o}C.

12.6 DRYING RATE CURVES

The drying rate curves show the rate of removal of moisture from the fruit or vegetable. There are three different ways to express this physical phenomenon. They are relation ships between drying rate, drying time and moisture content.

Drying time vs. drying rate: While drying, foods do not lose water at a constant rate and the rate of water removal under any set of fixed conditions drops-off as drying progresses (Figure 12.1). In practice, while we may remove 90% of the water in 2 hours, it may require more than 2 hours to remove most of the remaining 10% water. This becomes asymptotic so that zero moisture is never reached under practical operating conditions. This relation is explained in the drying curve "Drying time Vs Drying rate".

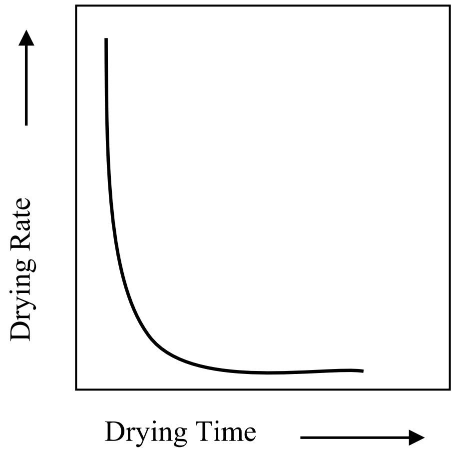

Figure 12.1: Drying time vs. drying rate

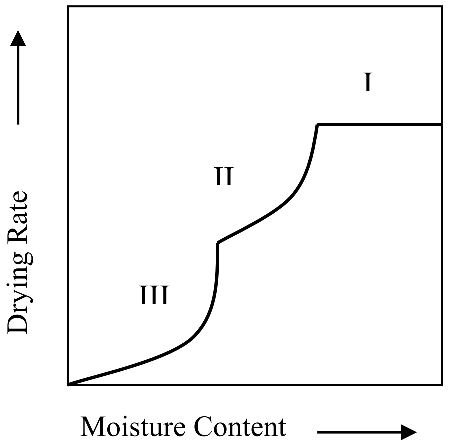
Moisture content vs. drying rate: At the beginning of drying, generally, water continues to evaporate from the food pieces at a rather constant rate. This is followed by an inflection in the drying curve, which leads to the falling rate period of drying. The precise shape of the normal drying curve varies with different food materials, different types of dryers and drying conditions. But the drying of most fruits and vegetables generally shows constant and falling rate periods. This relationship is as shown in the Figure 12.2. As the moisture content decreases, the drying rate changes from constant rate of drying to falling rate of drying. During the falling rate period, the rate of water movement from the interior of the food to the surface falls below the rate at which water evaporates to the surrounding air.



I- Constant rate of drying
II- First falling rate of drying
III- Second falling rate of drying

Figure 12.2: Moisture content vs. drying rate

Drying time vs. moisture content: The Figure 12.3 shows a drastic reduction of moisture in the initial phase of drying which reduces to a minimum as drying progresses. During drying process, the moisture content available in the commodity reduces and the removal of water to about 2% without product damage is exceedingly difficult.

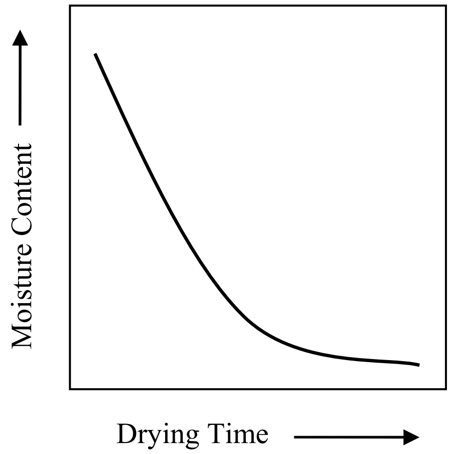


Figure 12.3: Drying time vs. moisture content

12.7 PROCEDURES FOR DRYING

Drying of fruit/ vegetable involves three stages; pre-drying treatments, drying of the commodity and post drying treatments. The flow diagram of drying process is shown in Figure 12.4.

12.8 PRE-DRYING TREATMENTS

Pre-drying treatments include raw material preparation and colour preservation.

12.8.1 Raw Material Preparation

This includes selection of fruits, sorting, washing, peeling (for some fruits and vegetables), cutting into the appropriate form, and blanching (for some fruits and most vegetables). Fruits and vegetables are selected and sorted according to size, maturity and soundness. It is then washed to remove dust, dirt, insect matter, mould spores, plant parts and other material that might contaminate or affect the colour, aroma, or flavour of the fruit or vegetable. Peeling or removal of any undesirable parts is followed by washing. The raw product can be peeled by hand, with lye or alkali solution, with dry caustic and mild abrasion, with steam pressure, with high-pressure washers, or with flame peelers.

12.8.2 Blanching

Blanching is used to destroy enzymatic activity in vegetables and some fruits, prior to further processing. To achieve adequate enzyme inactivation, food is heated rapidly to a preset temperature, held for a preset time and then cooled rapidly to near ambient temperatures. The factors that influence blanching time are: the type of fruit or vegetable, the size of the pieces of food, blanching temperature and method of heating. The two most widespread commercial methods of blanching involve passing food through a bath of hot water or an atmosphere of saturated steam. It involved immersion in hot water (95^o to 100^o C) or exposure to steam to inactivate the enzymes present in fruits and vegetables. Both types of equipments are relatively simple and inexpensive.

12.8.3 Sulphuring

The final step in the pre-drying treatment is colour preservation, also known as sulphuring. The majority of fruits are treated with sulphur dioxide (SO_2) for its antioxidant and preservative effects. The presence of SO_2 is very effective in retarding the browning of fruits. In addition, SO_2 treatment reduces the destruction of carotene and ascorbic acid, which are the important nutrients for fruits.

In addition to colour preservation, the presence of a small amount of sulphite in blanched, cut vegetables improve storage stability and makes it possible to increase the drying temperature during dehydration. This will decrease the drying time and increase the dryer capacity without exceeding the tolerance for heat damage.

12.9 DRYING METHODS – THEIR PRINCIPLES AND METHODOLOGIES

Dehydrated fruits and vegetables can be produced by a variety of processes. These processes differ primarily by the type of drying method used. The selection of the optimal method is determined by quality requirements, raw material characteristics, and economic factors. There are three types of drying processes:

- Sun and solar drying,
- Atmospheric dehydration including stationary or batch processes (kiln, Oven, and cabinet/tray dryers) and continuous processes (tunnel,

continuous belt, fluidized-bed, foam mat, spray, drum and microwave-heated dryers), and

- Sub-atmospheric dehydration (vacuum belt, vacuum drum and freeze dryers).

12.9.1 Sun Drying

Sun drying depends on the weather, honors of sunshine, the temperature and the relative humidity outside. If you live in a hot, dry climate, sun drying may be successful. Its advantage is the low cost. The only investments are drying trays, netting to protect against insects and the food itself. Its main disadvantage is time. What would take 6 to 10 hours to dry using other methods may take 3 to 5 days in the sun. To avoid scorching, move the food into the shade to finish when it is about two-thirds dry.

12.9.2 Solar Drying

It is a modification of sun drying in which the sun's rays are collected inside a specially designed unit with adequate ventilation for removal of moist air. The temperature in the unit is usually 20 to 30 degrees higher than in open sunlight, which results in a shorter drying time. While solar drying has many advantages over sun drying, lack of control over the weather is the main problem with both methods. Solar drying utilizes black-painted trays, solar trays, collectors, and mirrors to increase solar energy and accelerate drying. A typical solar dryer is shown in Figure 12.5.

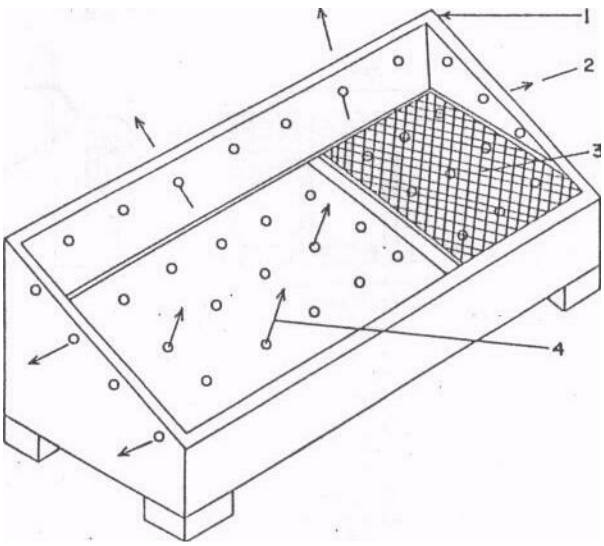

Figure 12.5: Solar cabinet driers: 1) Frame, 2) Exit air, 3) Drying tray, and 4) Air intake

12.9.3 Oven Drying

It is the most practical way to experiment with dehydration. It requires little initial investment, protects foods from insects and dust, and does not depend on the weather. Continual use of an oven for drying is not recommended because ovens are less energy efficient than dehydrators, and energy costs tend to be high. Also, it is difficult to maintain a low drying temperature in the oven, and foods are more susceptible to scorching at the end of the drying period. Oven-dried foods usually are darker, more brittle and of less flavour than foods dried by a dehydrator.

12.9.4 Osmotic Drying

Osmotic drying consists of removing a percentage of moisture from a fruit or vegetable by placing it in a concentrated solution of sugar, salt, or a combination of both. The principle of this drying is osmosis. It is the process of diffusion of water from dilute solution to concentrated solution through a semi permeable membrane. Here fruit cell wall itself will act as a semi permeable membrane. This is shown in Figure 12.6.

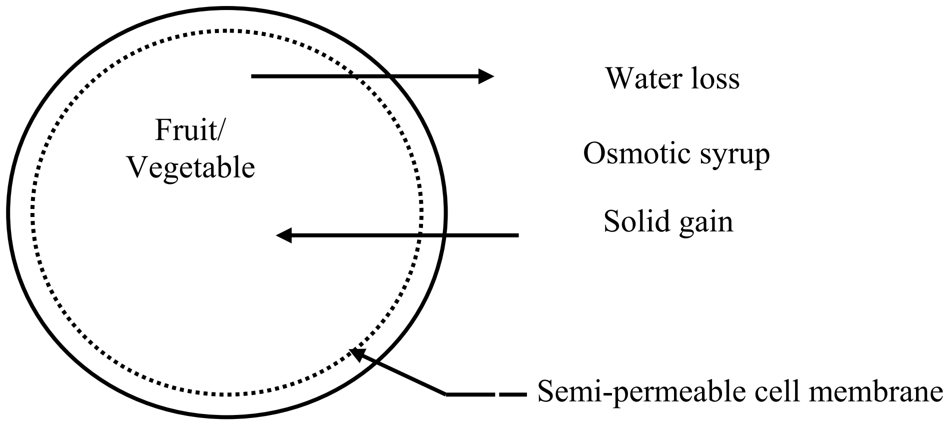

Figure 12.6: Principle of osmosis

The product is reduced to about 50% of its original weight by the osmotic dehydration process. This partial drying process is accompanied by any other drying processes viz. solar drying, vacuum drying, freeze drying, cabinet drying etc. The sugar syrup protects colour and flavour during the drying process. The product has a porous texture and retain a large percentage of the flavour volatiles of the fresh food. The various factors affecting the osmotic dehydration process are type of osmotic agent, concentration, temperature, agitation of syrup, size of the fruit pieces and fruit-to-syrup ratio.

12.9.5 Cabinet Dryers/Tray Dryers

In tray dryers, the food is spread out, generally as thin layer on trays in which the drying takes place. A typical tray dryer is shown in Figure 12.7. Heating may be by an air current sweeping across the trays, by conduction from heated trays or heated shelves on which the trays lie, or by radiation from heated surfaces. Most tray dryers are heated by air, which also removes the moist vapours. Hot air is circulated through the cabinet at 0.5–5.0 m/s per square metre tray area. A system of ducts and baffles is used to direct air over and/or through each tray to promote uniform air distribution. Tray dryers are used for small scale production (1-20 t/day) or for pilot scale work. They have low capital and maintenance costs but have relatively poor control and produce more variable product quality.

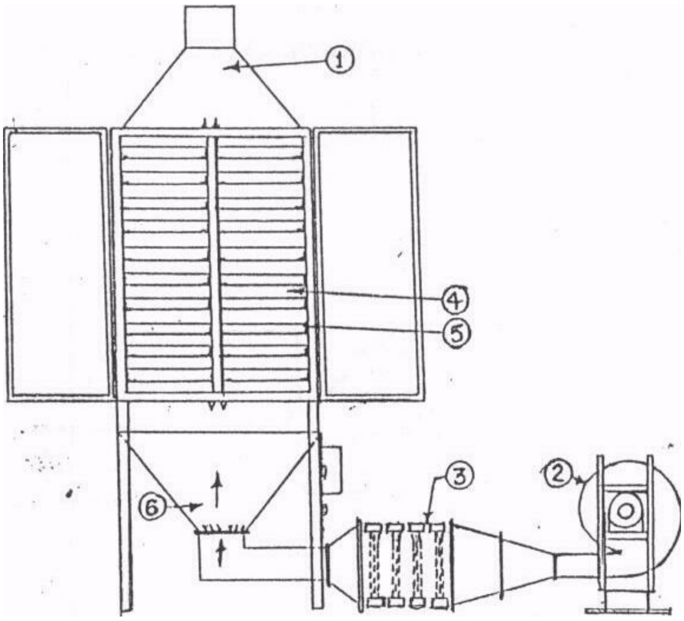

Figure 12.7: Schematic diagram of a typical tray drier: 1) Exit air, 2) Blower, 3) Heater, 4) Inter space between trays, 5) Trays, and 6) Plenum chamber

12.9.6 Tunnel Dryers

Tunnel dryers are the most flexible, efficient, and widely used dehydration system available commercially. These may be regarded as developments of the tray dryer, in which the trays on trolleys move through a tunnel where the heat is applied and the vapour removed. The product trucks are moved through the tunnel at a rate required to maintain the residence time needed for dehydration. The product may be moved in the same direction as the air flow to provide concurrent dehydration (Figure 12.8a), or the tunnel may be operated in a counter-current manner (Figure 12.8b) with product moving in the direction opposite to air flow. Sometimes the dryers are compartmented, and cross-flow may also be used. Typically a 20 m tunnel contains 12-15 trucks with a total capacity of 5000 kg of food. This ability to dry large quantity of food in a relatively short time (5-16 hours) made tunnel drying widely used.

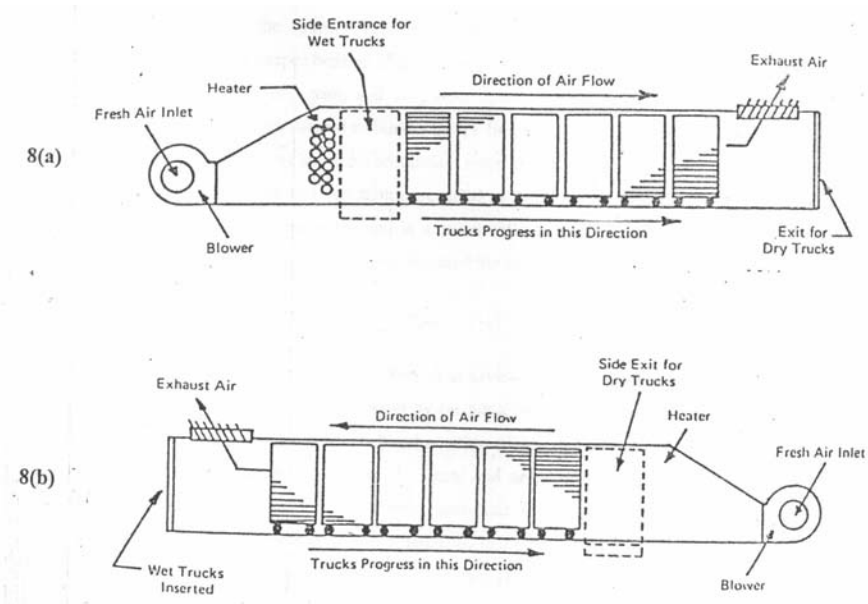

Figure 12.8: Schematic of tunnel driers: a) Concurrent flow drier, b) Counter-current flow drier

12.9.7 Conveyor Dryers or Belt Dryers

Continuous conveyor dryers are up to 20 m long and 3 m wide. Food is dried on a mesh belt in beds 5-15 cm deep. The air flow is initially directed upwards through the bed of food and then downwards in later stages to prevent dried food from blowing out of the bed. This is explained in the Figure 12.9. Two or three stage dryers mix and repile the partly dried shrunken food into deeper beds(to 15-25 cm and 250- 900 cm in three stage dryers). This improves uniformity of drying and save floor space. Foods are dried to 10-15% moisture content and then transferred to bin dryers for finishing. This equipment has good control over drying conditions and high production rates. It is used for large scale drying of foods (for example: fruits and vegetables are dried in 2-3.5 h at up to 5.5 t/h). It has independently controlled drying zones and is automatically loaded and unloaded, which reduces labour cost. As a result, it has largely replaced the tunnel dryer.

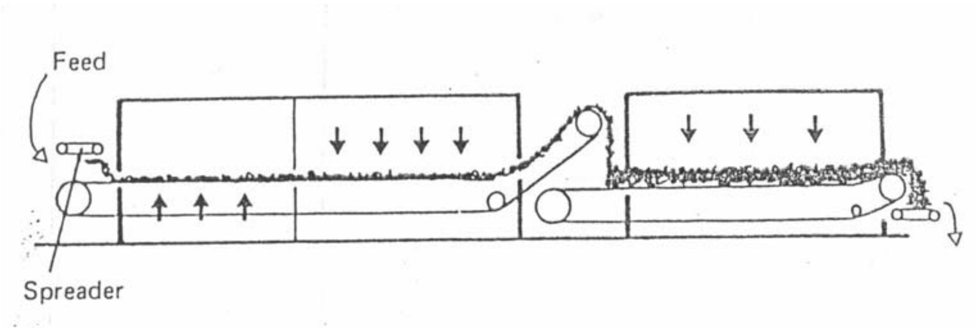

Figure 12.9: A typical two stage conveyor drier/belt drier

12.9.8 Foam Mat Drying

Foam mat drying is another application of conveyor dryers. In this method, liquid foods viz. fruit juices are formed into a stable foam by the addition of a stabilizer (e.g.: Xanthan gum, sorbitol, mannitol, alginic acid, etc.) and aeration with nitrogen or air. The foam is spread on a perforated belt to a depth of 2-3 mm and dried rapidly in two stages by concurrent and then counter current air flows. Foam mat drying is approximately three times faster than drying a similar thickness of liquid by belt drying. The thin porous mat of dried food is ground to a free flowing powder which has good rehydration properties. The rapid drying and low product temperatures result in a high quality product. However a large surface area is required for high production rates, and capital costs are therefore high.

12.9.9 Fluidized Bed Dryers

In a fluidized bed dryer, the food material is maintained suspended against gravity in an upward-flowing air stream. The air thus acts as both the drying and fluidizing medium, and the maximum surface area of food is made available for drying. There may also be a horizontal air flow helping to convey the food through the dryer. Heat is transferred from the air to the food material, mostly by convection. A schematic diagram of fluidized bed dryer is shown in Figure 12.10.

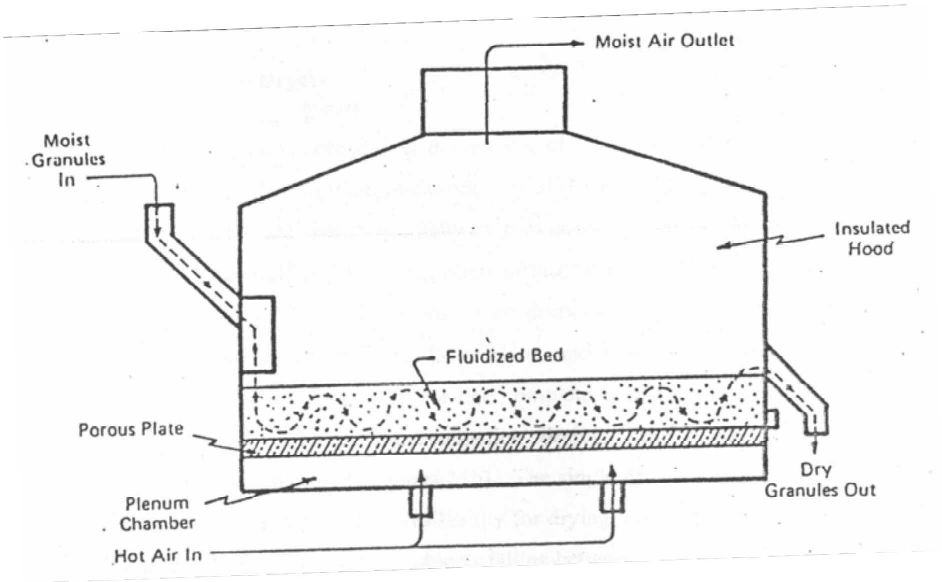

Figure 12.10: Schematic illustration of fluidized bed drier

Fluidized bed dryers are compact and have good control over drying conditions. They have relatively high thermal efficiencies and high drying rates. Fluidized bed dryers are limited to small particulate foods that are capable of being fluidized without excessive mechanical damage (e.g.: peas, diced or sliced vegetables, powders etc.)

12.9.10 Roller or Drum Dryers

In these dryers, the food in liquid or slurry form is spread over the surface of a heated drum. The drum rotates, with the food being applied to the drum at one part of the cycle. These drums are made of hollow steel drums and are heated internally by pressurized steam to 120-170^{o}C. A thin layer of food is spread uniformly over the outer surface by dipping, spraying, spreading or by auxiliary feed rollers. The food remains on the drum surface for the greater part of the rotation, during which time the drying takes place, and is then scraped off by using a 'doctor' blade. Usually the time taken for one complete revolution is 20s to 3 minutes. Drum drying may be regarded as conduction drying. Dryers may have a single drum (Figure 12.11a) or double drum (Figure 12.11b). The single drum is widely used as it has greater flexibility, a larger drum area availability for drying, easier access for maintenance and no risk of damage caused by metal objects falling between the drums.

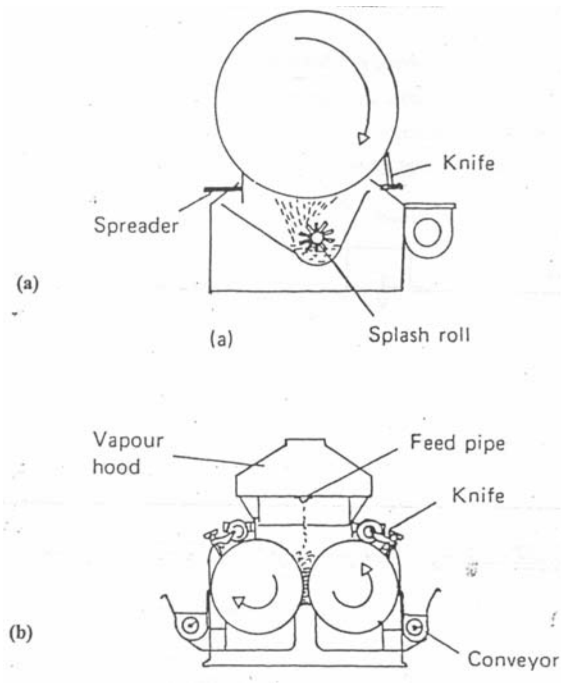

Figure 12.11: Drum driers: a) Single drum, b) Double drum

12.9.11 Spray Dryers

In a spray dryer, liquid or fine solid material in a slurry is sprayed or "atomized" in the form of a fine droplet (10–200 µm)dispersion into a current of heated air (150-300 ^{o}C). Complete and uniform atomization is necessary for successful drying. Air and solids may move in parallel or counter flow. A schematic of spray dryer is shown in Figure 12.12.

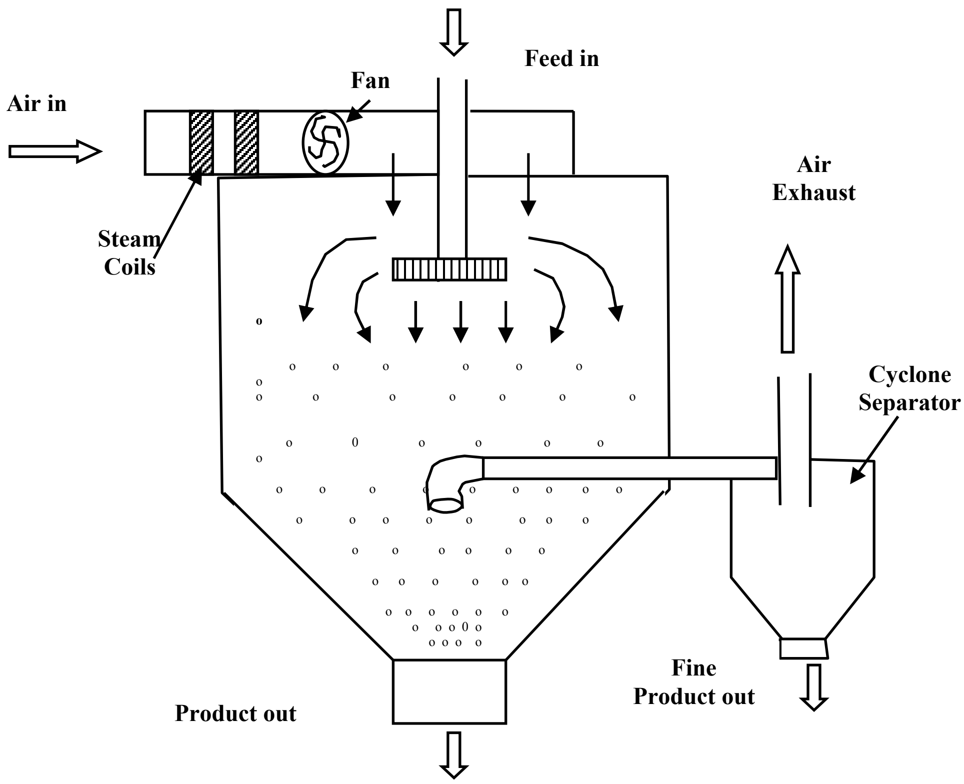

Figure 12.12: Typical schematic arrangement of a spray dryer

Drying occurs very rapidly, so that this process is very useful for materials that are damaged by exposure to heat for any appreciable length of time. The dryer body is large so that the particles can settle, as they dry, without touching the walls on which they might otherwise stick. Commercial dryers can be very large of the order of 10 m diameter and 20 m high. The dry powder is collected at the base of the dryer and removed by a screw conveyor or a pneumatic system with a cyclone separator.

The main advantages are rapid drying, large-scale continuous production, low labour costs and simple operation and maintenance. The major limitations are high capital costs and the requirement for a relatively high-free moisture content to ensure that the food can be pumped to the atomizer.

12.9.12 Microwave Drying

Microwaves are the portion of the electromagnetic spectrum between far infrared and the conventional radio frequency region. As the microwaves passes through the material such as fruits, the molecules within the food attempt to align themselves with the electric field direction. As they oscillate around their axis, heat is produced by the intermolecular friction within the product. This heat is responsible for the moisture removal from the fruits and vegetables. The depth of penetration is an important factor in microwave drying. A typical microwave dryer and its parts are shown in Figure 12.13.

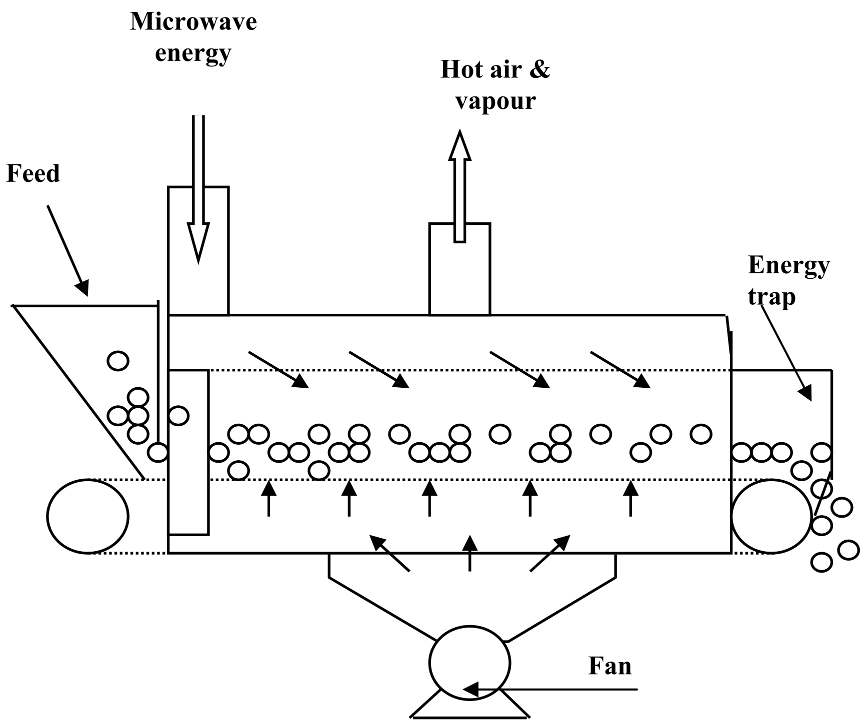

Figure 12.13: Schematic of a continuous microwave drying equipment

This method has been made use in drying of fruit juices, pulps, and fruit segments. Microwaves are endowed with some special characteristics such as (i) A penetrating quality which results in uniform heating of materials, ii) Selective absorption of radiation by liquid water, and iii) Capacity for easy control. These imparts some unique effects to the dehydrating materials such as improved quality and good texture.

12.9.13 Pneumatic Dryers

In a pneumatic dryer, the solid food particles are conveyed rapidly in an air stream, the velocity and turbulence of the stream maintaining the particles in suspension. Heated air accomplishes the drying and often some form of classifying device is included in the equipment. In the classifier, the dried material is separated, the dry material passes out as product and the moist remainder is recirculated for further drying. Pneumatic dryers have relatively low capital costs, high drying rates and thermal efficiencies, and close control over drying conditions. They are often used after spray drying to produce food which have a lower moisture content than normal. In some applications the simultaneous transportation and drying of the food may be useful method of material handling.

12.9.14 Rotary Dryers

The foodstuff is contained in a horizontal inclined cylinder through which it travels, being heated either by air flow through the cylinder, or by conduction of heat from the cylinder walls (Figure 12.14).

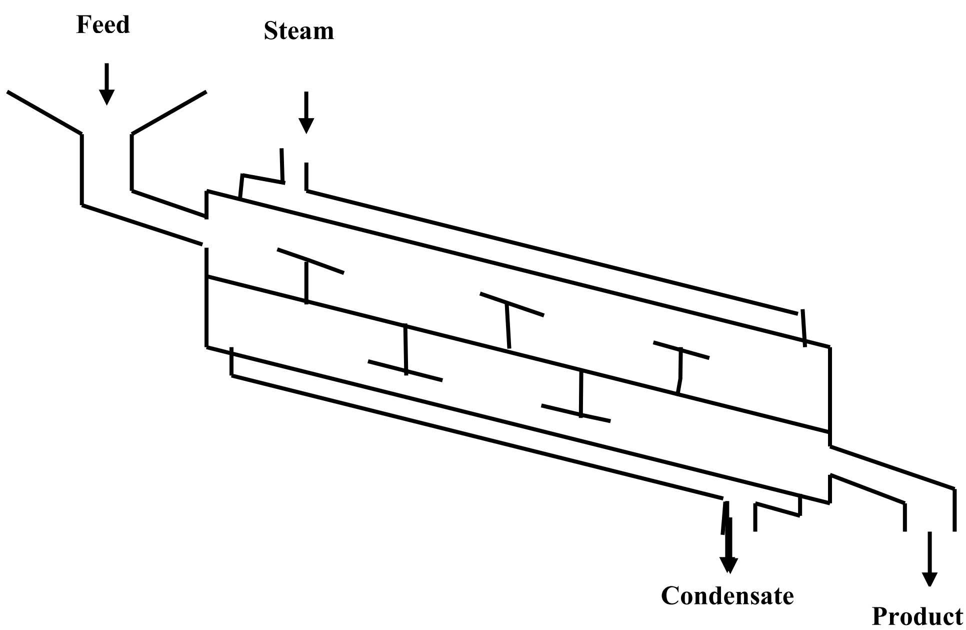

Figure 12.14: Rotary dryer

In some cases, the cylinder rotates and in others the cylinder is stationary and a paddle or screw rotates within the cylinder conveying the material through. The air flow may be parallel or counter current. The agitation of the food and the large area of food exposed to the air produce high drying rates and a uniformly dried product. This method is especially suitable for foods that tend to mat or stick together in belt or tray dryers. However, the damage caused by impact and abrasion in the dryer restrict this method to relatively few foods.

12.9.15 Vacuum Drying

Vacuum dryers are substantially the same as tray dryers, except that they operate under a vacuum, and heat transfer is largely by conduction or by radiation. It occurs at low air pressures and includes vacuum shelf, vacuum drum, and vacuum belt and freeze dryers. The main purpose of vacuum drying is to enable the removal of moisture at less than the boiling point under ambient conditions. Because of the high installation and operating costs of vacuum dryers, this process is used for drying raw material that may deteriorate as a result of oxidation or may be modified chemically as a result of exposure to air at elevated temperatures. In vacuum drying, the moisture in the food is evaporated from the liquid to the vapour stage.

12.9.16 Freeze Dryers

The material is held on shelves or belts in a chamber that is under high vacuum. In most cases, the food is frozen before being loaded into the dryer. Heat is transferred to the food by conduction or radiation and the vapour is removed by vacuum pump and then condensed. Schematic illustration of freeze drying system shown in Figure 12.15a. In one process, given the name accelerated freeze drying, heat transfer is by conduction; sheets of expanded metal are inserted between the foodstuffs and heated plates to improve heat transfer to the uneven surfaces, and moisture removal. The pieces of food are shaped so as to present the largest possible flat surface to the expanded metal and the plates to obtain good heat transfer. A refrigerated condenser may be used to condense the water vapour. A cross sectional view of freeze dryer is shown in Figure 12.15b.

(a)

b)

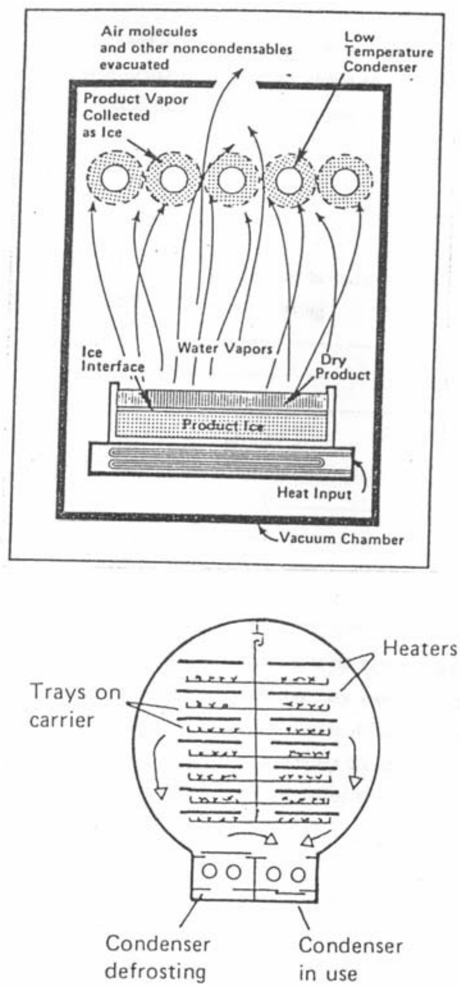

Figure 12.15: Freeze drying: a) Schematic illustration of freeze drying system; b) Cross-sectional view of a continuous freeze drier.

The advantages of freeze drying are high flavour retention, maximum retention of nutritional value, minimal damage to the product texture and structure, little change in product shape and colour, and a finished product with an open structure that allows a fast and complete rehydration. Disadvantages include high capital investment, high processing costs, and the need for special packing to avoid oxidation and moisture gain in the finished product.

12.10 POST-DEHYDRATION TREATMENTS

Treatments of the dehydrated product vary according to the type of fruit or vegetable and the intended use of the product. These treatments may include sweating, screening, inspection, and packaging. Sweating involves holding the dehydrated product in bins or boxes to equalize the moisture content. Screening removes dehydrated pieces of unwanted size, usually called 'fines'. The dried product is inspected to remove foreign materials, discoloured pieces, or other imperfections such as skin, carpal, or stem particles.

12.11 PACKAGING

It is commonly done for most of the dehydrated products and has a great deal of influence on the shelf life of the dried product. Packaging of dehydrated fruits and vegetables must protect the product against moisture, light, air, dust, micro-flora, foreign odour, insects and rodents. It should provide strength and stability to maintain original product size, shape and appearance throughout storage, handling, and marketing. The packaging materials used should be approved for contact with food. Cost is also an important factor in packaging.

Package types include cans, plastic bags, bins, and cartons, and depend on the end-use of the product. The details of packaging materials and its advantages are explained under the unit 1. It is better to pack dried foods in small amounts, since opening of a package can lead to moisture absorption and deterioration of its quality. Technical solutions for maintaining a low dehydrated products moisture are:

- Use packages that are water vapour proof. The most efficient packages are tin boxes or drums (mainly for long term storage periods); combined packages (boxes, bags, etc.); from complexes (carton with metallic sheets, plastic materials, etc.) mainly for small packages.
- Modern solutions are oriented not only to maintain the product moisture during storage but also to reduce the moisture by the use of desiccants (substances which absorb moisture) introduced in hermetically closed packages.
- Another factor that can deteriorate dried/dehydrated vegetables is atmospheric oxygen through the oxidative phenomena that it produces. In order to eliminate the action of this agent some packing methods under vacuum or in inert gases (carbon dioxide or nitrogen) are in use. Such packaging systems are used for packing dried carrots in order to avoid beta-carotene oxidation. To avoid the action of oxygen it is also possible to add ascorbic acid as antioxidant (for example in carrot powder).
- Sun or artificial light action on dehydrated vegetables generally causes discolouration which can be avoided by using opaque packaging materials.
- Store in a place with relative humidity below 78%.

12.12 STORAGE

The containers of dried foods are stored in a cool, dark, dry area such as a basement or cellar. Exposure to humidity, light or air decreases the shelf life of foods. Storage temperature has an important role because this reduces or inhibits the speed of all physico-chemical, biochemical and microbiological processes, and thus prolongs storage period. The lower the temperature, the better will be the shelf life of the product.

Foods stored at temperatures below 15°C will keep for approximately one year. At 27°C to 32°C the food begins to deteriorate within several months. In general, for every 10°C drop in temperature, the shelf life of fruits increases three to four times. The storage temperature should be below 25°C (and preferably 15°C); lower temperatures (0-10°C) help maintain taste, colour and water rehydration ratio and also, to some extent, vitamin C.

12.13 SUITABILITY AND ACCEPTABILITY OF DIFFERENT FRUITS AND VEGETABLES FOR DEHYDRATION

Fruits and vegetables selected for drying should be of the highest quality – fresh and ripe. Drying does not improve the quality. Immature produce will lack flavour and colour. Over mature produce may be fibrous or mushy. If the food is not perfect for eating, it is not suitable for drying. Different foods requiring similar drying times and temperatures can be dried together. Vegetables with strong odours or flavours (garlic, onion and pepper) should be dried separately. Don't dry strong-smelling vegetables outside in an electric dehydrator, because dehydrators are not screened and insects may invade the food.

Blanching is essential for all vegetables except onions, peppers, okra, herbs, and some new types of corn that get sweeter as they mature. Most fruits such as berries, cherries, seedless grapes, melons, prunes and plums does not require blanching before drying. Sulfuring has to be done for light-coloured fruits, especially apples, apricots, peaches, nectarines and pears, which tend to darken during drying and storage

Vegetables are sufficiently dried when they are leathery or brittle. Leathery vegetables will be pliable and, spring back if folded. Edges will be sharp. Sufficiently dry green peas shatter when hit with a hammer.

Fruits are adequately dried when moisture cannot be squeezed from them, and if tough and pliable when cut. Fruit leathers may be slightly sticky to touch, but should separate easily from the plastic wrap.

12.14 EFFECTS OF DRYING ON PRODUCT QUALITY

12.14.1 Nutritional Quality

The nutritive value of food is affected by the dehydration process. Large differences in the nutritive value of dried foods are due to wide variation in the preparation procedures, the drying temperature and time, and storage conditions. In fruits and vegetables, loss during preparation usually exceed those caused by the drying operation. Vitamins A and C are destroyed by heat and air. Sulfite treatment prevents the loss of some vitamins, but causes the destruction of thiamin. Blanching vegetables before drying results in some loss of Vitamin C, B-complex vitamins and some minerals because these are all water soluble. On the other hand, the loss of vitamins A, C and thiamin during dehydration and storage is reduced by blanching process.

Oil- soluble nutrients (vitamins A, D, E & K) are mostly contained within the dry matter of the food and they are not therefore concentrated during drying. However, water is a solvent for heavy metal catalysts that promote oxidation of unsaturated nutrients. As water is removed, the catalysts become more reactive, and the rate of oxidation accelerates. Fat soluble vitamins are lost by interaction with the peroxides produced by fat oxidation. Losses during storage are reduced by low oxygen concentration, low storage temperature and by exclusion of light.

There are more calories in dried foods on a weight-for-weight basis because of the concentration of nutrients. For example, 100 grams of fresh apricots have 51 calories, while 100 grams of dried apricots have 260 calories. Nutritive value, as well as flavour and appearance, is best protected by low temperature and low humidity during storage.

12.14.2 Texture

Changes in texture of solid foods are an important cause of quality deterioration. The nature and extent of pre-treatments, the type and extent of size reduction, peeling, affect the texture of rehydrated fruits and vegetables. In foods that are adequately blanched, loss of texture is caused by gelatinisation of starch, crystallization of cellulose, and localized variations in the moisture content during dehydration, which set up internal stresses. These stresses will rupture, compress and permanently distort the relatively rigid cells, to give the food a shrunken shriveled appearance. On rehydration, the product absorbs water more slowly and does not regain the firm texture associated with the fresh material.

The rate and temperature of drying have a substantial effect on the texture of foods. In general, rapid drying and high temperature cause greater changes than do moderate rates of drying and lower temperatures. In powders, the textural characteristics are related to bulk density and the ease with which they are rehydrated. These properties are determined by the composition of the food, the method of drying and the particle size of the product. Low fat foods (e.g.: fruit juices) are more easily transformed into free flowing powders than those rich in fat (e.g.: whole milk).

12.14.3 Flavour and Aroma

Heat not only vaporizes water during drying but also causes the loss of volatile components from the food. The extent of volatile loss depends on the temperature and solid concentration of the food and on the vapour pressure of the volatiles and their solubility in water vapour. Volatiles which have a high relative volatility and diffusivity are lost at an early stage in drying. Fewer volatiles components are lost at later stages. Control of drying conditions during each stage of drying minimizes losses.

A second important cause of aroma loss is oxidation of pigments, vitamins and lipids during storage. The open porous structure of dried food allows access of oxygen. The rate of deterioration is determined by the storage temperature and the water activity of the food. Flavour changes due to oxidative or hydrolytic enzymes are prevented in fruits by the use of sulphur dioxide, ascorbic acid or citric acid, by pasteurization of fruit juices and by blanching of vegetables.

Other methods which are used to retain flavours in dried foods include

- Recovery of volatiles and their addition to the product during drying.
- Mixing recovered volatiles with flavour fixing components, which are then granulated and added back to the dried product.
- Addition of enzymes, or activation of naturally occurring enzymes, to produce flavours from precursors in the food.

12.14.4 Colour

Drying changes the surface characteristics of food and hence alters the reflectivity and colour. Chemical changes to carotenoid and chlorophyll pigments are caused by heat and oxidation during drying. In general, longer drying times and higher drying temperatures produce greater pigment losses. Oxidation and residual enzyme activity cause browning during storage. This is prevented by improved blanching methods and treatments of fruits with ascorbic acid or sulfur dioxide.

12.14.5 Rehydration

Rehydration is the process of adding water to the dried products and is restored to a condition similar to that when it was fresh. This enables the food product to be cooked as if the person was using fresh fruits or vegetables.

Factors that affects rehydration process of the dehydrated or dried products are time, temperature, air displacement, and pH. Rehydration rate can be accelerated by ultrasonic treatment of the product to be rehydrated. Gamma radiation increases the rehydration rate of freeze dried products.

The level of reconstitution or rehydration is evaluated by using rehydration coefficient and rehydration ratio. *Rehydration ratio* is the ratio of the weight of the drained rehydrated sample to the weight of the dehydrated sample.

Rehydration coefficient is calculated by the following equation.

$$\text{Rehydration coefficient} = \frac{\text{DRW}\,(100 - \text{MC}_1)}{(\text{WD} - \text{MC}_2) \times 100}$$

where, DRW is the drained weight of the rehydrated sample.

MC_1 is the moisture content of the sample before drying.

WD is the weight of dried sample taken for rehydration.

MC_2 is the amount of the moisture present in the dried sample taken for rehydration.

12.15 SPECIAL CARE TO BE TAKEN DURING DRYING

There aren't many problems in food drying. However, here are some things to watch for.

Case Hardening – If the drying temperature is too high or the humidity too low, the food may harden on the surface. This makes it more difficult for the moisture inside to escape and for the food to dry properly.

Scorching – When black streaks or areas appear on the food, it has scorched. This is most common in sun drying and is why we recommend you to move the food into the shade when it is about two-thirds dry.

Souring – At the beginning of drying, if the temperature is too low or if the humidity is high,, the food may sour or ferment. It may even mould if conditions are too cold. Overloading the trays can also cause this problem.

Mould – Mouldy dried food should always be discarded. Check stored dried foods frequently to be sure that they remain dry. The presence of moulds demands either removal of more moisture in subsequent trials or storage of the dried food in the freezer.

Insects – All sun-dried foods should be pasteurized before storing to destroy insects or their eggs. Heat fruit and vegetables on trays in a 66°C oven for 30 minutes or put in freezer for 48 hours. Store food in insect-proof containers.

12.16 LET US SUM UP

Drying is an important and oldest preservation method in food processing. The main purpose of dehydration is to extend the shelf life of foods by a reduction in water activity. It also saves energy, money and space in shipping, packaging, storing and transportation. Due to these advantages the dried fruit or vegetable is known as high value low volume food.

In this section, we have detailed the procedure of dehydration which includes various pre-treatments, methods of dehydration and post treatments. The comparative advantages and limitations of the drying techniques are also discussed. You have also studied the different factors affecting drying and the suitability of commodities for drying. The importance of packaging, storage and rehydration of dried commodities are also briefed in this unit.

The future prospects of the drying industry seems to be quite encouraging since the dried/concentrated products are nutritionally good and easy to handle. There exists quite a good scope for the export of dehydrated fruits and vegetables as the demand for these products is on the rise in the world market.

12.17 KEY WORDS

Sulphuring : Pre-treating fruits with the fumes of burning sulfur.

Rehydration : Process of restoring moisture to a dried food.

Blanching : It is the process of inactivation of enzymatic activity in vegetables and in some fruits, prior to further processing.

Concurrent/Co-current flow dryer : Hot dry air and wet material enter at the same end and travel through the dryer in the same direction.

Counter flow dryer : Air flows in a direction opposite to the direction of travel of material through the dryer.

Sweating : Keeping the dehydrated product in bins or boxes to equalize the moisture content

Water activity : It is the water in a system available to support biological and chemical reactions

Bound water : This is the water bonded to the cell solutes or cell sap.

Fluidization : When the air velocity becomes higher than the critical velocity, the bed (drying product) progressively expands until it reaches a state of boiling or bubbling. This phenomenon is called fluidization.

Osmosis : It is process of diffusion of water from dilute solution to concentrated solution through a semi permeable membrane.

12.18 SELF TEST FOR THE COMPLETE UNIT/ ASSIGNMENT

1. Define drying?
2. Where should the dried foods be stored?
3. Does the calorie content of foods change during drying?
4. What are the common quality changes that may occur when foods are dried?

12.19 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Water activity (a_w) is defined as the ratio of the vapour pressure on the aqueous solution to that of pure water at the same temperature. Quantitatively, water activity is a measure of unbound, free water in a system available to support biological and chemical reactions. The a_w has a major role to play on microbial spoilage and chemical changes produced in the food. The energy required to remove a molecule of water from a food increases as the water activity decreases. This is important for drying operations, since energy is required to provide sufficient driving force for drying.
2. Various factors that effect the rate of drying of fruits and vegetables include: i) The Composition of raw material, ii) Size, shape and arrangement of stacking of the produce, iii) Temperature, relative humidity and velocity of air, iv) Pressure, and v) Heat transfer to the surface.
3. Blanching is the process to inactivate the enzymes present in the fruits and vegetables, prior to further processing. These enzymes cause deterioration of colour, vitamins, odour and flavour during storage.

Check your Progress Exercise 2

1. The advantages of freeze drying are high flavour retention, maximum retention of nutritional value, minimal damage to the product texture and structure, little change in product shape and colour, and a finished product with an open structure that allows a fast and complete rehydration.
2. As the microwaves passes through the material such as fruits, the molecules within the food attempt to align themselves with the electric field direction. As they oscillate around their axis, heat is produced by the intermolecular friction within the product. This heat is responsible for the moisture removal from the fruits and vegetables.

Answers to Assignments

1. Drying or dehydration means the process of removal of moisture by the application of artificial heat under controlled conditions of temperature, humidity and air flow.
2. Store dried foods in a dry, cool, dark place. The higher the temperature, the shorter the storage time. Use clean, dry, insect-proof, moisture/vapour proof containers and package in small amounts to avoid constantly opening a container and exposing it to air.
3. The calorie content of foods does not change but is concentrated into a smaller mass as moisture is removed during drying. Therefore, on a per kg basis, dried foods contain considerably more calories than do the same foods fresh.
4. The various quality factors affected by the dehydration process includes nutritive value of food, fat oxidation, colour changes, texture changes, flavour and aroma changes.

UNIT 13 SITE SELECTION AND LAYOUT

Structure

13.0 OBJECTIVES

After studying this unit, you should be able to:

- understand the importance of proper plant layout for efficient and optimum working environment;
- describe the general guidelines for layout of a fruits and vegetables processing plant; and
- explain various steps that can be taken for maintenance of clean working environment and workers' safety in a fruit and vegetable processing plant.

13.1 INTRODUCTION

In this unit we shall study about the various aspects of plant layout, which is nothing but the arrangement of different facilities and equipment in a plant. It begins with the importance of proper plant layout followed with the general principles of a plant layout. We will also discuss how a proper plant layout helps in saving of manpower and energy, and maintaining efficient and optimum working environment. And as you know, all of these parameters lead to the maximisation of profits.

This unit also covers different considerations for maintenance of clean working environment and safety of workers, which are very important for the survival of any industry. You will be able to comprehend that the working environment of the food processing plant and ultimate sustainability of the plant do not depend only on the plant operation management; rather a major part of it is also dependent on the plant layout, design and installation of different equipment and the safety measures. You will also know about the guidelines for placement of different equipment and other facilities in a fruit and vegetable processing plant.

13.2 SITE SELECTION

Suppose you want to establish a mango processing industry in a particular area, what type of questions would immediately come to your mind?

The first set of questions you would ask yourself is:

- Is sufficient quantity of good quality raw material available in the locality, or what will be the transportation cost for bringing raw material from another locality to the proposed processing site?
- Whether the auxiliary facilities such as electricity, water, labour, etc. are available in the locality?
- Is there any other associated problem for establishment of industry in the particular place?

The answers to all these questions should be favourable. These are some of the factors, which affect the site selection for any type of manufacturing industry. In fact many such factors have an effect on the site selection for any industry. If we don't give a realistic consideration to all these factors, we may face problems in running the industry in future.

In general, a proper site for a fruits and vegetables processing plant should have the following features.

- Adequate quantities of good quality raw materials should available in the nearby locality, because fruits and vegetables are highly perishable and deteriorate in very long distance transport.
- The fruits and vegetables processing plant requires a huge amount of water for processing, cleaning and other operations. Hence the area should have a good source of quality water supply, or a permanent water source should be created for the purpose.
- The environment should be as far as possible clean and free from debris and dust. The site should be at a considerable distance from other industrial factories, which may affect adversely the quality of processed product by spreading smoke, disagreeable odours, etc.
- There should not be any problem for availability of electrical power in the area. A standby generator will help in maintaining operation during power failures.
- There should exist proper transport facilities for the movement of raw materials and finished products.
- There should be easy availability of labour in the area.
- There should also be facilities for disposal of the waste, as this is becoming a matter of growing concern these days.
- There should be scope for future orderly expansion of the factory.

After we have selected an area or region for locating the plant, the next job is to select a specific site. The final site selection requires a careful scrutiny of experts. We should shortlist some probable sites and test their soil condition. If the soil doesn't have good bearing capacity, there will be more investment on foundation costs. Good natural drainage is another desirable feature. If the site is located near a stream or other body of water, we should check the flood history. In addition, consultation with officials of the neighbouring plants on the various nature of locations in the area and attitude of the local community is also helpful for deciding a suitable location for the plant.

13.3 IMPORTANCE OF PROPER PLANT LAYOUT

13.3.1 What is Plant Layout?

We may consider any food processing operation as a transformation process. In a fruit and vegetable processing plant, the raw materials (raw fruits and vegetables) are transformed into finished product (processed fruits and vegetables) by a series of operations, whose sequence and numbers are specified for the input. For example, the sequence of operations that are carried out in an onion dehydration plant, can be shown as in Figure 13.1.

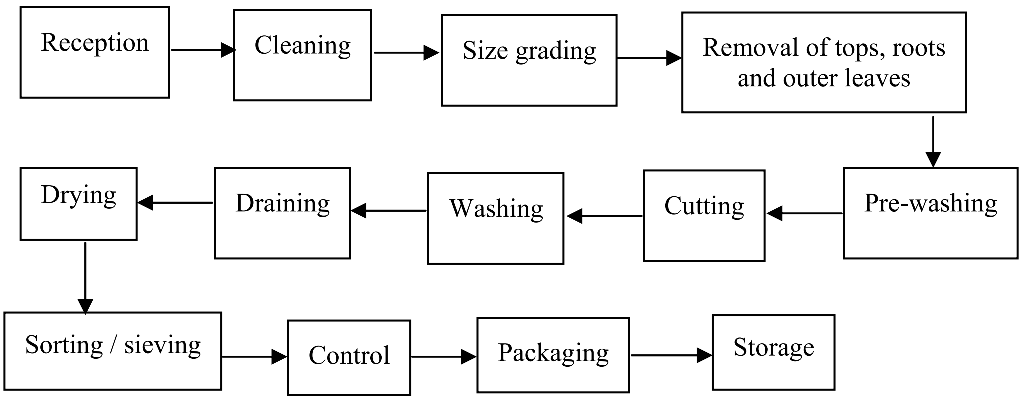

Figure 13.1: Processing of dehydrated onions

We can not change the sequence of these operations as per our desire. In this case, after receiving, the dust and dirt sticking to the surface of the onion bulbs must be cleaned first. Then the bulbs should be graded for size, then the tops and roots be removed, and so on. Therefore, for efficient utilisation of energy, labour (these are the other inputs than the raw materials), and of course money, the cleaning section should be kept adjacent to the receiving section followed by the grading section, and so on.

Now, suppose we place the size grader between the receiving yard and the cleaning section or the drying section between the packaging section and storage section, what do you think will happen? It will unnecessarily increase the materials handling cost and time, and reduce overall performance. In addition, it will also cause collision between the workers and wastage of manpower and energy. Hence, we should arrange the work areas, equipment and auxiliary facilities judiciously in the processing plant such that the operation will be economical and the employees will feel safe and satisfying.

Thus, the arrangement of the different facilities and equipment in a food processing plant plays an important role in the overall viability of the project. This physical arrangement of the industrial facilities is known as **plant layout**. The arrangement also includes the space needed for material movement, storage, indirect labour and all other supporting activities, or services, as well as for operating equipment and personnel.

13.3.2 Advantages of Good Plant Layout

In general, a good plant layout will permit simple and forward movement for the product and containers through the plant. Let us take a simple example.

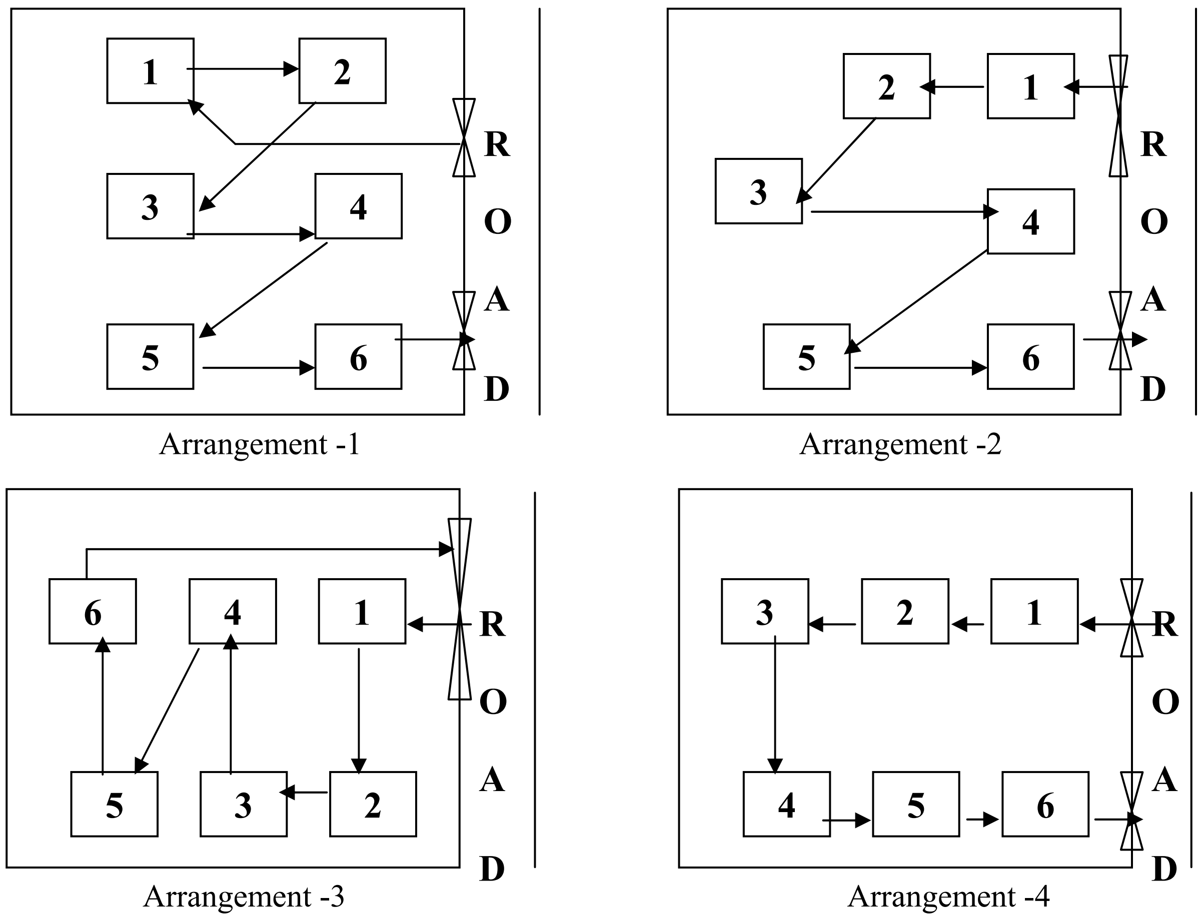

Figure 13.2: Understanding what plant layout means

In Figure 13.2, we have shown you some equipment in boxes, in which the numbers show the sequence of operations. Say, the first operation (may be cleaning) will be done by the Equipment-1, the second operation by Equipment 2 and so on. The Equipment 6 does the packing and then the product has to be taken out of the factory. I have shown you four possible arrangements for these equipment. Which pattern or arrangement do you think will be the best to reduce the cost of operation and improve performance?

Obviously Arrangement No. 4 will be the most ideal one. Remember, we are yet to learn the general guidelines for a good plant layout. However, you will definitely agree that if the machines are not properly arranged, as in the cases 1, 2 or 3, the total material movement inside the plant is unnecessarily increased. Besides, there is also crossing of the flow paths, which would interrupt a smooth operation.

The sequence of operations is one of the major criteria, but not the only criteria for designing plant layout, which we will discuss later in the unit. But as we are discussing about the advantages of a good plant layout, we wee that a proper plant layout helps us in reducing cost of operation, which is very important for survival of any industry.

A good plant layout, in general, has the following advantages.

- Saving in floor space;
- Better utilisation of machine and man power, and services;
- Reduced material handling, thus saving in labour and cost, less production delays;
- Reduced inventory in process, thus saving in investment and working capital;
- Increased output/ production per unit time, labour, money and energy; and
- Easier and better supervision.

In addition to the above, a properly designed layout helps to maintain proper sanitation and safety standards in a plant. It reduces confusion between different sections of workers, and improves moral of the workers. All these factors directly affect the output. Careful layout planning can identify and remedy bottlenecks and trouble spots before the plant is built, and thus prevents troubles later.

……………………………………………………………………………………

13.4 GENERAL PLANT LAYOUT

In this section, we will discuss about the different requirements and general guidelines for a good plant layout. As we go on discussing the general guidelines, you will discover that a careful planning is very essential for the health of any industry, and in particular the industries processing fruits and vegetables.

13.4.1 Requirements/Factors in Planning Layouts

As we have already discussed, the basic objectives of a good plant layout are smooth operation and reduced cost in handling and processing. Further good layout must include arrangement of specified areas for processing, storage and handling in efficient coordination. This should also consider the following factors.

- ***Proper placement of equipment and conveying machines*** – All the equipment and conveying machines should be arranged in proper coordination depending on the flow sequence and characteristics of equipment. Depending on requirements, the layout can be single level, multi storied, or combined designs.

- ***Economic distribution of services*** – The layout, in addition to proper placement of important equipment, should also have provision for efficient and economic distribution of water, process steam, power, and gas, etc. The distribution lines for these utilities should not interrupt the normal working of the people.

- ***Suitable use of floor and elevation space*** – This will depend on the type of food processing plant and the special facilities and equipment used for the system.

- ***New site development or addition to a previously developed site*** – If we want to plan the plant on a site, which already has some installed equipment, office rooms and storage godowns, etc., then the layout should consider these amenities. Our objectives will be to see that minimum alterations or modifications are made to the existing facilities without affecting the overall objective of the layout.

- ***Future expansion*** – The layout should have sufficient provision for future expansion. Suppose at this stage we are interested in a 1 tph (tonne per hour) dehydration plant for ginger. But after some years, we want to increase the capacity to 4 tph or want to prepare dehydrated onion and garlic from the same plant. It requires installation of some more equipment. We will also need more space for godown and processing operations. In that case, we will be in trouble if the present arrangement doesn’t have sufficient provision for expansion. Another alternative is to install a completely new plant in another location. It will involve some unnecessary cost and further it will also be difficult to manage two plants at two different locations. To overcome such type of difficulties, the layout should have provision for future expansion.

- ***Waste disposal problems*** – The layout should have adequate provision for disposal of solid, liquid and gaseous wastes. Or else, the project may not be even passed by the pollution control authorities.

- ***Safety considerations*** – We should keep the equipment or areas having chances of hazards like fire or explosion away from normal working of the people. For example, we should isolate the boiler room.

- ***Other factors*** – The building code requirement, weather conditions like extreme high or low temperatures, maximum wind speed in the area, etc. are some other factors which need to be considered during planning the layout.

13.4.2 Types of Layouts

There are generally two types of product flow in food processing industry, namely, **line flow process** and **intermittent flow process.** In the line flow process, the product flows from one operation to the next in a prescribed sequence as in the preparation of homogenised and pasteurised milk in an automatic dairy plant. The individual work tasks are closely coupled. There may be side flows, which impinge on this line, but they are integrated to achieve a smooth flow. In an intermittent flow process the production is carried out in batches at intermittent intervals. In this case, we can organise the equipment and labour into different work centres by similar types of skill or equipment. The product can be sent to any of the work centres as per requirement. For example, in a mango processing plant, the mango slices can be sent to a dehydrator for preparing dried mango slices or sent to the canning section for getting canned mango slices, or may be filled with syrup and frozen to prepare frozen mango slices. Similarly mango pulp can be processed in different work centres to get frozen mango pulp, mango squash, mango nectar, mango bar, mango powder or mango cereal flakes. Or, say the particular squash manufacturing section can be used for different commodities like mango, pineapple, lime or watermelon at different times. This often results in a jumbled pattern of flow. The volume of product handling can be changed easily in this type of flow.

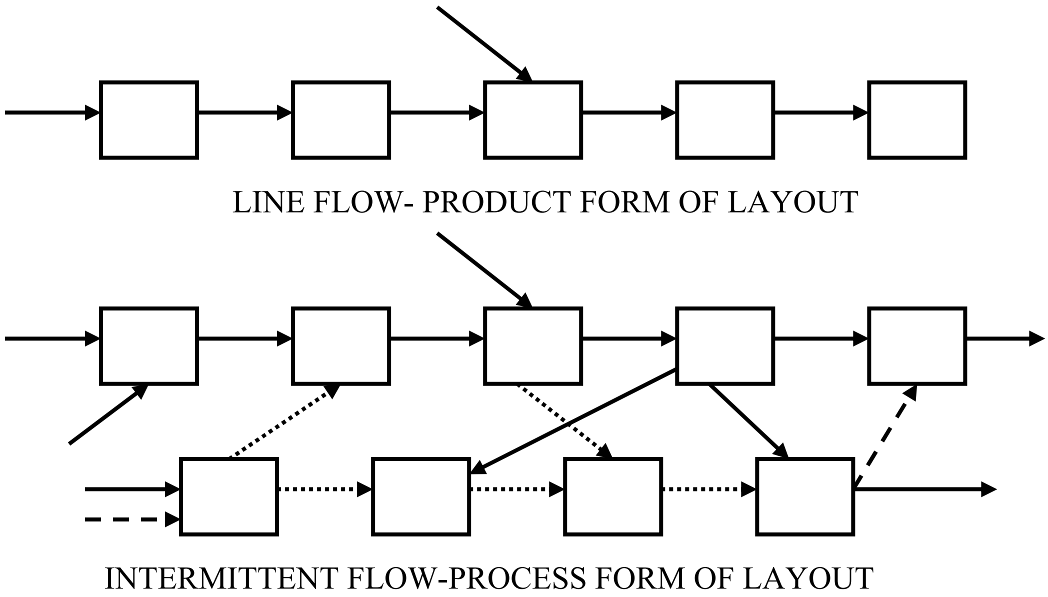

Figure 13.3: Product form and process form of layout

Based on the above classification of flow processes, the layouts also differ. The intermittent process is also known as a **process form of layout** as similar equipment and processing operations are grouped together. It is also known as 'layout by function'. The line flow is also called a **product form of layout** because various process equipment, and labour skills are put into sequence according to the way the product is made.

When a product lacks standardisation or the volume of product is low, the intermittent operation is economical and involves least risk. If an industry produces high volume of one or a few products, then layout by product or flow-line layout can be used. The equipment are placed in sequence, either on a straight line, or in shapes like U, L or convoluted or serpentine shape. As the raw material is processed, some products and by-products may move away from the principal direction of the flow.

Many modifications to above flow patterns are possible. A **hybrid layout** is one, where some portions may be layout by process and some portions by product. Generally the small food processing plants have process form of layout, whereas bigger industries have hybrid layouts.

Another type of classification of layout is single level, multi-storey or combined layout.

13.4.3 General Guidelines for Layout of a Fruit and Vegetable Processing Plant

After obtaining some idea on the factors affecting the layout planning and the different types of layout plans, in this section, we will give a closer look at different aspects of layout of a fruit and vegetable processing plant.

Layout of different sections / buildings

After a complete study of the requirements of the plant, the selection of the building or buildings must be considered. The building should be designed around the process, not a beautiful structure into which the process must fit.

Different products may each have their own processing room or area, or they may be housed in a single room with different allocated area. The primary rooms should be planned larger than necessary, for possible future expansions. We should keep in mind that the height is also equally important as the floor space requirement for layout planning.

The office room needs to be accessible to suppliers, customers and visitors. In large plants it can be kept at the main entrance as a separate building. The office accommodation should also contain a reception room and a demonstration room for study groups, etc. For small plants such offices are contained in the main building. The main laboratory can be conveniently put on an upper floor of the administrative building or next to the office room so that manager can easily control both administrative and technical services.

Reception and dispatch rooms should be situated on the ground floor having good access to main gate. The reception platform should be at a height to suit the vehicles concerned. In small plants loading and unloading, and conveying within the plant are done manually, In large plants, if mechanical conveyors or hydraulic conveyors are to be used, then the conveying section has to be planned simultaneously with the reception section.

Storage facilities for raw materials and intermediate and finished products may be located either in isolated areas or in adjoining areas. While considering for storage, the amount of handling involved for carrying the materials from reception to the storage section or from the storage to the processing section should be considered. However, sometimes storage of materials in adjoining areas to reduce materials handling may create problem for future expansion of the plant. Hazardous materials, if stored in large quantities, should be isolated.

Areas involving dust, dirt, oil and fumes, which may contaminate the products must be separated from processing or storage areas. The boiler room, fuel store, repair shop, compressor rooms are such types of areas.

The orientation of prevailing winds, the polluting potential of the air, topography of the site and access to roads must be considered when fixing the position of different rooms. Direct exposure of certain areas of the plant to the summer sun may be undesirable.

Layout of equipment

The information on exact space needed for installation of each equipment is very important for planning. The design and capacity of equipment will determine the floor space. Manufacturers normally give the dimensions of their equipment including floor space required. Besides, there should be adequate space for convenience in operation and maintenance, while still practising economy of floor space and good housekeeping in the plant. Allowances for working space should be five times the floor space occupied by the equipment. Floor area for dry store and office spaces should each be 25% of the plant floor area. The floor areas should also include space for possible additional equipment.

The equipment that need frequent servicing needs special care. There should be space for lowering the overhead equipment for maintenance. Besides, it is not wise to fit the equipment too closely in a building. A slightly larger building that appears unnecessary will cost little more than the one that is crowded, but this will help in maintenance of proper sanitation, safety and comfort of the operators.

We must consider the relative levels of several pieces of equipment and their accessories before placement. For gravity flow, the materials are first lifted to a higher level, and hence, a multi-storey layout is often necessary. The cost of mechanical transportation is greatly reduced in single storey plant.

In most of the cases, a group of operations are carried out simultaneously, for example, in a canning plant the can filling, exhausting, and can closing are such type of operations. So we can group the necessary equipment in proper sequence in a single room. It helps us in division of operating labour so that some specialised operators can be trained to attend all equipment of the group.

Suppose at any point of time we need to bypass a machine or a section, then the plant layout should be such that it allows that with minimum of alterations.

Layout of materials handling equipment

As we have discussed previously, considerations for materials handling should accompany the equipment and buildings layout. Suppose the materials are to be carried by crates on a chain conveyor from the receiving yard to storage, then the layout should have provision for that, in addition to working space for the labourers. Wherever possible, we should take advantage of the topography of the site location. The working surface of the conveyor must be at a height to facilitate the operations, which may be involved.

Lay out of service facilities

The important service facilities for any type of food processing plant are water, steam, power, electricity, gas and air. Proper placement of the distribution lines for the above services help in ease of operation, orderliness, and reduction in costs of maintenance. For example, we must not lay any pipe on the floor or up to a height of 7 ft level, where the operator is expected to move during the work. Chaotic arrangement of piping invites chaotic operation of the plant.

The service lines should be as short as possible to reduce capital investment and running costs. In small plants it is practicable to provide accommodation for steam production, refrigeration and electricity within the main building. In large plants, this is often not possible, and the service rooms are grouped in a separate building. The switch room may be as central as possible, to economise in wiring. In large plants more than one switch room may be necessary. The generator room should be adjacent to the switch room.

The boiler house must provide accommodation for the steam boilers and auxiliary equipment, such as feed water tank, feed water treatment plant etc. The type and capacity of the boilers greatly influence the space required. A working space of 1-2 m should be allowed between boilers and other equipment or wall of the building to give access for maintenance. The space in front of boiler must be much higher than this for cleaning of flue tubes and their replacement. The room or house for the boiler is usually separated from the main plant building in compliance with legal requirements.

The refrigeration machinery should be grouped in one room, but if separate compressor(s) are used for direct refrigeration, they must be placed close to the room, which they cool. Longer service lines need more cost of refrigerant required to charge the system, and thus higher will be the running costs.

Layout of waste disposal system

The disposal of wastes, which include liquors, fumes, dusts and gases, need special attention. The wastes should not affect the local community. If the wastes are not disposed properly, they will attract local dissatisfaction and prosecution by law, which will harm the unit in long run. The special equipment installed for ventilation, fume elimination, and drainage should not interfere with the flow of materials in process.

Other considerations

We should locate the windows / doors/ ventilators to allow maximum possible thermal circulation of air. Proper orientation of the buildings in respect to the solar position and prevailing wind direction is also important.

The local and national safety and fire code requirements are important factors while arranging the equipment and buildings in a plant. Different fire protection devices must be incorporated to protect costly plant investment and reduce insurance rates.

Existing or possible future rail roads and roads adjacent to the plant should be considered for placing the layout of building and auxiliary facilities. There should be proper access to all parts of the plant. Sufficient free space should be kept in the initial planning for future expansion.

13.4.4 Steps of Layout Planning

The steps involved in layout development are as follows:

First we have to decide the process and the type of layout design. The factors affecting process selection are capital, market conditions, labour, management, raw materials and viability of technology. As mentioned before, a complete understanding of the different unit operations involved in the process is essential. Layout has to be done for individual sections, and for individual equipment inside each section.

Then the preparation of the product flow charts is the next step in planning. The product flow chart shows 'how the product is processed', in addition to the transportation and storage activity. An example of a simple flow chart is shown in Figure 13.4 for manufacture of tomato sauce.

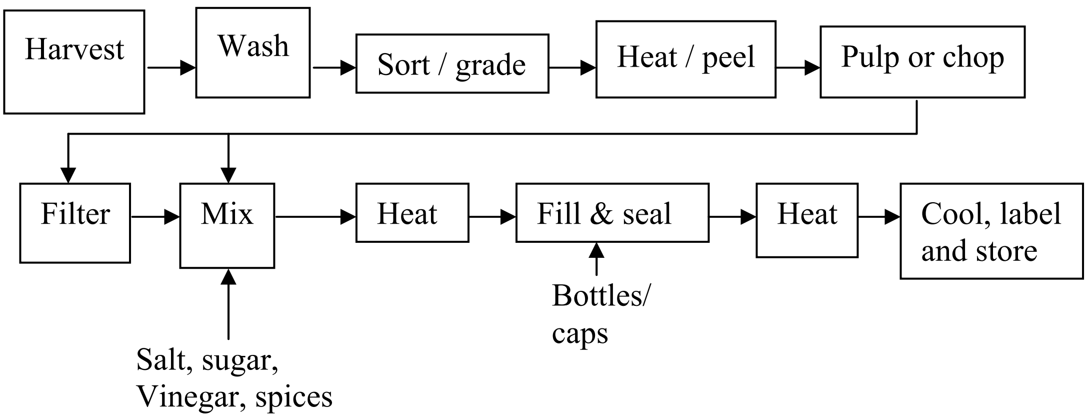

Figure 13.4: Product flow chart for tomato sauce

After preparing the product flow chart, we have to decide the principal equipment; the flow lines are then converted to machine lines. The designer must have a complete knowledge on the space requirements for individual pieces of equipment, for processing, storage of products and by-products, and for the working of people. At a later stage of process planning, the make or capacity of certain item may be changed when the particular details of the equipment become fully available, or we find better equipment during the planning process.

As the layout design develops it should be drawn on paper. After appropriate revisions, detailed drawings can be made to show the exact location of equipment and distances. Scale drawings are widely used in layout planning. We arrange the basic blocks or sections and arrange them in plot plans. Thus, the shape and extent of any area/section is described and the interrelationship between each area is shown. This is also known as 'Unit area concept' of planning.

Two dimensional scaled templates or small cutouts of unit areas and equipment within each area are placed on crosshatched scale paper. After repeated investigations and with different combinations/alterations, a basic plot plan is prepared with detailed two-dimensional diagrams, and is shown in a series of drawings.

Three dimensional scale models prepared from blocks of wood and cardboard give a better representation than the two-dimensional drawings. In bigger models, the piping and utilities can be shown. Now-a-days softwares are available for layout planning of process facilities using computers.

13.4.5 Example of Plant Layout

In Figure 13.5, we have shown you a typical example of fruit processing plant layout. Check how the raw materials receiving and storage and processed product storage are isolated from each other. See that the raw material enters

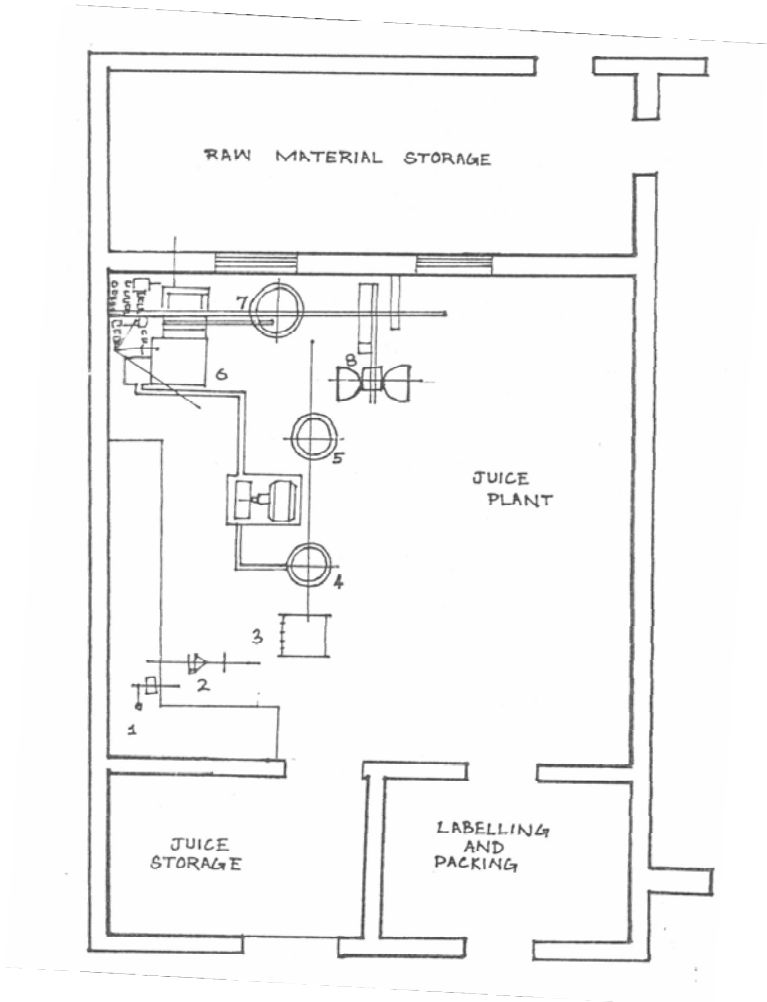

Figure 13.5: Layout plan of a fruit juice plant: 1) Capsular, 2) Corker, 3) Filler, 4) Syrup agitator, 5) Syrup maker, 6) Pulping M/C, 7) Pump, and 8) Pulp extractor

the processing room from one side and exits from the other. In the processing section, all the equipment are arranged in sequence so as to avoid criss-crossing of the flow lines. Besides, also observe that sufficient working space is kept in the processing room, which will avoid collision between workers and avoid accidents, and also help in maintenance of the equipment. Many arrangements or alternate layouts are possible for this kind of plant. But the basic features that we have studied in the previous section should be carefully incorporated in the system for optimum working conditions.

13.5 ANALYSIS OF MAN AND MATERIAL MOVEMENT

In a fruit and vegetable processing plant, in addition to the cost of raw material and its processing, the other major costs involved are the cost of labour, storage, transport and distribution. Hence we must try to minimise the material handling cost as well as employee travelling time, which also affect the viability of the project. Similarly, mechanical handling equipment consume a lot of power and by generously planning the layout, a considerable saving is possible with this aspect.

The total cost involved in a plant for transportation can be expressed as follows:

$$C = \sum_{i=1}^{N} \sum_{j=1}^{N} T_{ij} C_{ij} D_{ij}$$

where C = Total cost

T_{ij} = Trips between section i and section j

C_{ij} = Costs per unit distance per trip travelled from i to j

D_{ij} = Distance from i to j

N = Number of sections

Here C can be considered in rupees or time units to accommodate materials handling or travelling time criteria. The trips between any two sections will depend on the quantity of materials handled, and hence, once the plant capacity is decided, the number of trips between sections becomes apparently constant. The cost per trip is regulated by the labour rates or power utilised in the conveying machines, and for the purpose of this analysis, may be assumed constant. Hence to minimise the total cost due to man and material movement, the sections need to be arranged in such a manner that the distance travelled by the people or product between the time it enters the processing plant till the time it is dispatched will be minimum. The same approach can be thought of the movement between equipment in a particular room or department. In other words, our objective will be to find out particular D_{ij} combinations for minimising C.

Generally we proceed as follows:

- Determine the number of trips between each pair of sections per unit time such as a day, week, month or year, and with this information draw the ***trips matrix***.

- Ascertain the costs of material handling per unit of distance and draw the ***cost matrix***.

- Draw the ***distance matrix*** with the knowledge of distance between each pair of sections. These distances will depend on layout chosen.

- Compute the total materials handling cost per each pair of sections with the help of above three matrices.

The following example of Figure 13.6 will help you understand how this can be done.

Let us take the example of a small food processing plant, which has only five sections. In the first matrix, I have shown the number of trips required per week between each pair of section for a fixed quantity of raw material (Figure 13.6). Say for example, there will be 23 trips between sections 2 and 3, and 26 trips between sections 3 and 5.

I have put the costs of material handling per unit of distance between each pair of sections in the 2nd matrix. Subsequently on the basis of the layout plan, I found the distance between each pair of sections, and substituted the values in distance matrix.

It will be interesting for you to see that the **total cost matrix** is computed by multiplying the corresponding figures in the trips matrix, cost matrix and the distance matrix. Observe in Figure 13.6 that for sections 2 to 4 the cost of materials handling is (22)(23)(5) = Rs. 2530. After I have calculated all costs, I added all cells in the total cost matrix to get the total cost as, C = Rs. 38561 per week. This completes the evaluation of the equation for a particular layout plan.

Sections	1	2	3	4	5

Total cost matrix

Figure 13.6: Computation of total cost of man and material movement for a layout plan

After this step, we may think of improvements by exchanging pairs of sections, and recalculating the total cost again. Alternate combinations of the locations, i.e. every possible layout are evaluated to find out the optimal solution.

In the above example of Figure 13.6, we have only 5 sections, and hence, we have only 4! combinations, i.e. only 24 arrangements are possible. However, as the number of sections increases the possible combinations would increase. For example with a plant having 8 sections the number of possible combinations will be 7! or 5040. You calculate yourself what will be the possible combinations for a plant having 20 sections. In such cases the use of a computer becomes inevitable.

13.6 MAINTENANCE OF CLEAN WORKING ENVIRONMENT

Cleanliness is very essential in any food processing establishment. It aims at protecting the food safety as well as improving and maintaining the quality of food. It is also the key to good health and efficient work. It is not only the responsibility of the plant manager to take care of sanitation aspects during operation, but proper layout, suitable placement of equipment, proper construction of building, doors, windows, selection of building materials etc. are also vital in maintaining a clean working environment during the plant operation. What do you do to remove bad gases or odours during cooking? The answer will be to switch on the exhaust fan or open the windows. But if the kitchen has no provision of exhaust fan/ventilator or windows, then what shall you do? It is the fault of planning the kitchen that the cook will suffer.

So, we should think about sanitation from the preparation stage of building plan. Provision of built-in sanitation in the construction design as well as in every piece of equipment, fittings, fixtures and utilities help us in maintaining a clean working environment. If the work area is not properly planned, the employee may tend to overlook hygienic practices while handling food. For example, if the wash basin is at a considerable distance from the working table, the worker may tend to skip proper washing of hands when required. There should be sufficient space to provide convenience and comfort to workers.

While selecting a site, we must have taken care that the area should be at a considerable distance from other industries, which might cause pollution. But after selecting the site also, we must be very careful for maintenance of clean environment within the industry and its vicinity. As discussed previously, we should isolate the areas/equipment producing dust, fumes, etc., so that they would not pollute the other working places. The processed food area should be kept away from the raw food area, receiving and cleaning sections. For example, if ginger or turmeric is collected directly from the field, then the washing operation should be carried out in a separate room or in an open yard away from the main room. The drying yard should not be kept near to the road or dusty areas. We should install the grinding mills or cyclones collecting powders in a separate room, or else, it will make the whole environment dusty.
In the ceiling if there are exposed beams or girders of iron or reinforced concrete, they would harbour dust and dirt. These dust and dirt get into the plant atmosphere and contaminate both equipment and products. The best ceiling is therefore one with a plain smooth horizontal surface. Light fixtures embedded or inset into the ceiling are more sanitary than the suspended ones. Windows must be properly constructed and maintained to provide adequate light and ventilation. The panes, frames, and screens must be easily and regularly cleaned. The doors and windows must be fly and rodent proof.

Smooth surfaces on the floor and glazed surfaces on the walls up to a height of at least 150-200 cm are satisfactory from sanitation point of view. Drains with proper slope should be provided in all rooms to carry away the liquid wastes promptly from the main working areas. Suitable slope of the floor helps easy cleaning. Garbage dumps and stagnant water in the vicinity encourage breeding of rodents, flies and mosquitoes, and hence should be at a considerable distance from the working areas.

13.7 WORKERS' SAFETY

Safety of workers is one of the prime concerns of any type of industry, and as mentioned in the preceding section, safety considerations start even from the stage of layout planning. Some of the important points that can be considered for workers' safety during designing of a food processing plant are as follows:

- There should be adequate space around all working equipment including those used for material handling to avoid collision between workers and the equipment and between workers themselves. This is more important for equipment, which need frequent servicing.
- The foundation and structure of the floor must be capable of supporting equipment, especially large storage tanks, work load and traffic.
- In the processing plant, fruit juices may fall on the floor throughout the processing area. If the floors have pores, cracks, joints then these get deposited on the floor and ferment to produce acid. The acids react chemically with the floor materials, corroding and damaging the floor. Hence, all parts of the food processing plant should have suitable acid resistant floors. The floors should also be able to tolerate physical abuse and thermal shock.
- The surface of the floors must not be slippery. However, rough surfaces are not preferred as they are difficult to clean; hence we should give a suitable slope to the floor for proper drainage. The design of the drains must permit quick flow of effluent. Drains should be covered with grills or perforated grate, which are inset and level with the floor. This allows normal traffic across a floor area without interference by the drains.
- We should assure proper lighting to all parts of the plant. The areas where there is more chance of water pouring onto the floors or the moist areas need special attention.
- The dangerous and moving parts of the machines need to be fenced. The places where the persons are likely to fall as dangerous pits, sumps, openings in floor, etc. should also be fenced. There should be provision for suitable safety devices in the moving machines so that they can stop immediately if any problem occurs.
- During operation, untrained and unskilled workers must not be allowed to operate any machine or equipment.
- There should be provision of emergency doors for escape in case of fire, necessary fire fighting equipment and training to workers.
- Proper maintenance measures should be taken for each and every machine and periodic routine checkups are essential to avoid accidents.

Safety is a matter of concern for all directly or indirectly involved in the industry, and small cares taken for maintenance of a better work place and during operation can help prevent major accidents and improve the performance of the food processing plant.

13.8 REGULATIONS AND STANDARDS

The Factories Act, 1948 is applicable to all types of food processing industries. The main objectives of the Factory Act are (i) to regulate working conditions in factories; and (ii) to ensure that basic minimum requirements of safety, health and welfare of the factory workers are provided. Besides, the Act envisages regulating the working hours, leave, holidays, overtime, employment of children, women and young persons, etc. The revision of the Act in 1987 included rules for use and handling of hazardous substances and procedures for setting up hazardous industries. The State Governments are empowered to make the rules for ensuring the administration of the provisions of the Act in their respective states. The occupier of a factory is required to get prior approval of the State Govt. for the site on which the factory has to be situated. The Chief Inspector of Factories is responsible for the approval. The occupier of the factory is also required to get the factory registered for obtaining a license for operating it and send a notice of occupation to the Chief Inspector of Factories, at least 15 days before it begins to occupy the factory.

Some important aspects of the Act as regards to health, safety and layout aspects are as follows:

1. Maintain all places of work in a condition that is safe and without risks to health.

2. Make arrangements for ensuring safety and absence of risks to health in connection with the use, handling, storage and transport of articles and substances.

3. Fencing of all dangerous and moving parts of the machinery while in motion or use.

4. Providing sufficient space for workers to operate self-acting machines; encasing and guarding of all machinery installed in the factory and every set of screw, bolt, spindle, wheel or pinion so as to prevent danger

5. Taking necessary steps to ensure that the maximum safe working peripheral speed of every revolving machine, etc. and the maximum safe working pressure of any pressure plant are not exceeded.

6. Keeping floors stairs, steps, free from obstructions and slippery substances and providing with substantial handrails, wherever necessary.

7. Providing suitable striking gear or such device for the movement of driving belts of any transmission machinery and proper locking of device which can shift inadvertently from 'off' to 'on' position.

8. Ensure that workers do not overcrowd the workplace. There should be a provision of minimum space of 14.2 m^3 per worker in a new factory and 9.9 m^3 per worker in an existing factory. Suitable provisions for lighting, drinking water, latrines, urinals and spittoons are also covered under the Act.

Besides, as I have mentioned previously, there are specific standards for ergonomical considerations for design of equipment or arrangement of workspace. Some more standards related to maintenance of clean working environment come under the Pollution Control Laws.

Check Your Progress Exercise 3

Note: a) Use the space below for your answer.

b) Compare your answers with those given at the end of the unit.

1. How does the analysis of man and material movement help in layout planning of a food processing industry?

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

2. What is the need to have enough working space around the equipment?

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

3. Write True / False:

   a) In a fruit and vegetable processing plant, the processed food area and raw food area should be kept close to each other.

   b) The drying yard should be kept close to the roads.

   c) The floors of a food processing room should be made rough to avoid slipping of the workers.

13.9 LET US SUM UP

In this unit, we have studied the various aspects of site selection and layout of a fruit and vegetable processing plant. We began with the factors affecting site selection and plant layout and then discussed the general considerations for a food plant layout. We discussed some rules for layout of different buildings, equipment, service facilities and waste disposal systems. We also studied the different steps involved in a layout planning process. How the analysis of man and materials movement, cleanliness and safety affect the plant layout are also discussed here. The unit has acquainted you with the general principles of site selection and plant layout, which are the primary steps in planning any type of industry.

13.10 KEY WORDS

Plant layout : Physical arrangement of the industrial facilities

Line flow process : When the product flows from one operation to the next in a prescribed sequence

Intermittent flow process : When the production is carried out in batches at intermittent intervals. We can organise the equipment and labour into different work centres by similar types of skill or equipment

Process form of layout : The intermittent process is also known as process form of layout as similar equipment and processing operations are grouped together.

Product layout : The line flow is also called a product layout because various process equipment, and labour skills are put into sequence according to the way the product is made.

13.11 SELF TEST FOR THE COMPLETE UNIT/ ASSIGNMENT

1. Describe the different guidelines for layout of different buildings in a food processing plant?
2. Describe the different guidelines for layout of different equipment in a food processing plant?
3. Explain the different steps that can be taken during layout planning for maintenance of clean working environment and workers' safety?

13.12 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. The major factors for selection of site for a fruits and vegetables processing plant are availability of raw material and good quality water, good surroundings, availability of electrical power, good transport facilities, easy availability of labour, facilities for disposal of wastes and scope for future expansion.
2. A good plant layout has the following advantages: saving in floor space, better utilisation of machine, manpower and services, reduced material handling, reduced inventory in process, increased output/ production per unit time, labour, money and energy, easier and better supervision

Check Your Progress Exercise 2

1. The basic objectives of a good plant layout are smooth operation and reduced cost in handling and processing.
2. If during the preparation stage of a plant layout, possible future expansion is not considered, we will face problems in expanding our industry or business, either by addition of new products or by increasing the capacity.

3. The layouts can be process form of layout and product layout. Also hybrid layouts, which are a combination of the above two are possible. The layout can also be classified as single level, multi-storey or combined layout.

4. Three dimensional scale models give a better representation of relative positions of different equipments and spaces than the two-dimensional drawings. In bigger models, the piping and utilities can be shown, which give idea on the actual work area that will be available.

Check Your Progress Exercise 3

1. The analysis of man-material movement helps to select a layout among many possible alternatives, which will reduce the total cost of movement and materials handling within the plant. This helps in minimising the cost of operation of food processing industry.

2. There should be adequate space around equipment to avoid collision between workers and the equipment and between the workers themselves. This will also help in servicing of the equipment.

3. a) False
   b) False
   c) False

UNIT 14 EQUIPMENT AND MACHINERY

Structure

14.0 OBJECTIVES

After studying this unit, you should be able to:

- know how the equipment are selected, installed and maintained in a food processing plant;
- visualise how the different ergonomical factors influence the design and arrangement of equipment and work area; and
- acquaint yourself with different managerial skills such as proper maintenance planning, management of inventory of spare parts and good manufacturing practices, which help in improving the performance of equipment and workers in an industry.

14.1 INTRODUCTION

In this unit we shall discuss about the different factors for selection of equipment for a fruit and vegetable processing plant. You will observe that the entrepreneur can himself decide the type of equipment with a proper understanding of different unit operations that are to be carried out in the processing plant. Then we will discuss how the human factors such as body posture, selection of tools, environmental factors, etc. affect the selection and installation of different equipment and improve the work efficiency. You will also know about the different maintenance and inspection schedules, workers' safety and spare parts management aspects. Our basic objective in this unit will be to understand the skills needed to upkeep the operational area and equipment, minimise the plant downtime, and to improve overall performance of the setup.

14.2 SELECTION OF EQUIPMENT

In the previous unit, we discussed about the plant layout and how a proper plant layout helps in maximisation of profits. After we have decided the process, prepared a good plant layout, and have constructed the building as per requirement, the next job is the selection of equipment and their installation. In fact these considerations start even before the civil construction work is started. We must remember that the equipment constitutes a major part of the initial investment and if not decided properly, may create problems in future. The problems could be of many types, such as low performance than rated capacity or frequent disorders. Sometimes the workers do not find the equipment comfortable to work with. Therefore, we must be very careful for selection of each individual equipment for the processing plant.

14.2.1 Selection Procedure

The selection of the types and sizes of equipment for the process plant requires considerable experience. However, as most of the food processing operation that we will be dealing with are established ones and are in operation elsewhere, the task becomes chiefly of comparative evaluation of standard equipment available from different manufacturers, scaling of the equipment and accessories up and down, and incorporating pertinent improvements that previous users have suggested.

First, we have to list the required equipment from engineering flow sheets. The next step is to make the necessary design calculations with the help of an expert and prepare the specifications for each equipment. The equipment not only include the major processing equipment and boilers, but also other accessories as suitable weighing scales, small hand tools, sieves, basins, buckets, and quality assurance equipment. If outside bids are required, detailed specification sheets must be presented to suppliers.

Standard vs. special equipment

We may use standard equipment already available in the market, or may design and fabricate equipment as per our need. However, use of the standard equipment is always better as it has the following advantages over the specially fabricated equipment.

- The initial investment for standard equipment will be significantly lower as compared to the special equipment.

- The duplication of equipment is easier.
- The repair and maintenance are easier and standard spares are easily available. Most often the equipment comes under a guarantee of satisfactory performance.
- Standard equipment has gone through long periods of experimentation and has been tested elsewhere. Usually it is the result of many modifications of its original design.

Hence, unless it is absolutely necessary, we should not be involved in the design of equipment. When we are sure that we have completely exhausted the trade literature for our requirements, then only we should think of design of a special equipment.

Specifications and competitive bidding

As we discussed earlier, a range of equipment for almost all types of operations in any food processing plant are available; our job is to specify our requirement for a particular duty and then select suitable machines from the above range. The specification should contain all essential information such as characteristics of the material handled, kind and quality of service requirements, delivery requirements and quotation. A comparison of the different machines available in the market often helps our decision with respect to principal components, materials of construction, service requirements, and accessories furnished along with the cost. Minor modifications may be suggested for an equipment for particular applications. We must also consider the delivery time, experience, and reliability of the supplier before final selection of the supplier.

14.2.2 Example of Selection of Equipment

Standard guidelines for selection of different types of process equipment are available in different *Chemical Engineers Handbooks*. For a general understanding of these guidelines, we will discuss about the selection of a dryer in the following paragraphs.

Drying equipment can be classified according to the following design and operating features.

1. Batch or continuous.
2. Physical state of feed: liquid, slurry, wet solid.
3. Method of conveyance of the solid: belt, rotary, fluidised.
4. Heating system: conduction, convection, radiation.

Dryers can be either batch type or continuous type. Batch dryers are normally used for small-scale production and where drying cycle is likely to be long. Continuous dryers require less labour, less floor space and produce a more uniform quality product.

The choice of suitable drying equipment cannot be separated from the selection of the upstream equipment feeding the drying stage. The main factors in the selection of drying equipment are the nature and concentration of the feed. For example the dryer to be selected for drying tomato paste will be different from the dryer for drying peas. For the first case a drum or spray dryer is considered suitable, and in the second case a fluidised bed dryer is better as it gives a more uniform product with higher drying rate for particulate solids.

In general with solids feeds, the material should be placed in the drying chamber in such a way that it will produce a bed of solids with an open, porous structure. For pastes and slurries, some form of pre-treatment such as extraction or granulation is often needed.

Besides the feed condition and the initial liquid content, the other product factors, the required quality of the end product such as its physical form and dryness, and the heat sensitivity of the product also play a major role in selection of the dryer. Hot air is mostly used as drying medium in industrial dryers. The air is directly heated by electrical heating coils, gas or oil, or indirectly heated, usually by banks of steam-heated finned tubes.

A range of dryers is available for use in a food processing industry, viz. tray dryers, conveyor dryers, rotary dryers, fluidised bed dryers, pneumatic dryers, spray dryers, drum dryers, infrared dryers. Our type of dryer should be picked from these available types depending on our requirement. After the type of dryer to be installed has been decided, the capacity of the dryer is decided based on the throughput required.

14.2.3 Other Considerations

After a brief discussion on some general guidelines, some more points that need consideration before making the final selection for any equipment are:

- How many operators are required to operate the equipment and the kind of technical knowledge they must possess?
- Whether servicing the equipment needs outside technicians or can it be serviced by available staff?
- What is the power consumption of the equipment?
- Whether the equipment can be easily cleaned and sanitised?
- What is the durability of the material used in the equipment?
- Whether the equipment is silent or noisy when operating?

14.3 MOVEMENT AND INSTALLATION OF EQUIPMENT

In our every day experience we observe many physical equipment and facilities, which are not suitable to use because of their installation features. Examples include kitchen sinks that are too low, uncomfortable chairs, narrow staircases, very little space near a equipment that needs repair, and so on. Therefore, installation of the equipment is as important as the selection of proper equipment.

In most of the cases the manufacturers take up the responsibility of proper packing of the equipment so that it does not damage during transit. The movement within the plant is done by labour or by trolleys or cranes. They may also take up the installation job with or without charging an extra amount. However the plant manager has the responsibility to check that the machine/equipment is properly installed for convenient working, cleaning and maintenance operations. The machine should have a proper foundation. In particular the machines which produce significant vibration and noise should have a proper base. Sufficient working space should be kept around the machine.

Almost all equipment are designed for standard people. But installation is very important for comfortable working for a special group of people. The physical location and arrangement of such items (and of their specific features) can affect the comfort of the users as well as physical well being. For example, the comfortable working height of the tables and control panels will differ for ladies and gents. Therefore, special care should be taken during installation of equipment, working tables, etc. which could ultimately affect the work performance.

14.4 ELECTRICAL WIRING

A factory generally needs 3 phase 4 wire supply. For motors whose ratings exceed 2 or 3 kW, 3 phase 3 wire supply is required; and for light and fan circuits single-phase supply is required.

For internal wiring for supply to motors, conduit system of wiring with vulcanised Indian rubber (VIR) or PVC insulated cables of suitable size are used. The conduits are usually run on surface rather than laying them in covered trenches to facilitate additions and alterations. Use of separate conduit for every motor is preferred. The conduit used in power wiring should be electrically continuous throughout and connected to the frame of the motor. The frame of the motor is to be earthed by two separate and distinct connections to earth. Under-ground cables are preferred for very large capacity motors.

In domestic installations single earthling is sufficient but in an industry double earthling of motors, medium voltage regulating or controlling equipment etc. is necessary. Circuits and sub-circuits to 400 V motors must be provided with fuses on all poles, i.e. on all three phases of the a.c. supply.

In a large industry, power distribution is made from a suitable location, known as distribution centre, through a switchboard. This switchboard consists of a set of insulated bus bars. Each incoming and outgoing circuit is controlled by an automatic circuit breaker (or linked switch and cutouts). The outgoing circuits feed different sub-distribution boards erected at convenient places, which further distribute power to a number of equipment. A line diagram, showing the tapping supply from bus bar chamber to the individual machine is shown in Figure 14.1. In small industries, sub-distribution boards are not needed and a switchboard or distribution board is used for distribution of power. All equipment used in power wiring should be of iron clad construction and wiring shall be of the armoured cable or conduit type. Every motor, regardless of its size, shall be provided with a switch fuse close to it, and with a suitable starter placed at a convenient place. The starters are used to limit the starting current to a desirable value. Electrical wiring diagrams must be prepared for all sections and a qualified/trained personnel should be given the responsibility of electrical wiring of the complete plant.

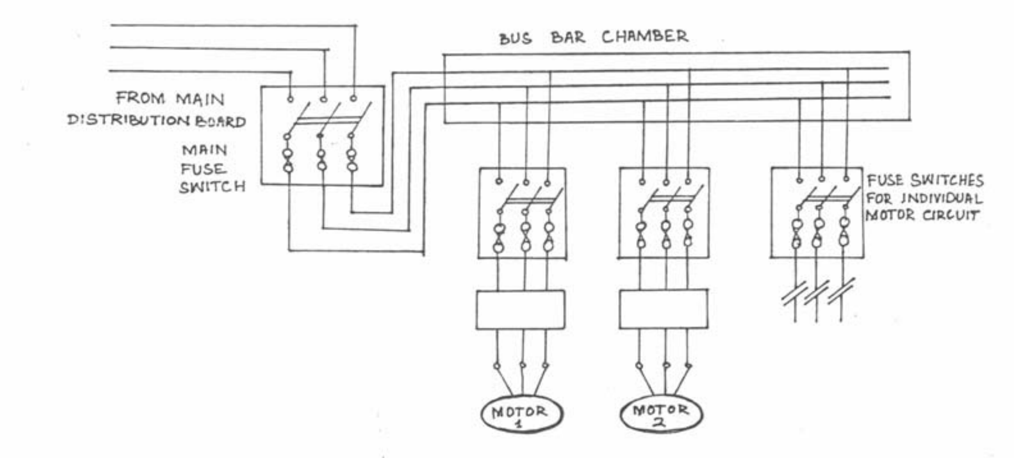

Figure 14.1: Supply from busbar chamber to individual machines

14.5 ERGONOMIC CONSIDERATIONS

The word ergonomics is derived from the Greek words 'ergon' (work) and 'nomos' (law). In the United States, the term 'human factor' is used for ergonomics. It is defined as the scientific discipline concerned with understanding the interactions among humans and other elements in a system, and the profession that applies theory, principles, data and methods to design, in order to optimise human well being and overall system performance. In other words ergonomics aims to design appliances, technical systems and tasks in such a way as to improve human safety, health, comfort and performance at work and everyday life. Motivating the man at work and making the work to suit him is the prime objective of ergonomics.

The application of ergonomics includes plant and workspace layouts, selection, training and placement of personnel, design of equipment, power tools, displays, jigs, fixtures, and even furniture, motivation of the worker, working conditions and environments, and computation of relaxation allowances.

The ergonomical factors include body posture and movement (standing, sitting, lifting, pulling and pushing), environmental factors (noise, vibration, illumination, climate, chemical substances), information on different machines and operational characteristics (information gained visually or through other senses, controls), as well as work organisation (type of task, nature of job, etc., whether the job is interesting or not?). Brief descriptions on these factors is given below.

14.5.1 Body Posture and Movement

Posture and movement play a vital role in ergonomics. Poor design or installation of equipment, technical systems and tasks has often reported to cause back pain, psychological illness (e.g. stress) and occupational disability. In addition, it also reduces performance and sometimes leads even to accidents. Some of the ergonomic considerations may be that the important components should be placed in convenient locations. The body size of the workers should be kept in mind for designing the working tables. Particularly the assembly tables and packaging section need special attention as in a food processing plant the workers need to stand or sit at a constant place for longer times. During movements, the body joints ought to be kept as far as possible in a neutral position. The workers should not be overloaded during conveyance of loads. Lifting accessories like lever, raising platforms and cranes and transport accessories such as conveyor, sack barrow, mobile raising platform, forklift, etc. should be used wherever possible.

14.5.2 Environmental Factors

The environmental factors such as noise, vibration, lighting, and climate can affect people's safety, health and comfort. The chemicals do also affect. The presence of high noise levels during a task can be annoying and prolonged exposure can result in impaired hearing. The noise level should be below specified levels; in most cases it is 80 decibels.
Ensure that floors are hard and even, and machines have proper foundation. It not only reduces vibration and noise, but also avoids other types of accidents. Well-maintained machines are quieter. There must be proper illumination in all parts of the factory. The air temperature, humidity and ventilation affect the comfort and productivity of the workers. The location of the building and its surroundings, convenience of transportation, size and number of rooms, design of ceiling heights and slopes, windows, style of architecture, type of building materials, colour, cleanliness, etc. are considered under environmental factors, which affect the work performance.

14.5.3 Information and Operation

The workers should be well informed about the work they are doing, with their important contribution in the work. They should feel responsible for their role in the final product development. This way they will be more involved in the work and their performance will increase. Suitable warnings at desirable places, display of the steps of operation and maintenance of the machines, putting different colours for different switches, etc. are some ways to improve the performance of equipment and workers, and reduce accidents.

14.5.4 Work Organisation

The worker must find the equipment comfortable, and he must enjoy the technical systems and tasks, which can be achieved by proper work organisation. Selection of the right kind of tool come under this category. Suppose we use a dull knife in cutting of vegetables, we expend a lot of extra energy that is, in effect, wasted. It is also important to train the workers on the proper way of using the tools. Further, the tools can not be designed in isolation. Often a redesign of the workspace, which includes the work envelope, work surfaces (such as desks, tables, etc.) and seats (if used) as well as the design and relocation of equipment used. The important components need to be placed at convenient locations.

You must bear in mind that safety can be improved by 3 E's, viz. education, engineering and enforcement. A range of ergonomic subjects is covered by international ISO standards, European EN-standards, as well as national standards. In addition, there are specific ergonomic standards, which are applied to individual companies and industrial sectors. These should be followed for the overall effectiveness of the industry.

……………………………………………………………………………………

14.6 UPKEEP OF OPERATIONAL AREA

Proper upkeep of operational area improves performance of workers and increases production. A systematic and scientific maintenance of operational area assures instant operational readiness and optimal availability for production at all times without compromising on the safety of man and machine. It also reduces worker frustration and improves job satisfaction, which in turn improve the working life of personnel, and productivity.

The health and safety of both workmen and machines need careful maintenance. This is more important for a fruits and vegetables processing plant where they affect food safety. The orderliness and cleanliness of the workplace has to be assured to improve total productivity and the conditions of the labour force, and to avoid accidents. There should be proper light and aesthetic environment.

For most projects, a maintenance planning system is included in the preparation stage of the project to protect the investment in machinery, plant and buildings through regular and adequate maintenance. These all help in reduction in downtime, which is very significant in a food processing plant, as we have the responsibility to process the produces within the shortest possible time after harvest. Further, with ever increasing cost of labour and material, this is good economy also. It maximises the utilisation of labour and other resources and prevent waste of spares, tools and materials.

14.7 MAINTENANCE AND INSPECTION SCHEDULE

14.7.1 Maintenance Scheduling

You must have experienced the importance of scheduled maintenance for the performance of any machine. For example, we change the gear oil of our motorcycles after every 3000 km of running as a scheduled maintenance practice. A **maintenance schedule** is the sequential arrangement by which maintenance is done. In an industry, the schedule indicates, what is the work to be done, how often it is to be done, by which it is to be done, and the estimated time required to complete the work. Separate schedules have to be prepared for each type of maintenance activity, and for each equipment/machine.

The decision on a sequence is based on the priority, the availability of spares, materials and specific tradesman. It should be remembered that most critical equipment has to receive prompt attention in maintenance caring and should be the first items to be scheduled. The other priorities could be emergency breakdown, preventive maintenance, predictive maintenance, and/ or other maintenance systems prevalent in the organisation.

The guideline for the maintenance are often laid down by the manufacturer. But the actual conditions of operation, the severity of use, and the skill level of operators are also to be considered. Schedules must be made in two parts: the **long term schedule** to be made 8-12 weeks in advance, and the **short term schedule**, just a week or two in advance. This will help in preparing and planning in advance for materials, spares, tools, and test equipment. The short-term schedule is finally broken up into daily schedules for day-to-day implementation and for assuring that close control would be exercised. The supervisor assigns work individually to each worker and keeps him informed as to what work is expected of him within a small frame of time limit, may be the next morning. This allows the worker to plan his own activities. Revisions in schedules are expected, and hence, they must be kept flexible enough to accommodate any change.

14.7.2 Inspection Scheduling

Inspection is the examination of equipment and machines or their parts to determine their condition. Periodic inspection helps detect extent of deterioration and plan for its repairs and rectification, or if need be, even make replacements before an actual breakdown occurs.

Take for example the daily inspection routine for a fan or a pump would involve carrying out checks for:

a) any abnormal vibrations, or any abnormal noise;

b) the temperatures of all the bearings to ascertain that they are at acceptable levels and that there is no overheating;

c) leakages from the glands and gauge to see whether they are excessive;

d) oil levels in cups; and

e) grease nipples to ensure that they are not dry.

Different checklists are required for the same machine, depending on whether the machine needs a weekly, monthly or annual check up.

The frequency of inspection is affected by many factors, such as:

a) age of the machine or equipment, its condition and value;
b) severity and intensity of service;
c) hours of utilisation- are they prolonged- or intermittent;
d) susceptibility to wear and tear or any other damage;
e) susceptibility to losing adjustment during use- Will the maladjustment and non-alignment affect the accuracy or functioning? Will the lack of proper balancing affect performance?
f) safety requirements and considerations;
g) criticality of item- if the item is very critical, then it may need daily inspection.

14.8 PERIODIC MAINTENANCE PRACTICES

14.8.1 Classification of Maintenance System

The different maintenance systems can be classified as: a) Breakdown maintenance, b) Routine maintenance, c) Planned maintenance, d) Preventive maintenance, e) Predictive maintenance, f) Corrective maintenance, g) Design out maintenance, h) Total productive maintenance, and i) Contracted out maintenance.

Breakdown maintenance or repair maintenance is carried out only in case of a need of repair or when the machine ceases to work. **Routine maintenance** involves routine checks such as daily lubrication and inspection of the machines, monthly inspection of motors. **Planned maintenance** is maintenance organised and carried out with a predetermined plan depending on the machine's needs, expected requirement of the machines and manufacturer's recommendation.

Preventive maintenance system refers to the steps taken to reduce the likelihood of failures to the absolute minimum. **Predictive maintenance** can be defined as "methods of surveillance used to indicate as to how well the machine is, while performing its intended tasks". **Corrective maintenance** is defined as maintenance carried out to restore (including adjustment and repair on item) machinery, which have ceased to meet an acceptable condition. **Design out maintenance** (DOM) tries to eliminate or to minimise the need for maintenance to the lowest possible level.

The basic concept of **total productive maintenance** is to change the attitude and improve the skill of all personnel by using quality equipment. **Contract maintenance** is using specialised maintenance personnel on contract basis, mostly for specific equipment.

Each individual organisation, big or small, simple or complex, or using highly advanced or simple technology must choose the maintenance system that suits it best. Total maintenance planning includes: a) inspection, b) lubrication, c) planned maintenance, d) preventive maintenance, e) predictive maintenance,

f) corrective maintenance, g) modifications h) retrofits, i) refurbishing, j) overhaul, k) replacement of equipment, l) discarding of equipment, m) standardisation, n) material requirement planning, o) spares planning, p) documentation, q) spare parts manufacture, r) exercising of spare parts and sub-assemblies held under long term storage (Particular attention should be given to rubberised components).

14.8.2 Maintenance Steps in a Fruit and Vegetable Processing Plant

In general the maintenance steps for a general food processing plant includes following steps.

- Carry out a visual check of the equipment and all operational area for cleanliness.
- Check if safety devices are present and functional. If not, do not operate the equipment.
- Operate the machine and check for any unusual noise, vibration, friction and instruction.
- Check if lubrication cups are replenished to correct levels and grease nipples so that they are not dry; then operate the machine. This is mainly required for conveying machines and elevators.
- Never operate the machine beyond laid down conditions of speed and feed.
- Make sure that no tools or any smaller parts of containers, glass pieces, etc. have dropped inside any equipment.
- Follow the manufacturer's recommendations for maintenance of each individual equipment.

Check Your Progress Exercise 2

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. How proper maintenance and inspection help improve performance of a food processing plant?

14.9 INVENTORY OF SPARE PARTS

An **inventory** is a stock of materials used to facilitate production or to satisfy customers. All idle resources other than materials are considered as capacity, e.g. equipment or idle workers. Capacity is used to produce, while inventories are the products at some point in conversion and distribution process.

Spare parts are those parts of machines, which because of wear and tear, use or breakage, need replacement. However, it is often not possible to obtain each and every spare in the market as and when needed. Besides, purchasing anything in small quantity is expensive also. There is also chance of getting improper spares. Hence it is necessary for any industry to carry inventories of frequently used spare parts. In particular, in a food industry when the work is in progress inventories of spares are an absolute necessity.

The finance department generally prefers to keep the inventory level low to conserve capital, marketing prefers high levels of inventories to enhance sales, while operations department prefer adequate inventories for efficient production and smooth employment levels. Inventory management must balance these conflicting objectives and manage inventory levels in the best interests of the factory as a whole.

The decision problems in inventory management are a) which items should be carried in stock, b) how much should be ordered, c) when should an order be placed, d) what type of inventory control should be used. Whether to buy a spare or make it in the workshop / local market is another criteria. This decision is dependent on the cost, assurance of availability, opportunity to control quality, availability of equipment and expertise, desire to preserve confidentially, and saving in transportation costs.

14.9.1 Optimisation of Total Cost of Inventory

What is the quantity to be purchased is one major decision in inventory management. The **economic order quantity (EOQ) model** is a tool, which helps to know the quantity that will optimise the total cost. The motivating factor to control inventory is the cost incurred by carrying it. The different costs involved in the calculation of the total cost are:

1. **Item cost** or the cost of buying or producing the items;

2. **Ordering** or **setup cost,** which is the cost of getting an item including the cost of transportation, and salary of personnel working in stores and stock verification department;

3. **Carrying** or **holding cost,** which includes capital cost, storage cost or rents, depreciation charges, cost due to deterioration of the part or obsolescence; and

4. **Stock-out cost**, which reflects the economic consequences of running out of stock, since the sale is lost if material is not on hand. The profit is lost on sale, and good will in the form of future sales.

The quantity, which optimises total cost, is known as **economic order quantity (EOQ)**. For a general case, EOQ is given by,

$$\text{EOQ} = \sqrt{2C_o M/(C_c p)},$$

where, C_0 is the order cost or setup cost, Rs. per order,

C_C is the carrying cost, expressed as percent of Rs. values per year,

M is the annual consumption, units per year, and

p is the unit price, Rs. per unit.

We will see the applicability of this formula with the help of a small example. A fruit processing plant purchases 600000 bottles per year for handling juice. The order cost is Rs. 70 per order, and the carrying cost is 15% per year. If each bottle costs Rs.2 only, find out the economic order quantity?

Solution

$$\text{EOQ} = \sqrt{2\frac{(70)(600000)}{(0.15)(2)}} = 16733 \text{ units.}$$

It means that the plant should purchase 16733 bottles at a time. This will result in 600000/16733 = 36 purchases per year, i.e. one purchase almost in every 10 days. This quantity will involve minimum total cost for maintaining the inventory. Now, check that if the order cost is increased to Rs. 210 per order, the EOQ will be 28983, i.e. the plant has to purchase 28983 bottles in each order to minimise the total cost. In that case it will go for 20 purchases in the year.

We suggest you to change the unit price and other parameters and see how these changes affect the EOQ. You will observe a definitive change in the EOQ with changes in the above parameters. Even though the EOQ model has several limitations as it assumes a constant demand, a constant unit price, a constant setup cost, etc. throughout the year, still it is widely used in the industry as a standard tool for the inventory management.

14.10 MINIMISATION OF EQUIPMENT DOWNTIME

As we have already discussed, the downtime for any equipment or for the complete plant can be reduced by proper upkeep of operational area, by properly scheduling the maintenance and inspection, and judicious management of the inventory of spare parts. In this section we will give a closer look at this area.

14.10.1 What is Downtime?

Downtime in general may be considered as the time when the plant or any specific equipment is down or not performing. Thus the downtime directly affects the production. However, downtime does not always imply / cause a direct production loss. There are certain conditions under which downtime does not create a production loss, e.g. when the plant does not operate at full capacity utilisation level, or when the completely processed product is not lifted for delivery to customers but is stored.

14.10.2 Reasons of Downtime

The main reasons for downtime in an industry or a section are as follows:

- Breakdown of a machine due to any reason.
- Failure in power supply or load shedding.
- Non-availability of suitable raw material.
- Improper planning, scheduling or machine loading.
- Lack of proper tools, jigs or fixtures.
- Non-availability of calibrated test equipment.
- Shortage or absence of operator.

14.10.3 How to Reduce Downtime

Once we know the different possible reasons for downtime in our plant, the planning to reduce the downtime becomes much easier. Both the operator and the maintainer have to jointly make efforts to lower and control down time.

Simple dos and don'ts are to be specified for an operator, which if followed can eliminate a large number of breakdowns. For example, before the start of the machine the operator should check all the safety devices, lubrication points and cleanliness. Then he should operate the machine for a short time to check for the presence of any unusual noise, vibration, friction, etc. The management should have the responsibility to educate and train the workers on these aspects.

Some basis steps that are useful in reduction of downtime are as follows:

- Adopt proper maintenance planning, maintain and carry out repair of buildings, utilities and allied equipment.
- Ensure scheduled inspection and lubrication of all necessary points
- Adopt rapid fault-finding systems and the use of diagnostic charts
- Ensure and carry out faithful recording and documentation of all maintenance work, and review of the records. Analyse repetitive failures of any particular equipment and replace the faulty parts / redesign the machine.
- Standardise equipment for replacement and purchase.
- Monitor procurement of spare parts and material for maintenance.
- Design and enforce safety standards.
- Recruit and train personnel to carry out maintenance work.

It is very important to record all breakdowns with care and absolute accuracy, so that the parts that have failed may be segregated and analysed to find out the reasons for the failure. Every single person working in the maintenance department must know his or her exact function. Once the cause has been diagnosed, corrective actions are to be planned and taken. We must understand that it is a collective job and all persons associated in the plant operation have individual important responsibilities for reduction of downtime.

14.11 MAINTENANCE OF RECORDS

It is very important for an organisation to maintain different records and document them properly. This is quite beneficial. For example, if the job cards and history record cards are properly maintained, one can choose machine or equipment wise information about how much has been the annual maintenance cost on each of them.

Facility register: A facility register is a complete list of all the machinery, plant, equipment and buildings, which have to be maintained. If the number of such items is very large, then they can be maintained in different groups depending on their usage, technical practices, or by the maintenance methods which are being used. For example, a food processing plant can be divided into sections by their maintenance needs. The shut down can be done section-wise for maintenance. This can help in working at all other sections while a particular section is undergoing maintenance. Such types of information are maintained either by cards or by computers.

Equipment record card: An equipment record card or **Plant record card** keeps all information about each individual machine, such as the name and address of supplier, date of purchase, price, etc. It is very useful when a repeat order has to be placed for procurement after many years and the necessary information is not available from any other source.

History record card: A history record card or **Log card** carries information on all corrections, replacements, repairs, and other modifications that have been carried out on a particular equipment from the day it was inducted to the day it is scrapped, or disposed of. If an equipment is moved from one section to another, its History record card has also to move along with it. The card is quite helpful in analysing the total downtime, the frequency of occurrence of specific faults, and which parts or spares are frequently being replaced. Thus it will help in making standardisations and replacement decisions.

Defect analysis record: This is another type of record, where the focus is on defect analysis.

Besides, the food processing plant has to maintain several other records related to financial and marketing departments, operation departments, etc., which help in the analysis of raw materials status, production status, money flow and similar factors of interest to the plant manager.

14.12 CERTIFICATION

In India, the fruit and vegetable processing industry come under the **Fruit Products Order (FPO)** issued by the Govt. of India. No person shall carry on the business of a manufacture except under and in accordance with the terms of an effective license granted to him. A manufacturer using different manufacturing premises for manufacture of fruit products shall take out a separate license from each such premises.

The FPO has many quality standards relating to production, quality of processed products, and packaging aspects. It also covers the **Prevention of Food Adulteration (PFA)** Act. FPO has standards for the sanitary requirements of a factory manufacturing food products. The 2nd part of the 2nd schedule has specifications for different types of processed fruits and vegetable products. This is just to acquaint you with the FPO. For details, I suggest you to go through the draft of the FPO.

You must have also heard about **International Organization for Standardization (ISO)** certification. At present there are two series: ISO 9000 series and ISO 14000 series. ISO 9000 is concerned with "quality management". This means what the organisation does to enhance customer satisfaction by meeting customer and applicable regulatory requirements and continually improving its performance in this regard. ISO 14000 is primarily concerned with "environmental management". This means what the organisation does to minimise harmful effects on the environment caused by its activities, and continually to improve its environmental performance. The vast majority of ISO standards are highly specific to a particular product, material, or process.

ISO standards contribute to making the development, manufacturing and supply of products and services more efficient, safer and cleaner. They make trade between countries easier and fairer. ISO standards also serve to safeguard consumers, and users in general, of products and services. This certificate is very useful to industrial and business organisations of all types, and to suppliers and customers of products and services in both public and private sectors.

There are several methods and tools to help with the implementation of a Food Safety Management System, such as **HACCP (Hazard analysis and Critical Control Points)**, **Good Hygiene Practice (GHP)** and **Good Manufacturing Practice (GMP)**. Together with a Quality Management System, e.g. ISO 9001, they form the basis for an overall Food Safety Management System.

Hazard analysis is the identification of all ingredients, stages in progress, environmental features and human factors that can lead to hazards for the customers. The risks and likelihood of their occurring is estimated. Critical Control Points are the points at which control is essential to guarantee that potential hazards do not become actual hazards. A CCP is a location, a practice, a procedure or a process, which if not controlled, can result in an unacceptable risk. Examples include inspection of goods at delivery or before use, correct temperature ranges during sterilisation or blanching, etc. Thus HACCP is preventive in nature and it protects the consumers from exposure to potential food hazards. Thus HACCP should be the top priority in any food firm.

A HACCP certificate proves that our food safety system has been measured against a best practice standard and found compliant. Issued by a third party accreditation body/registrar, the certificate proves to customers that we have implemented the necessary routines to ensure food safety. It is a prevention-based food safety system. It provides a systematic method for analysing food processes, determining the possible hazards, and designating the critical control points necessary to prevent unsafe food from reaching the consumer. HACCP is based on the Codex Alimentarius developed by the Food and Agricultural Organisation of the United Nations and the World Health Organisation.

14.13 GOOD MANUFACTURING PRACTICES

A food processing industry has the responsibility to make safe and wholesome processed food available to the consumers. In addition, it has to take care of the sustainability of the industry. Hence, good manufacturing practice (GMP) should look at the above two factors.

The aim of good manufacturing practice in the food industry is to provide food that meets the consumers needs and wants, and also to give them the security of safety ad reliability. GMP is based on the knowledge and skills throughout the food system, from primary production of the raw materials, through processing of the industrial ingredients, manufacturing of the consumer products, distribution of the final retail products till the cooking and eating of the final food. The objectives of GMP are to control the changes in the food materials so as to develop desired qualities in the product, to ensure that the food is safe to eat, and to stop or slow down any deterioration in the food. GMP means understanding, analysing and controlling the manufacturing process.

GMP guidelines include location requirements, design of facilities, facilities to be provided such as supply of potable water and water standards, equipment selection, storage, pest control, packaging, transportation, personal hygiene, etc. It also includes training, maintenance of records, quality control, inspection and testing, verification, etc. It means it covers all aspects of food processing operation and management.

For example, GMP says that the food plant establishment should be located away from environmentally polluted areas and industrial activities, which pose a threat of contaminating food; areas subject to flooding unless sufficient safeguards are provided; areas where wastes can not be removed effectively; and areas prone to infestation of pests. GMP requires that the equipment should be located and installed in a manner that permits adequate maintenance and cleaning, functions in accordance with its intended use, facilitates good hygiene practices including monitoring. The equipment should be installed at a distance from the floor and walls to allow proper cleaning and avoid dirt accumulation (recommended minimum 30 cm from floor and minimum 60 cm from walls and other equipment). GMP requires that the conveyors in dry product area should be covered. Guidelines for plant layout, upkeep of operational area, electrical wiring, ergonomic considerations in arranging the work space and almost all the aspects that we have studied in this unit and previous unit come under the purview of GMP. Personal hygiene is a very important component of good manufacturing practice.

Check Your Progress Exercise 3

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. What do you call the quantity of purchase, which optimise total cost in inventory management?

14.14 LET US SUM UP

In this unit we have discussed about the different guidelines for selection of equipment for a fruit and vegetable processing plant, and other commissioning features as movement and installation of equipment, electrical wiring. We also studied the ergonomic considerations for selection and installation of equipment for improvement in workers' performance. The different aspects of maintenance and inspection of equipment and inventory of spare parts are also covered which are very important for reduction of downtime. We also studied about the maintenance of different records, which are helpful in analysis of performance of specific equipment and make replacement decisions. Brief discussions on the certification aspects and Good Manufacturing Practice for a plant are also made at the end of the unit.

14.15 KEY WORDS

Ergonomics : The scientific discipline concerned with understanding the interactions among humans and other elements in a system, and the profession that applies theory, principles, data and methods to design, in order to optimise human well being and overall system performance.

Inventory : It is a stock of materials used to facilitate production or to satisfy customers

EOQ : It is the quantity, which optimises total cost in inventory management.

Downtime : It is the time when the plant or any specific equipment is down or not performing.

14.16 SELF TEST FOR THE COMPLETE UNIT/ ASSIGNMENT

1. Explain the different steps for upkeep of operational area and reduction of downtime?

2. Write short notes on (a) Ergonomics in a food plant design, (b) Inventory management, (c) Selection of equipment.

14.17 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. The initial investment for a standard equipment is lower and duplication of equipment is easier. The repair and maintenance are easier as standard spares are easily available. Standard equipment usually come under some guarantee and are usually the result of many modifications of its original design.

2. The ergonomical factors include body posture and movement, environmental factors (noise, vibration, illumination, climate, chemical substances), information and operation, and the work organisation.

Check Your Progress Exercise 2

1. Proper inspection and maintenance reduce the total downtime, ensure operational readiness, improve job satisfaction and improve safety of workers. Proper inspection helps detect the extent of deterioration of any equipment/machine or their parts, which helps repair/replacement before an actual breakdown occurs.

2. A maintenance schedule is the sequential arrangement by which maintenance is done.

Check Your Progress Exercise 3

1. Economic Order Quantity.

2. The different costs involved in the analysis are the item cost, ordering or setup cost, carrying or holding cost, and stock-out cost.

3. Zmain reasons for downtime are breakdown of a machine, failure in power supply or load shedding, non-availability of suitable raw material, and improper planning, scheduling or machine loading.

4. Facility register, Equipment record card or Plant record card, History Record Card or Log card and Defect analysis record.

5. Fruit Products Order
   International Organization for Standardization
   Good Hygiene Practice
   Good Manufacturing Practice

UNIT 15 PLANT SANITATION AND EFFLUENT TREATMENT

Structure

15.0 OBJECTIVES

After studying this unit, you should be able to:

- know the importance of plant sanitation for a fruits and vegetables processing industry;
- know the properties of process water and different methods for treatment of process water as well as waste water;
- familiarise yourself with the methods for waste solids upgrading and methods to reduce the discharge volume from a fruits and vegetables processing plant; and
- acquaint yourself with the regulations relating to plant sanitation and waste disposal.

15.1 INTRODUCTION

Plant sanitation plays an important role in the overall work performance of any industry. In particular, in a fruit and vegetable processing industry as we are concerned with handling of food, plant sanitation plays a very vital role. It directly affects food safety. If the food produced by an industry is not safe, then the unit will ultimately loose customers, and may have to shut down. In this unit, we will discuss the various aspects of food processing plant sanitation and see how it affects food safety. Water is one of the major inputs in any fruit and vegetable processing plant as it is needed for a variety of operations such as cleaning, blanching, preparation of syrup or brine, as heat exchange medium or boiler feed, and many other uses. It also directly affects food safety and food plant sanitation. So we will discuss about the requirements of process water and its properties. Another important aspect for any type of industry is waste disposal, as it not only affects food safety, but also affects the surroundings and work environment. Hence, we will discuss about the waste disposal methods. Still more important are the methods that can be taken to reduce the discharge volumes and upgrade the waste solids for further uses, which are not only important for reducing environmental pollution, but also for the economy of operation in a plant. In addition, we will also discuss briefly about the waste and effluent disposal regulations.

15.2 IMPORTANCE OF PLANT SANITATION WITH RESPECT TO FOOD SAFETY, RISKS AND HAZARDS

The word “sanitation” derived from latin word ‘*Sanus*’ means sound and healthy or clean and whole. Thus plant sanitation includes all possible activities to maintain a healthy environment.

Will you consume a food, which is very attractive in colour and aroma, but has a chance of some toxic or otherwise harmful material in it. Of course your answer will be ‘No’; it means that the food plant sanitation principles are mandatory in the production of foods primarily for gaining public acceptance of the products. The processed food obtained from an industry should not only be attractive and nutritious, but also be wholesome and bacteriologically safe. The processed food, even though processed for killing pathogenic organism, is at a greater risk of contamination because it is prepared in large quantities and is handled by many people. Hence, along with proper control on the qualities of raw materials used in processing, proper hygiene at all the work places is very important for obtaining safe food. Since food sanitation has a direct effect on the health of individuals patronising the specific food processing industry, the management needs to lay down definite guidelines for implementation and maintenance of hygienic conditions. This is required even for the survival of the industry itself.

We must realise that sanitation affects every phase of food handling such as purchasing and receiving raw material, transportation and processing operations; and quality control should be maintained throughout. The major sources of contamination of food are air, water, plant, soil, food handler, machinery and equipment, sewage and trucks or cans during transport. The contamination can be in the form of visible contamination by insects, rodents, stones or other extraneous materials, or visible and invisible contamination by micro-organisms. The third type is potential chemical contamination. It means, if slight negligence is observed at any point that would directly bear a risk of food contamination. We should also bear in mind that all the above sources of contamination are directly related with many decisions as selection of a proper site, layout and orientation, ventilation, illumination, water supply and disposal of wastes.

Sanitation is every person's job in a food plant. It should be a part of everyday's policy of the food firm, as ultimately a good sanitation gives us a product free of risks and hazards. If properly practised, sanitation removes the concern about the spreading of communicable diseases or potential food poisoning. Further properly maintained sanitation gives us a product free of contamination and eliminates waste and spoilage. A food prepared under hygienic conditions commands respect in the market. From a legal obligation stand point also, it is important. If the food is prepared, packed, or held under unsanitary conditions, whereby it may become contaminated with filth, it invites legal action.

Sanitation is a responsibility that every person handling or working with food must constantly fulfill. The value of a planned sanitation programme utilising good manufacturing practice includes the following.

- A better product to meet the competition's demands and consumer's expectations.
- A more efficient food plant operation.
- Greater employee productivity.
- Fewer food plant employee accidents.
- Fewer consumer complaints.

Thus food plant sanitation is of prime importance, and several requirements such as adequate supply of potable water, proper sewage disposal facilities have to be fulfilled for maintaining sanitation. However, whatever may be the expense of maintaining a quality sanitation system, there is no point of compromise, as we are going to handle food and ultimately the health and life of the people.

15.3 PROPERTIES AND REQUIREMENTS OF PROCESSING WATER

Water is one of the major inputs in a fruit and vegetable processing plant. It is used in the preparation of brine or syrup, in blanching, in cleaning and washing of fruits and vegetables, different equipment and containers. The other important applications include its use as boiler feed and as heat exchange medium. More than 10,000 litres of water are required to process a tonne of fruits or vegetables.

The processing water must meet the health standards for potable (drinking) water and should be low in mineral salts (calcium, magnesium, sulphur and iron). Potable water is one, which is safe to drink, pleasant to taste and usable for domestic purposes. The water for food processing plants should also be chemically pure to prevent turbidity, off-colour, and off-flavour. The tap water may not be sufficiently pure for use in food products.

15.3.1 Water Hardness

Hardness of water is one of the major properties of water as regards to food processing industry. We all know that if water forms a lather with soap which lasts for at least five minutes, it is called **soft water**. If lather is not formed easily then it is termed as **hard water**. The compounds of calcium and magnesium ions dissolved in water mainly cause the hardness. These ions form precipitates with bicarbonates, sulphates or chlorides present in water instead of forming lather, which is known as hardness.

Hardness of water is further classified as **carbonate hardness** and **non-carbonate hardness**. The carbonate hardness is due to the presence of calcium and magnesium bicarbonate. This type of water is found in chalk and lime stone regions. Non-carbonate hardness is due to the presence of calcium and magnesium sulphates, chlorides, and nitrates. The water in areas having rocks containing these salts is of this type. The carbonate and non-carbonate hardness are also referred to as **temporary hardness** and **permanent hardness,** respectively.

Hardness of water is expressed in terms of milli-equivalents per litre (mEq/l). One mEq/l of hardness producing ion is equal to 50 mg calcium carbonate (50 ppm) in one litre of water.

Table 15.1: Types of hardness

Sl. No.	Degree of hardness	Amount of dissolved compounds	
		mEq/l	mg/l
1.	Soft water	Less than 1	Less than 50
2.	Moderately hard	1-3	50-150
3.	Hard	3-6	150-300
4.	Very hard	More than 6	Over 300

Disadvantages of hard water in processing industry

As hard water fails to give lather with soap, it creates a problem in cleaning operations.

Hardness causes scale on equipment, which acts as an insulating layer against efficient heat transfer and may eventually clog pipes and foul valves. When hard water is used as boiler feed, the growing layer of scale not only reduces boiler efficiency, but also tends to contaminate steam generated in the boilers. Such steam can become alkaline and corrosive to aluminium and tin cans. There is also danger of overheating of the boilers.

The life of pipes and fixtures is reduced as they may rust.

These deposits can harbour bacteria and add to the difficulty of equipment cleanup and may affect food products directly.

Calcium ions have firming effect on certain fruits and vegetables, which may be used to advantage under controlled conditions. But in excessive amounts, the calcium from hard water can cause various textural defects.

Advantages of hard water

As mentioned before, calcium ions have firming effect on certain fruits and vegetables.

The dissolved calcium salts in hard water increases the dietary intake of calcium.

Hard water is more suitable in brewing industries, as it produces better beer.

Methods of removing hardness in water

There are various ways to soften water, depending primarily on the nature of hardness.

Boiling: If water is boiled, temporary hardness only is removed. The bicarbonates are broken down into carbonates, water and carbon dioxide.

$$Ca(HCO_3)_2 \rightarrow CaCO_3\downarrow + H_2O + CO_2$$

The equation of magnesium bicarbonate is similar. The carbonates are precipitated and therefore have no action on soap, being out of solution.

Addition of slaked lime (Clark's process): Slaked lime also removes temporary hardness only. The lime must be added in calculated quantities so that it just neutralises the bicarbonate. Insoluble calcium carbonate is formed.

$$Ca(HCO_3)_2 + Ca(OH)_2 \rightarrow 2\ CaCO_3\downarrow + 2\ H_2O$$

Addition of washing soda: The method removes both temporary and permanent hardness. Washing soda (sodium carbonate) reacts with the calcium and magnesium salts in hard water forming soluble sodium salts and insoluble calcium and magnesium salts, which remain as a precipitate. The equations are as follows:

For temporary hardness: $Ca(HCO_3)_2 + Na_2CO_3 \rightarrow CaCO_3\downarrow + 2\ NaHCO_3$

For permanent hardness: $CaSO_4 + Na_2CO_3 \rightarrow CaCO_3\downarrow + Na_2SO_4$

Ion exchange process: This method is used in domestic and industrial installations for removing both types of hardness. It involves the use of natural and synthetic resins such as '***permutit***' and '***zeolite***'. The hard water is passed through a column packed with resin and the calcium and magnesium ions in the water are exchanged for sodium ions in the resin. The resin is regenerated from time to time by flushing the column with a concentrated salt (sodium chloride) solution. This replenishes the sodium ions.

Use of sequestering agents: A sequestering agent such as '***Calgon***' (sodium hexametaphosphate), when added to hard water, encloses the calcium and magnesium ions in stable complexes, which are soluble but do not react with soap. *Calgon* is used extensively for domestic purposes, but has limited industrial use, as it is quite expensive.

15.3.2 Other Impurities

The water may have natural pollutants like suspended impurities (clay, silt, sand and mud), dissolved gases like carbon dioxide and ammonia, dissolved minerals like calcium and magnesium salts, lead and microscopic plants or animals. The artificial pollutants include sewage that contains decomposable organic matter and pathogenic agents, industrial wastes, agricultural pollutants, pesticides, fertilizers and physical pollutants such as radioactive substances. Occasionally, the well waters and municipal waters entering a plant will be contaminated with moderate numbers of proteolytic and lipolytic food spoilage organisms. Thus the water to be used for processing needs a critical analysis and remedial steps as required. The municipal water may have a pH as low as 5 or as high as 8.5. Higher pH corresponds to hard water. In-plant water softening or direct neutralisation rectifies it. Pure water has a pH of 7.

We know that chlorine disinfects water; but shall we like to consume water having a sharp chlorine smell? It implies, even though the water is safe from health point of view, still it may not be acceptable to food processing industries. A sharp detectable taste or odour of chlorine may be due to over-chlorination or due to the presence of traces of phenol in the water. Phenol reacts with chlorine to give a strong medicinal odour. Such type of odour can be removed by filtration of water through a bed of carbon or adsorbent clay. Materials such as hydrogen sulphide or organic impurities, if present in water, react with chlorine and inactivate it before chlorine can exert its germicidal effect. Therefore, the amount of chlorine required to disinfect water is dependent on other substances present in the water.

Decomposition of organic matter in water by non-pathogenic bacteria may produce off-flavours and off-odours. When water contains sulphates and reducing types of bacteria, production of sulphite odours may occur. These types of odours can be removed by filtering water through carbon. But prevention of formation of off-odour needs pipeline sanitation to destroy microorganisms.

Dissolved salts in water may impart some colour to the water. Iron salts, if present in water, can be oxidised to ferric hydroxide, which is red-brown in colour. Manganese hydroxides are gray-black in colour. The ion-exchange treatment removes the dissolved mineral impurities. Activated carbon or clay is used to adsorb the colouring pigments. Treatment with alum (aluminium and potassium sulphates) causes flocculation of suspended materials, which are then removed by filtration and centrifugation.

If the supplied water is not suitable for direct food processing applications due to one or more of the above reasons, they can still be used for other uses as heating canned food in a retort, in pre-chilling operations or as a heat exchange medium in evaporator. After the process water has been used, it can be recycled for cleaning of the processing plant and conveying of fruits and vegetables. However, if this recycled water poses threat to the overall sanitation and safety of food, then it is further purified or discarded depending upon the situation.

15.3.3 Disinfection of Water

Chlorination of water is done to kill or inhibit the growth of microorganisms. In addition, chlorinated water is used in the plant for disinfecting products and machinery. Effective chlorination must take into account the chlorine demand of water before a germicidal effect can be achieved. The **chlorine demand** is equal to the amount of chlorine added minus the amount of residual chlorine remaining at the end of 60 minutes of contact at a given temperature and pH. Therefore, it is the amount of chlorine required to destroy bacteria and oxidise organic matter. The break point is when the chlorine demand of water is met, after which further addition results in the formation of free residual chlorine.

For drinking purposes, the residual chlorine level should be less than 0.4 ppm. For cleaning of working equipment and conveyors water containing about 5 ppm of residual chlorine is used. Water to be used in general food plant cleanup may require a residual chlorine level as high as 25 ppm. This is because much of this chlorine will be used up in satisfying the chlorine demand of soil before it can have disinfecting properties. Chlorine is available in cylinders in the form of gas, which are discharged into the water. It may also be derived from hypochlorite preparations.

Ozone eliminates undesirable odour and taste, has a strong viricidal effect and is a powerful oxidising agent. The advantage is that it has no residual effect. **UV rays** are very effective against most viruses and microorganisms. However, the treatment is very expensive, and colour and turbidity of water reduces its effectiveness.

15.3.4 Water for Canning Industry

Chlorinated water should be used in a cannery to maintain hygienic conditions. As far as possible soft water should be used. The hardness of water, especially the temporary hardness, should be low for obtaining clear syrups (sugar solutions). The degree of hardness is still of greater importance in canning of vegetables, as the presence of lime in the blanching water or brine causes toughening of the skins of products such as peas and beans. The addition of sodium hexametaphosphate or sodium phosphate in desirable quantity overcomes the problems.

15.4 PROPERTIES OF WASTE WATER

The composition and contamination loads of the waste water obtained from a fruit and vegetable processing plant varies greatly as it may contain a wide variety of materials (e.g. pulp and peels, soil, detergents, etc.). The treatment of waste water is necessary for converting it into an acceptable final effluent and also to dispose off the solids removed in the process. The nature of the impurities and extent of pollution decide the suitable treatment methods and the degree of treatment, which will ultimately decide the design of the treatment plant.

15.4.1 Nature of Impurities in Waste Water

The wastewaters can be conveniently categorised according to their physical, chemical and biological natures of impurities.

The **physical characteristics** include appearance and odour. The materials in waste water from a fruit and vegetable processing plant are in solution and suspension, which are mostly organic with some inorganic matters. Water in-soluble liquids such as oils and certain solvents may also be present. The materials which remain as particles in the waste water must be removed before sending it to treatment plants or dumping, and should be treated separately. These materials, if discharged into streams and lakes, cause pollution and impart unaesthetic appearance. After removal of gross particulates, the wastewater may contain colloidal and dissolved impurities beyond the specified upper limit for discharge into streams or acceptable to sewage treatment plants. Therefore, further treatments depending upon the impurities are often required.

Under **chemical classification** of impurities, the colloidal and dissolved impurities in waste waters are divided into organic and inorganic materials. The peels, pulps, etc., which form a major part of the waste, are organic in nature. The ratio of nitrogenous constituents to carbohydrate materials present in the organic materials are very important from sewage treatment point of view. The nitrogen rich wastes accelerate the decomposition process by helping growth and activity of the sewage microorganisms, and hence sewage treatment plants are designed to receive wastes rich in nitrogen. Many vegetable wastes have higher nitrogen:carbohydrate ratio. As the fruit wastes have a high carbohydrate-low nitrogen content, they need supplementation with nitrogenous material before treatment in a sewage plant.

Very high and low pH waste water require neutralisation to bring down the pH to about 6-9 before discharging as it may kill aquatic life and essential microorganisms in sewage treatment plants or natural waters. The synthetic detergents and surface-active materials cause operating problems in sewage treatment plants, which can be easily avoided by using biodegradable detergents. If there is any bad odour from the wastewater, it needs an additional treatment.

The **biological nature** of impurities is very important. As previously discussed, the food plant wastes are generally organic, which are biodegradable. Mostly aerobic organisms are responsible for the degradation. In this process, carbohydrates are transformed into carbon dioxide and water, and nitrogen residues are converted to nitrates. Intermediate products such as alcohols, acids, amines, and ammonia are also produced during the process if the oxidation/ decomposition is incomplete. These intermediates often impart bad odour, and may be toxic to plant and fish life. These intermediates will undergo further degradation in nature.

15.4.2 Biological Oxygen Demand

Oxygen is required in the process of decomposition of organic waste by microorganisms. The amount of oxygen required is directly proportional to the amount of organic pollutants. This amount of oxygen, which is consumed for oxidation of organic contaminants is termed the biological oxygen demand (BOD).

BOD is an important measure of the dissolved organic wastes in water, and is of essential importance for the improvement of sewage and water. The BOD test measures the quantity of oxygen in ppm (parts per million) required by aerobic microorganisms to stabilise waste or polluted water under specific conditions (generally 20°C for 5 days). For example, the BOD of tomato processing wastes and citrus processing wastes vary between 80-4000 and 1000-5000 ppm. The BOD of milk processing waste water varies between 20-650 ppm only. When the BOD of waste discharged into a stream is excessive, there is fast depletion of the stream’s oxygen, which disturbs stream’s ecology, kills aquatic wild life and destroys beneficial microorganisms. The higher the BOD values, costlier will be the treatment before it is discharged into municipal wastes.

Sewage and waste treatment plants can be rated in terms of their BOD-removing capacity. The result of the BOD test determines whether a simple primary sewage treatment plant is sufficient or a complete treatment plant is required. The classification of streams by regulatory agencies is also often based upon BOD standards. Antipollution regulations are written to include maximum permissible BOD loadings into natural waters.

15.4.3 Chemical Oxygen Demand

The chemical oxygen demand (COD) is another useful test, which measures chemically oxidisable material in a liquid sample. This test is based upon the fact that all organic compounds, with a few exceptions can be oxidised quantitatively by strong oxidising agents, such as potassium dichromate, potassium permanganate, etc. under acid conditions. Thus it also measures chemically oxidisable inorganic materials.

15.4.4 Other Chemicals

The food plant wastes may sometimes be contaminated with highly toxic materials such as pesticides and disinfectants. Such toxic substances may kill the plant's normal microbial flora essential to sewage and waste treatment. Under such cases, it is advisable store it separately before discharging it into a convenient location or to dilute the wastes substantially and then send it to the treatment plant in very small quantities at a time.

15.5 WASTE WATER TREATMENT

The extent to which the pollution load must be decreased before waste water leaves a food processing plant is highly variable. It depends on many factors such as whether the waste water will be discharged to a municipal sewage or commercial waste treatment plant, and if so what is the maximum pollution load this plant can treat; what will be the cost for such treatment and can it be done more economically by the food plant itself; what dumping privileges does the food plant have and what pollution laws apply, and so on. The waste water treatments may be classified under the following headings.

15.5.1 Primary Treatments

The primary treatments include screening, filtration, centrifugation and settling or sedimentation. Large solid matters and heavy sediments are removed by screening through vibrating sieves. This is essential to protect and safeguard the subsequent treatment units. Smaller particles may be removed by filtering or centrifuging. Mostly the slow sand or biological filters and rapid sand or mechanical filters are used for the purpose.

Suspended impurities are allowed to settle or rise in large sedimentation tanks and removed. The rate of sedimentation can be enhanced by the use of alum or ammonium sulphite, which produces a sticky flocculant precipitate. Scum or oil is readily skimmed from such tanks, and settled solids are concentrated. These primary treatments may remove some 40% of the wastewater's BOD and about 75% of total solids, depending on the nature of the waste.

15.5.2 Secondary Treatments

The primarily treated sewage in small food processing industries is discharged into municipal treatment plants. But in large plants, some additional treatments similar to those carried out in municipal sewage installations are carried out after the primary treatments. The basic purpose of these treatments is to reduce the BOD level of the wastes. These secondary treatments commonly involve the use of trickling filters, activated sludge tanks, and ponds of various types. Sometimes these are preceded by use of anaerobic digesters.

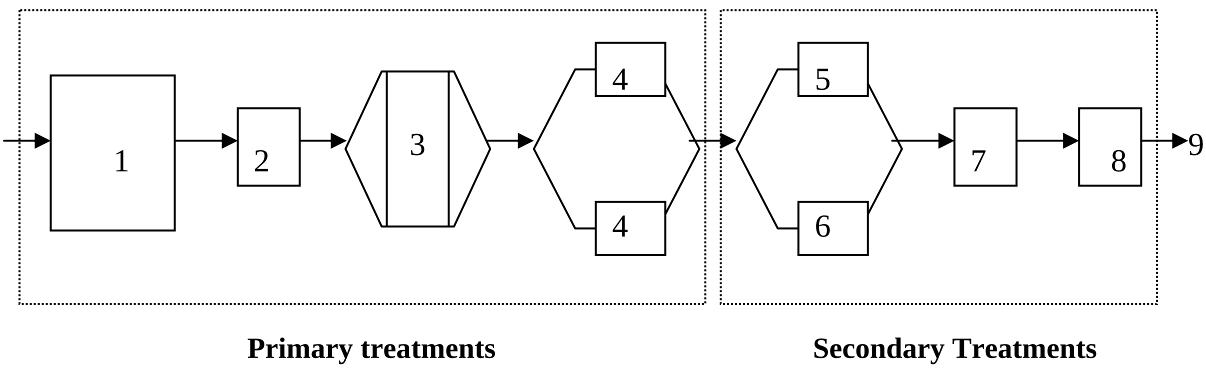

Figure 15.1: Waste water treatments: 1) Screen, 2) Shredder, 3) Grit chamber, 4) Primary sedimentation tank, 5) Trickling filter, 6) Activated sludge tank, 7) Secondary sedimentation tank, 8) Chlorination tank, and 9) final effluent.

15.5.3 Tertiary Treatments

The tertiary treatments or final treatments or advanced treatments applied to potable water for special food processing uses include water softening, ion exchange and carbon filtration. These treatments are also referred to as "polishing treatments". These are generally not needed or used to treat food plant wastewaters.

When a food plant has no means for disposing of treated waste waters, it may choose to discharge these waters into sewer lines for further handling by a municipal plant. The municipal plants usually chlorinate the waste waters before disposal into waterways or irrigation channels.

15.6 WASTE SOLIDS UPGRADING AND TREATMENT

You must have observed how a significant portion of the raw material is wasted during household processing of fruits and vegetables or cooking. Can you guess how much would be the amount of waste materials from a 10 tonne per day capacity fruit processing plant. If these wastes are not utilised properly, it affects the economic success of the industry. These wastes include crown, peel, core, seeds, pomace, trimmings, shells, stalks, etc. Table 15.2 gives an idea of the extent of waste during processing for different fruits and vegetables.

Table 15.2: Extent of wastes during processing for selected fruits and vegetables

Items	Waste as percent original raw material	Items	Waste as percent original raw material
Apples	30-35	Grapes	20-30
Mango	25-35	Peas	20-25
Guava	40-45	Beans	15-20
Pineapple	45-50	Carrots	5-7
Lemon	40-45	Tomato	8-10
Orange	50-55	Misc. vegetables	20-25

Most of the above wastes obtained from a fruit and vegetable processing industry are generally mixed with water. By suitable upgrading and treatment, they can be of several beneficial uses, as mentioned below.

- The by-products can be recovered from the waste water and spread out thinly on agricultural land for grazing of cattle. The unused material may be disposed off by burning.
- If the waste food are collected separately taking care that it does not mix with other refuse like broken glass, polythene pieces etc., they can be boiled, shredded, dried and enriched with minerals and can be used as poultry feed.
- Under favourable economic conditions most wastes can be processed or altered to a more useful and valuable material. Table 15.3 gives some beneficial uses of fruits and vegetables processing by-products. In fact, you will soon discover that no part is a waste during the processing of fruits and vegetables.
- Fruit and vegetable skins, pulp, and pits can be pressed to further remove water and be converted into compost for improving soils. Some wastes are ground into the plough as fill. Vermicomposting is one novel way for getting bio-fertiliser from bio-degradable wastes with the activities of earthworms.
- Sludge and residues remaining after waste water and sewage treatment have been dried and sold as fertilizer or used wet for this purpose. Sometimes they are incinerated, leaving only a small amount of ash, which can be disposed conveniently.
- Fruit and vegetable wastes are also used as a source of fermentable carbohydrate.
- All kinds of glass, solids, polythene, paper and metal can be recycled. Each of these materials should be collected separately for recycling.
- When none of these uses are feasible, then waste may be burned as garbage where law permits.

Table 15.3: Beneficial uses of fruits and vegetable wastes

Fruit	Nature of waste	Uses
Mango	peels, stones, pulping waste	starch, fat, pectin, vinegar, syrup, alcoholic beverage
Pineapple	peels, cores, trimmings	vinegar, syrup, citric acid, candied cores
Grapes	stem, seeds, seed hulls	cream of tartar, seed oil, tannin, vinegar, pectins, wines, stock seed
Apple	pomace, Cores cull	Pectin, cider, vinegar, soft drink, jelly base, Ingredient in cattle feed
Citrus	peels, pomace, seeds	pectin, essential oil and seed oil
Peaches, apricots and cherries	piths, kernels	oil, stock feed
Tomato	seeds, peels, and cores	animal feed, fertiliser, resin from peels, oil from seeds for soap making and edible use, peels

15.7 LOWERING DISCHARGE VOLUMES

Even though there are several ways to treat waste water, but you will agree that for minimising costs involved with waste water treatment and reducing the size of treatment plant, it is better to try to lower the discharge volume. The first step in lowering the discharge volume from a food plant is to reduce the amount of water used in the plant, which can be achieved by some modification in processing methods. Other means are recycling of the used water or treated waste water for some other non-priority areas.

15.7.1 Waste Water Treatment

For very large quantities of waste disposal, land treatment is the cheapest and best. The recovery of by-products from the wastes not only offers good economy, but also reduces pollution. However, these practices are viable only for big processing plants.

It is better to separate the solid wastes from the liquid. The coarse particulates and fine solids can be separated with different types of screens and settling tanks, as discussed in the previous section. The clear and problem free effluent can be drained.

Instead of segregating the different waste streams from a particular plant, the concentrated and high BOD wastes need to be handled separately. Thus large volumes of dilute waste water can be saved from high contamination. Some pre-processing ingredients are available which can reduce waste loads needing treatment.

15.7.2 Recycling and Modified Processing Methods

There are many modified processing operations, which can give lesser volumes of waste water as compared to conventional processing methods.

Reuse of water for less demanding operations is the most suitable one. The water obtained from heat exchangers or the boiler feed can be used for cleaning and conveying of fruits and vegetables. This decreases waste load to a considerable extent.

Recovery of salt by evaporation of the brine and crystallisation is possible. In addition to a potential saving in salt costs, it also avoids pollution that might have been caused due to discharge of the brine. However, the crystallised salt slurry may contain some organic matter, which has to be separated before the salt can be reused. This is done by incineration of the slurry, which leaves a trace of carbon. The salt can be reused after certain modifications such as adjusting the pH, and filtering to remove the carbon. Such processes, however, must also be considered in terms of benefit-cost ratio.

Loosening the skins of fruits and vegetables for peeling is usually done in dilute caustic solution. This method consumes a lot of water, which is ultimately wasted after peeling. Instead, we can achieve a considerable saving in water by peeling using concentrated sodium hydroxide (NaOH) solution combined with vigorous mechanical action. The BOD of the wastewater per weight of raw material obtained by this 'dry caustic method' is only about one-third that generated by the dilute caustic solution.

Similarly, steam blanching of vegetables saves considerable water from being polluted as compared to conventional hot water blanching. Further, as less amount of solids are dissolved in the blanching medium, the effluent has low BOD level. It is also reported to give better texture of the vegetables after freezing, thawing, and cooking as compared to the hot water blanching method.

Check Your Progress Exercise 2

Note: a) Compare your answers with those given at the end of the unit.

1. State True / False:

   a) The primary treatment of wastewater involves the use of activated sludge tanks.

   b) The secondary treatments of wastewater are also known as "Polishing treatment".

   c) In small food processing plants the secondary treatment of wastewater is not carried out.

   d) The amount of wastes from mango fruits is in the range of 5-10 percent of the raw material.

   e) Recycling of water in food processing plant reduces considerable wastewater.

15.8 PLANT SANITATION AND EFFLUENT TREATMENT AS A CONTINUOUS RESPONSIBILITY

The ever increasing population, increase in number of industries and vehicles, migration of the people from rural areas to cities and towns, and several other factors have added to the amount of wastes. Now there is more concentration of people in areas of processing than the areas of production. This has added to a growing problem of waste disposal, which has always meant expense to food processors. In particular, in fruit and vegetable processing industry huge amount of waste and effluents are released. Most often the wastes are more than the preserved edible materials. It must be disposed off regularly and efficiently to prevent contamination of any food product. In addition, it is very important to prevent pollution of atmosphere and water supplies by proper disposal of the waste and effluents from such plants.

The wastes obtained from a fruit and vegetable processing plant are mostly organic and biodegradable. Large quantities of inorganic impurities from fruit / vegetable washing process may also be obtained. Small doses of pesticide residues, nitrates and nitrites formed out of residual protein and ammonical compounds during processing may also occur. All of these, if disposed as such to the surrounding, will pollute the surface and ground waters used for drinking purposes. This will ultimately add to the ever-growing problems of the human being. Therefore, every necessary step should be taken for effluent treatment of a food processing plant to protect the environment. All of these are moral obligations also.

The major source of air pollution in a fruit and vegetable processing industry is fuel burning in boiler for steam raising and heating which mainly emits smoke/ particles/dust, sulphur oxides and oxides of nitrogen. The intensity of emission varies with the type of fuel and boiler used, and the boiler-firing practice adopted. Minor discharge of benzpyrenes and trace metals contained in coal may also be present. Provision of inadequate smoke stack (lower height) and / or existence of unfavourable meteorological conditions may result in increased ground level concentration of pollutions which can result in discomfort and respiratory complaints initially and impairment of lung functions in the long run.

Therefore, it is our responsibility to take a holistic approach of production and processing as well as for the minimisation of wastes disposed from a food plant. Besides, if a food plant pollutes the surrounding atmosphere, it ultimately earns bad reputation and looses customers.

15.9 WASTE / EFFLUENT DISPOSAL REGULATIONS

Setting of the project has a very important role to play in the control of pollution. While deciding the location of the project, the weightage has to be given to the availability of power and water. It is also necessary to know in advance whether no objection certificate from the pollution control angle would be admissible for the proposed industry.

There are several pollution control acts to protect and improve the natural environment including forests, lakes, rivers and wild life and have compassion for leaving creatures. The Pollution Control Law Series: PCLS/02/1992 has the details of these regulations. It also contains standards notified with respect to the important pollutants as well as rules governing hazardous wastes, hazardous chemicals, etc. notified under Environment (Protection) Act, 1986. The Environment Ministry / Department and the State Pollution Control Boards are responsible for giving clearance on these aspects to any industry.

The Act specifies the wastewater discharge standards for any food and fruit processing industry, as given in Table 15.4. Table 15.5 gives the specified emission levels from boilers as covered under the Act.

Table 15.4: Wastewater discharge standards for food and fruit processing industry

Category	Concentration not to exceed				Quantum
	pH	Suspended solids (mg/l)	Oil and grease (mg/l)	BOD at 27°C for 3 days (mg/l)	g/tonne of product
a) Above 0.4 tonnes/day	6.5-8.5	50	10	30	-
b) 0.1-0.4 tonne/day	6.5-8.5	-	-	300	-

Table 15.5: Limits of emission from boiler houses

Capacity of Boilers	Particulate matters emission (mg/Nm³)
Less than 2 ton/h	1200*
2 to less than 10 ton/h	800*
10 to less than 15 tons/h	600*
15 tons/hr and above	150**

(* To meet the respective standards, cyclone / multicycle is recommended as control equipment with the boiler. ** Bag filter/ESP is recommended as control equipment. In the above table, 12% of carbon dioxide correction shall be the reference value for particulate matter emission standards for all categories of boilers.)

There are several other schedules in the Pollution Control Act dealing with discharge of effluents, ambient air quality standards, standards for control of noise pollution, etc. The Bureau of Indian Standards (BIS) has also specified regulations for manner, condition and fees for grant and renewal license for environmental management system.

The Factory Act, 1948 has several clauses relating to health measures and waste disposal aspects in any type of factory. Under the Act, the occupier is required to keep the factory premises clean and free from waste and effluvia. He shall make arrangements for sweeping and removing dirt and refuse daily, cleaning with disinfectant, painting the walls, doors and windows at specified time intervals. Effective arrangement shall be made for treatment of wastes and effluents due to the manufacturing process carried on therein, so as to render them innocuous and for their disposal.
If any process or machine gives off dust/fumes or other impurity which are likely to be injurious or offensive to the workers, effective measures should be taken to prevent its inhalation and accumulation in any workroom. The exhaust appliance, if used, shall be applied as near as possible to the point of origin of the dust, fume or other impurity. Besides, such points shall be enclosed as far as possible. The factory premises should be adequately ventilated by circulation of fresh air and comfortable temperature should be maintained in every workroom.

15.10 ENVIRONMENT IMPACT

Now-a-days we have become very conscious of the environmental pollution and degradation aspects at all levels. Therefore possible environmental impacts are taken into serious consideration before and after setting up an industry in a particular location. For example, the discharge of solid and liquid wastes, smoke and polluted air will change the physical and chemical characteristics of surrounding environment and water body. Sometimes, it has so happened that due to deposition of solids and/or discharge of harmful chemicals, streams have become unfit for drinking water purpose, or even for bathing. Similarly you must have observed how the surroundings near a thermal power plant or stone crushers are heavily polluted, which affect the normal life of the people. Hence, preparation of environmental management plan is required for formulation, implementation and monitoring of environment protection measures during and after commissioning of the projects.

The environmental impact not only considers the changes in air or water qualities in the area, but it also considers the biological, cultural and socio-economic components of the environment. It is essential to assess these environmental impacts and the tool used for the purpose is known as **Environmental Impact Assessment** (EIA).

In recognition of the role that EIA could play, Ministry of Environment and Forests, has published a list of 29 industries, which are required to obtain environmental clearance from competent authority in addition to a NOC from Pollution Control Board. Even though, the food and fruit processing industry, at present, is not included in the list, still the environmental impact for such industry can not be ignored.

Environmental impact has a very wide scope in the formulation of a project. Even for site selection, the environmental attributes such as topography, geology, water resources (quantity and quality), soil characteristics, land productivity, flora and fauna, socio-economic conditions are considered. The proximity to water resources, raw materials, markets, availability of land and human resources etc. are other project attributes. An environmental management plan is formulated to ensure that the resources are used with maximum efficiency, waste generation is minimised, residuals are treated adequately and products are recovered and recycled to the maximum possible extent.

EIA consists of establishing quantitative values for selected parameters, which indicate the quality of the environment before, during and after the proposed development activity. EIA involves three steps, viz. identification, prediction and evaluation of impacts. First the environmental parameters to be investigated for possible impacts are listed. Then with the help of suitable models real impacts for proposed development are assessed. Though fairly good models are available for prediction with respect to air and water components, predictions of biological, socio-economic and cultural impacts are often subject to uncertainty. The degree of uncertainty could however be ascertained mathematically or indicated in qualitative terms while presenting prediction results. The evaluation step calls for conversion of predicted values for various environmental parameters to a comparable set of units using some system of normalisation. At present many consultancy firms are also doing EIA studies, which can be hired for the purpose.

Check Your Progress Exercise 3

1. Fill in the blanks:

   a) The major source of air pollution in a fruits and vegetables processing industry is _________________.

   b) The extended form of EIA is _________________________________.

15.11 LET US SUM UP

In this unit we studied about the importance of plant sanitation for a fruits and vegetables processing plant and we observed that sanitation is very important for the safety of food and overall performance of the industry. We discussed about the different properties of process water and steps for removal of hardness and disinfection of water so as to make it fit to be used as process water. We also discussed about the methods for waste water treatment and water solids upgrading and treatment. The different methods for lowering discharge volumes such as waste water treatment and recycling and modified processing methods are also covered in the unit. Thus we are now familiar with the general sanitation and waste disposal aspects of a fruits and vegetables processing plant.

15.12 KEY WORDS

Carbonate hardness : Hardness due to presence of calcium and magnesium bicarbonates; also known as temporary hardness.

Non-carbonate Hardness : Hardness due to the presence of calcium and magnesium sulphates, chlorides and nitrates; also known as permanent hardness.

Chlorine demand : It is the amount of chlorine required to destroy bacteria and oxidise organic matter.

BOD : The amount of oxygen consumed for oxidation of organic contaminants in water.

15.13 SELF TEST FOR THE COMPLETE UNIT/ ASSIGNMENT

1. Explain the different methods for disinfection of water?
2. Explain the importance of waste solids upgrading and treatment?
3. Explain the requirement of process water?

15.14 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Hard water creates a problem in cleaning operations. Hardness causes scale on equipment, which reduces heat transfer and contaminates steam produced in boilers. The life of pipes and fixtures is reduced as they may rust. The scales house bacteria and affect food products directly. Calcium present in hard water in excess amounts can cause various textural defects.

2. The methods for removal of hardness of water are boiling, addition of slaked lime, addition of washing soda, ion exchange process, and use of sequestering agents.

3. Chlorine, Ozone, UV rays

4. There will be fast depletion of the stream's oxygen, which disturbs stream's ecology, kills aquatic life, and beneficial micro-organisms for sewage conversion.

EXPERIMENT 1 PREPARATION OF FRUIT BEVERAGES – SQUASH, CORDIAL, RTS BEVERAGE, FRUIT NECTAR AND SHARBETS

Structure

1.1 INTRODUCTION

Tropical countries, like India, have a vast scope of providing delicious cold drinks during hot summer particularly the fruit beverages. Due to increased consumer awareness with respect of quality, safety and health, these fruit beverages are becoming more and more popular and are gradually acquiring a chunk of the market share of cold drinks.

Fruit beverages are easily digestible, highly refreshing, thirst quenching, appetizing and nutritionally far more superior to the synthetic aerated drinks. Fruit beverages can be classified as fermented and unfermented. In this practical, however, we will only deal with unfermented beverages which do not undergo any alcoholic fermentation.

Objectives

After going through this experiment, you should be able to:

- describe methods of preparation and preservation of unfermented fruit beverages; and
- know the difficulties, precautions to be taken and technical know-how of the final product quality.

1.2 EXPERIMENT

1.2.1 Principle

Fruit beverages are prepared from fruit juices or pulp and preserved by chemical preservatives or by heat application.

1.2.2 Requirements

Raw materials, equipment and apparatus

1. Fruit/vegetable, sugar
2. Peeler
3. Juicer
4. Pulper
5. Filter cloth / sieve
6. Pans of suitable size
7. Heaters
8. Thermometer
9. Crown corking / capping machine
10. Corks / caps
11. Sterilizer/Pasteurizer
12. Volumetric flask
13. Measuring cylinder
14. Weighing balance
15. Potable water

Chemicals and reagents

1. Hydrochloric acid
2. Citric acid / ascorbic acid
3. Potassium metabisulphite
4. Sodium benzoate

1.2.3 Procedure

General method for preparation of fruit juice

The general process for the preparation and preservation of unfermented fruit beverages is as follows:

- Select only fully ripe and quality fruits. Care should be taken not to include either over ripe or under ripe fruits as it affects the final product quality.
- Sort and reject/trim diseased, damaged or decayed fruits. Wash them properly with water or dilute hydrochloric acid (1 part acid: 20 parts water) to remove dirt and spray residues of arsenic, lead, etc.
- Extract juice from fresh fruits by crushing and pressing them by using suitable juice extractors, basket presses or fruit pulpers. Fruits, which require preheating, should be preheated before extraction.
- Strain and filter the juice to remove suspended matter consisting of broken fruit tissue, seed, skin, etc. Clarify the juice if required using a suitable method.
- Fortify the juices with vitamins to enhance their nutritive value, to improve taste, texture or colour and to replace nutrients lost in processing, if required.
- The preservation could be by physical methods (pasteurization, sterilization, etc.) or by chemical preservatives.
- Wash bottles thoroughly with hot water and fill them leaving 1.5-2.5 cm headspace. Seal with crown corks (by a crown corking machine) or with caps (by capping machine).

a) Squash

Squash should contain at least 25% fruit juice or pulp and 40 to 50% total soluble solids commercially. About 1% citric acid and 350 ppm Sulphur dioxide or 600 ppm sodium benzoate are added as preservatives.

Method of preparation

For the preparation of 10 litres of squash follow the procedure given below:

- Calculate the amount of juice required as per commercial specification

  Required juice = (25/100) × 10 = 2.5 lts.

- Measure the TSS using a refractometer (say the TSS is 30%)

  Calculate the total solids content of the juice i.e. 0.3 X 2.5 = 0.75 kg

- The final required TSS content in the product is to be say 50%. The TSS required to be added to obtain the final product is (0.5 × 10 – 0.75) kg = 4.25 kg

- The amount of soluble solids in the form of citric acid and KMS is

  Citric acid @ 1%, in the final produce is 100 g i.e. 0.1 kg.

  600 ppm SO_2 (1.5g/litre of KMS being equivalent to 1000 ppm) @ 0.9g KMS/litre. i.e. 0.9 x 10 = 9 g i.e 0.009 kg.

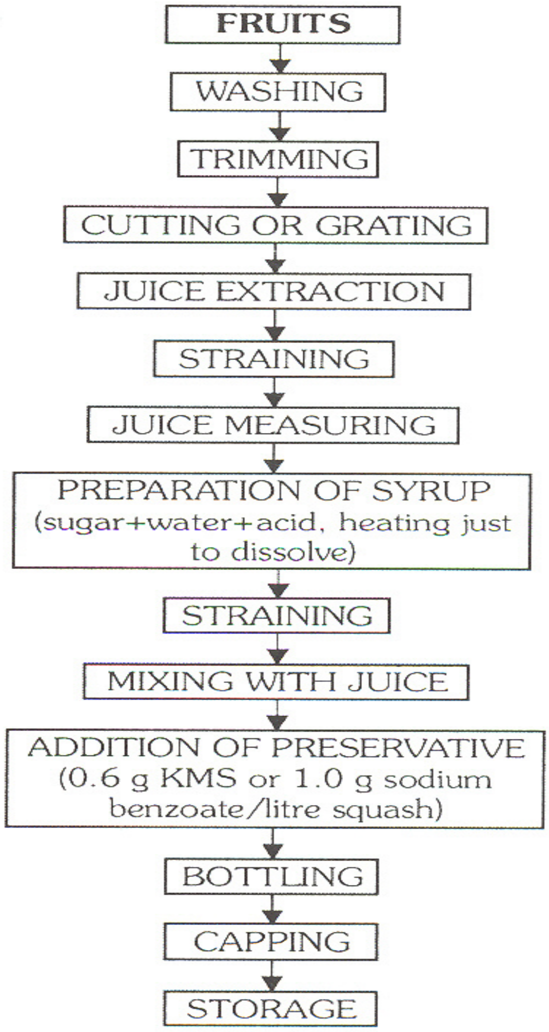
- Amount of solids to be added in the form of sugar is 4.25–(0.1+0.009)= 4.141 kg.

- Ingredients

	Juice	-	2.5 kg	
	Sugar	-	4.141 kg	4.25 Kg
	Citric acid	-	100 g	
	KMS	-	9 g	
	Water	-	(10-2.5+4.25) = 3.25 Lts	

- As prescribe dissolve sugar in water, add citric acid and give a boil, strain through a fine muslin cloth. Cool the syrup completely. Mix the fruit juice with syrup. Add colour as required and then essence. Grind the preservative in a saucer with a spoon. Add little water. Pour into squash. Add more juice and transfer all the preservative to the squash.

Flow sheet



b) RTS Beverage

This is a type of fruit beverage containing at least 10% fruit juice and 10% total soluble solids besides about 0.3% acid. It is not diluted before serving and, hence, is known as ready-to-serve (RTS) beverage.

Method of preparation

For the preparation of 10 lts. of RTS beverage, follow the procedure given below:

- Calculate the amount of juice required as per commercial specification

  Required juice = (10/100) × 10 = 1.0 lts.

- Measure the TSS using a refractometer (say the TSS is 30%)

  Calculate the total solids content of the juice i.e. 0.3 × 1.0 = 0.30 kg

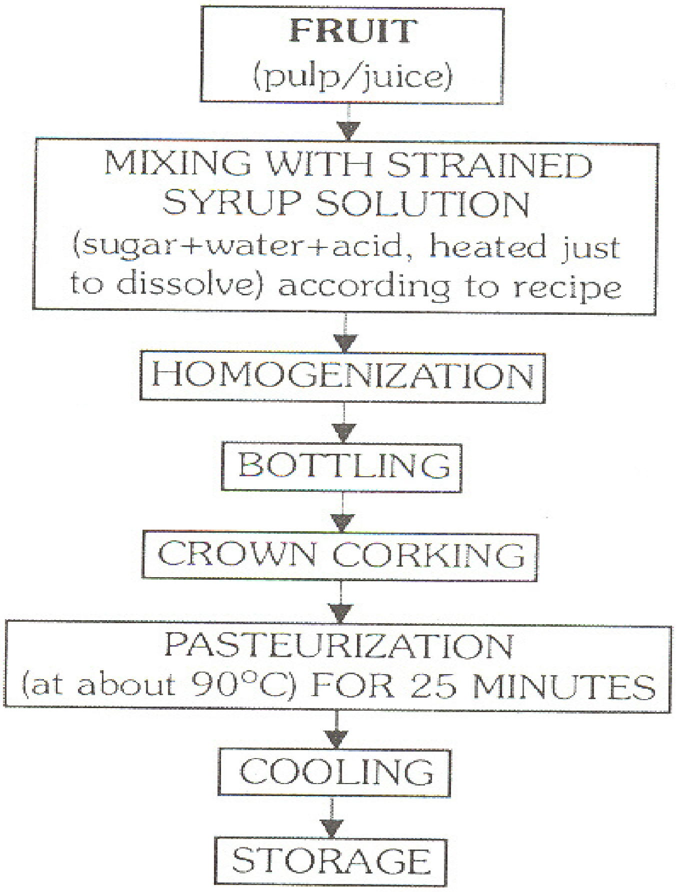
- The final required TSS content in the product is to be say 10%. The TSS required to be added to obtain the final product is (0.1×10–0.30)kg = 0.70 kg

- The amount of soluble solids in the form of citric acid and KMS is

  Citric acid @ 0.3%, in the final produce is 30 g i.e. 0.03 kg.

- Amount of solids to be added in the form of sugar is 0.70–0.03=0.67kg.
- Add calculated amount of sugar to about 2 lts of water and heat it till it dissolves completely. Add citric acid and juice to the sugar syrup and makeup the volume to 10 lts. Mix it well.
- Heat up to 90°C, fill hot in clean pre-sterilized glass bottles up to brim, seal and cool in the air or fill in bottle, seal and heat process (90°C for 25 min.).

Flow sheet



c) Fruit Nectar

This is a type of fruit beverage containing at least 20% fruit juice/pulp and 15% total soluble solids besides about 0.3% acid. It is also not diluted before serving.

Method of preparation

For the preparation of 10 lts. of fruit nectar, follow the procedure given below:

- Calculate the amount of juice required as per commercial specification

  Required juice = (20/100) × 10 = 2.0 lts.

- Measure the TSS using a refractometer (say the TSS is 30%)

  Calculate the total solids content of the juice i.e. 0.3 × 2.0 = 0.60 kg.

- The final required TSS content in the product is to be say 15%. The TSS required to be added to obtain the final product is $(0.15 \times 10 - 0.60)$ kg = 0.90 kg.
- The amount of soluble solids in the form of citric acid and KMS is

  Citric acid @ 0.3%, in the final produce is 30 g i.e. 0.03 kg.

- Amount of solids to be added in the form of sugar is 0.90–0.03=0.87kg.
- Add calculated amount of sugar to about 2 lts of water and heat it till it dissolves completely. Add citric acid and juice to the sugar syrup and makeup the volume to 10 lts. Mix it well.
- Heat the RTSB / Nectar up to 90°C, fill hot in clean pre-sterilized glass bottle up to brim, seal and cool in the air or Fill in bottle, seal and heat process (90°C for 25 min.).

d) Cordial (Lime)

- Extract the juice and strain through a fine muslin cloth to remove all pulp
- Add preservative (KMS) 2 gms per litre of lime juice
- Pour in bottles and keep for 1-2 months. All the sediment settle down and the juice becomes clear
- Pour all clear juice without disturbing the sediment. Use the recipe and proceed as for squash.

Flow sheet

Same as RTS Beverage

e) Sharbet

Sharbet should contain at least 65% total soluble solids, suitably acidified and may or may not contain fruit juice.

Method of preparation

For the preparation of 10 lts. of sharbet follow the procedure given below:

- Take about 6 lts. of water and add approx. 6.5 kg of sugar and dissolve it properly.
- Add the required flavour.
- Make up the volume to 10 lts. and adjust the TSS to 65%.

1.2.4 Observations

Determine TSS and acidity.

Note: The procedure for the calculation of TSS and acidity can be seen in the practical manual of BPVI-007 Course VII ‘Food Quality Testing and Evaluation’ and BPVI-003 Course III ‘Food Chemistry and Physiology’.

1.2.5 Result

Acidity of the given squash, cordial, nectar, RTS beverage = % (w/v)

TSS of the given squash, cordial, nectar, RTS beverage = %

1.3 PRECAUTIONS

- All equipment used in the preparation of fruit juices and beverages should be rust and acid proof.
- Copper and iron vessels should be strictly avoided as these metals react with fruit acids, and cause blackening of the product.
- Avoid exposure of juice to atmosphere as it will spoil the colour, taste and aroma and also reduce the Vitamin content.

EXPERIMENT 2 PRODUCTION OF FRUIT JAM, JELLY, MARMALADE, FRUIT BUTTERS, CONFECTIONARY AND CHEESE, PRESERVE AND CANDIES

Structure

2.1 INTRODUCTION

Jam, jellies and preserves etc., are very common products made out of fruits and vegetables that permit consumers to taste the fruits of their liking even during lean periods or when the fresh produce is expensive. These products also permit the diversification of the fruit use to avoid distress sale during the production season and to minimize the post harvest wastages. These practices of preparing the processed products are simple and could be attempted at household levels even in rural settings if adequate food safety related precautions are put in place. Besides, there are several fruits that are not cultivated in large quantities to permit large scale processing. Still these fruits are novel enough to convert them into the processed products and present them to consumers as niche products.

Objectives

After going through this experiment, you should be able to:

- describe methods of preparation and preservation of jam, jelly and preserve etc.; and
- know the difficulties, precautions to be taken and technical know-how of the final product quality.

2.2 EXPERIMENT

2.2.1 Principle

Jam, Jelly and Preserve are prepared from fruit pieces or pulp and preserved by high sugar concentration/chemical preservative or by heat application.

2.2.2 Requirements

Raw materials, equipment and apparatus

1. Fruit/vegetable, sugar
2. Peeler
3. Pulper
4. Filter cloth / sieve
5. Pans of suitable size
6. Heaters
7. Thermometer
8. Crown corking / capping machine
9. Corks / caps
10. Sterilizer/Pasteurizer
11. Volumetric flask
12. Measuring cylinder
13. Weighing balance
14. Potable water

Chemicals and reagents

1. Hydrochloric acid
2. Citric acid / ascorbic acid
3. Potassium metabisulphite
4. Sodium benzoate

2.2.3 Procedure

a) Jam

- Jam is a product made by boiling fruit pulp with sufficient sugar to a reasonably thick consistency, firm enough to hold the fruit tissues in position. Apple, pear, sapota, apricot, loquat, peach, papaya, karonda, carrot, plum, strawberry, raspberry, mango, tomato, grapes and muskmelon are used for preparation of jams.

- It can be prepared from one kind of fruit or from multiple kinds. Commercial jams such as tutti-frutti can be prepared from pieces of fruit, fruit scraping and pulp adhering to cores of fruits, which are available in plenty in canning factories.

- Jam contains 0.5 - 0.6% acid and invert sugar should not be more than 40%.

Method of preparation

For the preparation of 10 kg of jam follow the procedure given below:

- Calculate the amount of fruit pulp required as per commercial specification

  Required pulp = $(45/100) \times 10 = 4.5$ kg.

- Measure the TSS using a refractometer (say the TSS is 50%)

  Calculate the total solids content of the juice i.e. $0.5 \times 4.5 = 2.25$ kg.

- The final required TSS content in the product is to be say 68%. The TSS required to be added to obtain the final product is $(0.68 \times 10 - 2.25)$ kg = 4.55 kg.

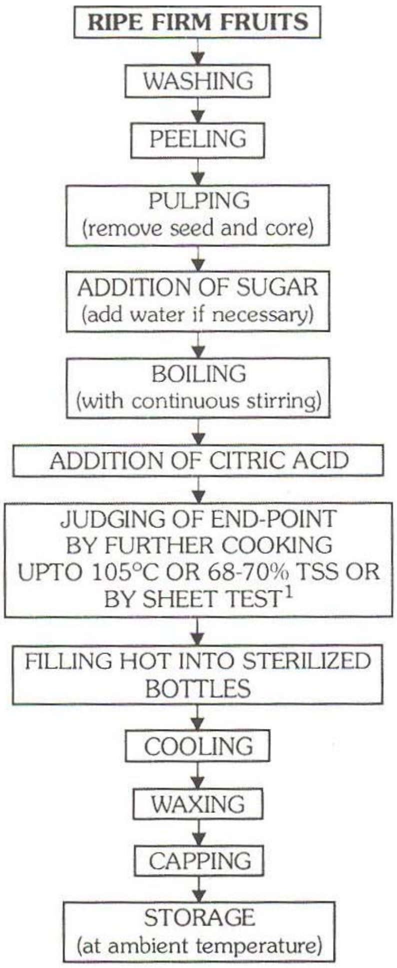
- The amount of soluble solids in the form of citric acid and KMS is

Citric acid @ 0.5%, in the final produce is 50 g i.e. 0.05 kg.

- Amount of solids to be added in the form of sugar is 4.55–0.05=4.5 kg.

- Add the calculated amount pulp and sugar to about 2 lts of water and boil it to 105°C so that the sugar dissolves completely. Add citric acid and juice to the sugar syrup and judge the end point by measuring its TSS or using sheet test.

Flow sheet



1. **Sheet or flake test:** A small portion of jam is taken out during boiling, in a spoon or wooden ladle and cooled slightly. It is then allowed to drop. If the product falls off in the form of a sheet or flakes instead of flowing in a continuous stream or syrup, it means that the end-point has been reached and the product is ready, otherwise, boiling is continued till the sheet test is positive.

b) Jelly

- A jelly is a semi-solid product prepared by boiling a clear, strained solution of pectin-containing fruit extract, free from pulp, after the addition of sugar and acid.

- A perfect jelly should be transparent, well-set, but not too stiff, and should have the original flavour of the fruit. It should be of attractive colour and keep its shape when removed from the mould. It should be firm enough to retain a sharp edge but tender enough to quiver when pressed.

- It should not be gummy, sticky or syrupy or have crystallized sugar. The product should be free from dullness, with little or no syneresis (weeping), and neither tough nor rubbery.

- Guava, sour apple, plum, karonda, wood apple, loquat, papaya, and gooseberry are generally used for preparation of jelly. Apricot, pineapple, strawberry, raspberry, etc., can be used but only after addition of pectin powder, because these fruits have low pectin content. Its acid content should be 0.5-0.75%.

Method of preparation

For the preparation of 10 kg of jelly follow the procedure given below:

- Take about 10 kg of fruit and boil in 15 lts of water for 20 – 30 min.

- Add to it about 20 g (@ 2g/kg) of citric acid and strain it.

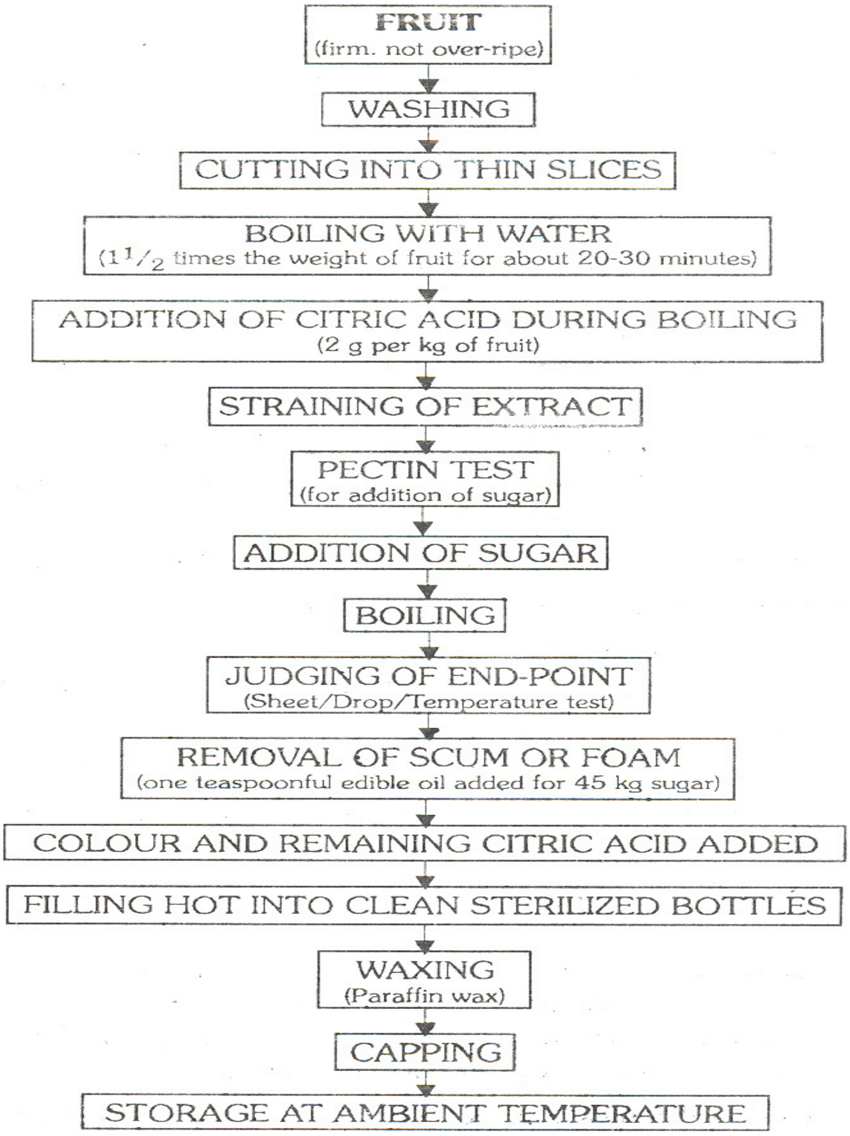
- Determine the pectin content using alcohol or Jelmeter test.

- Add the required amount of sugar (1:1 for extracts rich in pectin; 1:0.75 for extract moderate in pectin; and 1:0.5 for extract poor in pectin.

- Boil the mixture judge the end point using sheet test as mentioned in the preparation of jam.

- Add the calculated amount pulp and sugar to about 2 lts of water and boil it to 105°C so that the sugar dissolves completely. Add citric acid and juice to the sugar syrup and judge the end point by measuring its TSS or using sheet test.

Flow sheet



c) Preserve and its Method of Preparation

- A mature fruit/vegetable or its pieces impregnated with heavy sugar syrup till it becomes tender and transparent is known as a preserve.
- Aonla, bael, apple, pear, mango, cherry, karonda, strawberry, pineapple, papaya, etc., can be used for making preserves.
- It can be prepared using 1 kg of fruit, 1 litre of water and 1 kg of sugar. A. little quantity of acid (citric or tartaric) is added during the preparation to prevent crystallization of the syrup.

Method of preparation

The following steps are required in a good preserve:-

1. Pre-treatment
2. Leaching
3. Pricking
4. Penetration of Sugar
5. Finishing

1. Pre-treatment

After selecting good fruit, it is washed and given pretreatment for the following functions

a) To reduce bitterness
b) Softening and Maturity
c) Hardening the tissues
d) Storing for long period
e) Reducing the shrinkage of fruit

2. Leaching

Leaching is carried out in the following functions:

a) To remove salty taste from fruit
b) To soften the fruit so that penetration is quick
c) To remove bitterness in intercellular space

3. Pricking

a) Pricking is carried out for facilitating of the penetration of sugar.
b) This is usually done by piercing fork needles or stamp having painted nails or needle.

4. Penetration of Sugar

This is done to achieve the following:

a) Uniform penetration
b) Retention of natural colour and flavour
c) Retention of nutrition
d) Method should be quick

5. Finishing

Generally preserve is packed along with syrup covering 45% portion in the container.

For the preparation of 10 kg of jelly follow the procedure given below:

- Take about 10 kg of fruit and prepare it for sugar treatment as mentioned in the table in the following section.
- Make 10 lts of sugar solution of 40% TSS (Dissolve 4 kg of sugar in about 5 lts of water and make up the volume to 10 lts.).
- Dip the fruit in the sugar syrup for 24 hrs. Remove the fruit and boil the sugar solution to increase its consistency to 60%. Again steep the fruits in it for 24 hrs.
- Repeat the process on alternate days raising the TSS % of the sugar solution by 5% up to 70%. Steep the fruits in 70% TSS sugar solution for a week and the preserve is ready.
- The preserve should be stored in air tight jars with adequate sugar solution of 68% TSS to cover the fruits.

Preparation of fruits and vegetables for preparing preserve

Fruit/ vegetable	Steps of Process			
	Step I	Step II	Step III	Step IV
1	2	3	4	5
Aonla	Prick with fork, needle or gooseberry pricker (avoid iron needle as it causes browning due to tannin in fruit)	Steep in 2% salt solution for 24 hours to remove astringency	Wash and dip in 2% alum solution for 24 hours then wash thoroughly	Blanch until soft but segments do not break or crack
Apple and pear	Peel, prick with needle or fork (do not remove core and stem of whole fruit to be used otherwise peel and cut into halves or quarters, remove core and prick)	Steep in 2% salt solution for 24 hours to prevent browning and disintegration of fruit tissues during blanching	Wash and dip in 2% alum solution for 24 hours and wash again	Blanch in water containing small quantity of potassium metabisulphite to bleach or in water containing edible deep green or red colour
Bael	Remove shell, slice peeled fruit crosswise into 2.5 cm thick pieces and wash with water, prick on both sides	Steep in cold water for 24 hours	-	Blanch in water containing edible red colour until soft and sufficient colour absorbed
Ber	Prick whole fruit	Steep in 2% salt solution containing 0.2% potassium metabisulphite for a week and wash thoroughly	-	Blanch until soft
Mango	Peel and remove green portion (because it turns black during subsequent operations), cut fruit lengthwise into large pieces	-	-	Blanch until soft and then prick pieces
Karonda and Cherry	Cut into two pieces and remove seeds	Steep in 2% salt solution containing 600 ppm sulphur dioxide (in orm of potassium metabisulphite) for 24 ours to bleach, thereafter wash and prick with fork	-	Blanch in water containing 0.05% erythrosine and 0.25% citric acid to soften sufficiently and fix the artificial colour

Pineapple	Peel, cut into 1cm slices, remove core and eyes, prick slices on both sides	Steep in 2% salt solution for 24 hours	Wash and steep in cold water for 12 hours	Blanch until soft
Papaya	Peel, cut into rectangular pieces 4 cm long and 0.5-1.0 cm thick, remove seeds and prick	Steep in 2% salt solution for 24 hours	Wash thoroughly	Blanch until soft
Strawberry and Raspberry	Remove stems	-	-	Blanch for a minute
Petha (Ash gourd)	Cut lengthwise into large pieces, remove fluffy portion, peel, prick and cut into pieces of suitable size	Soak in dilute lime water for 24 hours to harden texture	Wash and soak in 2% alum solution for 24 hours and a wash again	Blanch (until tender) in water containing little potassium metabisulphite to bleach
Ginger	Scrape off skin from tender, fibreless, large sized rhizomes, and cut into pieces	-	-	Boil for an hour with 0.5% citric acid solution (to improve colour) in pressure cooker, then prick and wash
Carrot	From tender carrot having soft pith, scrape off thin peel and green leafy portion, prick and cut into suitable sized pieces	-	-	Blanch until soft
Citrus peel	Remove the rags from thick rind orange, citron, pummelo, etc.	Dip in 2% hot sodium bicarbonate solution for 30 minutes, then wash and prick	-	Blanch until tender and to remove bitterness

CANDIES – Glaced and Crystallized

Principles

Candy is fruit penetrated with sugar and dried to give a sugar coated solid fruit pieces. The glaced candy are coated with a thin transparent layer of heavy sugar syrup, while crystallized candy are derived from coating pure white crystallized sugar. In preparing candies all steps are same as that up preserve except that of finishing.

Fruit butters

This product is prepared by boiling the fruit pulp with or without the addition of sugar, fruit juices and spices to a semi-solid mass of homogeneous consistency. It differs from jam in being of higher concentration and finer consistency. It is usually heavily spiced. The appearance and texture look like butter. They are packed in can and sterilized in boiling water.

Fruit confections

This is a general term used to describe candies in which fruits are used. They are on the market a large number of products of the character which vary greatly in appearance, texture, flavour and the proportion of fruit used in their manufacture.

Guava jelly and cheese

Guava are available plenty and cheap during the season all over India. It is rich source of Vitamin C. You can prepare jelly and thereafter cheese from residue of fruit. Jelly is prepared from the extract of the fruit.

Recipe in cheese

Pulp 1 kg Sugar 1.25 kg Salt 3g Butter 20g	Cook sugar and pulp till it becomes very thick add salt, butter and continue cooking till it does not stick to bottom of the vessel. Smear a tea spoon of ghee on tray and spread cooked guava pulp. When it is cold roll out glass jar to make surface smooth. Next day cut into small pieces and wrap them into Butter paper.

2.2.4 Observations

Determine TSS, acidity, pectin (alcohol method/jelmeter test) and consistency of gel (sheet/flake test).

Note: The procedure for the calculation of TSS, acidity, pectin (alcohol method/jelmeter test) and consistency of gel (sheet/flake test) can be seen in the practical manual of Course III 'Food Chemistry and Physiology' and theory of course IV 'Food Processing and Engineering – I'.

2.2.5 Result

Acidity of the given jam, jelly, preserve = % (w/v)

TSS of the given jam, jelly, preserve = %

2.3 PRECAUTIONS

- All equipment used in the preparation of fruit juices and squashes should be rust and acid proof.
- Copper and iron vessels should be strictly avoided as these metals react with fruit acids, and cause blackening of the product.

EXPERIMENT 3 PREPARATION OF PICKLES AND CHUTNEYS, RELISHES AND SAUCES

Structure

3.1 INTRODUCTION

Pickling is the result of fermentation by lactic acid-forming bacteria, which are generally present in large numbers on the surface of fresh vegetables and fruits. These bacteria can grow in acid medium and in the presence of 8-10 % salt solution, whereas the growth of a majority of undesirable organisms is inhibited. Lactic acid bacteria are most active at 30°C, so this temperature must be maintained as far as possible in the early stage of pickle making. When vegetables are placed in brine, the brine penetrates into the vegetable tissues and soluble material present in them diffuses into the brine by osmosis. The soluble material includes fermentable sugars and minerals. The sugars serve as food for lactic acid bacteria that in turn convert the sugars into lactic and other acids. The acid brine thus formed acts upon vegetable tissues to produce the characteristic taste and aroma of pickle. Pickles are consumed as minor item in food to make meals more a) appetizing, b) digestive, c) antiseptic due to the presence of spices, d) supplying protective food as vitamins and minerals. The commercial varieties of pickles can be divided into five classes.

1. Fermented Pickle
2. Oil Pickle
3. Acid Pickle
4. Mustard Pickle
5. Brine Pickle

Out of five classes only first four are sold in form of finished pickle where as the last one mainly brine pickle is generally not sold for consumer but is kept for further processing to make other types of pickle.

Objectives

After going through this experiment, you should be able to:

- know the pickling processes by pickling the available fruits and vegetables;
- describe the methods of chutney, relishes and sauces; and
- explain the precautions during the processes of product making.

3.2 EXPERIMENT

3.2.1 Principle

Pickles and chutneys are prepared with salt, vinegar, oil or with a mixture of salt, oil, spices and vinegar.

3.2.2 Requirements

Raw materials, equipment and apparatus

1. Fruit/vegetable, sugar
2. Peeler
3. Juicer
4. Pulper
5. Filter cloth / sieve
6. Pans of suitable size
7. Heaters
8. Thermometer
9. Crown corking / capping machine
10. Corks / caps
11. Volumetric flask
12. Measuring cylinder
13. Weighing balance
14. Potable water

Chemicals and reagents

1. Hydrochloric acid
2. Citric acid / ascorbic acid
3. Potassium metabisulphite
4. Sodium benzoate

3.2.3 Procedure

a) Pickles and its Method of Preparation

Pickles are prepared with salt, vinegar, oil or with a mixture of salt, oil, spices and vinegar. The general process for the preparation and preservation of is as under:

1. Preservation with salt

Salt improves the taste, flavour and hardness of the tissues of vegetables and controls fermentation. Salt content of 15 % or above prevents microbial spoilage. This method of preservation is generally used only for vegetables which contain very little sugar and hence sufficient lactic acid cannot be formed by fermentation to act as preservative. However, some fruits like lime, mango, etc., are also preserved with salt. The preparation of some pickles is described below:

i) Lime pickle: Lime 1 kg, salt 200 g, red chilli powder 15 g, cinnamon, cumin, cardamom (large) and black pepper (powdered) each 10 g, clove (headless) 5 numbers.

(in cool and dry place)

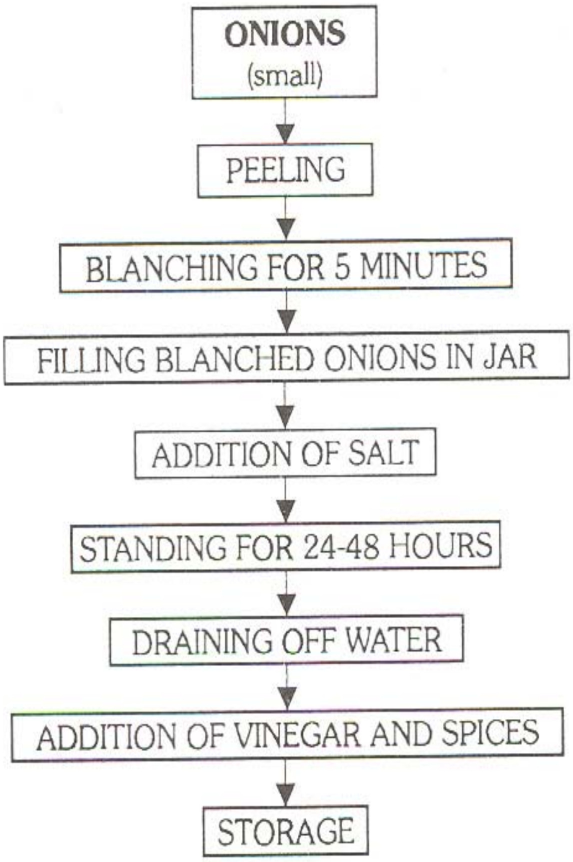
2) *Preservation with vinegar*

A number of fruits and vegetables are preserved in vinegar whose final concentration, in terms of acetic acid, in the finished pickle should not be less than 2 %. To prevent dilution of vinegar below this strength by the water liberated from the tissues, the vegetables or fruits are generally placed in strong vinegar of about 10 % strength for several days before pickling. This treatment helps to expel the gases present in the intercellular speces of vegetable tissue. Vinegar pickles are the most important pickles consumed in foreign countries. Mango, garlic, chillies, etc., are preserved as such in vinegar.

i) *Onion pickle:* Onions 1 kg, vinegar 1 litre, salt 250 g, red chilli powder 10 g, cardamom (large), black pepper, cumin (powdered) each 10 g, clove (headless) 5 numbers.

PROCESSING FLOW-SHEET FOR ONION PICKLE

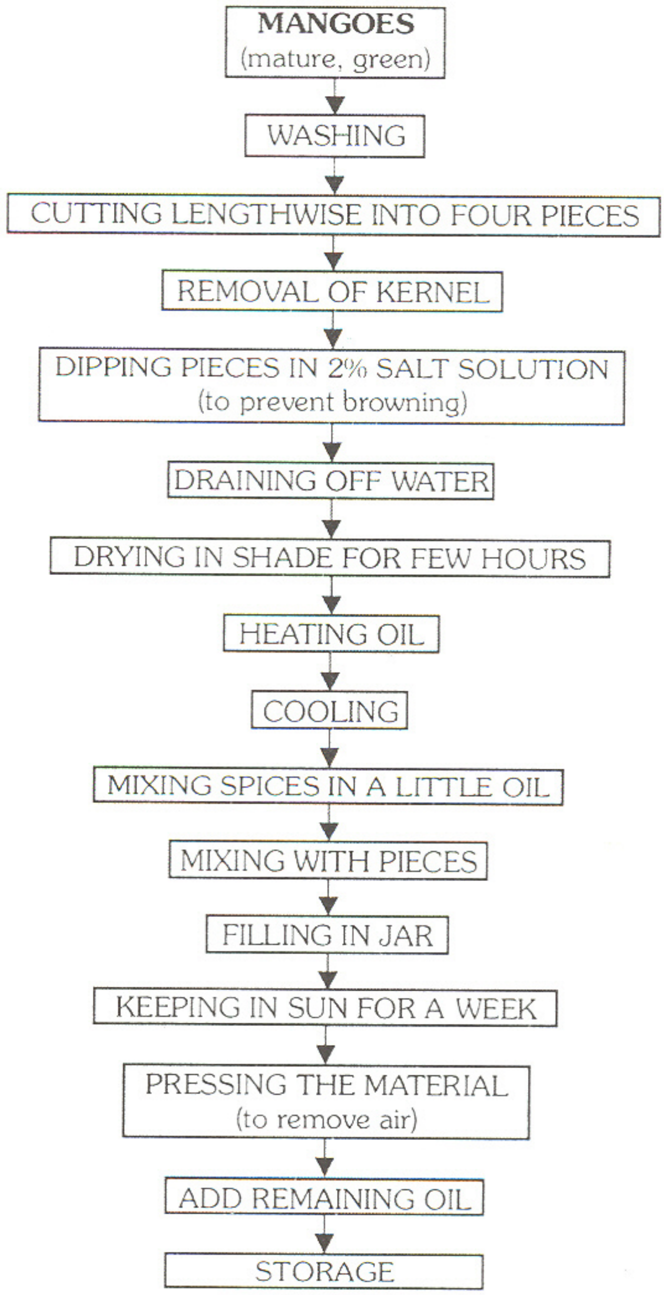


3) *Preservation with oil*

The fruits or vegetables should be completely immersed in the edible oil. Cauliflower, lime, mango and turnip pickles are the most important oil pickles.

i) *Mango pickle:* Mango pieces 1 kg, salt 150g, fenugreek (powdered) 25g, turmeric (powdered) 15 g, nigella seeds 15g, red chilli powder 10g, clove (headless) 8 numbers, black pepper, cumin, cardamom (large), aniseed (powdered) each 15g, asafoetida 2g, mustard oil 350 ml Gust sufficient to cover pieces).

PROCESSING FLOW-SHEET FOR MANGO PICKLE



b) Chutney and its Method of Preparation

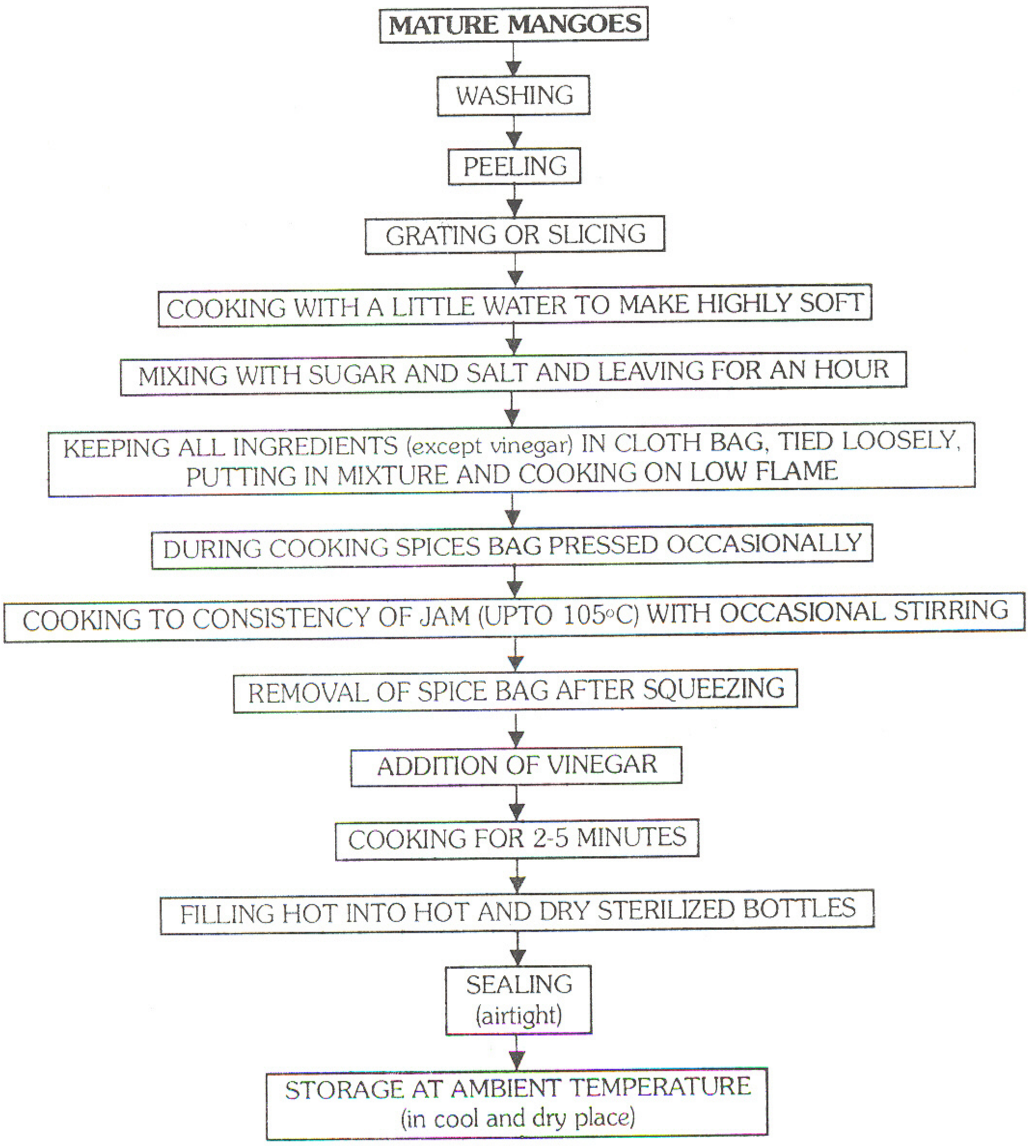
- The method of preparation of chutney is similar to that for jam except that spices, vinegar and salt are added.
- The fruits/vegetables are peeled, sliced or grated, or cut into small pieces and cooked in water until they become sufficiently soft.
- The quality of a chutney depends to a large extent on its cooking which should be done for a long time at a temperature below the boiling point.
- To ensure proper thickening, cooking is done without a lid even though this results in some loss of volatile oils from the spices.
- Chopped onion and garlic are added at the start to mellow their strong flavours. Spices are coarsely powdered before adding.

- Vinegar extract of spices may be used instead of whole spices. Spice and vinegar are added just before the final stage of cooking, because prolonged boiling causes loss of some of the essential oils of spices and of vinegar by volatilization.
- In mango and apricot sweet chutneys, where vinegar is used in large quantity, the amount of sugar added may be reduced because vinegar itself acts as a preservative.
- The chutneys are cooked to the consistency of jam to avoid fermentation. Some of the common recipes for preparation of chutney are given below.

1. *Sweet mango chutney*

   Mango slices or shreds 1 kg, sugar 1 kg, salt to taste, onions (chopped) 50g, garlic (chopped) 15g, ginger (chopped) 15g, red chilli powder 10g, black pepper, cardamom (large), cinnamon, cumin, aniseed (powdered) 10g each, clove (headless) 5 numbers and vinegar 170 ml.

PROCESSING FLOW-SHEET FOR SWEET MANGO CHUTNEY



2. *Apple chutney*

Apple slices 1 kg, sugar 750 g, dried dates (chopped) 100g, salt to taste, raisins 50g, ginger (chopped) 15g, red chilli powder 10g, black pepper, cardamom (large), cinnamon, cumin, aniseed (powdered) 10g each, clove (headless) 5 numbers, onions (chopped) 250g, garlic (chopped) 15g, and vinegar 200 ml.

c) Relish

Relish is a semi solid or vinegar extract prepared by mixing fruit or vegetable pulp and used in making food more flavourful and relishing. It can also include the sauces and chutney.

In the preparation of relish mayonaise comes fore most. The next comes is mustard paste and third one is spice vinegar.

Mayonaise

Recipes	1kg Salad oil	Preparation Egg yolk and oil is beaten together and kept aside spiced vinegar is taken and mixed with the mixture of oil and egg yolk. Add sugar to the mixture. Gum tragcanth can be used as stablizer in immulsion.
	100g egg yolk	
	1 kg vinegar spiced	
	100 g sugar	
	Sod. Benzoat 200 ppm	

Mustard paste

The mustard paste is prepared by mixing mustard powder with spiced vinegar to make a smooth paste. It is preserved with 0.05% BHA and 250ppm sodium benzoat.

Spiced Vinegar is nothing but malt vinegar infused with spices and herbs. Whole spices are put in a muslin bag and suspended for 3-4 days. After that it is simmered and spiced oils are added.

d) Sauces

Sauces are made from fruit/vegetable pulps, flavoured with vinegar and spices. There are two types of sauces namely 1) Thin sauces and 2) Thick sauces.

Thin sauces: Thin sauces are those where the flavour of spices, grains fruits, vegetables are extracted in Vinegar. The most popular in this category are a) Worestershire Sauce, b) Soya Sauce, c) Walnut Ketchup.

Thick sauces: Thick sauces are those where spices, vinegar, sugar and starch are mixed with fruit and vegetable pulps. They are concentrated to desired consistency. Thick sauces are generally prepared from tomatoes or from vegetables.

Vinegar: It is one of the ingredient used in pickles its types are given in Annexure I.

3.2.4 Observation

Determine TSS, acidity and salt.

3.2.5 Result

TSS, acidity and salt = %

3.3 PRECAUTIONS

- All equipment used in the preparation of fruit juices and squashes should be rust and acid proof.
- Copper and iron vessels should be strictly avoided as these metals react with fruit acids, and cause blackening of the product.
- The spices should be free from foreign matter and microbial contamination.

EXPERIMENT 4 PRODUCTION OF TOMATO JUICE, KETCHUP, PUREE AND PASTE

Structure

4.1 INTRODUCTION

Tomato is grown in our country in abundance, both in summer and winter seasons, but those grown in winter are superior in quality because they contain more total solids. They are a good source of vitamin C. Often they are sold at distress prices during the peak harvest season and nearly 25% of the produce is spoiled due to mishandling. Such losses can be avoided by converting tomatoes into delicious products like paste, puree, juice, ketchup and sauce. This processing of tomato will not only minimize the chances of distress sale but also permit the growers/ their dependents to generate more income.

The quality of a tomato product is judged by its colour, which is dependent on the redness of the tomatoes used. In fact, the red pigment (lycopene) can be used as an index of the amount of tomato actually present in a product. High quality tomato products can be prepared only by: (i) using plant-ripened uniformly red tomatoes as the yellow and greenish portions not only mask the red colour but also cause browning due to oxidation; (ii) avoiding prolonged heating, and cooling the product quickly after preparation; and (iii) not using iron and copper equipment at any stage of processing. Lycopene (self-oxidizing isomer of carotene) turns brown when it comes into contact with iron. Iron also forms black compounds with the tannin in the tomatoes and the spices used. Equipment used should be glass-lined or made of stainless steel.

Objectives

After going through this experiment, you should be able to:

- understand the general concepts of tomato processing and those of processed products;
- know the flow charts of production methodologies; and
- explain experience in the production of tomato juice, ketchup, puree and paste.

4.2 EXPERIMENT

4.2.1 Principle

Tomato products are prepared from ripe tomatoes and preserved by chemical preservatives or by heat application.

4.2.2 Requirements

Raw materials, equipment and apparatus

1. Tomato, spices, etc.
2. Pulper
3. Filter cloth / sieve
4. Pans of suitable size
5. Heaters
6. Thermometer
7. Crown corking / capping machine
8. Corks / caps
9. Sterilizer/Pasteurizer
10. Volumetric flask
11. Measuring cylinder
12. Weighing balance
13. Potable water

Chemicals and reagents

1. Salt
2. Sugar
3. Citric acid/Vinegar
4. Spices

4.2.3 Procedure

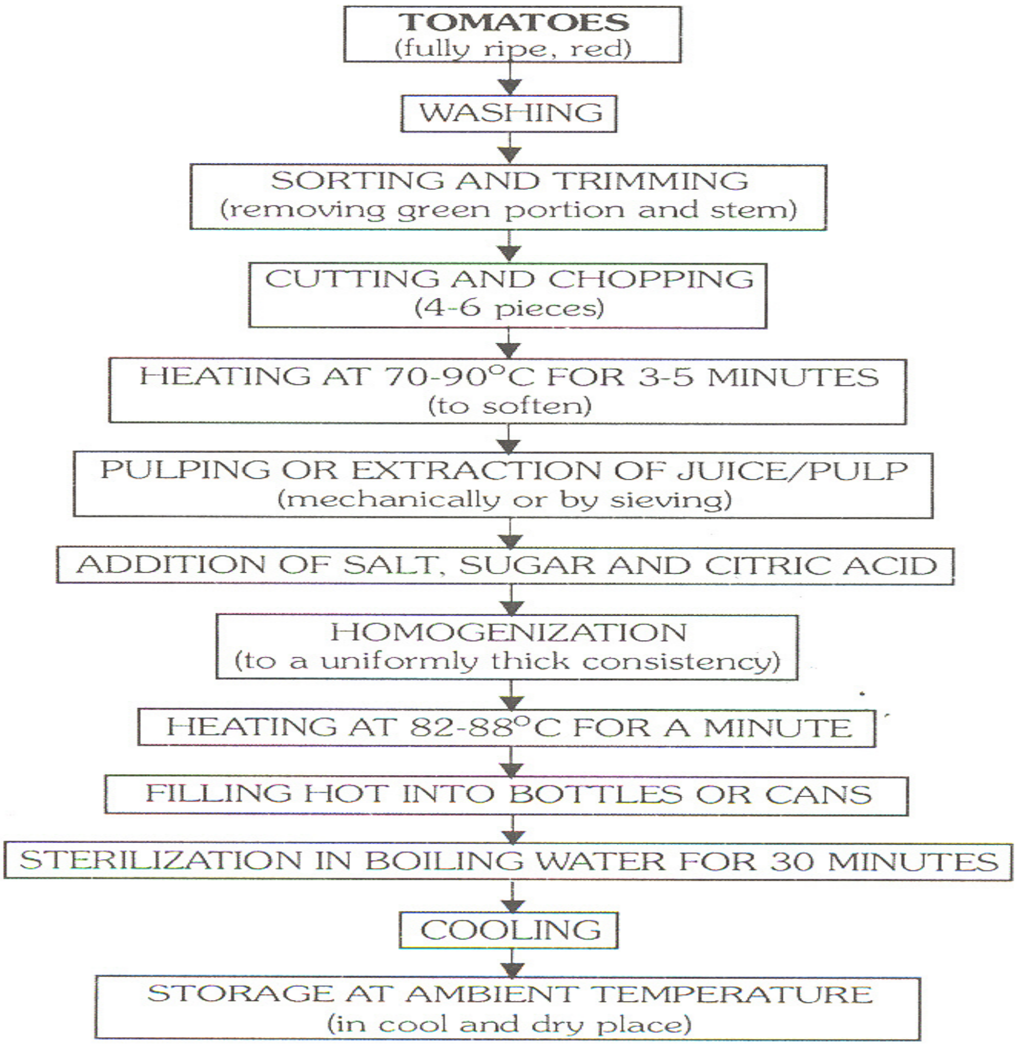
a) Tomato Juice

Plant-ripened, fully red fruits are selected, discarding all green, blemished and over-ripe fruits. A good quality juice should be of deep red colour, possess the characteristic taste and flavour of tomato, contain about 0.4 % acid (in terms of citric acid), be uniform in appearance and have high nutritive value. In addition the juice should contain 0.5% salt, and 1% sugar.

An average of 10 kg of tomatoes yields 7 litres of juice. Wash tomatoes, remove stems, and trim off bruised or discoloured portions. To prevent juice from separating, quickly cut about 0.5 kg of fruit into quarters and put directly into saucepan. Heat immediately to boiling while crushing. Continue to add and crush freshly cut tomato quarters to the boiling mixture. Make sure the mixture boils constantly and vigorously while you add the remaining tomatoes. Simmer 5 min. after you add all pieces. Press heated tomatoes through a sieve or food mill to remove skins and seeds. Heat juice again to boiling.

Hot pulping is superior to cold pulping because in the latter case, extraction of juice is somewhat difficult and its yield is less, vitamin C is oxidized more rapidly, the juice is lighter in colour and there are chances of microbial spoilage. On commercial scale, a pulper or continuous spiral press is used for juice extraction but in homes tomatoes are strained through a steel sieve. To one litre of juice add 10g of sugar, 5g of salt, 1g of citric acid and 1g of sodium benzoate. Herbs, onion, garlic, and spices may be added to meet individual's taste requirements.

PROCESSING FLOW-SHEET FOR TOMATO JUICE



b) Tomato Sauce/Ketchup

It is made from strained tomato juice or pulp and spices, salt, sugar and vinegar, with or without onion and garlic, and contains not less than 12% tomato solids and 25% total solids.

General considerations: About one-third of the sugar required is added at the time of commencement of boiling to intensify and fix the red tomato colour. If the whole quantity of sugar is added initially, the cooking time will be longer and the quality of pulp will be adversely affected. Generally, the sugar content in ketchups/sauces varies from 10-26%. On the other hand, salt bleaches the colour of the tomato product. It is, therefore, desirable to add it towards the end of the cooking process. Spices are generally added in powdered form to the product by spice bag method. Instead of whole spices, essential oils of spices, oleoresins and spice extract can also be used. Essential oils, however, do not give the characteristic true aroma of whole spice but oleoresins provide true aroma. At present, spice extract is used in many industries for sauce/ketchup preparations. These do not adversely affect the colour of the product and are generally added a few minutes before the end of cooking.

The salt content of the product should be 1.3-3.4%. Good quality vinegar is essential for the preparation of high quality sauce/ketchup. It should contain 5.0-5.5% acetic acid and should be added when the product has thickened sufficiently, so that the acid is not lost by volatilization. Tomato sauce/ ketchup generally contains 1.25-1.5% acetic acid. Sometimes glacial acetic acid (100% acetic acid) is used which is colourless and cheaper than vinegar. In order to increase the viscosity and prevent the separation of pulp form clear juice, pectin can be added to the extent of 0.1-0.2% by weight of the finished product. The ketchup should be filled hot (about 88°C) to prevent browning and loss of vitamins during subsequent storage. If it is made from tomatoes of good quality, using sugar, salt, vinegar and spices in the correct proportion, it does not spoil for a fairly long time, even after opening the sealed bottle, if the latter is kept in a cool and clean place. It is, however, advisable to add 0.025% sodium benzoate to the product before bottling and then pasteurize the bottles as a precaution against spoilage during the 3 to 4 weeks that the ketchup remains in the opened bottle before it is used up.

Recipe: Tomato pulp 1 kg, sugar 75g, salt 10g, onion (chopped) 50g, ginger (chopped) 10g, garlic (chopped) 5g, red chilli powder 5g, cinnamon, cardamom (large), aniseed, cumin, black pepper (powdered) 10g each, clove (headless) 5 numbers, vinegar 25 ml or glacial acetic acid 5 ml and sodium benzoate 0.25g per kg final product.

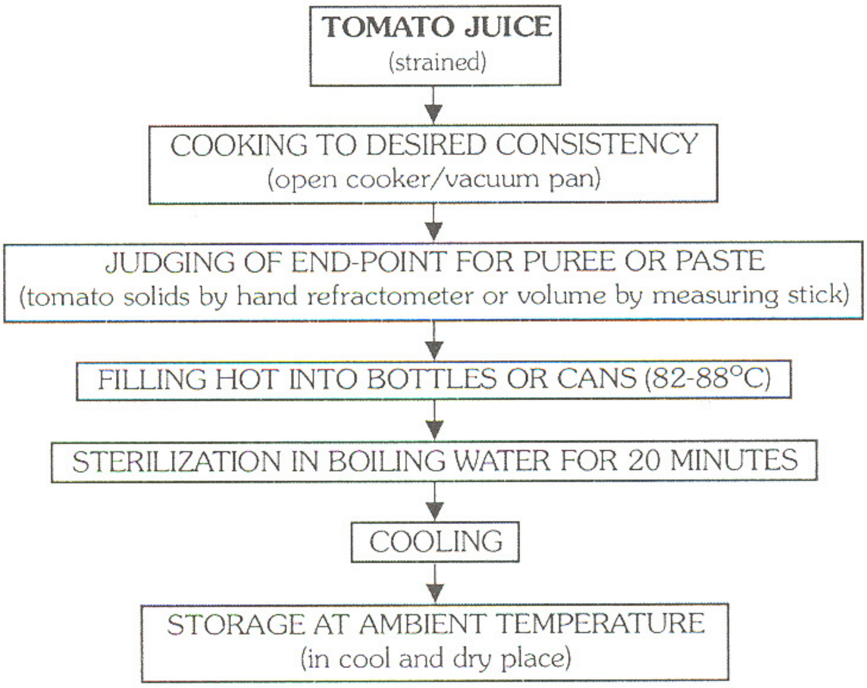
c) Tomato Puree and Paste

Concentrated tomato pulp without skin or seeds, with or without added salt, and containing not less than 9.0 % of salt-free tomato solids, is known as 'medium tomato puree'. It can be concentrated further to 'heavy tomato puree', which contains not less than 12% solids. If this is further concentrated so that it contains not less than 25% tomato solids, it is known as tomato paste. On further concentration to 33% or more of solids, it is called concentrated tomato paste.

Tomato pulp is prepared from plant ripened tomatoes in the same manner as tomato juice. Cooking for concentration of the pulp can be done either in an open cooker or a vacuum pan. In the former most of the vitamins are destroyed and the product become brown. On the other hand, use of vacuum pans, which are expensive, help to preserve the nutrients and also reduce the browning to a great extent. In vacuum pans the juice is boiled at about 71°C only. Ordinarily tomato juice can be concentrated to 14-15% solids in an open cooker, but for obtaining higher concentrations a vacuum pan is required. Moreover, sterilization of the product is also possible in a vacuum pan. While cooking in an open cooker, a little butter or edible oil is added to prevent foaming, burning and sticking.

If, after cooking, the total solids content of the juice is higher than required, more juice is added to lower it, if it is lower, cooking is continued till the desired concentration is reached. The end-point of cooking puree and paste can be determined either with a hand refractometer or by measuring the volume (a known volume of juice is concentrated to a known volume of final product) with the help of a measuring stick.

PROCESSING FLOW-SHEET FOR TOMATO PUREE/PASTE



d) Tomato Cocktail

Tomato cocktail is gaining popularity in many high class hotels and restaurants. It is prepared before serving and is also served from stock. The cocktail is preserved by pasteurizing it in bottles. The main constituent is tomato juice to which tobasco sauce, common salt, vinegar, lemon, worcestershire sauce are added in different proportions to suit the palate.

e) Chili Sauce

This is highly spiced product and is prepared from plant-ripened and peeled tomatoes. It is mostly used as a flavouring material in cooking and to some extent as a table relish also.

f) Tomato Soup

The main constituents of the soup are tomato juice, butter or cream, spices, arrowroot (a thickening agent), etc. These are added in various proportions to suit the table.

4.2.4 Observations

Determine TSS and acidity.

4.2.5 Result

Acidity of the tomato product	=	% (w/v)
TSS of the tomato product	=	%

4.3 PRECAUTIONS

- All equipment used in the preparation of fruit juices and squashes should be rust and acid proof.
- Copper and iron vessels should be strictly avoided as these metals react with fruit acids, and cause blackening of the product.
- Avoid exposure of juice to atmosphere as it will spoil the colour, taste and aroma and also reduce the Vitamin content.

EXPERIMENT 5 DRYING AND DEHYDRATION OF FRUITS AND VEGETABLES

Structure

5.1 INTRODUCTION

Dehydration is an age-old method of preservation of fruits and vegetables by removal of moisture. It is the process of removal of moisture by the application of artificial heat under controlled conditions of temperature, humidity and air flow. Various factors that affect the rate of drying of fruits and vegetables include the following:

i) Composition of raw materials
ii) Size, shape and arrangement of stacking of produce
iii) Temperature, humidity and velocity of air
iv) Pressure (barometric or under –vacuum)
v) Dehydration technique

Depending upon the type of dryers and drying environments available, the drying studies could be conducted.

The dried product could either be consumed directly or it needs to be rehydrated before use. For example, most vegetables need to be rehydrated. The practical will permit the study of rehydration behavior of the dehydrated products.

Their concentrated form, low cost, and convenient and easy transportability made dried products very popular among the armed forces.

Sun-Drying

Sun drying is practiced in tropical and sub-tropical regions where there is plenty of sunshine and almost no rain during the drying season. The equipment consist essentially of drying trays and few other items like knives, lye-bath, etc. Most of the work is done in a drying yard which is kept free from dust, flies, bus etc.

Packing and Storage

The dried products should be put into confectionary tins and sealed air-tight with tin or wax depending upon the length of the period of storage. Dried fruits and vegetables are subject to insect attack even when they have been properly dried and stored.

Sulphuring and Sulphitation

In order to obtain good results during drying and storage. Fruits are given sulphuring treatment before and sometimes after drying. In case of vegetables they are dipped in a solution of KMS (Potassium Meta bisulphite 0.1 to 0.5%) after blanching and then they are dried. This treatment will help in preventing non-enzymatic browning during storage.

Objectives

After going through this experiment, you should be able to:

- know the process of drying of fruits and vegetables; and
- demonstrate the computation of moisture content, drying rates, rehydration ratio.

5.2 EXPERIMENT

5.2.1 Principle

A sample of 'X' mass is dried to the final 'Y' mass in a period of T time.

Amount of moisture loss = X – Y

Percent moisture loss = 100 ((X – Y)/ X)
(wet basis)

Percent moisture loss = 100 ((X – Y) / Y)
(dry basis)

Rate of drying = (X – Y) /T

Dehydrated vegetables need to be rehydrated for consumption. The process of dehydration that results into highest rehydration in considered to be the best.

Rehydration ration = B/A

Where, B is the drained weight of the rehydrated sample. The initial weight of the sample is A.

5.2.2 Requirements

- Selected fruits and vegetable
- Knife
- Cutting board
- Water for washing
- Peeler
- Dry and wet bulb thermo meter
- Perforated drying trays
- Desiccators
- Petri dishes
- Weighing balance (Top pan, digital)
    - 100 g cap., 10 mg. Least Count
    - 5 kg cap., 1g least count

- Hot air oven with temperature control in the range of 50 C – 200 C.
- Selected dryers/ drying environments

5.2.3 Procedure

The steps for moisture content determination, drying experiment and rehydration experiment are being given below.

I) Moisture content determination

- Wash the fruit/vegetable and pat dry to remove surface moisture.
- Cut the fruit/vegetable into small pieces of desired size (**IS- 1708, 1734, 4332**).
- Weigh a sample of about 10 gm in a clean and dry Petri dish. (let the initial weight be X g).
- Heat the oven to the desired temperate and place the sample of fruit/vegetable for the desired time.
- Remove the sample after the desired time from the oven and place it in a desiccator till it cools down to room temperature.
- Weigh the dried sample (Let the final weight be 'Y' g).

II) Drying experiment

- Wash the fruit/vegetable to remove dust and other adhering objects. Remove surface moisture by pat drying or air jet drying.
- Cut the fruit/vegetable into small pieces of desired size using knife and cutting board.
- Spread the cut fruit/vegetable in the drying tray in a thin uniform layer.
- Note the initial weight of the tray with and without the fruit/vegetable sample.
- Place the tray in the selected drying environment (dryer).
- Weigh the tray periodically (1/6, ¼, 1/3, ½ hr, etc.) till the tray weight becomes constant.
- Note the final weight of the tray with dried fruit/vegetable.

III) Rehydration experiment

In rehydration, water is added to the product which is restored to a condition similar to that when it was fresh. The following rehydration test is used to find out the quality of the dried products.

Rehydration test

- Weigh out a sample of 35 grams from the dehydrated product.
- Put the sample into a small container (beaker) and add 275 ml of cold water (and 3.5 g salt).
- Cover the container (with a watch-glass) and bring the water to the boil.
- Boil gently for 30 minutes.

- Turn out the sample onto a white dish.
- At least two people should then examine the sample for palatability, toughness, flavour and presence or absence of bad flavours. The testers should record their results independently.
- The liquid left in the container should be examined for traces of sand/soil and other foreign matter.

Rehydration ratio

If the weight of the dehydrated sample (A) used for the test is 35g and the drained weight of the rehydrated sample (B) 210g, then

$$\text{Rehydration ratio} = \frac{B}{A} = \frac{210}{35} = 6:1$$

5.2.4 Observations

i) Moisture content determination

Weight of Petri dish. = a g.

Initial weight of Petri dish and sample = X g.

Final weight of Petri dish and sample = Y g.

ii) Drying rate

Weight of empty tray = a kg.

Initial weight of tray and the fruit/vegetable sample = X kg.

Periodic weight of tray and the fruit /vegetable sample = Y_i kg.

i = 1,2,3,4 time intervals

Final weight of the tray & the fruit/Vegetable = Y_f kg

Time duration of final drying = T hours.

Table 5.1: Observations for drying experiment

Sl. No.	Time	X	X–a	Drying rate (wet basis)
1.	0.0	X_0	X_0–a	$(X_0 - X_{DT}) / DT$
2.	DT	X_{DT}	X_{DT}–a	$(X_{DT} - X_{2DT}) / DT$
3.	2DT	X_{2DT}	X_{2DT}–a	–
4.	–	–	–	–
5.	T-DT	$X_{(n-2)DT}$	$X_{(n-2)DT}$ –a	–
6.	T	Y	Y–a	$(X_{(n-2)DT} - Y) / DT$

iii) Rehydration

Initial weight of sample to be rehydrated = A g

Final weight of the drained rehydrated sample = B g

5.2.5 Results

1. Moisture Content Determination.

   Moisture content (wet basis) = $((X-Y)/ (X-a)) \times 100$

   Moisture content (dry basis) = $((X-Y) / (Y-a)) \times 100$

2. Drying Rate

   Instantaneous drying rate is computated as given in column 5 of Table 5.1.

   Final drying rate = $(X-Y)/T$ kg/hr.

3. The rehydration ratio can be calculated as the ratio B/A

5.3 PRECAUTIONS

- All measurements of a type should be done uniformly and recorded to the same decimal point. For example, if temperatures are being measured to one decimal point, all values should be recorded to one decimal point only.
- All instruments used in the practical should be properly calibrated.
- The oven needs to be preheated to the desired temperature before the sample is put into it for moisture content determination.
- Petri dishes should be handled gently to avoid any spillage or breakage.
- The computed values need to be rounded off to just one more decimal point than that used for measurement.

EXPERIMENT 6 REPAIR AND MAINTENANCE OF MACHINES

Structure

6.1 INTRODUCTION

Good maintenance and repair procedures contribute significantly to the safety of the maintenance crew as well as that of machine operators and a reduction in the cost of production. Training and aptitude of people assigned to these jobs should make them alert for the intermittent electrical failure, the worn part, the inappropriate noise, the cracks or other signs that warn of impending breakage or that a safeguard has been damaged, altered, or removed. Sometimes all that is needed to keep things running smoothly and safely is machine lubrication or adjustment. Any damage observed or suspected should be reported to the supervisor; if the condition impairs safe operation, the machine should be out of service for repair. Safeguards that are missing, altered, or damaged also should be reported so appropriate action can be taken to insure against worker injury.

Objectives

After studying and performing these experiments, you should be able to:

- know the basic understanding of factory using the available energy utilities with emphasis on up-keep, safety and economy, organisation of the maintenance department; the staff; duties and responsibilities;
- impress upon the workers and managers in a food processing facility that prevention is better than cure;
- ascertain the practices of regular maintenance schedule along with record keeping have been introduced;
- highlight human and equipment safety concerns; and
- explain maintenance of an inventory of critical components is essential to avoid long down times.

6.2 EXPERIMENT

6.2.1 Principle

Machinery breakdowns are always costly. We must strive to avoid the breakdowns through preventive measures.

- Read the operator's manual and ensure proper installation and suggested periodic inspections.
- Maintain regular and complete schedule for greasing and lubrication.
- Ensure proper electrical connections and clean away dust and dirt in areas where connectors are located. Use compressed air instead of water to keep moisture away from the wires.
- Use the machine at its maximum performance level but not beyond it.
- Replace worn parts, and not just broken parts, to avoid frequent break-downs.
- Check for any misalignments and fix them.
- Proper storage of the machine when it is not in use by adequate cleaning and covering.
- Avoid high humidity or condensing environment during machine operation.
- Do not ignore warning signals such as low hydraulic pressure or if a shaft isn't turning on. The warning signals from the digital and analog displays must be taken seriously. Some operators not only ignore the signals but disconnect them completely to stop the signal from beeping or flashing. This too can result in breakdowns. Signals commonly disconnected include those for engine temperature, hydraulic oil, shaft speeds, or other parts that might not be turning at the correct speed.
- Provide adequate training to the machine operator (s).

6.2.2 Requirements

General hand tools required for the maintenance are as follows:

1. Set of open-ended spanners double ended.
2. Set of bihexagon ring spanners double ended.
3. Set of box/ tubular spanners.
4. Set of socket with extension and ratchet.
5. Set of screwdrivers regular and engineering pattern.
6. Set of allen key wrenches.
7. Set of pliers- combination, nose, circlip, adjustable, radio etc.
8. Set of punches.
9. Set of chisels.
10. Set of hammers.
11. Set of G-clamps.
12. Special tools, pullers etc.
13. Grease and oil guns.

6.2.3 Procedure

Daily maintenance

1. Cleaning of the machine so that there is no dirt or any other foreign material in the machine. The machine should usually be clean after the operation is over or after the day work is over. The cleaning operation should not be left over to the next working day. The cotton waste, cloth,

compressed air etc. may be used for cleaning of the processing machines and equipment.

2. Before switching on the machine inspect it externally and carry out the greasing and oiling as per manufacturers recommendation.

3. Check all the nuts and bolts and tighten them if required.

4. Check the belt tensions and adjust if required.

5. Switch on the machine and let it run idle for 5 minutes and observe the machine sound or noise. In case there is some unusual noise, identify it and take appropriate steps for repairs.

Weekly maintenance

In addition to daily maintenance check the oil levels of the various chambers and top them to required levels. Be sure that the recommended oil is used for topping the chambers.

Monthly maintenance

In addition to daily and weekly maintenance, drain the oil from the chambers, clean the chambers and refilled the oil. If the oil change is required may be done according to manufactures recommendations.

Yearly maintenance

1. In addition to daily, weekly and monthly maintenance, the cleaning of bearings and repacking of the grease may be done according to the manufacturers' recommendations.

2. The worn out nut and bolts may be replaced.

3. The belts checked and replaced if required.

4. Changing of the oil according to manufacturers recommendations. Cleaning of oil filters and replacing them if required.

5. Checking of the alignment of the machine and its adjustment if required.

6. Carrying out small repairs or replacement of worn out parts if required.

7. Carrying out all the maintenance as per manufacturers recommendations

6.2.4 Observations

It is recommended to mount a service record chart for each machine on the wall of the work area, with 10-, 50-, 100-, 250- and 500-hour maintenance intervals indicated so they can be performed regularly and the hours marked down. Recommended maintenance operations listed in the operator's manual should be attached to the chart to help operators do all required maintenance procedures.

Also useful is a large planning calendar with machine operating manuals stuck in pockets or hung in a vertical row on the left and columns for each of the months of the year to the right. Use this calendar for noting major repair and service operations to be carried out on each piece of machinery in the months.

Given below is a sample of weekly maintenance chart. Such record not only ensures daily compliance of the inspection/ maintenance work, it becomes a valuable record of the machine performance history.

Table 6.1: Weekly maintenance chart (Machine No.), Week No.
(Tick √ against the activity performed for the day)

Sl. No.	Activity	Mon	Tue	Wed	Thur	Fri	Sat	Sun
1.	Cleaning of the machine							
2.	External inspection before switching the machine							
3.	Greasing/ oiling as per manufacturer's instructions							
4.	Check all the nuts and bolts and tighten them if required							
5.	Check the belt tensions and adjust if required							
6.	Switch on the machine and let it run idle for 5 minutes and observe the machine sound or noise							
7.	check the oil levels of the various chambers and top them to required levels (**weekly**)							
	Remarks							
	Signatures: Operator							
	Signatures: Supervisor							

A suggested service chart to be maintained in the office of the supervisor is given below:

Suggested Service Schedule Format

Service Schedule for ______________________________

Hours of Operation	HOUR METER READINGS																			
10 Hour Service																				
10 Hour Service																				
10 Hour Service																				
10 Hour Service																				
10 Hour Service																				
50 Hour Service																				
100 Hour Service																				
250 Hour Service																				
500 Hour Service																				
1000 Hour or Yearly																				

Place chart in a prominent place in the shop. Perform the required service and write down the hour meter reading. Continue down the column to the 50 hour level and move to the top of the next column after the next 10 hour interval.

6.3 PRECAUTIONS

- As a rule of thumb, spend one to two days in the slack season servicing equipment to avoid breakdowns during the service.
- Before attempting any maintenance, disconnect and lock out the machine from all of its power sources, whether the source is electrical, mechanical, pneumatic, hydraulic, or a combination of these.
- Energy accumulation devices must be "bled down." Open the circuit at the switch box and lock the switch in the "off" position.
- Notifying all affected employees (usually machine or equipment operators or users) that the machine or equipment must be shut down to perform some maintenance or servicing.
- Verifying that the machine or equipment is isolated from the energy source.
- When the servicing or maintenance is completed, inspect the machine or equipment to ensure that all guards and other safety devices are in place and functional,
- Check the area to ensure that energization and start up of the machine or equipment will not endanger employees.

- Remove the lockout devices.
- Re-energize the machine or equipment, and notify affected employees that the machine or equipment may be returned to service.
- All the right tools should be on hand and in good repair.
- Lubricating oils and other common supplies should be readily available and safely stored.
- Commonly used machine parts and hardware should be kept in stock.

ANNEXURE I

Vinegar

The name 'Vinegar' is derived from Latin word Vine-gry means wine-sour. The name itself indicates that vinegar is prepared by fermenting of wine into vinegar or alcohol into acetic acid, because during fermentation Alcohol is converted by micro-organism into acetic acid. Generally vinegar contain 4% Acetic Acid. Vinegar can be calssified into four groups according to the source of materials namely:

1. Synthetic Vinegar
2. Brewed Vinegar (Malt)
3. Spirit Vinegar
4. Distilled Vinegar

1. ***Synthetic Vinegar:*** Is self explanatory. It is prepared by diluting glacial acetic acid to 4% and colouring with suitable colour (caramel) to give appearance like brewed vinegar or natural fermented vinegar. According to FPO it must contain 4% acetic acid.

   Preparation: a) Boil water, strain and allow it to cool, b) Add acetic acid at the rate of 50ml/1Litre of water, c) Fill in bottles, cork, label and store. A little caramel colour is added to improve colour and flavour.

2. ***Brewed Vinegar:*** Is prepared by fermenting and food material which contain sugar into alcohol and from alcohol into vinegar by natural process of fermentation. It must contain minimum 3.75% acetic acid weight/volume.

3. ***Spirit – Vinegar:*** When vinegar is prepared directly from alcohol without any sugar, it is known as spirit vinegar. The source of alcohol could be any sugary material. It must also have 3.75% acetic acid.

4. ***Distilled Vinegar:*** It is colourless vinegar prepared by distilling any brewed or spirit vinegar. It must also contain 3.75% acetic acid weight/volume.

   It is easy to differentiate all the types of vinegar by analysis. Synthetic vinegar does not have any other volatile substance than acetic acid. While other three types of vinegar have volatile other than acetic acid in varying degree and from this one can easily find out whether vinegar has prepared synthetically, fermentation or distillation.

   In preparing vinegar any food containing appreciate quantity of sugar e.g. fruits and vegetables waste, dried fruits honey etc. can be used.

ANNEXURE II

Boiling Temperatures

Juice, sugar mixtures (Jam Boiling Temperature)

Boiling Point			
	Percentage sugar	At sea level	500' Above sea level
	50	216	215.2
	52	216.6	215.8
	54	217	216.2
	56	217.15	216.7
	58	218.1	217.3
	60	218.7	217.9
	62	219.4	218.6
	64	220.2	219.4
	66	221.2	220.1
Jam, Jellying Temperature	68	222.2	221.4
	70	223.5	222.7
	72	225.0	224.2
	74	226.8	226
Toffee Setting Temperature	76	229.1	228.3

Approximate Conversion of Measure

1 Tea spoon	= 5 ml
1 Table spoon	= 15 ml (3 tea spoon)
1 Oz	= 2 table spoons = 30 ml
1 Cup	= 8 oz = 230 ml
1 Soda Bottle	= 7 oz = 200 ml
1 Ketchup Bottle	= 12 oz = 350 mls
1 Sugar Bottle (big)	= 24 oz = 720 mls
1 Pint	= 568 mls
1 Litre	= 1000 mls = 7½ cups

UNIT 1 CLASSIFICATION OF MICROORGANISMS IMPORTANT IN THE FOOD INDUSTRY: BACTERIA, YEASTS AND MOLD

Structure

1.0 OBJECTIVES

The objectives of this unit are to enable you to understand the important genera of microorganisms associated with food. This unit gives a brief account of the morphological, physiological and cultural characteristics of various microorganisms. After going through this unit, you should be able to:

- know the various types of microorganisms;
- explain the requirements for their growth;
- learn the classification of these organisms based on their characteristics; and
- distinguish between the useful and harmful microorganisms.

1.1 INTRODUCTION

We already know that the microorganisms use our food as a source of nutrients for their own growth. This, of course can result in deterioration of the food. By increasing their numbers, utilizing nutrients, producing enzymatic changes and contributing off flavors by means of breakdown of a product or synthesis of new compounds they can "spoil" a food. When the microorganisms involved are pathogenic, their association with our food supply is critical from a public health point of view. Therefore a classification of different organisms and their growth requirements is required to prevent spoilage of foods.

1.2 VARIOUS TYPES OF MICROORGANISMS

Microbes are single-cell organisms so tiny that millions can fit into the eye of a needle. They are the oldest form of life on earth. Microbe fossils date back more than 3.5 billion years to a time when the Earth was covered with oceans that regularly reached the boiling point, hundreds of millions of years before dinosaurs roamed the earth. Without microbes, we couldn't eat or breathe. Without us, they'd probably be just fine.

Bacteria

Many of us know bacteria only as "germs," invisible to naked eyes that can invade our bodies and make us sick. Few know that many bacteria not only coexist with us all the time, but help us do an amazing array of useful things like make vitamins, break down garbage, and even maintain our atmosphere. These are unicellular microorganisms that are classed as plants. A bacterial cell is about 1µm in length and somewhat smaller in diameter. Bacteria are classified according to their shape. Cocci are spherical, bacilli are cylindrical and spirilla and vibrios are spiral. Bacterial spores are more heat resistant than yeast or mold spores to most processing conditions. Bacteria, with a few exceptions cannot grow in acid media in which yeasts and molds thrive. They multiply by 'binary fission'. When a bacterium becomes mature it divides into two, these two become four and so on. Bacteria can be found virtually everywhere. They are in the air, the soil, and water, and in and on plants and animals, including us. A single teaspoon of topsoil contains about a billion bacterial cells (and about 120,000 fungal cells and some 25,000 algal cells). The human mouth is home to more than 500 species of bacteria. Some bacteria (along with archaea) thrive in the most forbidding, uninviting places on Earth, from nearly-boiling hot springs to super-chilled Antarctic lakes buried under sheets of ice. Microbes that dwell in these extreme habitats are aptly called extremophiles. The growth of bacteria is very rapid and depends upon the nature of the food material, moisture, temperature and air. Some bacteria do not grow in air but temperature plays a major role in their growth, the optimum being generally 37°C for bacteria pathogenic to humans.

Bacteria are very sensitive to acids and are destroyed in their presence even at temperature of boiling water. Hence, most fruits being acidic can be easily sterilized at 100°C whereas vegetables being non-acidic require a higher temperature of 116°C.

A bacterium's genetic information is contained in a single DNA molecule suspended in a jelly-like substance called cytoplasm. In most cases, this and other cell parts are surrounded by a flexible cytoplasmic membrane that is itself surrounded by a tough, rigid cell wall. A few species, such as the mycoplasmas, don't have cell walls.

Even though bacteria have only one cell each, they come in a wide range of shapes, sizes, and colours.

The important groups of bacteria are:

a) Bacillus: rod-shaped.

b) Coccus: spherical.

c) Coccobacillus: oval-shaped.

d) Aerobes: require atmospheric oxygen for growth, e.g., *Acetobacter aceti*.

e) Facultative anaerobes: can grow with or without atmospheric oxygen.

f) Obligate anaerobes: do not grow in atmospheric oxygen.

g) Mesophiles: require a temperature below 38°C for growth.

h) Obligate thermophiles: grow between 38°C and 82°C.

i) Facultative thermophiles: grow over a wide range of temperatures covered by mesophiles and obligate thermophiles and below.

j) Psychrotrophs: grow fairly well at refrigeration temperatures and some can even grow slowly at temperatures below freezing.

Some bacteria have natural colours. Certain species contain pigments, such as various chlorophylls, that make them naturally green, yellow, orange, or brown. Colonies of millions of bacteria may appear pink, yellowish, or white.

Important Food Spoilage Bacteria

Group	Genus
Acetics	*Acetobacter* and *Gluconobacter*
Lactics	*Lactobacillus, Leuconostoc, Pediococuus, Sreptococcus*
Butyrics	*Clostridium*
Propionics	*Propionibacterium*
Proteolytics	*Bacillus, Pseudomonas, Closridium, Proteus etc.*

Some useful bacteria

The following bacteria are of great importance in the food processing industry.

Acetobacter sp.

These bacteria, also known as "vinegar bacteria", cause significant spoilage in the wine industry but are necessary for vinegar production. The important species are *Acetobacter aceti, A. orleansis and A.schutzenbachi*. They are very small, usually non-motile and generally do not form spores. These bacteria are aerobes and in the presence of oxygen convert ethyl alcohol to acetic acid. These bacteria can be easily destroyed by heating to 65°C.

Lactobacillus sp.

Different organisms of this group, also known as "lactic acid bacteria", have different properties but all of them produce lactic acid from carbohydrates. The important species include *Lactobacillus plantarum, Pediococcus cerevisiae, Leuconostoc mesenteroides, Streptococcus faecalis* and *Lactobacillus brevis.* These bacteria cause "lactic souring" and spoil wines, which can be easily prevented by maintaining a sulphur dioxide concentration of 0.007 per cent in wine.

Yeasts

Yeasts are unicellular fungi which are widely distributed in nature. They are somewhat larger than bacteria. The cell length is about 10µm and the diameter is about a third of this. Most yeasts are spherical or ellipsoidal. Yeasts that multiply by means of 'budding' are known as 'true yeasts'. Yeasts grow luxuriously at a moderate temperature in a solution of sugar in plenty of water.

Under suitable conditions the sugar is converted into alcohol and carbon dioxide is evolved. This is the reason that carbon dioxide is evolved from food materials spoiled by yeasts and pushes out corks from bottles with great force. Most of them do not develop in media containing more than 66% sugar or 0.5% acetic acid. Boiling destroys the yeast cells and spores completely. Some of the yeasts which grow on fruits are *Saccharomyces, Candida* and *Brettanomyces.*

Pseudo-yeasts

These are like true yeasts but do not form spores. All the members of this group are particularly unsuitable for fermentation purposes as they produce off-flavours and cloudiness.

Yeasts causing food spoilage

Yeast	Product Spoilage
Saccharomyces	Low sugar products
Candida	High-acid foods, salty foods, butter
Brettanomyces	Beers, wines
Zygosaccharomyces (osmophillic)	Honey, syrups, molasses, wines, soy sauce
Pichia	Wines
Hansenula	Beers
Torulopsis	Milk products, fruit juices, acid foods
Rhodotorula	Meat, sauerkraut

Fungi (Molds)

Fungi are eukaryotic organisms. This means that their DNA-containing chromosomes are enclosed within a nucleus inside their cells. (The chromosomes of bacteria and archaea are not walled off inside nuclei, making them prokaryotic organisms). Molds are multicellular, filamentous fungi which are devoid of chlorophyll. They are larger than yeasts. They are strict aerobes and require oxygen for growth and multiplication and tend to grow more slowly than bacteria.

Fungi are lower thallophytic plants but do not make their own food via photosynthesis like green plants. They feed on organic matter like rotting leaves, wood, and other debris, or upon the tissues of living plants and animals.

Fungi, along with bacteria, are the planet's major composters and recyclers. Although fungi may seem like a nuisance when they grow in your fruit bowl or refrigerator, their ability to degrade some of the toughest organic materials, including tree wood and insect exoskeletons, means that our planet is not cluttered with a mass of debris. Fungi secrete digestive enzymes in order to break down complex food sources, such as animal corpses and tree stumps, into smaller components they can absorb.

The principle parts of a mold are a web-like structure known as mycelium and the spore. The mycelium is often white and cottony and penetrates into the attacked foodstuff. After fixing itself the mold produces viable spores which resist the favourable conditions after the dispersal and germinate when they get favourable conditions. They thrive best in closed, damp and dark situations with an adequate supply or warm, moist air but require less free moisture than yeasts and bacteria. They prefer sugar containing substances and may spoil jams, jellies and other sugar-based products. Acid medium favours their growth and, therefore, they grow well in pickles, juices etc. this is the main reason that fruit and fruit products are attacked by molds which not only consume nutrients present in the food thereby lowering its food value but also spoil the flavour, texture and appearance of the product. Molds are sensitive to heat; boiling quickly destroys molds and their spores. The most important molds are:

a) *Penicillium* sp. (Blue moulds)
b) *Aspergillus* sp. (Black moulds)
c) *Mucor* sp. (Gray moulds)
d) *Bysslchlamyces fulva*

Classification of Microorganisms

A) On basis of temperature for growth

Microorganisms can be classified into:

– Thermophillic: Microbes who require high temperature for their growth and survival (optimum temperature=45-65ºC).

– Thermoduric: Microbes which do not grow at high temperatures but can survive in it.

– Mesophillic: Microorganisms which require optimum temperature of 20-50ºC for growth and multiplication.

– Psychrophillic: Microorganisms requiring less than 20ºC as optimal temperature for growth.

– Psychroduric: Microorganisms which do not grow at low temperature but can survive.

B) On basis of oxygen requirement for growth:

– Obligate Aerobes: Require oxygen for growth and multiplication e.g. molds.

– Obligate Anaerobes: Strictly grow only in absence of oxygen.

– Facultative: Microorganisms than can grow in both presence and absence of oxygen e.g. yeasts.

– Microaerophillic: Organisms which are able to grow at very low oxidation-reduction potential.

C) On basis of requirement of water activity.

In general, bacteria require more moisture than yeasts and yeasts more than molds.

The classification according to requirement of a_w is as follows:

Group of microorganism	Minimal a_w value
Bacteria	0.91
Yeast	0.88
Molds	0.80
Halophillic bacteria	0.75
Xerophillic fungi	0.65
Osmophillic Yeasts	0.60

- Halophillic bacteria: Bacteria which grow in high salt solutions
- Osmophillic Yeasts: Yeasts which can grow best in high concentrations of sugar
- Xerophillic Fungi: Fungi which can grow in low water activity

D) On basis of nutrient degradation capacity:

- Proteolytic: Microorganisms which are capable of protein degradation because of extracellular proteinases produced.
- Lipolytic: Microbes which catalyxe the hydrolysis of fats to fatty acids and glycerol.
- Sacchrolytic: These microorganisms hydrolyse disaccharides or polysaccharides to simpler sugars.
- Pectinolytic: These microorganisms hydrolyse pectin.

E) On basis of staining:

On basis of staining the bacteria can be classified as:

- Gram positive: Those bacteria that stain violet after Gram stain test. In these the cell wall is mostly comprised of peptidoglycan layer.
- Gram negative: Those bacteria that do not stain violet after Gram stain test. Cell wall mainly comprised of lipopolysaccharides.

1.3 CHARACTERISTICS (MORPHOLOGICAL, CULTURAL AND PHYSIOLOGICAL) OF MICROORGANISMS

1.3.1 Bacteria

Morphological Characteristics

One of the first step in the identification of bacteria in food is microscopic examination to ascertain the shape, size, aggregation, structure and staining reactions of the bacteria present. The following characteristics may be of special significance:

Encapsulation: The presence of capsules or slime may account for sliminess or ropiness of a food. Most capsules are polysaccharides of dextrin, dextran or levan and they serve as a source of reserve nutrients and increase the resistance of bacteria under adverse conditions.

Formation of Endospores: Bacteria of genera *Bacillus, Clostridium, Sporosarcina* etc have the ability to form endospores. Endospores are formed at an intracellular site and are resistant to heat, ultraviolet light and dessication. Lysis of the vegetative cell releases the free endospore, which may remain dormant with no detectable metabolism for years. Sporulation usually appears in the late logarithmic phase of growth, possibly because of nutrient depletion or product accumulation. The acquisition of heat resistance is closely related to the formation of dipicolinic acid and the Ca^{2+} uptake. Germination is favoured by conditions that are favourable for growth.

Formation of Cell Aggregates: It is characteristic of some bacteria to form long chains or of others to clump under certain conditions. It is more difficult to kill all bacteria in intertwined chains or sizable clumps than to destroy separate cells.

Cultural Characteristics

Bacterial growth in and on foods often is extensive enough to make the food unattractive in appearance or otherwise objectionable. Pigmented bacteria cause discolouration on the surfaces of foods; films which may cover the surfaces of liquids; growth may make surfaces slimy; or growth throughout the liquids may result in undesirable cloudiness or sediment.

Physiological Characteristics

Most bacteria may be placed into one of three groups based on their response to gaseous oxygen. Aerobic bacteria thrive in the presence of oxygen and require it for their continued growth and existence. Other bacteria are anaerobic, and cannot tolerate gaseous oxygen, such as those bacteria which live in deep underwater sediments, or those which cause bacterial food poisoning. The third group are the facultative anaerobes, which prefer growing in the presence of oxygen, but can continue to grow without it.

Bacteria may also be classified both by the mode by which they obtain their energy. Classified by the source of their energy, bacteria fall into two categories: heterotrophs and autotrophs. Heterotrophs derive energy from breaking down complex organic compounds that they must take in from the environment – this includes saprobic bacteria found in decaying material, as well as those that rely on fermentation or respiration.

The other group, the autotrophs, fix carbon dioxide to make their own food source; this may be fueled by light energy (photoautotrophic), or by oxidation of nitrogen, sulfur, or other elements (chemoautotrophic). While chemoautotrophs are uncommon, photoautotrophs are common and quite diverse. They include the cyanobacteria, green sulfur bacteria, purple sulfur bacteria, and purple nonsulfur bacteria. The sulfur bacteria are particularly interesting, since they use hydrogen sulfide as hydrogen donor, instead of water like most other photosynthetic organisms, including cyanobacteria.

Microbe is a term for tiny creatures that individually are too small to be seen with the unaided eye. Microbes include bacteria (*back-tear-ee-uh*), archaea (*are-key-uh*), fungi (*fun-jeye*) and protists (*pro-tists*). You've probably heard of bacteria and fungi before. Archaea are bacteria-like creatures that have some traits not found in any true bacteria. Protists include primitive algae (*al-gee*), amoebas (*ah-me-buhs*), slime molds and protozoa (*pro-toe-zoh-uh*). We can also include viruses (*vye-rus-is*) as a major type of microbe, though there is a debate as to whether viruses can be considered living creatures or not.

1.3.2 Molds

General Characteristics

The term "mold" is a common one applied to certain multicellular, filamentous fungi whose growth on foods usually is readily recognized by its fuzzy or cottony appearance. The main part of the growth commonly appears white but may be coloured or dark or smoky. Coloured spores are typical of mature mold of some kinds and give colour to part or all of the growth. The thallus, or vegetative body, is characteristic of thallophytes, which lack true roots, stems and leaves.

Morpohological Chactacteristics

The morphology, i.e. the form and structure, of molds, as judged by their macroscopic and microscopic appearance, is used in their identification and classification.

Hyphae and Mycelium: The mold thallus consists of a mass of branched, intertwined filaments called hyphae (singular hypha), and the whole mass of these hyphae are known as the mycelium.

Reproductive Parts or Structures: Molds can grow from a transplanted piece of mycelium. Reproduction of molds is chiefly by means of asexual spores. Some molds also form sexual spores.

Culture Characteristics

The gross appearance of a mold growing on a food often is sufficient to indicate its class or order. Some molds are loose and fluffy; others are compact. Some look velvety on the upper surface, some dry and powdery, and others wet or gelatinous. Some molds are restricted in size, while others seem limited only by the food or container. Pigments in the mycelium – red, purple, yellow, brown, gray black, etc. – are characteristic, as are the pigments of mass of asexual spores; green, blue-green, yellow, orange, pink, lavender, brown, gray, black, etc.

Physiological Characteristics

The physiological characteristics of molds will be reviewed only briefly here and will be discussed in more detail subsequently.

Moisture Requirements: In general most molds require less available moisture than do most yeasts and bacteria. It has been claimed that below 14 to 15 percent total moisture in flour or some dried fruits will prevent or greatly delay mold growth.

Temperature Requirements: Most molds would be considered mesophilic i.e. able to grow well at ordinary temperature. The optimal temperature for most molds is around 25 to 30°C, but some grow well at 35 to 37°C or above, e.g. *Aspergillus* spp. And some at still higher temperatures. A number of molds are psychrotophic or psychroduric i.e. they grow fairly well at temperatures of refrigeration, and some can grow slowly at temperatures below freezing. Growth has been reported at as low as – 5 to 10°C. A few are thermophilic; i.e. they have a high optimal temperature.

Oxygen and pH Requirements Molds are aerobic; i.e. they require oxygen for growth; this is true at least for the molds growing on foods. Most molds can grow over a wide range of hydrogen-ion concentration (pH 2 to 8.5), but the majority are favoured by an acid pH.

Food Requirements: Molds in general can utilize many kinds of foods, ranging from simple to complex. Most of the common molds possess a variety of hydrolytic enzymes, and some are grown for their amylases, pectinases, proteinases, and lipases.

Inhibitors: Compounds inhibitory to other organisms are produced by some molds, such as penicillin from *Penicillium chrysogenum* and clavacin from *Aspergillus clavatus.* Certain chemical compounds are mycostatic, inhibiting the growth of molds (sorbic acid, propionates, and acetates are examples), or are specifically fungicidal, killing molds.

Initiation of growth of molds is slow compared to that of bacteria or yeasts, so that when conditions are favourable for all these organisms, molds usually lose out in the competition. After mold growth is under way, however, it may be very rapid.

1.3.3 Yeasts

Like mold, the term "yeast" is commonly used but hard to define. As used here it refers to those fungi which are generally not filamentous but unicellular and ovoid or spheroid and which reproduce by budding or fission.

Yeasts may be useful or harmful in foods. Yeast fermentations are involved in the manufacture of foods such as bread, beer, wines, vinegar, and surface-ripened cheese, and yeasts are grown for enzymes and for food. Yeasts are undesirable when they cause spoilage of sauerkraut, fruit juices, syrups, molasses, honey, jellies, meats, wine, beer, and other foods.

Morphological Characteristics

Form and structure: The form of yeasts may be spherical to ovoid, lemon-shaped, pear-shaped, cylindrical, triangular, or even elongated into a false or true mycelium. They also differ in size.

Reproduction: Most yeasts reproduce asexually by multilateral or polar budding, a process in which some of the protoplasm bulges out the cell wall; the bulge grows in size and finally walls off as a new yeast cell. A new species or yeasts reproduce by fission, and one reproduces by combination of fission and budding.

Sexual reproduction of "true" yeasts *(Ascomycotina)* results in the production of ascospores, the yeast cell serving as the ascus. The ascospores may differ in colour, in smoothness or roughness of their walls, and in their shape (round, oval, reniform, bean or sickle-shaped, hemispherical, angular, fusiform, or needle-shaped).

"False" yeasts, which produce no ascospores or other sexual spores, belong to the *Fungi Imperfecti.* Cells of some yeasts become chlamydospores by formation of a thick wall about the cell, for example, *Candida, Rhodotorula, and Cryptococcus.*

Cultural Characteristics

For the most part, the appearance of massed yeast growth is not useful in the identification of yeasts, although growth as a film on the surface of liquid media suggests an oxidative or film yeasts, and production of a carotenoids pigment indicates the genus *Rhodotorula.* However, the appearance of the growth is important when it causes coloured spots on foods.

Yeasts are oxidative, fermentative, or both. The oxidative yeasts may grow as a film, pellicle, or scum on the surface of liquid and then are termed *film yeasts.* Fermentative yeasts usually grow throughout the liquid and produce carbon dioxide.

Physiological Characteristics

Most common yeasts grow best with a plentiful supply of available moisture. But since many yeasts grow in the presence of greater concentration of solutes (such as sugar or salt) than most bacteria it can be concluded that these yeasts require less moisture than the majority of bacteria. Most yeast require more moisture than molds, however, on the basis of water activity or aw yeasts may be classified as ordinary if they do not grow in high concentrations of solutes, i.e. in a low aw, and as osmophilic if they do. However limits of aw for ordinary yeasts tested thus far ranges from 0.88 to 0.94.

The range of temperature for growth of most yeasts is, in general, similar to that for molds, with the optimum around 25°C to 30°C and the maximum about 35°C to 47°C. Some kinds can grow at 0°C or less. The growth of most yeasts if favoured by an acid reaction in the vicinity of pH 4 to 4.5, and they will not grow well in an alkaline medium unless adapted to it. Yeasts grow best under aerobic conditions, but the fermentative types can grow anaerobically, although slowly.

In general, sugars are the best source of energy for yeasts, although oxidative yeasts, e.g., the film yeasts, oxidize organic acids and alcohol. Carbon dioxide produced by bread yeasts accomplishes the leavening of bread, and alcohol made by the fermentative yeasts is the main product in the manufacture of wines, beer, industrial alcohol, and other products. The yeasts also aid in the production of flavors or "bouquet" in wines.

Nitrogenous foods utilized vary from simple compounds such as ammonia and urea to amino acids and polypeptides. In addition, yeasts require accessory growth factors.

Microorganisms, namely, bacteria, yeasts and molds can be found in any environment. The eight environmental sources of organisms to foods are: soil and water, plants and plant products, food utensils, intestinal tracts of humans and animals, food handlers, animal feeds, animal hides, air and dust. Although we see that the microorganisms are beneficial to the humans in many ways, there are many microorganisms that are the causative agents for food borne diseases. e.g. *Staphlococcus aureus* and *Clostridium botulinum* cause food borne intoxication whereas *Salmonella, E.coli, Campylobacter, Listeria,* *Yersinia, Bacillus* etc cause food borne infections. Molds are responsible for causing food intoxication by production of mycotoxins, which are lethal for the human body e.g. Aflatoxin produced by *Aspergillus flavus*, patulin produced by *Penicillium expansum*, ochratoxins produced by *Aspergillus ochraceus* etc. All these will be discussed in Unit 3.

1.4 LET US SUM UP

This unit briefly outlines the identification and classification of food microorganisms. After reading this unit, you will be able to classify microorganisms broadly into three categories: bacteria, yeasts and molds. Further you will be able to categorize these microorganisms on the basis of their requirements of temperature, oxygen, water activity for growth and also on the basis of their ability to degrade certain nutrients. To prevent the spoilage of food products, appropriate measures have to be taken for preventing their growth and multiplication. Hence food microbiologists have to be well versed with the various morphological, cultural and physiological characteristics of the different microorganisms so as to prevent their growth and proliferation.

After reading this unit, you will get a knowledge of the factors that favour or inhibit the growth of microorganisms which are essential to give an understanding of the principles of food spoilage and preservation.

1.5 KEY WORDS

Bacteria	:	Unicellular microorganisms 1µm in length, lacking chlorophyll and multiply by binary fission.
Yeasts	:	Unicellular fungi, larger than bacteria, which multiply by budding.
Molds	:	Multicellular, filamentous fungi devoid of chlorophyll.
Endospore	:	Heat resistant structures formed by bacteria under unfavourable conditions (nutrient depletion or product accumulation) which remain dormant till exposed to favourable environment.
Capsule	:	Slimy material composed of polysaccharides that serve as a source of reserve nutrients and make cell resistant to adverse conditions.
Mycostatic	:	Substances which are inhibitory to mold growth.
Fungicidal	:	Substances capable of killing the fungi.
Thermophillic organisms	:	Microorganisms which require high optimum temperature for their growth and multiplication (45-60ºC).
Mesophillic organisms	:	Microorganisms whose optimum temperature for growth is 25-40ºC.
Proteolytic microorganisms	:	Microorganisms that have the capacity to break down complex proteins to amino acids due to production of extracellular protein degrading enzymes.
Gram positive bacteria	:	Bacteria that stain violet after Gram staining.
Gram negative bacteria	:	Bacteria that stain red after Gram staining.

Psychrophillic microorganisms : Microorganisms requiring less than 20ºC as optimal temperature for growth.

Obligate aerobes : Microorganisms that grow and multiply only in presence of oxygen.

Obligate anaerobes : Microorganisms that grow and multiply only in absence of oxygen.

Facultative microorganisms : Those microorganisms that can grow and survive under both aerobic and anaerobic conditions.

Microaerophillic microorganisms : Those microorganisms that can grow and survive under low concentrations of oxygen.

Thermoduric microorganisms : Those microorganisms that can survive at high temperatures but grows in mesophillic range.

1.6 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. On basis of morphology bacteria can be classified as:

   a) Bacilli: rod-shaped

   b) Coccus: spherical

   c) Coccobacillus: oval-shaped

   d) Spirilla: spiral shaped

2. Yeasts are unicellular fungi and are smaller in size whereas molds are multicellular and filamentous and are larger than yeasts. Yeasts multiply asexually by budding whereas molds reproduce sexually by spores. Yeasts can grow in anaerobic conditions but molds are strictly aerobic.

3. Classification of microorganisms on basis of temperature requirement:

   a) Thermophillic(45-60ºC)

   b) Thermoduric

   c) Mesophillic (25-40ºC)

   d) Psychroduric

   e) Psychrophillic

   Classification of microorganisms on basis of oxygen requirement:

   a) Obligate aerobes: Strictly grow in presence of oxygen

   b) Obligate anaerobes: Strictly grow in absence of oxygen

   c) Facultative: Can grow both in presence and absence of oxygen

   d) Microaerophillic: Grow at low oxygen concentrations

Classification of microorganisms on basis of a_w requirement:

a) Bacteria (a_w =0.9)

b) Yeast (0.88)

c) Mold (0.80)

d) Halophillic bacteria (0.75)

e) Xerphillic molds (0.65)

f) Osmophillic yeasts (0.60)

Classification of microorganisms on basis of nutrient degradation:

a) Lipolytic: Fat degrading

b) Saccharolytic: Sugar degrading

c) Pectinolytic: Pectin degrading

d) Proteolytic: Protein degrading

Classification of microorganisms on basis of staining:

a) Gram positive bacteria: Stain violet after staining

b) Gram negative bacteria: Stain red after Gram staining

Check Your Progress Exercise 2

1. Bacteria form special structures such as endospores, capsules and cell aggregates to combat the adverse environmental conditions. Bacteria of genera *Bacillus, Clostridium, Sporosarcina* etc have the ability to form heat resistant endospores. Sporulation usually appears in the late logarithmic phase of growth, possibly because of nutrient depletion or accumulation of toxic products. Endospores may remain dormant with no detectable metabolism for years and germinate when exposed to favourable conditions for growth. Capsules serve as a source of reserve nutrients and increase the resistance of bacteria under adverse conditions. They are composed of dextran and levan and account for sliminess or ropiness of a food. Bacteria may also form aggregates which helps them to combat unfavourable environments.

2. Physiological requirements of molds: Molds are mesophillic and grow well at 25-30°C. Some are psychrotrophic and can grow at –5 to 10°C. They are aerobic in nature and can grow at wide range of pH 2-8.5. They require a minimum moisture range of 14-15 per cent to grow. Owing to a number of hydrolytic enzymes, molds can proliferate on complex media also.

3. Yeasts may be useful or harmful in foods. Yeast fermentations are involved in the manufacture of foods such as bread, beer, wines, vinegar, and surface-ripened cheese, and yeasts are grown for enzymes and for food. Yeasts are undesirable when they cause spoilage of sauerkraut, fruit juices, syrups, molasses, honey, jellies, meats, wine, beer, and other foods.

UNIT 2 FACTORS AFFECTING GROWTH AND INHIBITION OF MICROORGANISMS IN FOOD

Structure

2.0 OBJECTIVES

After reading this unit you should be able to:

- list out the various factors that favour/inhibit the growth of microorganisms;
- explain the role played by pH in inhibition of microbial growth;
- explain the effect of water activity on microbial growth and activities;
- explain the influence of redox potential on the natural microflora of food and the type of spoilage occurring in food;
- understand the role played by nutrient composition on type of microorganisms growing in food;
- understand the role played by antimicrobial barriers in retarding microbial spoilage of food; and
- understand the role played by inhibitory substances in retarding microbial spoilage of food.

2.1 INTRODUCTION

Microorganisms use our food supply as a source of nutrients and energy. They increase their numbers by utilizing nutrients. This can result in a deterioration of the food. They produce enzymatic changes and off-flavours in food by breaking down a nutrient or synthesizing new compounds. Thus, they "spoil" our food and make it unfit for consumption. To prevent this we reduce the contact between microorganisms and our foods (prevent contamination) and also eliminate microorganisms from our foods, or adjust conditions of storage in such a way that their growth is prevented (preservation) and thus, there is no spoilage of food.

If the microorganisms involved are pathogenic, then their presence in our food will lead to outbreak of food borne diseases also. Many of our foods support the growth of pathogenic microorganisms or serve as a source of them. Here again, we attempt to prevent their entrance and growth in our foods or eliminate them by processing.

Interactions between microorganisms and our foods are also beneficial. Many of the cultured products consumed and enjoyed for example cultured buttermilk, yoghurt, sauerkraut, pickles and tofu are produced as a result of beneficial activities of microorganisms.

Food is the substrate for growth of microorganisms, so the characteristics of a food are important. Food or substrate will determine which microorganisms can or cannot grow on it so there is a need to understand the characteristics of the food or substrate. Then only one can make predictions about the microbial flora that may develop and flourish in it. This microflora will bring about the biochemical changes in food due to their activities. The types of biochemical changes will determine whether those changes are beneficial or harmful.

Knowledge of the factors that favour or inhibit the growth of microorganisms is very important. It will help us in understanding the principles of food spoilage and preservation. The chief compositional factors of food that influence microbial activity are hydrogen-ion concentration, moisture, oxidation-reduction (O-R) potential, nutrients, biological structure and presence of inhibitory substances.

2.2 HYDROGEN-ION CONCENTRATION (pH)

The acidity and alkalinity (pH) of an environment has a strong influence on the activity and stability of macromolecules such as enzymes. These enzymes play an important role during growth of microorganisms and in their metabolism. Thus, growth and metabolism of microorganisms are influenced by pH.

2.2.1 Effect on Microbial Growth

Every microorganism has a minimal, a maximal, and an optimal pH for growth. In general, bacteria grow in the pH range of 6.0–8.0, yeasts 4.5-6.0 and filamentous fungi 3.5-4.0. Molds can grow over a wider range of pH than most yeasts and bacteria, and many molds grow at acidities too high for yeasts and bacteria. Most fermentative yeasts grow well in pH range of about 4.0 to 4.5, eg. fruit juices, and film yeasts grow well on acid foods, such as sauerkraut and pickles. On the other hand, most yeast do not grow well in alkaline foods and thus do not have a significant role to play in the spoilage of food products with high pH. However, large number of yeasts grow well in near neutral pH. There are some exceptions for example some bacteria can grow in moderate acidity particularly those bacteria that produce large acids as a result of their activities like lactobacilli and acetic acid bacteria. These have pH optima between 5.0 and 6.0 and others like the proteolytic bacteria can grow in foods with a high (alkaline) pH, as found in the stored egg white. Bacteria are more sensitive to pH than molds and yeasts, with the pathogenic bacteria being the most sensitive amongst them. The pH values of some of the common foods along with the pH range for growth of some groups of microorganisms and a few of food associated pathogenic bacteria are given in Table 2.1.

Table 2.1: The pH ranges of some common food items and pH range of some common food microflora

Food	pH range	Organism	pH range
Citrus fruits	2-5	Molds	0-11
Soft drinks	2.5-4	Yeasts	1.5-8.5
Beer	3.5-4.5	Lactic acid bacteria	3.2-10.5
Meat	5.5-6.2	*Staphylococcus aureus*	4-9.8
Fish	6.5-7.3	*Salmonella* spp.	4.1-9
Egg white	8.6-9.6	*Escherichia coli*	4.3-9
Milk	6.5-7	*Yersinia enterocolitica*	4.5-9
Flour	6.2-7.2	*Clostridium botulinum*	4.8-8.2
Vegetables	4.8-7	*Clostridium perfringens*	5.4-8.7
Fermented shark	10-12	*Bacillus cereus*	4.7-9.3

pH minima and maxima of microorganisms also varies due to other important factors like temperature, moisture content, salt concentration, redox potential etc. For example, in the presence of 0.2 M NaCl, *Alcaligenes faecalis* can grow over a wider pH range than in the absence of NaCI or in the presence of 0.2 M sodium citrate. The pH minima of certain lactobacilli also depends upon the type of acid used, for example with citric, hydrochloric, phosphoric and tartaric acids growth can occur at lower pH than in presence of acetic or lactic acids. In general, yeast and molds are more acid-tolerant than bacteria.

When microorganisms are grown at pH either higher or lower than their optimum pH there is an increase in lag phase of the microbe. The increased lag would be of longer duration if the food has a good buffering capacity in contrast to one that has poor buffering capacity. Good buffering capacity of food would result in slower change in pH of food due to microbial activity. A respiring microbial cell is adversely affected by pH since it affects the functioning of enzymes and the transport of nutrients into the cell. In addition to the effect of pH on rate of growth of microorganisms, pH also affects rate of survival of microorganisms during storage, heating, drying and other forms of processing. Many times the initial pH may be suitable, but growth of the organism itself may alter the pH, thereby making it unfavourable. Conversely, the initial pH may be restrictive, but the growth of a limited number of microorganisms may alter the pH to a more favourable range for the growth of many other microorganisms.

The inherent pH of foods varies, although most are neutral or acidic. Materials with an alkaline pH generally have a rather unpleasant taste with some exceptions like egg white where the pH increases to around 9.2, as CO_2 is lost from the egg after laying. The pH of a product can be easily determined with a pH meter. However, this value alone is not sufficient for predicting microbial spoilages. It is also desirable, for example, to know the acid responsible for a given pH, because some acids, particularly the organic acids, are more inhibitory than others.

2.2.2 Effect on Microbial Ecology and Food Spoilage

The acidity of a product plays an important role in deciding the type microflora present in food and the rate and type of its spoilage. For example, most of the meats and seafoods have a final ultimate pH of about 5.6 and above. Thus, these products are susceptible to bacterial as well as to mold and yeast spoilage. Similarly, most vegetables have higher pH values than fruits, and thus vegetables would be more prone to bacterial than fungal spoilage since such pH values favour bacterial growth. Soft-rot producing bacteria such as *Erwinia carotovora* and pseudomonads play a significant role in their spoilage. In fruits, however, a lower pH (below 4.5) prevents bacterial growth and yeasts and molds dominate spoilage.

Fish is spoiled more rapidly than meat under chilled conditions. This is due to the fact that the pH of post-rigor mammalian muscle is around 5.6 and this contributes to the longer storage life of meat. On the other hand, fish have a pH between 6.2-6.5. *Shewanella* (formerly *Alteromonas*) mainly causes spoilage under chilled conditions. It is a pH-sensitive microbe and hence, plays a significant role in fish spoilage but not in normal meat (pH<6.0). Those fishes that have a naturally low pH such as halibut (pH~5.6) as a result have better keeping qualities than other fish. Thus, a food with inherently low pH would tend to be more stable microbiologically than a neutral food.

Upon the death of a well-rested meat animal, the usual 1% glycogen is converted into lactic acid, which directly causes a depression in pH values from about 7.4 to about 5.6. Most of the bacteria cannot tolerate lower pH, hence meat has a longer storage life. Meat from fatigued animals spoils faster than that from rested animals. This is because most of the glycogen present had already been used during its lifetime and hence, final pH attained upon completion of rigor mortis is not as low as that of a well-rested animal. Thus, bacteria are able to grow and spoil it.

The excellent keeping quality of certain foods is related to their restrictive pH, for example fruits, soft drinks, fermented milks, sauerkraut and pickles which have an acidic pH. Fruits, soft drinks, vinegar, and wines have an excellent keeping quality mainly due to pH, which falls far below the point at which bacteria normally grow. Fruits generally undergo mold and yeast spoilage, and this is due to the capacity of these organisms to grow at pH values < 3.5, which is considerably below the minima for most food spoilage and all food poisoning bacteria.

Some foods have a low pH because of inherent acidity; others, for example, the fermented products like sauerkraut, pickles and fermented milks have a low pH because of acidity produced due to the activity of microorganisms. This acidity is also known as biological acidity and is generally due to the accumulation of lactic acid during fermentation. Regardless of the source of acidity, the effect upon keeping quality appears to be the same. This ability of low pH to restrict microbial growth has been employed since the earliest times for preservation of foods using acetic acid and lactic acids.

2.2.3 Inhibition of Microbes by Weak Acids

With the exception of those soft drinks that contain phosphoric acid, in most other acidic foods acidity is due to the presence of weak organic acids. These do not dissociate completely into protons and conjugate base in solution but establish equilibrium:

$$HA \rightleftarrows H^+ + A^-$$

The partial dissociation of weak acids, such as acetic acid, plays an important role in their ability to inhibit microbial growth. Although addition of strong acids has a more profound effect on pH but at the same pH, they are less inhibitory than weak lipophilic acids. This is because microbial inhibition by weak acids is directly related to the concentration of undissociated acid (Figure 2.1). These undissociated lipophilic acid molecules can pass freely through the membrane, in doing so they pass from an external environment of low pH where the equilibrium favours the undissociated molecule to the high pH of the cytoplasm. At this higher pH, the equilibrium shifts in favour of the dissociated molecule, so the acid ionizes producing protons. These protons tend to acidify the cytoplasm. The cell tends to maintain its internal pH by expelling protons leaking in. This process requires energy and the microbe diverts energy from growth related functions to removing protons from the cell thereby slowing its growth. The burden on the cell becomes too great. The cytoplasmic pH drops to a level where growth is no longer possible and the cell eventually dies. Strong acids on the other hand dissociate completely into protons and conjugate base in solution. These dissociated acid molecules cannot pass freely through the cell membrane. Hence there is not much change in the pH of the cytoplasm. As a result these are less inhibitory than weak acids at the same pH.

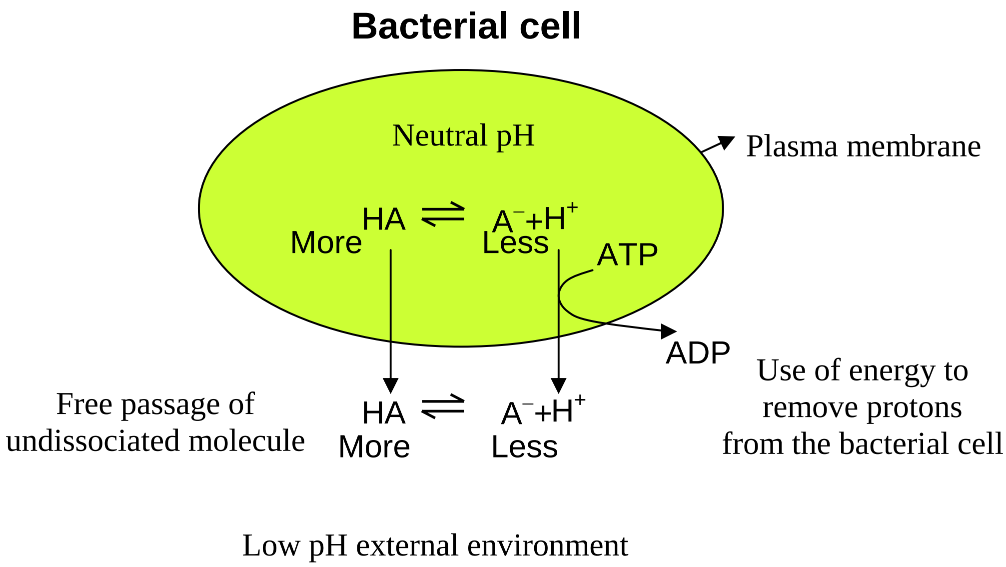

Figure 2.1: Inhibition of bacterial growth by weak acids

2.2.4 Buffers in Foods

Some foods are better able to resist changes in pH than others. These tend to resist changes in pH since these are buffered and the ability to resist changes in pH is known as buffering capacity. The buffers are the compounds present in food that resist changes in pH and thus are important. These are especially effective within a certain pH range. Buffers permit an acid (or alkaline) fermentation to go on longer with a greater yield of products and organisms than would otherwise be possible. In general, meats are more buffered than vegetables. Contributing to the buffering capacity of meats are their various proteins. Vegetables are generally low in proteins and consequently lack the buffering capacity to resist changes in their pH by the growth of microorganisms. Hence these permit an appreciable decrease in pH with the production of small amounts of acid by the lactic acid bacteria during the early part of sauerkraut and pickle fermentations. This is desirable since it enables the lactic acid bacteria to suppress the undesirable pectin-hydrolyzing and proteolytic organisms which cause spoilage. Low buffering power makes for a more rapidly appearing succession of microorganisms during fermentation than high buffering power. Milk is fairly high in protein (a good buffer) and therefore permits considerable growth and acid production by lactic acid bacteria during the manufacture of fermented milks before growth is suppressed.

2.3 MOISTURE REQUIREMENT/WATER ACTIVITY

One of man's oldest methods of preserving foods is drying or desiccation. The preservation of foods by drying is a direct result of removal of moisture. Microorganisms need water for growth. Without water no growth can occur. The exact amount of water needed for growth of microorganisms varies. This water requirement of microorganisms is best expressed in terms of available water or water activity a_w, the vapour pressure of the solution (of solutes in water in most foods) divided by the vapour pressure of the solvent (usually water). Thus a_w, for pure water would be 1.00. The water activity depends on the number of molecules and ions present in solution, rather than their size. Thus a compound like sodium chloride, which dissociates into two ions in solution, is more effective at reducing the water activity than a compound like sucrose on mole-to-mole basis.

2.3.1 Effect on Microbial Growth and Activity

Bacteria require higher values of a_w for growth than fungi. Gram-negative bacteria have higher requirements than gram positives. Most spoilage bacteria do not grow below a_w 0.91, while spoilage molds can grow as low as 0.80. However, food-poisoning bacteria like *Staphylococcus aureus* can grow at a_w as low as 0.86, while *Clostridium botulinum* does not grow below 0.94. Yeasts and molds can grow over a wider a_w range than bacteria. The lowest a_w values for bacteria is 0.75 for halophilic (meaning salt-loving) bacteria, while xerophilic (dry-loving) molds and osmophilic (preferring high osmotic pressures) yeasts can grow at a_w values of 0.65 and 0.60, respectively. The limiting value of water activity for the growth of microorganisms is about 0.6 and below this value the spoilage of foods is not due to microorganisms but may be due to insect damage or chemical reaction such as oxidation. At a water activity of 0.6, corresponding to a water potential of -68MPa (Mega Pascals), the cytoplasm would need to contain very high concentrations of an appropriate compatible solute and it is probable that the macromolecules such as DNA would no longer function properly and active growth may stop.

Most bacteria grow well in a medium with a water activity a_w approaching 1.00 (at 0.995 to 0.998), i.e., they grow best in low concentrations of sugar or salt. Culture media for most bacteria contain not more than 1 per cent of sugar and 0.85 per cent of sodium chloride (physiological salt solution). As little as 3 to 4 percent sugar and 1 to 2 percent salt may inhibit some bacteria. The optimal a_w and the lower limit of a_w for growth vary with the bacterium, as well as with food, temperature, pH, and the presence of oxygen, carbon dioxide, and inhibitors. The optimal a_w and the lower limit of a_w for growth is lower for bacteria which are able to grow in high concentrations of sugar or salt. Some examples of lower limits of a_w for growth of some food bacteria are given in Table 2.2. These figures would vary depending on conditions used for growth of the microorganisms as mentioned above.

Table 2.2: Minimum a_w values for growth of microorganisms of importance in food

Organisms	Water activity (a_w)	Organisms	Water activity (a_w)
Groups		**Specific organisms**	
Most spoilage bacteria	0.90	*Pseudomonas* spp.	0.97
Most spoilage yeasts	0.88	*Escherichia coli*	0.96
Most spoilage molds	0.80	*Bacillus subtilis*	0.95
Halophilic bacteria	0.75	*Enterobacter aerogenes*	0.945
Xerophilic molds	0.61	*Clostridium botulinum*	0.93
Osmophilic yeasts	0.60	*Staphylococcus aureus*	0.86

Molds differ considerably in optimal a_w and range of a_w for the germination of asexual spores. The minimal a_w for spore germination is as low as 0.62 for some molds and as high as 0.93 for others (e.g., *Mucor*, *Rhizopus*, and *Botrytis*). Each mold also has an optimal a_w and range of a_w for growth. Examples of optimal a_w are 0.98 for *Aspergillus* sp., 0.995 to 0.98 for *Rhizopus* sp., and 0.9935 for *Penicillium* sp. The a_w would have to be below 0.62 to stop all chances for mold growth, although a_w below 0.70 inhibits most molds that cause food spoilage. The reduction of the a_w below the optimum for a mold delays spore germination and reduces the rate of growth and therefore is an important factor in food preservation. Many of the molds can grow in foods with a_w approaching 1.00 (pure water).

With a reduction of water activity of food, the number of microorganisms capable of maintaining active growth in it decreases. On the other hand, there are microorganisms that grow better at reduced $a_{w.}$ These microorganisms are generally associated with foods having low water activity. Since low water activities are associated with three distinct types of food, the following three terms are used to describe the microorganisms especially associated with these foods:

i) **Halotolerant** – able to grow in the presence of high concentrations of salt

ii) **Osmotolerant** – able to grow in the presence of high concentrations of nonionized organic compounds such as sugars.

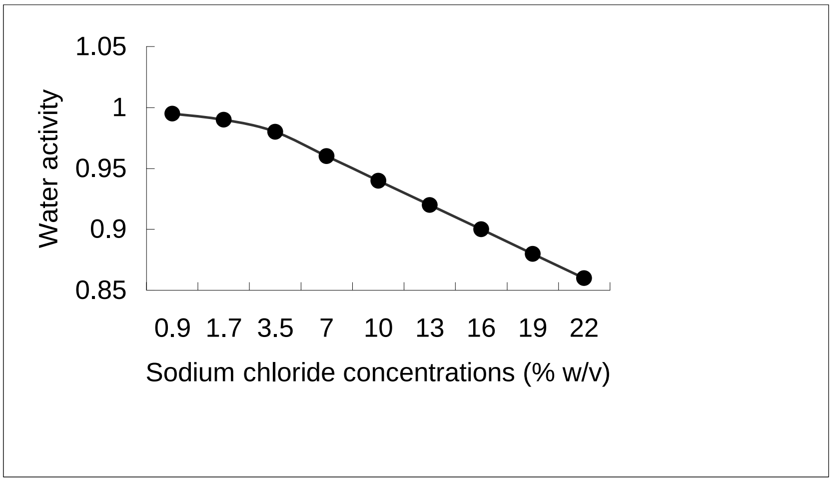
iii) **Xerotolerant** – able to grow on dry foods.

The halobacteria are obligately halophilic and cannot grow in the absence of high concentration of salt.

2.3.2 Ways of Reducing Water Activity

Water is made unavailable in various ways:

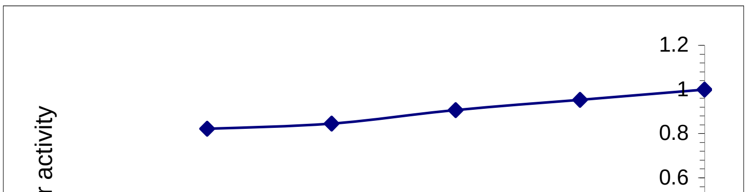
1. *Solutes and ions tie up water in solution.* Solutes lower a_w and this reduction in a_w depends on the total concentration of dissolved molecules and ions. Since these bind to water molecules, there is reduction in a_w. Therefore, an increase in the concentration of dissolved substances such as sugars and salts is in effect a drying of the material (Graph 2.1). Not only is water tied up by solutes, but also water tends to leave the microbial cells by reverse osmosis to maintain equilibrium between the concentration of solute outside and inside the cells.



Graph 2.1: Effect of sodium chloride concentration on water activity

2. *Hydrophilic colloids (gels) make water unavailable.* As little as 3 to 4 percent agar in a medium may prevent bacterial growth by leaving too little available moisture.

3. *Water of crystallization or hydration is usually unavailable to microorganisms*. Water itself, when crystallized as ice, no longer can be used by microbial cells. The a_w of water-ice mixtures (vapour pressure of ice divided by vapour pressure of water) decreases with a decrease in temperature below 0^oC (Graph 2.2). In a food, as more and more ice is formed, the concentration of solutes in the unfrozen water increases, thus lowering available water and thereby it's a_w is reduced.



Graph 2.2: Effect of temperature on water activity

The water activity a_w varies with temperature; these variations are only slight within the range of temperatures that permit microbial growth. Variations in temperature increase in importance with increasing concentrations of solutes and increasing effects on ionization of solutes.

Each microorganism has a maximal, optimal, and minimal a_w for growth. As the a_w is reduced below the optimal level, there is a lengthening of the lag period of growth, a decrease in the rate of growth and a decrease in the amount of cell substance synthesized, changes that vary with the organism and with the solute employed to reduce a_w. This range depends on a number of factors which are mentioned below.

2.3.3 Factors Affecting Water Requirement

Factors that may affect a_w requirements of microorganisms include:

1. *Kind of solute employed to reduce the a_w*: For some organisms, like molds, the lowest a_w for growth is independent of the kind of solute used. For other organisms, however, lower limiting a_w values differ from solute to solute. For example potassium chloride usually is less toxic than sodium chloride, and it in turn is less inhibitory than sodium sulphate. Thus, sodium sulphate at a lower concentration may be as effective in reducing a_w as potassium chloride at a higher concentration.

2. *Nutritive value of the culture medium*: In general, the better the medium for growth, the lower the limiting a_w permitting growth of microorganism.

3. *Temperature*: Most organisms have the greatest tolerance to low a_w at about optimal temperatures.

4. *Oxygen supply*: Growth of aerobes takes place at a lower a_w in the presence of air than in its absence, and the reverse is true of anaerobes.

5. *pH*: Most organisms are more tolerant of low a_w at pH values near neutrality than in acid or alkaline media.

6. *Inhibitors*: The presence of inhibitors narrows the range of a_w for growth of microorganism.

Each organism has its own characteristic optimal a_w and its own range of a_w for growth in a given set of environmental conditions. This range of a_w permitting growth is narrowed if any of the above mentioned environmental factors are not optimal and is narrowed still more if two or more conditions are not favourable. An unfavourable a_w will result not only in a reduction in the rate of growth but will also reduce the yield of cells. The delay (lag) in initiation of growth or germination of spores will be more under more unfavourable a_w of the substrate. It is known that growth of at least some cells may occur in high numbers at reduced a_w values, but the production of certain extracellular products may be limited or these may not be produced at all. For example, reduced a_w results in the cessation of enterotoxin B production by *Staphylococcus aureus* even though high numbers of cells are produced at the same time This often is as important in food preservation as reduction in the rate of growth of the organism. Microorganisms that can grow in high concentrations of solutes, e.g., sugar and salt, obviously have a low minimal a_w. Halophilic bacteria require a certain minimal concentration of dissolved sodium chloride for growth. Osmophilic yeasts grow best in high concentrations of sugar.

2.4 OXIDATION REDUCTION POTENTIAL

The tendency of a substrate to accept or donate electrons, is termed its redox potential (*E*h). The O/R potential of a substrate may be defined generally as the ease with which the substrate loses or gains electrons. When a substrate loses electrons, the substrate is oxidized while a substrate that gains electrons becomes reduced. Therefore, a substance that readily gives up electrons is a good reducing agent, while one that readily takes up electrons is a good oxidizing agent. In the equation below, this is represented in its most general form to include the many redox reactions, which also involve protons and have the overall effect of transferring hydrogen atoms.

$$[\text{Oxidant}]+H^{+}+ne \rightleftarrows [\text{Reductant}]$$

Where *n* is the number of electrons, e, transferred.

The tendency of an atom or molecule to accept or donate electrons is expressed as its standard redox potential, *E*o'. When electrons are transferred from one compound to another, a potential difference is created between the two compounds. This difference may be measured by use of an appropriate instrument and expressed as millivolts (mv). It can be measured against an external reference by an inert metal electrode, usually platinum. The more highly oxidized a substance, the more positive will be its electrical potential, and the more highly reduced a substance, the more negative will be its electrical potential.

2.4.1 Redox Couples in Food

Pair of oxidizing and reducing agents present in food are known as redox couples. A large positive *E*o' of food indicates that the oxidized species of the couple is a strong oxidizing agent and the reduced form only weakly reducing. A large negative *E*o' of food indicates the reverse. When the concentration of oxidant and reductant is equal, a zero electrical potential exists. The relative proportions of oxidized and reduced species present will also influence the measured Eh. If the balances of the various redox couples present favours the oxidized state then there will be a tendency to accept electrons from the electrode creating a positive potential, which signifies an oxidizing-environment. If the balance is reversed, the sample will tend to donate electrons to the electrode, which will then register a negative potential – a reducing environment.

With the notable exception of oxygen, most of the couples present in foods, *e.g.* glutathione and cysteine in meats and ascorbic acid and reducing sugars in plant products, would on their own tend to establish reducing conditions. Oxygen, which is present in the air at a level of around 21 %, is usually the most influential redox couple in food systems. It has a high *E*o' and is a powerful oxidizing agent. If sufficient air is present in food, a high positive potential will result and most other redox couples present will, if allowed to equilibrate, be largely in the oxidized state. Hence, increasing the access of air to food material by chopping, grinding or mincing will increase its *E*h. Similarly, exclusion of air as in modified vacuum packing or canning will reduce the *E*h.

2.4.2 Effect of Microbial Growth on Redox Potential of Food

Microbial growth in food reduces its *E*h. This is usually because during their growth, microorganisms consume oxygen and produce reducing compounds such as hydrogen. Oxygen is the most important terminal electron accepter in the electron transport chain, especially in case of aerobes. During passage of electrons through the electron transport chain, microorganisms generate energy and thereby oxygen is depleted. As the oxygen content of the medium decreases, so the redox potential declines from a positive potential to a negative potential.

The decrease in *E*h as a result of microbial activity is the basis of some rapid tests for determination of microbial load of food, particularly dairy products. Redox dyes such as methylene blue or resazurin are used to indicate changes in *E*h, which are correlated with microbial levels. These dyes become colourless when these are reduced. The time taken for reduction of the dyes will be inversely proportional to the microbial load of food i.e. more the microorganisms in food, less is the time taken for dye to be reduced and *vice versa*. The factors influencing redox potential of foods are summarized in Table 2.3 given below:

Table: 2.3 Factors affecting redox potential of foods

1. Redox couples present
2. Ratio of oxidizing species to reducing species
3. pH
4. Poising capacity
4. Availability of oxygen
5. Microbial activity

2.4.3 Effect on Microbial Growth and Ecology

Redox potential exerts an important selective effect on the microflora of a food since it will decide the type of microorganism which can grow in that food. Microbial growth can occur over a wide spectrum of redox potential. However, individual microorganisms have their own redox ranges over which they can grow. They are classified into one of several physiological groups on the basis of the redox range over which they can grow and their response to oxygen. Based on their ability to use free oxygen, microorganisms have been classified as

1. **Aerobic** when they require free oxygen.
2. **Anaerobic** when they grow best in the absence of free oxygen.
3. **Facultative** when they grow well either aerobically or anaerobically.

Molds are aerobic, most yeast grow best aerobically and bacteria may be aerobic, anaerobic, or facultative. A high (oxidizing) potential favours aerobes but will permit the growth of facultative organisms also, and a low (reducing) potential favours anaerobic or facultative organisms. Growth of an organism may alter the O-R potential of a food enough to inhibit other organisms. Anaerobes, for example, may lower the O-R potential to a level which is inhibitory to aerobes.

Obligate aerobes are those organisms that generate their energy from oxidative phosphorylation using oxygen as the terminal electron acceptor. Consequently, they have a requirement for oxygen and a high *E*h and will predominate at food surfaces exposed to air or where air is readily available, for example, pseudomonads, such as *Pseudomonas fluorescens*, which grows at an *E*h of +100 to +500 mv, and other oxidative Gram-negative rods. These grow on meat surfaces and produce slime and off-odours. *Bacillus subtilis (E*h -100 to +135 mv) produces ropiness in the open texture of bread and *Acetobacter* species growing on the surface of alcoholic beverages oxidize ethanol to acetic acid to produce vinegar or spoil the alcoholic beverage.

Plant juices, tend to have *E*h values of +300 to +400 mv. It is not surprising to find that aerobic bacteria and molds are the common cause of spoilage of products of this type. Minced meats have *E*h values of around +200 mv while in solid meats the *E*h is generally around -200 mv. Cheeses have *E*h values on the negative side from –20 to around –200 mv.

Obligate anaerobes grow only at low or negative redox potentials and require absence of oxygen. Anaerobic metabolism gives the organism a lower yield of utilizable energy than aerobic respiration. A reducing environment minimizes the loss of reducing power from the microbial cell and thus, is favoured. Hence, presence of oxygen, which provides an oxidizing environment to the microbes is not favoured. However, for many anaerobes, oxygen itself exerts a specific toxic effect. For example, *Clostridium acetobutylicum* can grow at an *E*h as high as +370 mv maintained by ferricyanide, but would not grow at +110mv in an aerated culture. This effect is due to the inability of obligate anaerobes to scavenge and destroy toxic products of molecular oxygen such as hydrogen peroxide and superoxide anion radical (0_2^-) produced by one electron reduction of molecular oxygen. They lack the enzymes catalase and superoxide dismutase, which catalyse the breakdown of these radicals.

Thus, in a highly oxidized food, there will be a predominance of aerobic organisms especially at food surfaces exposed to air. Whereas, in food with negative *E*h, the anaerobic microflora requiring reduced conditions will be favoured. For example, anaerobic bacteria do not multiply until the onset of rigor mortis (stiffening of body after death) of muscles of horse because of the high *E*h (+250 mv) in prerigor meat. At 30 h postmortem (after death), the *E*h falls to about -130 mv in the absence of bacterial growth and this low *E*h values favour the growth of obligate anaerobes like *Clostridium.* Obligate anaerobes, such as clostridia, have the potential to grow wherever conditions are anaerobic such as deep in meat tissues and stews, in vacuum packs and canned foods causing spoilage and C. *botulinum* is of major public health concern, since it causes botulism.

Aerotolerant anaerobes are incapable of aerobic respiration, but can nevertheless grow in the presence of air. Many lactic acid bacteria fall into this category. They can only generate energy by fermentation and lack both catalase and superoxide dismutase, but are able to grow in the presence of oxygen because they have a mechanism for destroying superoxide.

Microorganisms affect the *E*h of their environment during growth. This is true especially of aerobes, which can lower the *E*h of their environment while anaerobes cannot. As aerobes grow, oxygen in the medium is depleted, resulting in the lowering of *E*h. Growth is not slowed, however, due to the ability of cells to make use of oxygen donating or hydrogen-accepting substances in the medium. The result of this is that the medium becomes poorer in oxidizing and richer in reducing substances. Microorganisms can reduce the *E*h of a medium by their production of certain metabolic by-products such as hydrogen sulphide, which has the capacity to lower *E*h to –300 mv. Since hydrogen sulphide reacts readily with oxygen, it will accumulate only in anaerobic environments.

2.4.4 Poising Capacity of Food

As redox conditions change, there will be some resistance to change in a food's redox potential. This is known as poising capacity of food. This capacity is dependent on the concentration of the redox couple. Poising is greatest when the two components of a redox couple are present in equal amounts.

Most fresh plant or animal foods have a low and well-poised O-R potential in their interior: the plants because of reducing substances such as ascorbic acid and reducing sugars and the animal tissues because of SH (sulfhydryl) and other reducing groups. As long as the plant or animal cells respire and remain active, they tend to poise the O-R system at a low level, resisting the effect of oxygen diffusing from the outside. Therefore, a piece of fresh meat or a fresh whole fruit would have aerobic conditions only at and near the surface. The meat could support aerobic growth of slime-forming or souring bacteria at the surface at the same time as anaerobic putrefaction could be proceeding in the interior.

Processing procedures may alter this situation. For example, heating may reduce the poising power of the food by destroying or altering the reducing and oxidizing substances present and also allow more rapid diffusion of oxygen inward, either because of the destruction of poising substances or because of changes in the physical structure of the food. Processing also may remove oxidizing or reducing substances. For example, clear fruit juices loose reducing substances by their removal during extraction and filtration and therefore become more favourable to the growth of yeasts than the original juice containing the pulp.

In the presence of limited amounts of oxygen the same aerobic or facultative organisms may produce incompletely oxidized products, such as organic acids, from carbohydrates, while with plenty of oxygen available, complete oxidation to carbon dioxide and water might result. Protein decomposition under anaerobic conditions may result in putrefaction, whereas under aerobic conditions, the products are likely to less obnoxious. Thus, the redox potential of the food would decide the course of spoilage and the type of end products being produced due to microbial activities.

2.5 NUTRIENT CONTENT

Microorganisms use foods as a source of nutrients and energy. Each kind of microorganism has a definite range of food requirements. For some species that range is wide and growth takes place in a variety of substrates e.g. coliform bacteria; but others, e.g., many of the pathogens, being fastidious in their nutrient requirements can grow in limited kinds of substrates. The better the medium for an organism, the wider the ranges of temperature, pH, and a_w over which growth can take place.

The food based on their nutrient composition can be classified as (1) foods for energy, (2) foods for growth, and (3) accessory food substances, or vitamins, which may be necessary for energy or growth.

2.5.1 Foods for Energy

The carbohydrates, especially the sugars, are most commonly used as an energy source, but other carbon compounds may also serve the purpose, e.g., esters, alcohols, peptides, amino acids, organic acids and their salts. Comparatively few organisms can utilize complex carbohydrates, e.g., cellulose and starch. Microorganisms differ even in their ability to use some of the simpler soluble sugars. Many organisms cannot use the disaccharide lactose (milk sugar) and therefore do not grow well in milk. Some yeast do not attack maltose. Most organisms, if they utilize sugars at all, can use glucose. The ability of microorganisms to hydrolyze pectin, which is characteristic of some kinds of bacteria and many molds, is important in the softening or rotting of fruits and vegetables or fermented products got from them. The ability to synthesize amylolytic (starch degrading) enzymes will favour the growth of an organism on cereals and other starchy products. The addition of fruits containing sucrose and other sugars to yoghurt increases the range of carbohydrates available and allows the development of a more diverse spoilage microflora of yeasts.

Bacteria differ in their ability to utilize different foods as a source of energy. Some can use a variety of carbohydrates, e.g., the coliform bacteria and *Clostridium* spp., and others only one or two. Some can use other carbon compounds like organic acids and their salts, alcohols, and esters *(Pseudomonas* spp.). Some can hydrolyze complex carbohydrates, although others cannot.

A limited number of microorganisms can obtain their energy from fats but do so only if a more readily usable energy food, such as sugar, is absent. First, the fat must be hydrolyzed with the aid of lipase to glycerol and fatty acids, which then can serve as energy source for the hydrolyzing organism or others microbes that grow on products of lipid hydrolysis. Aerobic microorganisms are more commonly involved in the decomposition of fats than anaerobic ones, and the lipolytic organisms usually are also proteolytic.

Split products of proteins, for example, peptides and amino acids, serve as an energy source for many proteolytic organisms when a better energy source is lacking. These also serve as source of energy for some non-proteolytic organisms. Meats for example, may be low in carbohydrate and therefore will be decomposed by proteolytic species, e.g., *Pseudomonas* spp.

Molds in general can utilize many kinds of foods as energy source, ranging from simple to complex. Most of the common molds possess a variety of hydrolytic enzymes and some are grown for their amylases, pectinases, proteinases, and lipases.

Not only is the kind of energy food important but also its concentration in solution and hence it's osmotic effect and the amount of available moisture, which will determine its growth rate. For a given percentage of sugar in solution, the osmotic pressure will vary with the weight of the sugar molecule, Therefore, a 10% solution of glucose has about twice the osmotic pressure of a 10% solution of sucrose or maltose; i.e., it ties up twice as much moisture. Molds can grow in the highest concentrations of sugars and yeasts in fairly high concentrations but most bacteria grow best in fairly low concentrations. There are, of course, some exceptions to this generalization: osmophilic yeasts grow in as high concentrations of sugar as molds and some bacteria can grow in fairly high concentrations of sugar.

An adequate supply of foods for growth will favour utilization of the foods for energy. More carbohydrate will be used if a good nitrogen food is present in sufficient quantity than if the nitrogen is in poor supply. Organisms requiring special accessory growth substances might be prevented from growing if one or more of these vitamins were lacking, and thus the whole course of decomposition might be altered due to a change in the microflora.

2.5.2 Foods for Growth

Microorganisms differ in their ability to use various nitrogenous compounds as a source of nitrogen for growth. The primary nitrogen sources utilized by heterotrophic microorganisms are amino acids. A large number of other nitrogenous compounds may serve this function for example, nucleotides, free amino acids, peptides and proteins. Simple compounds such as amino acids will be utilized by most of the organisms before they utilize complex compounds such as high molecular weight proteins. The nitrogen requirements of some bacteria such as *Pseudomonas* spp. may be satisfied by simple compounds like ammonia or nitrates whereas for others like lactics, more complex compounds like amino acids, peptides, or proteins may be utilized or even required.

Many molds are proteolytic, but comparatively few bacteria and very few yeast are actively proteolytic. Proteolytic bacteria grow best at pH values near neutrality and are inhibited by acidity. Only exceptions are the acid-proteolytic bacteria that hydrolyze protein while producing acid. Carbon for growth for most of the microorganisms is derived from organic compounds but some can use carbon dioxide also.

The minerals required by microorganisms are nearly always present at the low levels required.

2.5.3 Accessory Food Substances or Vitamins

Bacteria also vary in their need for vitamins or accessory growth factors. Some microorganisms are unable to synthesize some or all of the vitamins needed for their growth. For example, *Staphylococcus aureus* synthesizes part while *Pseudomonas* or *Escherichia coli* all of the factors needed. The lactics and many pathogens must have all of the vitamins furnished. Most natural plant and animal foodstuffs contain an array of these vitamins, but some may be low in amount or lacking. For example, meats are high in B vitamins and fruits are low, but fruits are high in ascorbic acid.

Microorganisms may require B vitamins in low quantities and most of the natural foods have an abundant quantity of these. Gram positive bacteria are the least synthetic and must, therefore, be supplied with one or more of these compounds before they will grow. Gram negative bacteria and molds are able to synthesize most of their requirements. Consequently, these two groups of organisms may be found growing on foods low in B vitamins. Fruits tend to be lower in B vitamins than meats. Thus, the usual spoilage of fruits is by molds rather than bacteria since fruits also have a low pH and positive *E*h, which favour mold growth.

Egg white contains biotin but also contains avidin, which ties it up, making it unavailable to microorganisms and thus eliminate spoilage of eggs through biotin requiring organisms. The processing of foods often reduces the vitamin content. For example, thiamine, pantothenic acid, folic acid and ascorbic acid (in air) are heat-labile. Drying causes a loss in vitamins such as thiamine and ascorbic acid. Even storage of foods for long periods, especially if the storage temperature is elevated, may result in a decrease in the level of some of these growth factors.

2.6 BIOLOGICAL STRUCTURE

The plants and animals that serve as food sources have all evolved mechanisms of defense against the invasion and proliferation of microorganisms. By taking these natural phenomena into account, one can make effective use of these in preventing the microbial spoilage of the products.

2.6.1 Antimicrobial Barriers

The inner parts of whole, healthy tissues of living plants and animals are either sterile or low in microbial content. Therefore, unless opportunity has been given for their penetration, spoilage organisms within raw food may be few or lacking.

The first barrier is the integument: a physical barrier to protect the food, e.g., the shell on eggs, the skin on poultry, the shell on nuts and the rind or skin on fruits and vegetables, or these may be surrounded by natural wax. It is usually composed of macromolecules relatively resistant to degradation and provides an inhospitable environment for microorganisms either with a low water activity or nutrients deficiency or antimicrobial compounds e.g. short chain fatty acids on animal skin, essential oils on plant surfaces etc. This physical protection to the food may not only help in its preservation but may also determine the kind, rate and course of spoilage. Layers of fat over meat may protect that part of the flesh, or scales may protect the outer part of the fish.

2.6.2 Effect of Destruction of Microbial Barriers

Physical damage to the integument allows microbial invasion of the underlying nutrient-rich tissues and it is a common observation that damaged fruits and vegetables deteriorate more rapidly than entire products and that this process is initiated at the site of injury. Consequently, it is important that during harvesting and transport these barriers are maintained intact as far as possible.

An increase in exposed surface, brought about by peeling, skinning and chopping may serve not only to distribute spoilage organisms but also to release juices containing food materials for the microorganisms. The disintegration of tissues by freezing may accomplish a similar result. In meat the growth of spoilage bacteria takes place mostly in the fluid between the small meat fibers and it is only after rigor mortis that much of this food material is released from the fibers to become available to spoilage organisms.

2.7 INHIBITORY SUBSTANCES

These may be originally present in the food, added purposely or accidentally, or developed there by growth of microorganisms or by processing methods. These may prevent growth of all microorganisms or, more often, may deter certain microorganisms. The mechanism of action for nearly all antimicrobials can be classified into one or more of the following groups: (1) reaction with the cell membrane, (2) inactivation of essential enzymes, or (3) destruction or functional inactivation of genetic material.

2.7.1 Biological Inhibitory Substances Originally Present in Food

The stability of some foods against attack by microorganisms is due to the presence of certain naturally occurring substances e.g. plants such as mustard, horseradish, watercress, cabbage and other brassicas produce antimicrobial isothiocyanates (mustard oils) (Fig. 2.2) and in *Allium* species (garlic, onions and leeks) thiosulfinates such as allicin. Antimicrobials collectively known as phytoalexins are produced by many plants in response to microbial invasion, for example phaseollin an antifungal compound is produced in green beans.
Many natural constituents of plant tissues such as pigments, alkaloids and resins also have antimicrobial properties. Benzoic and sorbic acids found in cranberries and mountain ash berries respectively are commonly used in their pure forms as food preservatives. The anthocyanins are a group of water-soluble pigments, which occur naturally in fruits. The aglycone portion of these compounds, the anthocyanidins, has antimicrobial powers against several bacterial spp.

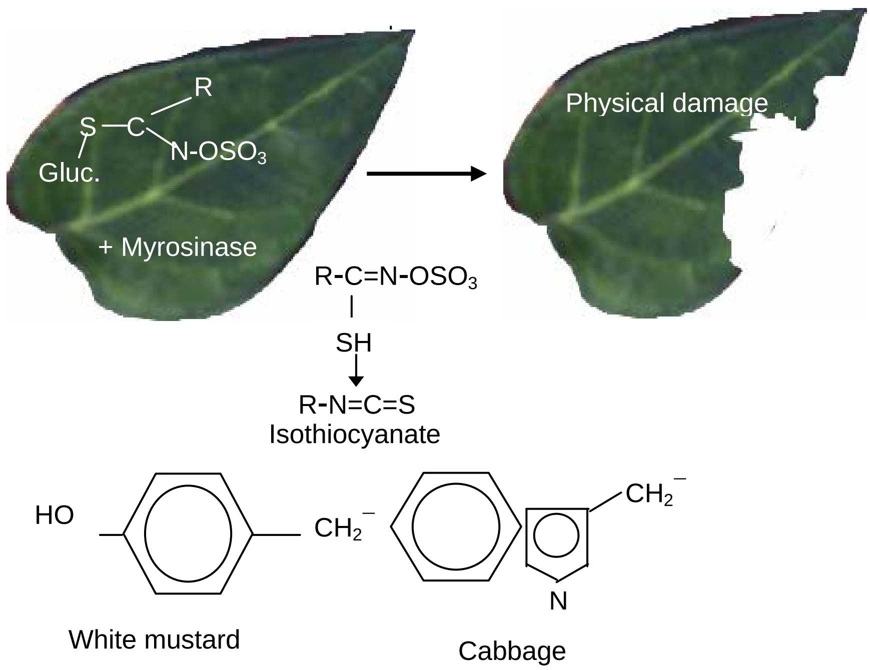

Figure 2.2: Production of plant antimicrobials as a result of physical damage

Some spices are known to contain essential oils that possess antimicrobial activity e.g. eugenol in cloves, allicin in garlic, cinnamic aldehyde and eugenol in cinnamon, allspice (pimento) and cloves, allyl isothiocyanate in mustard, eugenol and thymol in sage and carvacrol (isothymol) and thymol in oregano etc. As a consequence, herbs and spices may contribute to the microbiological stability of foods in which they are used. It has, for example, been claimed that inclusion of cinnamon in raisin bread retards mould spoilage. However, in some cases, they can be a source of microbial contamination leading to spoilage or public health problems. Outbreaks of botulism associated with crushed garlic in oil and home canned peppers demonstrate that even in relatively high concentrations plant antimicrobials are not a complete guarantee of safety.

These antimicrobial components differ in their spectrum of activity and potency. They are present at varying concentrations in the natural product and are frequently at levels too low to have any effect. Humulones contained in the hop resin impart the characteristic bitterness of the product but have also been shown to possess activity against the common beer spoilage organisms, lactic acid bacteria.

Antimicrobial oleuropein from green olives and its aglycone are also inhibitory to lactic acid bacteria and if not removed at this early stage, they would prevent the necessary fermentation occurring subsequently. The hydroxycinnamic acid derivatives (coumaric, ferulic, caffeic and chlorogenic acids) found in fruits, vegetables, tea, molasses and other plant sources all show antibacterial and some antifungal activity.

Animal products too, have a range of non-specific antimicrobial constituents, for example egg white or albumen possesses a variety of inhibitory components (Table 2.4). Similar factors can also be found in milk, however, in lower concentrations e.g. enzyme lysozyme which catalyses the hydrolysis of glycosidic linkages in peptidoglycan. Destruction or weakening of this layer causes the cell to rupture (lyse) under osmotic pressure. Lysozyme is most active against gram- positive bacteria, where the peptidoglycan is more readily accessible, but it can also kill gram- negatives if their protective outer membrane is damaged in some way.

Table 2.4: Antimicrobial substances in egg and milk

Egg	Milk
Ovotransferrin (conalbumin)	Lactoferrin
Lysozyme	Lysozyme
Avidin	-
Ovoflavoprotein	-
Ovomucoid and ovoinhibitor	-
-	Lactoperoxidase
-	Immunoglobulin

Other components limit microbial growth by restricting the availability of key nutrients. Ovotransferrin and conalbumin in egg white and lactoferrin in milk are proteins that scavenge iron from the medium. Iron is an essential nutrient for all bacteria. Infact, lysozyme with conalbumin provides fresh eggs with a fairly efficient antimicrobial system. In addition, egg white has powerful cofactor-binding proteins such as avidin and ovoflavoprotein, which remove biotin and riboflavin restricting the growth of those bacteria for which they are essential nutrients.

Cows' milk contains several other antimicrobial substances including conglutinin, lactenins, anticoliform factor and the lactoperoxidase system.

Casein as well as some free fatty acids that occur in milk have also been shown to be antimicrobial.

2.7.2 Inhibitory Substances Developed/ Destroyed in Food due to the Activity of Microorganisms

Microorganism growing in food may produce one or more substances inhibitory to other organisms, products such as acids, alcohols, peroxides, or even antibiotics. Propionic acid produced by the propionibacteria in Swiss cheese is inhibitory to molds; alcohol formed in quantity by wine yeasts inhibits competitors; and nisin a polypeptide produced by *Streptococcus lactis* may be useful in inhibiting lactate fermenting, gas-forming clostridia during curing of cheese. These may however, be undesirable during the manufacturing process since these would slow down some of the essential lactic acid streptococci. *Streptococcus cremoris* produces an inhibitor named diplococcin. The most pathogenic member of genus - *S. pyogenes* forms an inhibitor, streptococcin A-FF22. Streptococcin A-PF22 had many properties in common with nisin.

Gram-negative organisms and molds are insensitive to nisin. However, its effectiveness against sensitive gram-positive organisms depends on the bacterial load. As the number of organisms increases, the inhibitory effectiveness of nisin decreases. Nisin can be used along with heat processing since heat treated spores become more nisin sensitive. Thus, sterility might be attained with less heat treatment than presently used thereby decreasing the fuel consumption.

In addition to inhibitory polypeptides and bacteriocins, lactic streptococci produce acids and peroxides. These add up to a formidable array of substances designed to hinder and suppress other microbes. Hence, lactic acid bacteria are excellent competitors in foods. *S. diacetylactis* produces inhibitor inhibiting a broad-spectrum of gram-positive and gram-negative organisms. The undissociated molecule is the toxic component.

There is also the possibility of the destruction of inhibitory compounds in foods by microorganisms. Certain molds and bacteria are able to destroy some of the phenolic compounds that are added to meat or fish by smoking or benzoic acid added to foods; yeasts resistant to it destroy sulfur dioxide; and lactobacilli can inactivate nisin.

2.7.3 Inhibitory Substances Developed During Processing of Food

Heating foods may result in the formation of inhibitory substances e.g. heating lipids may hasten autoxidation and make them inhibitory and browning concentrated sugar syrups may result in production of furfural and hydroxymethylfurfural, which are inhibitory to fermenting organisms. Milk also has the capacity to generate antimicrobials in the presence of hydrogen peroxide. The milk enzyme lactoperoxidase will catalyse the oxidation of thiocyanate by hydrogen peroxide to produce *inter alia* hypothiocyanate. This can kill gram-negative bacteria and inhibit gram-positives, possibly by damaging the bacterial cytoplasmic membrane.

2.8 LET US SUM UP

Food is the substrate for growth of microorganisms. Since our foods are of plant and animal origin, all the characters of plant and animal tissues that affect the growth of microorganisms are important. In other words, food will dictate what grows or does not grow on it. Thus, knowledge about the factors that favour or inhibit growth of microorganisms is a must to make predictions about the microflora that may develop. The main factors, which influence microbial activity are pH, water activity, redox potential, nutrient composition, biological structure and presence of inhibitory substances in foods.

Each microorganism has a minimal, maximal and optimal range for pH, water activity and redox potential at which they can grow. These in turn would determine the microflora of food. Buffers in food and poising capacity of food also play an important role in deciding the succession of microorganisms and the extent of spoilage occurring in food.

Different microorganisms have different nutritional requirements. Some have a wide range while others are very fastidious in their nutritional requirements. The inability of an organism to utilize a component of food limits its growth and others with not so stringent requirements gain a competitive edge over it and predominate, thereby typifying the natural microflora of that food.

Plants and animals have also evolved mechanism of defense against invasion and proliferation of microorganisms. Antimicrobial barriers allow food to remain relatively free from microorganisms and the other inhibitory substances present in food/ produced during invasion by microorganisms tend to maintain low microbial counts in food.

These six parameters represent nature’s way of preserving plant and animal tissue from microorganisms. All these parameters have an important role to play in determining microbial ecology of food. These in turn decide the type of microbial activities likely to occur and the type of spoilage occurring. All these factors are interlinked and the changes in one factor may affect microbial requirements. By taking these natural phenomena into account, one can make effective use of each or all in preventing or retarding microbial spoilage of the products that are derived from them.

2.9 KEY WORDS

Aerobic : microorganisms are those, which require free oxygen for growth.

Anaerobic : microorganisms are those, which grow best in the absence of free oxygen.

Antibiotics : are substances produced by microorganisms which inhibit the growth of other microorganisms.

Antimicrobials : are substances which inhibit the growth of microorganisms.

Bacteriocins : are substances produced by a strain of bacterial spp. which inhibit growth of other strains of that bacterial spp.

Buffers : are the compounds that resist changes in pH.

Facultative : microorganisms are those, which grow well either aerobically or anaerobically.

Halotolerant : are those microorganisms, which are able to grow in the presence of high concentrations of salt.

Osmotolerant : are those microorganisms, which are able to grow in the presence of high concentrations of unionized organic compounds such as sugars.

Oxidising agent : is a substance that readily takes up electrons.

Phytoalexins : are a class of antimicrobials which are produced by many plants in response to microbial invasion.

Poising capacity : is the ability of food to resist change in a food's redox potential.

Proteolytic microorganisms : are those, which are able to hydrolyze proteins.

Redox potential : of a substrate may be defined generally as the ease with which the substrate loses or gains electrons.

Reducing agent : is a substance that readily gives up electrons.

Standard redox potential, *Eo*' : is the tendency of an atom or molecule to accept or donate electrons.

Water requirement or water activity a_w : is the vapour pressure of the solution (of solutes in water in most foods) divided by the vapour pressure of the solvent (usually water).

Xerotolerant : are those microorganisms which are able to grow on dry foods.

2.10 ANSWERS TO CHECK YOUR PROGRESS EXCERCISES

Check Your Progress Exercise 1

1. Fish is spoilt more rapidly than meat under chilled conditions. The pH of post-rigor mammalian muscle, around 5.6, is lower than that of fish (6.2-6.5) and this contributes to the longer storage life of meat. Those fishes that have a naturally low pH such as halibut (pH~5.6) have better keeping qualities than other fishes.

2. Your answer should include the following points:

   - pH attained upon rigor mortis of well rested animals
   - not much change in pH change in case of fatigued animal

3. Biological acidity is the acidity developed in food due to the activity of microorganisms growing in it. This generally occurs due to accumulation of lactic acid during fermentation.

4. Your answer should include the following points:

   - partial dissociation of weak acids
   - free passage of undissociated lipophilic acids into the cytoplasm
   - dissociation of lipophilic acids in the microbial cell
   - maintenance of internal pH by expulsion of protons

5. When microorganisms are grown on either side of their optimum pH range, an increased lag phase results. Adverse pH affects at least two aspects of a respiring microbial cell: the functioning of its enzymes and the transport of nutrients into the cell.

Check Your Progress Exercise 2

1. Your answer should include the Halotolerant, Xerotolerant and Osmotolerant microorganisms.

2. Water activity a_w, is the vapour pressure of the solution (of solutes in water in most foods) divided by the vapour pressure of the solvent (usually water).

3. Your answer should include the following points:

   - Solutes and ions tie up water in solution
   - Hydrophilic colloids (gels) make water unavailable
   - Water of crystallization or hydration is usually unavailable to microorganisms

4. Your answer should include the following points:

   - Kind of solute employed to reduce the a_w
   - Nutritive value of the culture medium
   - Temperature
   - Oxygen supply
   - pH
   - Inhibitors

Check Your Progress Exercise 3

1. The tendency of a substrate to accept or donate electrons, to oxidize or reduce, is termed its redox potential (*E*h).

2. Your answer should include aerobic, anaerobic and facultative microorganisms.

3. Poising capacity is the resistance to change in a food's redox potential with change in the redox conditions.

4. Your answer should include the following points:

   - Heating destroys/ alters reducing and oxidizing substances
   - Processing removes reducing and oxidizing substances

5. Factors affecting redox potential of foods are:

   - Redox couples present
   - Ratio of oxidant to reductant
   - pH
   - Poising capacity
   - Availability of oxygen
   - Microbial activity

Check Your Progress Exercise 4

1. Your answer should include the following points:

   - Concentration of sugars in food and their osmotic effect
   - Molds grow at high concentration of sugars
   - Osmophilic bacteria and yeasts grow at high concentration of sugars

Check Your Progress Exercise 5

1. Your answer should include the following points:

   - Type of physical barriers about food
   - These barriers provide inhospitable environment for the microbe
   - They determine type and rate of spoilage

2. Your answer should include the following points:

   - Physical damage allows microbial invasion into tissues
   - It distributes spoilage microbes
   - It releases juices from plant and animal tissues for microbial growth

Check Your Progress Exercise 6

1. The mechanism of action for nearly all antimicrobials can be classified into one or more of the following groups:

   a) Reaction with the cell membrane,

   b) Inactivation of essential enzymes, or

c) Destruction or functional inactivation of genetic material.

2. Your answer should include the following points:
   - Isothiocyanates – mustard oil
   - Thiosulfinates – in garlic, onions and leeks e.g. allium

3. Your answer should include the following points:
   - Antimicrobial substances present in egg
   - Antimicrobial substances present in milk

4. Your answer should include the following points:
   - Lysozyme catalyses the hydrolysis of glycosidic linkages in peptidoglycan
   - Destruction leads to cell lysis
   - Very active against gram positive bacteria

5. Your answer should include the following points:
   - Various types of inhibitory substances produced by microbes
   - Inhibitory substances produced by propionibacteria
   - Inhibitory substances produced by lactic streptococci

Structure

3.0 OBJECTIVES

After reading this unit you should be able to:

- state the fermenter, types of microorganisms involved in fermentation and their processes;
- explains the different products made by fermentation; and
- describe the waste from food processing industry and their utilization.

3.1 INTRODUCTION

Microorganism on one hand are responsible for causing a number of diseases, on the other hand they are employed to produce a number of useful products. These useful microorganisms include an array of yeasts, molds and bacteria. Traditionally, the man prepared wine, curd, vinegar and pickles using fermentation. Earlier, the term 'Fermentation' was used for the production of wine but at present it encompasses the foods made by the application of microorganisms including lactic acid bacteria (LAB). Lactic acid fermentation is one of the oldest method of preserving fruits and vegetables. Apart from contributing certain desirable physical and flavour characteristics, it also prolongs the availability and processing period of the products at relatively low cost. Many of the fermented products are made at industrial scale making use of microorganisms. Some of the fermented products and industrially important microorganisms are listed in Table 3.1.

Table 3.1: Production/synthesis of various compounds by micro-organisms

Product	Micro-organism(s) involved
Alcoholic beverages & related products	
Beer	*Saccharomyces cerevisiae*; *S. carlsbergensis*
Bourbon whiskey	*S. cerevisiae*
Cider	*S. cidri*
Palm wine	*Acetobacter* spp.; yeasts
Sake	*Aspergillus oryzae*; *Lactobacillus* spp.; *Leuconostoc* spp.; *S. cerevisiae*
Scotch whiskey	*S. cerevisiae*
Thumba	*Endomycopsis fibuliges*
Tibi	*Betabacterium vermiforme; S. intermidium.*
Vinegar	*Acetobacter* spp.
Wines	*S. cerevisiae* var. *ellispoideus*
Breads	
Idli	*Leuconostoc mesenteroids*
Rolls, cakes etc.	*S. cerevisiae*
Colour	
β-carotene	*Blakeslea trispora; Rhodotorula spp.*
Astaxanthine	*Phiffia rhodozyma*
Dairy products	
Acidophillus milk	*Lactobacillus acidophilus*
Bulgarian milk	*L. bulgaricus*
Cheeses (brie,	*Streptococcus lactis; S. cremoris*: *camembert, cheddar, S. durans; Penicillium camembertii*: *edam, P. candidum; P. roquefortii; Lactobacillus caseiroqueforte)*
Kefir	*Streptococcus lactis; L. bulgaricus; torula* spp.
Kumiss	*L. bulgaricus; L. leicuhmannii; Torula* spp.
Yoghurt	*L. bulgaricus*
Enzymes	
Amylases	*Bacillus* spp.; *Aspergillus niger; A. oryzae.*
Cellulases	*Trichoderma reesei.*
Glucose oxidases & catalase	*Corynebacterium* spp.
Invertase	*S. cerevisiae*
Lipase	*Saccharomycopsis lipolytica.*
Pectinases	*Aspergillus* spp.
Proteases	*B. licheniformis*; *B. subtilis; Aspergillus* spp.; *S. cerevisiae*

Meat and fishery products	
Country cured hams	*Aspergillus; Penicillium* spp.
Dry sausages	*Pediococcus cerevisiae*
Microbial cells as fermented products	
Bakers' yeast	*Saccharomyces cerevisiae*
Single cell	*Candida utilis; C. arborea;* protein (SCP) *Methylophilus methylotrophus; Saccharomycopsis lipolytica; Spirulina*
Mushrooms	*Agaricus bisporus*; *Morchella hortensis*
Non-beverage plant products	
Miso	*Aspergillus oryzae*
Saurkraut	*Neurospora sitophila*
Sufu	*L. delbrueckii*
Tempeh	*A. oryzae; Rhizopus oligosporus; R. oryzae*
Organic acids	
Acetic acid	*Acetobacter aceti; C. aceticum*
Citric acid	*Aspergillus niger; Saccharomycopsis lipolytica*
Lactic Acid	*Lactobacillus delbrueckii*
Polysaccharides	
Alginate	*Azotobacter vinelandii; Pseudomonas aeruginosa*
Dextrans	*Leuconostoc mesenteroids; Klebsiella; Acetobacter*
Pullulan	*Aureobasidium; Pullularia* spp.
Vitamins and Amino acids	
Riboflavin	*Eremothecium ashbyi*
Vit. B-12	*Bacillus megaterium; Streptomyces olivaceus, Propionibacterium*
Pro-Vit. A.	*Rhodotorula gravillis.*

3.2 CULTURING OF IMPORTANT MICROORGANISM

The human food supply consists basically of plants and animals or products derived from them, so our food supply can contain microorganisms in interaction with the food. The interactions between microorganisms and our food is beneficial as exemplified by many cultured products developed by fermentation and are consumed and enjoyed by many people (Bread, bear, wine etc). To produce such products microorganisms are added as pure culture or mixed cultures. However, in some cases no cultures may be added if the desired microorganisms are known to be present in sufficient numbers in the original raw material.

Starter culture, pure as well as mixed are usually employed in the manufacture of certain fermented food and dairy products. Cultures for food fermentations are selected primarily on the basis of their stability and their ability to produce desired products. Mother culture is usually prepared daily from a previous mother culture and originally from the stock culture. The mother cultures can be used to inoculate a large quality of culture medium to produce the mass or bulk culture to be used in the fermentation process.

Bacterial cultures: Most of the bacterial cultures employed as starters are for dairy products. Sausage and bread also use pure or mixed cultures of lactic acid bacteria (LAB) e.g. *Streptococcus lactis* sub sp *lactis, S. mesenteroides* sub-sp. *cremoris* etc.

Yeast cultures: Most yeasts of industrial importance are of the genus *Saccharomyces*. It is used to manufacture wine, beer and other alcoholic products.

Bakers' yeast: Yeast for baker's yeast production: Strains of *S.cerevisiae, S.uvarum* are used.

Wine yeast: *S. cerevisiae var. ellipsoidus* (Plate 1.1)

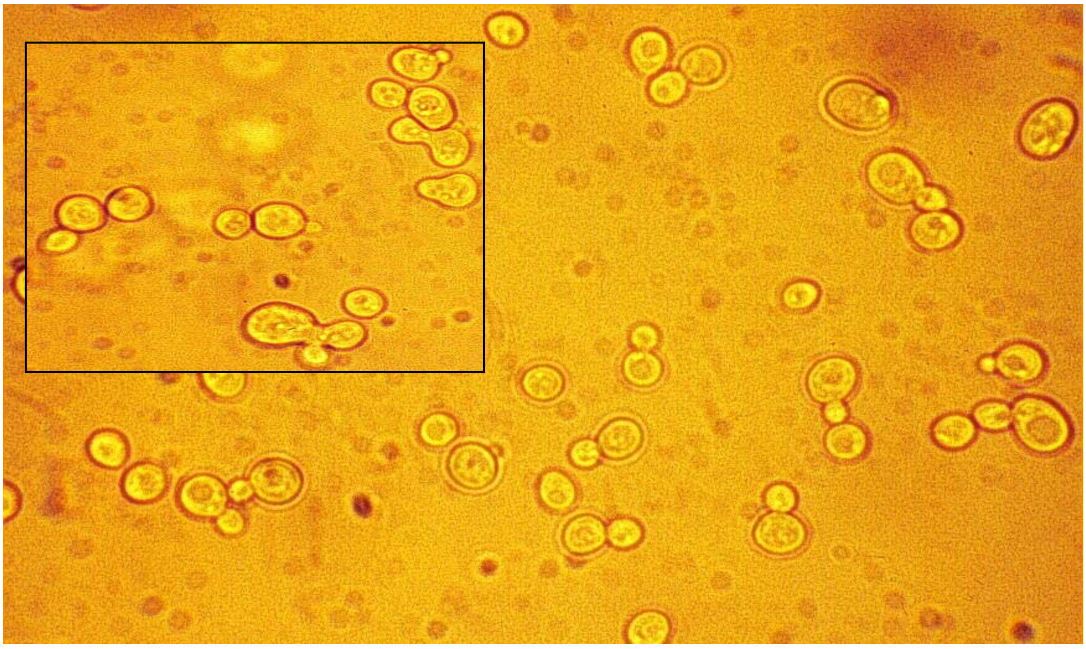

Plate 1.1: Photo micrograph of yeast cells showing budding (inset yeast cells are mating)

Distillers yeast: High alcohol yielding strains of *S.cerevisiae* var *ellipsoidus*.

Mold cultures: Stock of cultures of molds usually are carried in slants of a suitable agar medium and may be preserved as spore stab for a long period by freeze drying (*Penicillium roquefortii).*

3.3 ENZYMES AND KINETICS

Enzymes: Enzymes are biological catalysts possessing extraordinary efficiency, specificity and are mostly protein in nature. Enzyme commission has classified various enzymes on the basis of the type of the reactions catalysed. All the enzymes have been classified into 6 classes.

Class 1 : Oxido-reductase
Class 2 : Transferase
Class 3 : Hydrolase
Class 4 : Lyase
Class 5 : Isomerase
Class 6 : Ligase

Properties of Enzymes

- All enzymes are protein in nature except nucleases.
- All enzymes are specific in their functions.
- Enzymes are sensitive to temperature i.e. they are functional at optimal temperature.
- These are destroyed at higher temperature.
- Enzymes are not destroyed during their use.

Kinetics of Enzyme Reactions

The studies on the kinetics of enzyme reactions must be based on quantitative measurements of the rate of the catalyzed reactions. Main factors which influence the kinetics of enzymatic reactions are as follow:

Enzyme concentration: The velocity of enzymatic reactions is directly proportional to the concentration of the enzyme proteins.

Substrate concentration: When the velocity of the reaction is plotted vs. substrate concentration, classical enzymes give a rectangular curve.

pH: Almost every enzyme exhibits maximum activity at a particular pH which is called optimum pH.

Temperature: Almost every enzyme exhibits an optional temperature at which the enzyme exhibits maximal activity. A graph of enzyme velocity versus temperature, is a bell shaped curve.

Role of enzymes in food processing: The enzymes play a significant role in food processing. Pectinase enzymes are used in juice clarification (apple juice, guava juice), in softening of fruit (apple, tomatoes, peaches, avocadoes), and thereby resulting in increase in yield of juices and pulps extraction of juice from fruits. Proteases (papain) results in clarification and removal of cloudiness in beer and wine. Glucose oxidase enzyme is used in removal of glucose from egg white and thereby, improve, the colour of dehydrated egg powder. Pectinase with cellulase has been employed for extraction of oil from oil containing fruits (olive). Enzyme diastase converts starch to sugar during beer preparation.

3.4 TYPES OF FERMENTATION

Fermentations have been classified on the basis of relationship of the formation of product, substrate utilization or the free amount of water as given below:

Solid state fermentation: Fermentation processes which take place in the absence or near absence of free water in the substrate are termed as solid state fermentation (SSF). It is imperative, however, that the substrate contain enough moisture absorbed in the substrate particles within the substrate. SSF have been used mostly for food fermentation and production of a few enzymes.

Extractive fermentation: There are several industrially important products being catalysed by enzymes which are susceptible to end product or feedback inhibition. Hence, the increased concentration of the product inhibits the enzymes involved in its own synthesis so that the overall rate of conversion of substrate to the desired product is lowered. When the end product or anyone of the by-product of fermentation interacts with the enzyme, the synthesis of the final product proceeds sub-optimally and in extreme case may stop altogether. This problem has largely been overcome by using a technique called extractive fermentation. In it there is fast removal of product, or by-product of a metabolic pathway, so that their subsequent interference with the cellular or medium component is not possible. Hence, it involves all the actions taken for the separation of a product from its producing cell. Separation of the product can be achieved either inside the reactor (internal) or outside the reactor (external).

Submerged fermentation: Fermentation processes which take place in the presence of free water in the substrate are termed as sub-merged fermentation. Such fermentations have been used mostly to the produce fermented food and beverages.

3.5 TYPE OF FERMENTER, CONCEPT OF BATCH AND CONTINUOUS FERMENTATION

Fermenter: The industrial usage of micro-organisms often requires that they be grown in large vessels containing considerable quantities of nutritive media. These vessels are commonly called fermenters. Therefore, fermenter is the basic equipment of fermentation.

Types of fermenters: Some of the types of fermenter are listed below:

1. Shake flasks and bottles
2. Stirred tanks
3. Air-lift fermenters
4. Tower fermenter
5. Rotating disc fermenter
6. Fixed bed fermenter
7. Fluidized bed fermenter

Batch fermentation: In this fermentation, starter culture is added to the medium and the product is withdrawn only after completion of fermentation.

Continuous fermentation: In this fermentation, the substrate is continuously fed to the fermenter and the product is also withdrawn continuously.

3.6 MICROBIAL PRODUCTION OF WINE, VINEGAR, SAUERKRAUT, ETHYL ALCOHOL, BEER, ORGANIC ACID

3.6.1 Wines

The term ‘wine’ is applied to a beverage made by alcoholic fermentation of grape or grape juice and final production is obtained without distillation. But now-a-days, any fleshy fruit or flower in the new world may be employed for this purpose. Wine was suggested to have been made during the Neolithic period in the near East. These are the part of food of man ever since his settlement in Tigoris Euphorates basins and have also been used as a therapeutic agent.

Wines are produced by the fermentation of juices/extracts of many fruits such as apple, pear, cherries, most of berries, rhubarb, dandelion, honey, besides bananas, pineapple, cashew nut, pomegranate, lemons, tangerines, oranges, dates and figs. Wines from grapes are classified basically into red and white wines.

Types of Wines

Still wines: These wines retain none of the carbon dioxide produced during the fermentation.

Sparkling wines: These are the wines which have considerable amount of carbon dioxide. Champagne in France is the sparkling wine made in Champagne region.

Dry wines: These wines contain little or no unfermented sugar.

Sweet wines: Wines having either unfermented sugar or with added sugar later on are called sweet wines. Both types of wines generally contain 11 to 14% of alcohol.

Fortified wines: Wines to which distillate of wine called "Brandy" is added and may contain 15 to 21% of alcohol.

Table wines: It is a wine having comparatively low alcohol content (7 to 11%) and little or no sugar.

Sherry: It is produced by special processing technique from wine, containing 18 to 21% alcohol and could be sweet or dry.

Cider: Cider is a low alcoholic beverage obtained from apple by fermentation.

Perry: It is a wine made from pear juice.

Mead: This type of wine was prepared by the Indians from honey.

Vermouth: Wine flavoured with a characteristic mixture of herbs and spices, some of which impart an aromatic flavour and odour while others a bitter flavour. It can be sweet or dry with alcohol content of 15 to 21%.

Toddy: Sweet alcoholic drink, having alcohol content of 4-6%, is made by the fermentation of sap from coconut palm.

Pulque: National drink of Mexico, contains 6-7% alcohol and B-vitamins.

Method of Table Wine Preparation

Grape is the most widely used fruit to make wine but it can be prepared from any fruit having fermentable sugars, optimum acidity, nitrogenous compounds or other growth factors to make wine of acceptable quality. The major difference is in the extraction of sugar from the pulp of some fruits. From grape, red and white wines are produced the world over using black/red coloured and white varieties, respectively. The generalized flow sheets for wine making from grapes is shown in Figure 3.1.

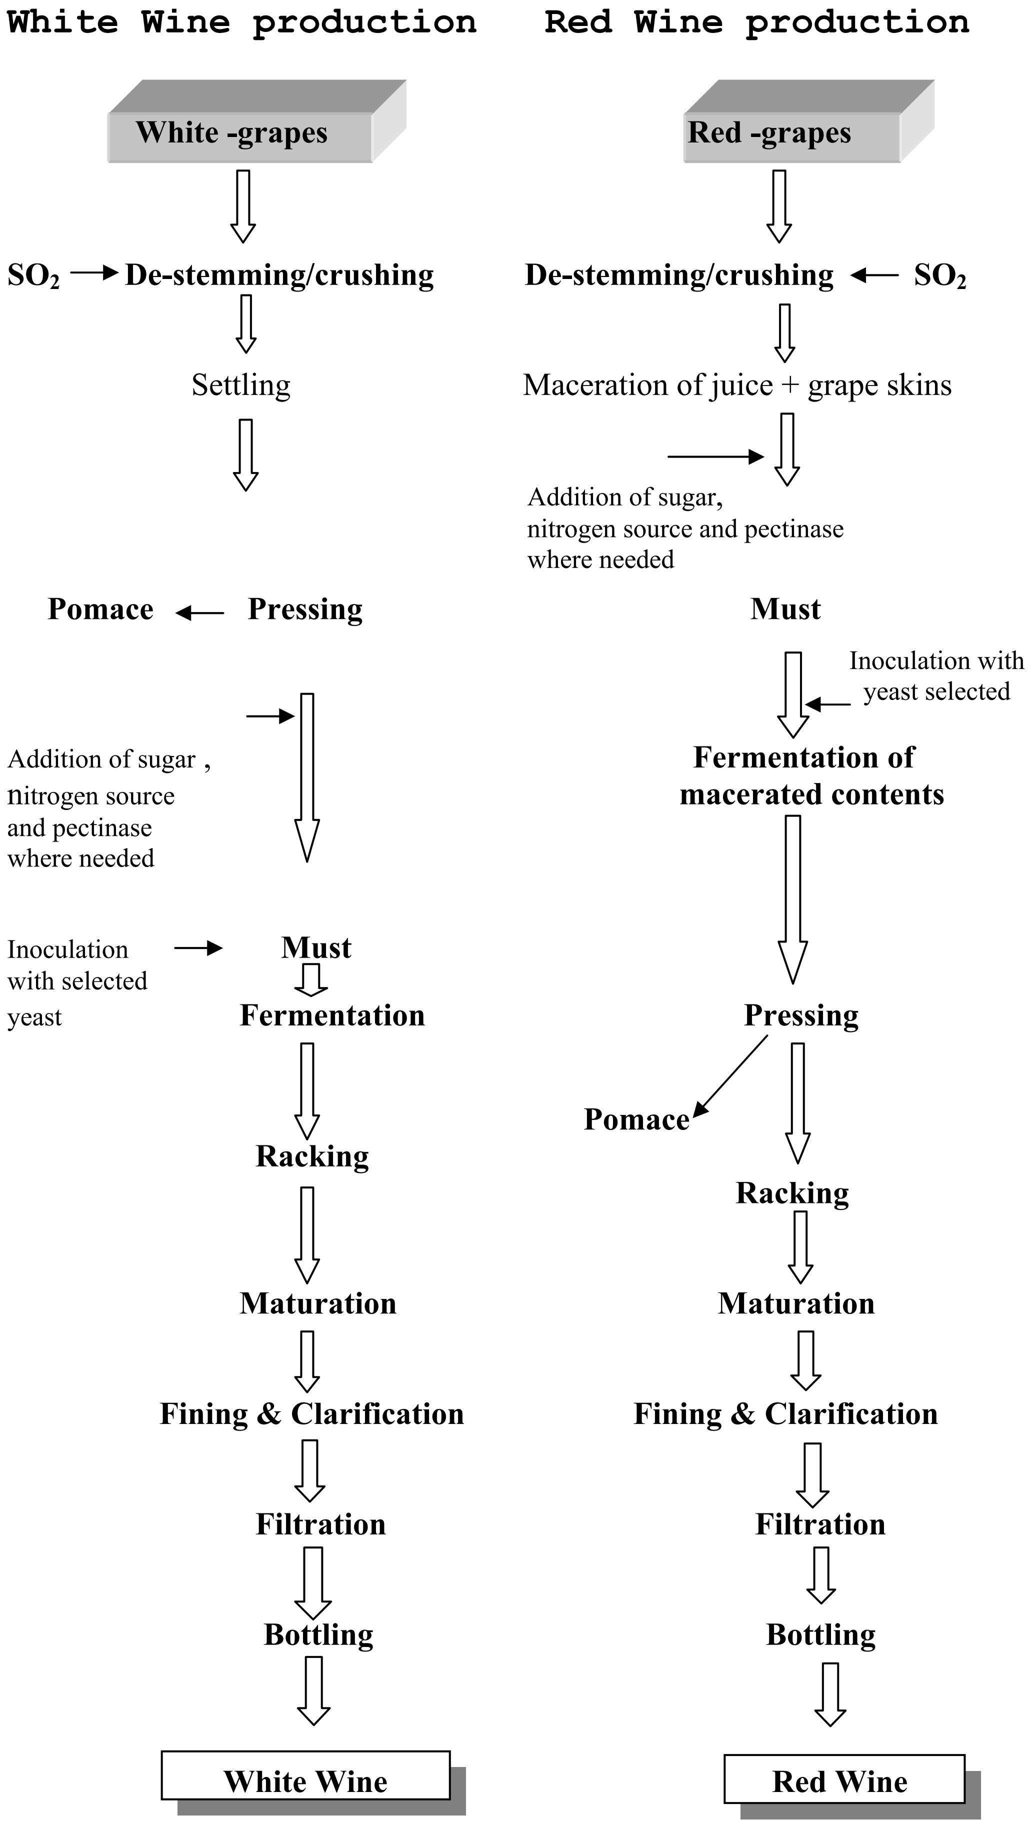

Figure 3.1: Flow–sheet of process to make red and white wine

Preparation of must: For wine preparation, the first step is the preparation of must which is prepared depending upon the type of fruits used and the type of wine to be made. Must is a juice or pulp corrected for sugar, acid/pH, nitrogen source or other requirements for the alcoholic fermentation. To prepare the must, the fruits are trimmed and washed and the must Juice is extracted or fruit is made into pulp. In the preparation of white wine only the free run juice is used while in the red wine, the skin and seeds along with pulp/juice are fermented together for some time to get attractive coloured wine. Proper dilution of fruit pulp is required as fruits like plum and apricot are highly acidic and effect the fermentability besides making the wine unpalatable. The sugar content of the juice or pulp is checked with an instrument called refractometer and is expressed as degree Brix. Sulphur dioxide ($S0_2$) is added to the must to control the wild microflora and to allow the yeast to act efficiently to conduct the alcoholic fermentation. Amelioration (or correction) of must for better fermentability with ammonium salt and vitamins like thiamine, biotin is necessary in some fruits.

Preparation of active yeast culture: An active culture of wine yeast (*Saccharomyces cerevisiae* var *ellipsoideus*) is prepared from the stock culture in the juice to be used for wine making.

Fermentation: After must preparation, activated yeast starter culture is added to the must and fermentation is carried out at a temperature of 20-25^{o}C, till the sugar content or the ^{o}Brix stabilizes.

Siphoning/racking

Siphoning or racking is a simple but important process wherein the wine is transferred through a clean pipe into another container, kept at a lower height than the vessel with wine. It is done after completion of fermentation. Two or three rackings are usually done at an interval of 15-20 days to separate the yeast and other settled materials at the bottoms of container.

Maturation

As the newly made wine is harsh and has yeasty flavour maturation (from 6 months upto a year) is allowed to make the wine mellow (It is the term used to signify the sensory quality of wine having smoothness i.e. is devoid of any harsh taste)in taste and fruity in flavour.

Clarification: Clarification of wine is done by using filter aids such as bentonite, celite and tannin/gelatin using a machine called filter press.

Blending: Blending is also practiced in some cases to make wine sweet or better flavoured before pasteurization.

Pasteurization: Wine is generally pasteurized at a temperature of 62^{0}C for 15-20 min, after bottling.

Storage: Low temperature storage is preferred for good quality wine.

3.6.2 Beer

Beer is an alcoholic beverage primarily prepared from barley besides other cereals in limited quantities and is consumed in large quantities throughout the world. Beer and ale the principal malt beverages made with hops, yeast, water and malt adjuncts. Adjuncts are the malted cereals other than barley, used in minor quantities. Brewing was one of the earliest processes undertaken on a commercial scale and became one of the first process that has developed from an art into a technology. Beer can be differentiated from ale as in beer bottom fermenting yeast is employed while in ale the top fermenting yeast is employed. In the preparation of ale, more hops is used. It is usually pale yellow in colour, tart in taste and have more alcohol content. On the basis of alcohol content beers can be classified as light beer having 3-5% v/v and hard beer having 5-8% alcohol content. Beer production is divided into four distinct process as described here.

Malting: It is obtained by soaking followed by germination of barley or other cereals and drying of the germinated cereal. Then, most of sprouts or germs are removed and the malt remains. The malt is crushed before its use in beer making.

Mashing: It is the process in which extraction of the ground malted barley with water is made. The mashing is done so as to make soluble as much as possible of the valuable constituents of the malt and malt adjuncts. It causes hydrolysis of starches, other polysaccharides and proteins. The insoluble material is then filtered. The liquid so obtained is called wort.

Wort boiling: Boiling of wort with hops (Hops is the female flowers of hops plant used in beer production to give flavour and bitter taste) is carried out to concentate the wort, inactivate the enzymes, extract soluble substances from the hops,coagulate and precipitate the proteins and other substances, caramelize sugar slightly and to contribute antiseptic substances (Chiefly the alpha resins humulone, co-humulone and adhumulone) to the wort and beer.

Fermentation: A special beer, bottom fermenting yeast strain *Saccharomyces cerevisiae* var *carlbergensis*, is used for the inoculation or pitching of the cooled wort. The wort temperature during the fermentation varies in different breweries but is usually in the range from 3.3 to 14^{o}C. The fermentation is usually completed within 8 to 14 days. During fermentation as the carbon dioxide is evolved in increasing amounts, the foaming increases; later it decreases to none when the fermentation is finished. At the later stage, the bottom yeast flocculates and settles down.

Aging or Maturation: The young, green or draft beer is stored or lagered in vats at about O^{o}C for several weeks to several months, during which period precipitation of proteins, settling of yeast, resin and other undesirable substances takes place and the beer becomes clear and mellowed or matured.

Finishing: After aging, the lager beer is carbonated to a CO_2 content of about 0.45 to 0.52 per cent, mostly by means of gas collected during the fermentation or by addition of CO_2 from cylinders. Then, beer is cooled, clarified or filtered and packaged in the bottles, cans or barrels.

3.6.3 Vinegar

The word vinegar is derived from two French words, *vin* and *aigre* meaning sour wine but the term is used to denote a condiment prepared from various sugar and starch containing materials by alcoholic and subsequent, acetic acid fermentation. It is one of the several fermented foods prepared and consumed by early man, even today. Earlier, it was used as a beverage, a condiment, a preservative, a household cleansing and medicinal agent. Vinegar mainly consists of a dilute solution of acetic acid in water, also contains colour, flavour and extracted substances besides fruit acids, esters and inorganic salts which vary according to its origin. The minimum legal strength for vinegar is 4% acetic acid (w/v).

Types and Composition of Vinegar

1. **Synthetic vinegar:** This type of vinegar is directly prepared from synthetic acetic acid with the addition of water and finally, it is coloured by caramel.
2. **Brewed vinegar:** Virtually, anything having enough sugar to produce alcohol can be used to make brewed vinegar. The vinegar usually derives its descriptive name from the material from which it is made such as: cider vinegar is made from apple juice, alegar from ale, malt vinegar from malted grains spirit vinegar from alcohol etc.

Vinegar Preparation

It involves two step fermentations as detailed below:

Alcoholic fermentation: The first is alcoholic fermentation, mainly carried out by yeast *Saccharomyces cerevisiae* either by pure culture inoculation or by the natural process of fermentation. The process can be represented by a simplified equation:

$$C_6H_{12}O_6 \rightarrow 2CO_2 + 2C_2H_5-OH + 55\ Kcal$$

Glucose   Carbon dioxide   Ethyl alcohol

In the process, ethyl alcohol is not the only product but small amounts of other compounds like glycerol, succinic acid, amyl alcohol, propyl alcohol etc. are also produced in this fermentation. The fermentation is anaerobic.

Acetous fermentation: The second fermentation is acetic acid fermentation. It is an oxidative fermentation carried out by acetic acid bacteria like *Acetobacter aceti*. In the vinegar production, pure culture of acetic acid bacteria is not used, due to more efficiency of mixed cultures. The oxidation reaction can be shown as:

$$C_2H_5OH + O_2 \rightarrow CH_3COOH + H_2O + 116\ Kcal$$

Ethyl alcohol   Acetic acid

The optimum temperature of fermentation is 26^{o}C which is achieved by the heat generated in the process.

Process of Vinegar Preparation

Slow process: This process takes a long period and is generally followed in countries like India. The juice kept in the barrels is allowed to undergo alcoholic and acetic fermentations slowly with the passage of time. The bung hole of the barrel is covered with a piece of cloth to screen-off the dust and flies, and the barrel is placed in a damp but warm place. It takes about 5-6 months to complete the whole alcoholic and acetous fermentation to produce the vinegar from the juice. The main drawbacks of this process are: alcoholic fermentation is often incomplete, the acetic fermentation is very slow and the yield is low coupled with an inferior quality vinegar.

Quick process: In the quick process like generator process alcoholic liquid is in motion and this process is applied mostly to the production of vinegar from spirit (alcohol). Fruit or malt liquors are well supplemented with food for the vinegar bacteria, but to maintain active vinegar bacteria in generator methods using alcohol denatured with ethyl acetate or vinegar, it must be supplemented with a combination of organic and inorganic compounds known as vinegar food. Combinations of substances such as dibasic ammonium phosphate, urea, peptones, yeast extract, glucose, malt, starch, dextrin, salts etc have been made. Materials such as pumice, branches of vines and grape stems for packing the generators are used. Schiizenbach introduced the use of a vat instead of cask for the acetification process and provided mechanical means for the repeated distribution of the acidic liquid over the packing.

Generator: The equipment used is known as "Upright Generator" which in its simplest form is a cylindrical tank that comes in different sizes and is usually made of wood. Its interior is divided into 3 parts:

i) **Upper section:** Here, alcoholic liquid is introduced.

ii) **Large middle section:** In this section, liquid is allowed to trickle down over beech wood shavings, corn cobs, charcoal, coke, or some other material that will provide a large total surface area yet not settled into a compact mass.

iii) **Bottom section:** This section is for the vinegar collection.

The alcoholic liquid is put at the top through an automatic feed trough or a sprinkling device (sparger) and trickled down over the shavings or other material on which a slimy growth of acetic acid bacteria has been developed and the bacteria oxidize the alcohol to acetic acid and the process is called acetification. Air enters through the false bottom of the middle section and after becoming warm, it is exhausted out through a ventilation above. As considerable heat is released by oxidation process, it is necessary to control the temperature below 30^{o}C. It is usually done by using cooling coils, by adjusting the rate of alcoholic liquid, feeding air and by cooling the alcoholic liquid before it enters the generator or by cooling the partially acetified liquid that is returned to the top from the bottom section of the tank for further acetification.

3.6.4 Lactic Acid Bacteria (LAB) and Fermented Foods

Lactic acid bacteria (LAB) are obligate microorganisms producing lactate from sugars as the main end product, besides producing inhibitory substances like organic acids, bacteriocin, hydrogen peroxide which are antagonistic towards other microorganisms. Fermented dairy products are known to be inhibitory to both pathogenic and spoilage causing microorganisms and Yoghurt is the best known fermented milk product (with fruit pulp).Cultured milk and milk products contain lactic acid bacteria that prevent the occurrence of stomach, colon and other cancers.

Traditional fermentations of vegetables were depended upon growth of naturally occurring lactic acid bacteria to metabolise sugars in the vegetables to mainly lactic acid and improve their taste and keeping quality. However, starter cultures are being used now to develop controlled fermentation

It is established that more than one species of lactic acid bacteria are responsible for vegetable fermentation. Lactic acid bacteria responsible for natural fermentation of vegetables are within the genera of *Streptococcus*, *Leuconostoc, Pediococcus* and *Lactobacillus*. Acidity, pH, salt concentration, temperature, naturally occurring inhibitors, chemical additives, exposed brined surface to air and sunlight, amount of fermentable carbohydrates in the vegetables and availability of nutrients in the brine are important factors affecting the lactic fermentation.

Sauerkraut

It is the clean, sound product of characteristic flavour, obtained by full fermentation, chiefly lactic of properly prepared and shredded cabbage in the presence of not less than 2% nor more than 3% of salt. It contains, upon completion of the fermentation not less than 1.5 per cent of acid expressed as lactic acid. To prepare sauerkraut rough outer leaves of fully mature solid cabbage heads are removed. Head are quartered, the cores are removed and then, shredded the quarters into thin strips which are mixed with salt. About 2.25 to 2.5% of salt by weight should be added to the shredded cabbage to obtain kraut of the best quality. Pack the cabbage loosely in a jar, place a wooden board on the top. In order to press out juice from the cabbage, a heavy stone is placed on the wooden board. The jar is kept at a warm place (24 to 31^{o}C) for 8 to 12 days to allow fermentation to complete. The brine is separated from the cabbage, boiled and poured hot over the cabbage shreds in the jars. Sauerkraut can be packed in cans also. The cans are filled with the hot juice, exhausted and processed till the temperature at the centre of can reaches 82^{o}C.

Prominent bacteria that attain appreciable number early in fermentation are *Enterobacter cloacea* and *Erwinia herbicola* and contribute some flavour. However, *Leuconostoc mesenteroides* bacteria begins to outgrow all organisms and continue acid production upto 0.7 to 1% (as lactic acid). Next, *Lactobacillus plantarum*, a non-gas forming lactobacilli continues the production of acid and can raise the acidity to 1.5 to 2.0%. These bacteria produce chiefly lactic acid in their fermentation of sugars. A final acidity of 1.7% as lactic acid is most desirable and fermentation can be stopped at this stage by canning or refrigerating the sauerkraut.

Kanji

Carrots of deep purple variety are fermented in Northern India and Pakistan to make a ready-to-serve beverage /drink called as *Kanji.* It is a popular beverage and is considered to have cooling and smoothing properties besides nutritional content. To prepare it, the carrots are washed, grated finally. For every Kg of grated carrot, 7Kg of water, 200g of salt, 40 g of crushed mustard seeds and 8g of hot chillies are added followed by placing the mixture in a glazed earthenware, leaving a tiny whole for the release of gases produced during fermentation. The mixture is fermented for 7-10 days. It is strained through a muslin cloth. The final product is acidic in taste with an attractive purple red colour and is usually consumed within 3-4 days.

Pickles from Vegetables

Vegetables like cucumber are pickled whole or in slices after washing in potable water. For every one Kg of cucumber, 15g salt is added which results in the formation of brine. It is followed by lactic acid fermentation. Depending upon the ambient temperature it takes one to four weeks. The fermented cucumbers are stored in clean capped jars after pasteurization.

Radish can also be pickled in a manner similar to sauerkraut as discussed earlier.

Kimchi

It is a fermented food of Korea with cabbage or radish as the main ingredient. Cucumbers can also be added. Cabbages are cut and brined in 5 to 7% salt solution for 12 hr or in 15% brine for 3 to 7 hr. Then, brined cabbage is rinsed and mixed with 10% seasoning ingredients i.e. garlic, green onions, peppers, ginger, mustard, parseley, sesame grains and fermented shrimp. This mixture is allowed to ferment in jars which takes a few days at temperature of more than 20^{o}C for a month below 10^{o}C. 'Kimchi' has a pH value of 4-4.5 and lactic acid content of 0.4 to 0.8%. The main organisms responsible for fermentation of 'kimchi' are *Leuconostoc mesenteroides* and acidifying microorganism is *Lactobacillus plantarum*.

3.6.5 Ethanol Production

The material rich in sugar can be converted into ethanol. The fermentation is carried out using yeast like *Saccharomyces cerevisiae*. The sugars like glucose is converted into ethyl alcohol and carbon dioxide, anaerobically. Ethanol is a liquid fuel or liquid fuel supplement and is used as a solvent in many industries.

The waste from fruits and vegetable processing industries being rich in polysaccharides (cellulose, hemicellulose and lignin) has been subjected to SSF for the production of ethanol. The cellulose and hemicellulose present in the processing waste like apple pomace are readily fermented by anaerobic bacteria. For ethanol production, the waste from processing industries has to be pre-treated due to presence of lignin. A SSF process has been used for production of ethanol from apple pomace by using *Saccharomyces cerevisiae*. Apple, pear, orange peel and cherry wastes have also been utilized for production of ethanol by fermentation with *Saccharomyces cerevisiae*.

3.6.6 Enzyme Production

Both submerged fermentation (SF) and solid state fermentation (SSF) are employed for production of enzymes. But SSF is a better method than SF for production of enzymes. Various enzymes have been produced by fermenting food processing waste. Invertase enzyme by fermenting sauerkraut waste with the help of *Canidida utilis* has been produced. This enzyme is widely used in the food processing industry. Subsequently, fungal amylase by using baked bean waste has been produced. Enzymes like cellulase and xylanase are produced by fermenting apple pomace, using *Trichoderma viridae* and *Aspergillus* sp. Pectinase is another enzyme which is produced from wastes like apple pomace.

Table 3.3: Food processing waste used as SCP/animal feed after microbial fermentation

Waste	Microorganisms utilised
Apple pomace	*Saccharomyces cerevisiae* *Candida utilis* *Torula utilis* *Aspergillus niger*
Corn cob	*Aspergillus niger*
Dried citrus peel	*Aspergillus niger*
Fodder beets	*Saccharomyces cerevisiae*
Orange peel and grape stalks	*Pleurotus ostreatus* *Agrocybe aegirata* *Armillarialla mellea*
Sugarcane bagasse	*Polyporus* sp. *Pleurotus* *Trichoderma*
Sugar beet pulp	*Trichoderma reesei* *Tricoderma viridae* *Fusarium oxysporum*

3.6.7 Citric Acid

Citric acid is being produced by fermenting brewery waste with *Aspergillus niger*. Apple pomace is a potential source of citric acid when fermented with *Aspergillus niger* by SSF on various substrates like pineapple juice, molasses, sweet potatoes residue, sugar cane bagasse impregnated with pineapple juice, mandarin orange waste, apple pomace, grape pomace. While production of citric acid by fermenting apple pomace, addition of methanol to the medium increases the yield of citric acid.

3.7 SINGLE CELL PROTEINS

In developing countries like India, deficiency of proteins leads to mal-nutrition. It has necessitated to explore new non-conventional resources of protein production. Amongst the various processes used to supply protein are those based on the microbial growth and microbial biomass especially using the waste material (Table 3.3). Microbial cells used as proteins as single cell protein (SCP) and can be used as protein supplement for feed or food. A number of micro-organisms like yeast, fungi, algae and bacteria can be employed production of SCP and each of them has its advantage and disadvantages. The micro-organism in turn use these substances as starting materials for fermentation and SCP production by assimilation.

The SCP however, is not without limitations also such as high nucleic acids which are metabolized to uric acid and can give rise to articular gout in human beings. Secondly, human being can eat a maximum of 2.0g SCP/kg body weight/day in their diet. To overcome the nucleic acid levels in SCP various methods have been tried but with a variable success. The success of SCP depends upon economics of SCP production.

3.8 MICROBIAL FERMENTATION FOR UTILIZATION OF WASTE

With the advent of post-harvest technology, the fruits and vegetables are processed for the production of various products. The processing of fruits and vegetables in this way generate a large quantity of bio-degradable waste. The waste from processing of fruits and vegetables include water and various organic substances e.g. simple and complex polysaccharides (Sugars, starch, pectin, etc.), vitamins and minerals. The large quantities of waste generated in this way leads to environmental pollution. In today's environment conscious society, there are regulatory laws for the discharge of industrial effluent under the water conservation and control of Pollution Act 1974 and Environmental Protection Act, 1986 and these are mandatory for the processing industries. The waste from the processing industries can either be disposed-off after necessary treatment as per the directions of the pollution control agencies or it can be utilized by applying suitable technologies as illustrated in Table 3.4.

Table 3.4: Microbial utilization of food processing industry waste

Sl.	Products	Waste
1.	Ethanol	Citrus industry waste, apple pomace, peach waste, cashew apple pomace, pineapple waste, pear cutting.
2.	Biogas	Waste from fruit and vegetable industry as a whole, fermentation (wine and beer) waste.
3.	Single Cell	Apple pomace, peach waste, cashew apple proteins pomace, citrus waste extract, molasses, potato peels, cabbage waste.
4.	Cider, beer and vinegar	Apple pomace.
5.	Pectin	Citrus waste, apple pomace.
6.	Citric acid	Apple pomace.
7.	Baker's yeasts/ industrial yeast	Waste from wine, beer and distillary.
8.	Colour	Apple pomace.
9.	Flavours/Xanthan gum	Fruits and vegetable waste, citrus waste
10.	Animal feed	Apple pomace, peach waste, potato industry waste, olive processing waste.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Define wine, toddy, vermouth, cider, beer and perry.

……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………

2. What is lagering, pitching and draft beer?

……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………

3. Name the yeast used in beer fermentation.

……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………

4. What is role of boiling wort?

……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………
……………………………………………………………………………………

5. Give various steps for wine and beer production.

....

....

....

....

....

....

6. What is vinegar and SCP?

....

....

....

....

....

....

7. Name the microorganisms and their sequence in lactic acid fermentation of cabbage.

....

....

....

....

....

....

8. Name the processes used in vinegar preparation.

....

....

....

....

....

....

9. Which is commercially available single cell protein source?

....

....

....

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

10. Classify enzymes and their role in industry?

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

11. Differentiate SF and SSF fermentation.

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

12. Name the microorganisms associated with production of following products: Sauerkraut, Beer, Wine, Organic acid (acetic acid) and SCP.

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

13. Define batch and continuous fermentation.

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

14. Why yeast is preferred as a single cell protein compared to bacteria and algae?

....

....

....

....

....

....

15. What are different types of fermenters? Enlist the same.

....

....

....

....

....

....

16. Write 2-3 lines about the following:

Sauerkraut, Kimchi, vinegar

....

....

....

....

....

....

3.9 LET US SUM UP

Fermentation is an ancient practice, carried out by natural or inoculated microflora. Several microorganisms are important as these are employed to produce the fermented food, additives and products of industrial significance. These include yeast, bacteria and fungi. Fermentation could be classified as solid state fermentation, submerged fermentation or extractive fermentation. Depending upon the mode of operation fermentation could be batch, fed batch or continuous type. At the industrial scale, the fermentationis carried outin the vessel called fermentor or bio reactors. Depending upon the type of fermentation or product, the type of fermentoris employed. Food fermentations include those to produce wine, beer, brandy, whisky, pickles, sauerkraut, kimchi, vinegar, yoghurt additives like citric acid, lactic acid, enzymes, ethanol, single cell proteins being produced commercially using microbial process.

3.10 KEY WORDS

Fermentation	:	was used for the production of wine but at present it encompasses the foods made by the application of microorganisms including lactic acid bacteria (LAB).
Bakers' yeast	:	The strains of *Saccharomyces uvarum* used to make bread.
Wine yeast	:	*S.* cerevisiae *var. ellipsoidus.*
Distillers yeast	:	High alcohol yielding strains of *S. cerevisiae* var *ellipsoidu* used to higher alcoholic beverages.
Controlled "starter" Culture	:	pure as well as mixed cultures of microorganisms are responsible for conducting fermentations, employed in the manufacture of certain food and dairy products such as fermented milk, butter, cheese, bread, malt beverages.
Enzymes	:	Enzymes are biological catalysts possessing efficiency and specificity and are mostly protein in nature.
Solid state fermentation	:	Fermentation processes which take place in the absence or near absence of free water in the substrate are termed as solid state fermentation (SSF).
Submerged fermentation	:	Fermentation processes which take place in the presence of free water in the substrate are termed as sub-merged fermentation.
Fermenter	:	The industrial usage of micro-organisms often requires that they be grown in large vessels containing considerable quantities of nutritive media. These vessels are commonly called fermenteors.
Wine	:	The term 'wine' is applied to the product made by the alcoholic fermentation of grape or grape juice. But any fleshy fruit or flower in the new world may be employed.
Beer	:	Beer is an alcoholic beverage prepared from barely or other cereals.
Vinegar	:	The word vinegar is derived from two French words, *vin* and *aigre* meaning sour wine but the term vinegar is used to denote a condiment prepared from various sugar and starch containing materials by alcoholic and subsequent, acetic fermentation.

Acetous fermentation : or acetic acid fermentation which is oxidative fermentation carried out by acetic acid bacteria viz. *Acetobacter aceti*.

Lactic acid bacteria (LAB) : These are the microorganisms that are obligate producing lactate from sugars as the main end product, besides producing inhibitory substances to other microorganisms.

Sauerkraut : It is the product of characteristic flavour, obtained by lactic fermentation of cabbage in the presence of 2-3% of salt.

Kimchi : It is a group of fermented vegetable foods of Korea with cabbage or radish as the main ingredient.

Single cell protein : The microbial biomass used as protein supplement for feed or food is called as single cell protein (SCP).

3.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

1. Your answer should include the following points:

   Wine: It is the product made by the alcoholic fermentation of grape or other fruit or flower.

   Cider: Cider is a low alcoholic beverage from apple juice.

   Vermouth: Wine flavoured with a characteristic mixture of herbs and spices, with an aromatic flavour and odour while others a bitter flavour, sweet or dry with alcohol content of 15 to 21%.

   Toddy: Sweet alcoholic drink, having alcohol content of 4-6%, made by the fermentation of sap from coconut palm.

2. Your answer should include the following points:

   Lagering: It is the process of storage of young, green or draft beer in vats at about O^{o}C for several weeks to several months, to make it clear and mellow.

   Pitching: It is the process of inoculation of yeast culture in the wort.

   Draft beer: The freshly prepared beer (not matured) is called draft beer.

3. Your answer should include the following points:

   The answer is *Saccharomyces cerevisiae* var *carlbergenesis.*

4. Your answer should include the following points:

   The boiling concentrates, sterilizes the wort and inactivates the enzymes.

5. Your answer should include the following points:

   Various steps are involved in beer production:

   Malting
   Mashing
   Wort boiling
   Fermentation
   Aging or Maturing
   Finishing
   Table wine
   Juice Extraction
   Must preparation
   Fermentation
   Siphoning/racking
   Maturation
   Clarification
   Blending
   Pasteurization

6. Your answer should include the following points:

   Vinegar: Vinegar is the product obtained by acetic acid fermentation of ethanolic liquid of any fruit and contains 3.75 %w/w acetic acid. It is prepared by alcoholic fermentation of fruit juice.

   SCP: Single cell proteins (SCP) are the microbial cells used as a source of proteins. To produce single cell proteins, suitable microorganism and medium is selected. The optimum conditions of growth are also determined and the same are given during the fermentation. The grown biomass is then harvested and the cells are used as a source of proteins.

7. Your answer should include the following points:

   First of all *Pediococus* comes, then *Streptococcus* followed by *Lactobacillus in* cabbage fermentation.

8. Your answer should include the following points:

   Slow process: This process takes long period wherein the juice is allowed to undergo alcoholic acetic fermentations. It takes about 5-6 months to complete the fermentation to form the vinegar from the juice.

   Quick process: In quick processes like generator process alcoholic liquid is kept in motion and this process is applied mostly to the production of vinegar from spirit (alcohol). The alcoholic fermented liquors is well supplemented with food for the vinegar bacteria, such as a combination of organic and inorganic compounds. The process needs additional supply of oxygen.

9. Your answer should include the following points:

   Spirullina which is used as a SCP commercially.

10. Your answer should include the following points:

    All the enzymes have been classified into six classes.

    Class 1 – Oxido-reductase e.g. dehydrogenases, peroxidases.

    Class 2 – Transferase

    Class 3 – Hydrolase

    Class 4 – Lyase

    Class 5 – Isomerase

    Class 6 – Ligase

    Uses of enzymes in food processing: Pectinase enzyme are used in clarification of juices (apple juice, guava juice), lemon juice etc. Pectinase enzyme result in softening of apple fruit, tomatoes, peaches, avocadoes and thereby resulted in increase in yield of juice and pulp during processing. Pectinase enzyme result in easy extraction of juice from fruits. Proteases resulted in clarification and removal of cloudiness in beer and wine. Glucose oxidase enzyme is used in removal of glucose from egg white and thereby, improve, the colour of dehydrated egg powder. Pectinase with cellulase enzymes are also used for extraction of oil from oil containing fruits. Beer cloudiness can be removed by use of proteases e.g. papain. Enzyme diastase resulted in conversion of starch to sugars during beer preparation.

11. Your answer should include the following points:

    The submerged fermentation (Smf) makes use of free liquid while in that of solid state fermentation (SSF) no free water is available.

12. Your answer should include the following points:

    The microorganisms used for the products are listed as below:

    Sauerkraut: Lactic acid bacteria

    Beer: *Saccharomyces cerevisiae* var *carbergenesis*

    Wine: *Saccharomyces cerevisiae* var *ellipsoideus*

    Organic acid (Acetic Acid): *Acetobacter aceti*

    SCP: *Spirullina, Saccharomyces cerevisiae, Candida utilis*

13. Your answer should include the following points:

    Batch fermentation: Here the starter culture is added to the medium and the product is withdrawn after completion of fermentation.

    Continuous fermentation: Here the substrate is continuously fed to the fermenter and the product is also withdrawn continuously.

14. Your answer should include the following points:

    1. Yeasts have nutritive value especially proteins and vitamins.

    2. Able to grow on a variety of carbon and nitrogen source.

3. Has faster growth and high yield, ability to grow at low pH.
4. Can grow on a large number of waste including that from processing industries.

15. Your answer should include the following points:

Types of Fermentors:

1. Shake flasks and bottles
2. Stirred tanks
3. Airlift fermenters
4. Tower fermenter
5. Rotating disc fermenter
6. Fixed bed fermenter
7. Fluidized bed fermenter

16. Your answer should include the following points:

Sauerkraut: It is the clean, sound product of characteristic flavour, obtained by full fermentation, chiefly lactic of properly prepared and shredded cabbage in the presence of not less than 2% nor more than 3% of salt.

Kimchi: It is a group of fermented vegetable foods of Korea with cabbage or radish as the main ingredient with or without cucumbers.

Vinegar: The word vinegar is derived from two French words,*vin* and *aigre* meaning sour wine but the term vinegar is used to denote a condiment prepared from various sugar and starch containing materials by alcoholic and subsequent, acetic fermentation.

UNIT 4 SPOILAGE AND ASSOCIATED CHEMICAL/PHYSICAL CHANGES IN FOOD

Structure

4.0 OBJECTIVES

After reading this unit you should be able to:

- state the meaning of spoilage;
- principle of preservation of food;
- discuss various causes of spoilage;
- describe different types of spoilages; and
- preventive measures which should be taken.

4.1 INTRODUCTION

We all know that food is the basic necessity of all the living entities. Needless to say that such a commodity has to be absolutely safe and of highest possible quality especially free from toxins and spoilage. A food is said to be spoiled if it has been damaged or injured making it unsuitable for human use. "A product is fit as a food if a discriminating consumer, knowing the story of its production and seeing the material itself, will eat it, and conversely, the same product is spoiled when such an examiner refuses it as a food". All of us would agree that a food is spoiled if it is not harvested at proper maturity, is contaminated with dirt, handled by dirty or diseased person, is fertilized with sewage and has objectionable changes due to the activity of microorganisms or action of enzymes of the food. The major causes of spoilage are: the microorganisms or their enzymes, the native enzymes of food, rodents, environmental factors and purely chemical reactions.

It must be admitted that despite of the improvement in the methods of production, handling and processing, the microbiological quality still remains the most important factor. This aspect assumes significance from toxin production, spoilage of fresh and processed products and quality control and as sanitation indicators in a processing unit. Microbial quality is also on the top of the different hazards which are associated with the safety of food for consumption by human beings. Various fruits, vegetables and their products may be spoiled by one or more factors like unsuitable packaging, chemical changes or action of microorganisms, tissue enzymes, insects, rodents or improper methods of processing, under processing, etc. Different spoilage causing agents for various fruit and vegetable products, their prevention and health hazards associated with spoilage are also discussed here.

4.2 PRINCIPLES OF FOOD PRESERVATION

In accomplishing the preservation of food by various methods, three main principles are involved:

I. Delay or prevention of microbial decomposition of food
II. Delay or prevention of self-decomposition of food
III. Prevention of damage caused by insects, rodents, birds, mechanical causes etc.

Various principles and sub-principles of preservation of food are summarized in Table 4.1. First principle of food preservation is based mainly on the following considerations:

- By delaying the microbial decomposition of food
- By preventing the microbial decomposition of food

Most of the methods of food preservation depend not only on the destruction or removal of microorganisms but also on the delay in the initiation of their growth, and hindrance to growth once it has begun. Knowledge of growth curve of microorganisms is very helpful for developing the appropriate technique to delay the microbial decomposition of the food.

Table 4.1: Detailed principles of preservation

I. Delay or prevention of microbial decomposition of food

i) by keeping out microorganisms (asepsis).

ii) by removal of microorganism.

iii) by hindering the growth and activity of microorganisms.

iv) by killing the microorganisms.

II. Delay or prevention of self decomposition of food

i) by inactivation of food enzymes.

ii) by delay or prevention of purely chemical reactions.

III. Prevention of damage to food caused by insects, rodents, birds and mechanical causes

4.3 CLASSIFICATION OF FOODS BASED ON PERISHABILITY

1. *Perishable foods:* The foods which spoil readily unless special preservation methods are used such as meat, fish, most of fruits and vegetables, egg, poultry and milk etc.

2. *Semi-perishable foods:* Semi-perishable foods like waxed potatoes and some varieties of apple, if handled and stored properly, shall remain unspoiled for a fairly long period.

3. *Non-perishable foods:* These foods do not spoil until and unless they are handled carelessly. Such foods are also called as stable foods such as cereals, sugar.

4.4 FACTORS GOVERING SPOILAGE

Since microorganisms are the main spoilage causing factors, major emphasis remains on the factors related to microbial spoilage of the foods. Here bacteria cause most of the problems since these are not killed at ordinary temperatures. The yeasts and molds have low resistance to heat (processing temperatures). The main factors responsible for such spoilage are described here.

4.4.1 Number and Kind of Microorganisms

The initial number of microorganisms present on the food has direct relationship with its spoilage. More the number of microorganisms present, rapid is the spoilage. The effect of initial number of spores on time required to kill them is shown in Table 4.2. The heat resistance of bacteria involved in food poisoning is of major concern from public health view point. Usually, only one type of microorganisms will be there because of the particular environmental conditions involved. However, contamination may increase the number as well as new kinds of microorganims.

Table 4.2: Effect of initial number of spores on time required to kill them

Initial concentration of cells, number/ml	Thermal death time, or time required to kill all spores min. at 121°C
50,000	14
5,000	10
500	9
50	8

In addition to destruction or removal of microorganisms, the delay in the initiation of growth also prevents microbial spoilage. This is done by keeping the microorganisms in lag phase as long as possible. Once the microorganisms enter the log phase, it is very difficult to control them. A typical growth curve of microorganism is shown in Figure 4.1.

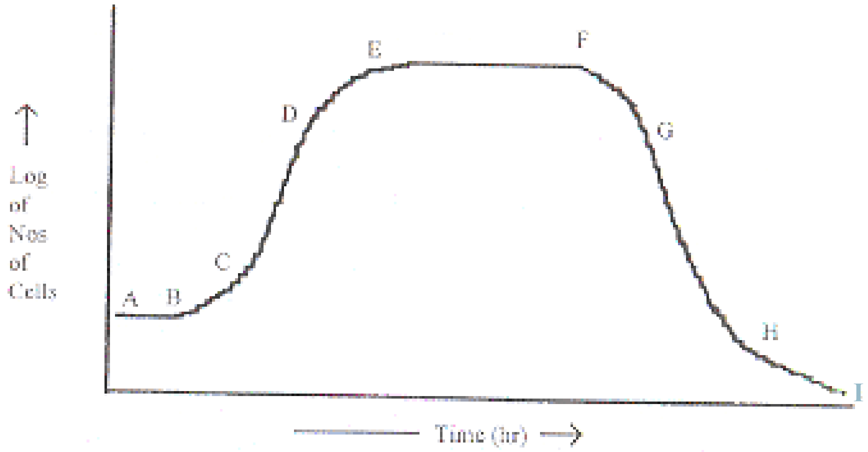

Figure 4.1: Growth curve of microorganism. A to B lag phase, B to C positive acceleration phase, C to D logarithmic phase, D to E negative acceleration phase, E to F stationary phase, F to G accelerated death phase, G to H death phase, H to I survival phase

4.4.2 Suitability of Temperature

Different microorganisms grow at different temperatures. Psychrophiles have affinity for low temperatures (8-10^{o}C), mesophiles grow best at medium temperatures (25-40^{o}C), while thermophiles appear at higher temperatures (50-55^{o}C). A large number of microorganisms grows at mesophilic temperature therefore processed foods are immediately cooled to arrest microbial activity / spoilage of foods. So, storage temperature is very important in relation to microbial growth and hence, the spoilage behaviour of foods.

Different types of microorganisms require different times to kill their cells or spores. The time required to kill all the spores of flat sour bacteria (*Bacillus stearothermophilus)* in relation to temperature is shown in Table 4.3.

Table 4.3: Effect of temperature of heating on the time needed to kill spores of flat sour bacteria

Temperature (^{o}C)	Thermal death time or time to destroy all spores, min.
100	1200
105	600
110	190
115	70
120	19
125	7
130	3
135	1

Source: Adapted from Frazier and Westhoff (1996).

4.4.3 Suitability of food

Different microorganisms prefer different kinds of foods. Some grow best on proteinacious foods, others on starchy or fatty foods. The physical state of the food whether heated, frozen, moistened or dried, also has an important influence on the spoilage it will undergo. The moisture content also influence the type of microorganisms in the foods since the requirements of moisture for their growth are different. Bacteria, yeast and molds have different moisture requirements in terms of water activity (Figure 4.2).

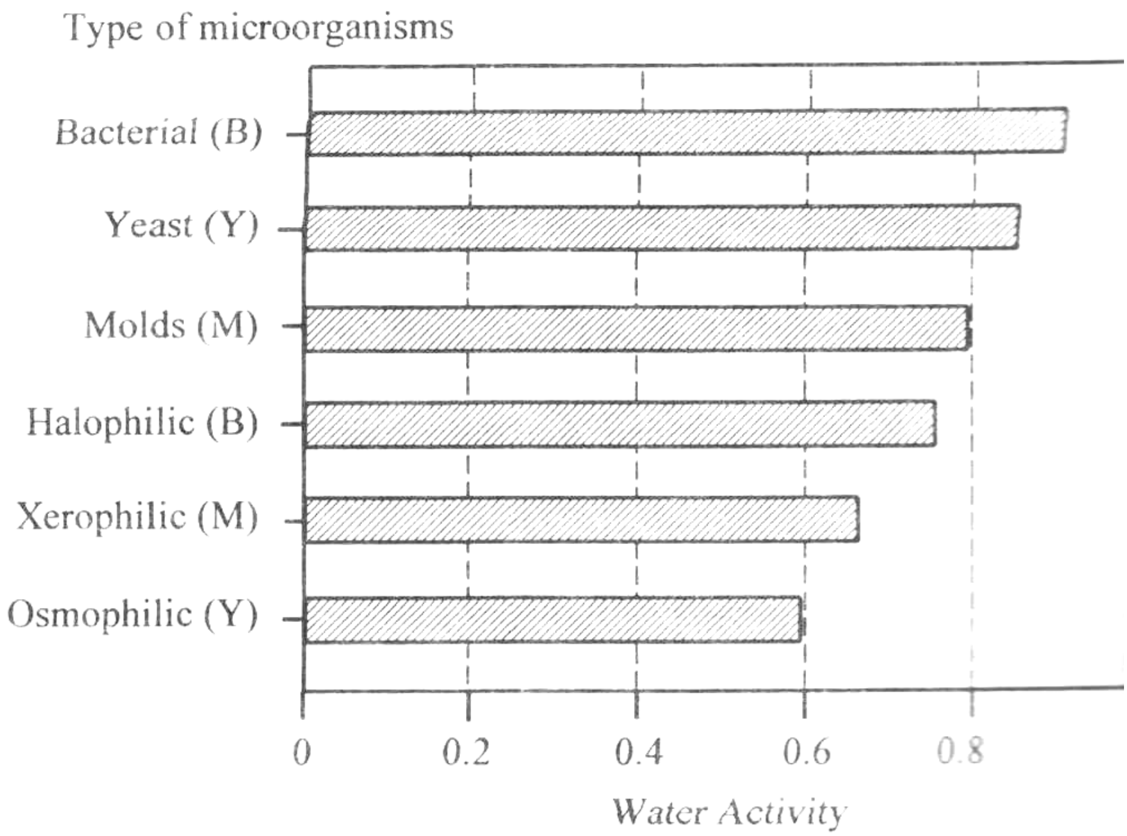

Figure 4.2: Water activity of different microorganisms

4.4.4 pH of Food

The pH of the food influences the kind and growth of microorganisms. The composition of the vegetable, its pH and moisture contents affect their type of spoilage. As a general rule, foods having pH<4.5 (acid foods) do not require heat processing (particularly cooking under pressure), but those with pH > 4.5 (low acid foods) always require processing under pressure.It is because of the reason that thermophilic bacteria may not be killed at normal temperatures as most bacteria thrive best at pH of 4-7.5, while the yeasts and molds require a pH of 2.5-8.0 and 1.5-8.5 for their growth.

4.4.5 Presence of Air

Aerobic or anaerobic microorganisms can be found in the spoiled fruit and vegetable products, depending upon the presence or absence of air (oxygen) in the container or package.

4.5 CHEMICAL AND PHYSICAL CHANGES ASSOCIATED WITH FOOD SPOILAGE

Changes in nitrogeneous organic compounds: Most of the nitrogen in the food present in the form of proteins which are hydrolysed by enzymes to produce amino acids. The anaerobic decomposition of the protein, peptide or amino acid results in the production of obnoxious odour which is called as putrefaction. When the microorganisms act on amino acid they deaminate or decarboxylate.

E. coli produces glyoxylic acid, acetic acid and ammonia from glycine and from serine it produces pyruvic acid and ammonia. Alanine is degraded into α-keto acid, ammonia and carbon dioxide by *E. coli*; acetic acid, ammonia, and CO_2 by *Psuedomonas*; and propionic acid, acetic acid, ammonia and CO_2 by. *Clostridium nigrificans*. Other nitrogenous compounds like amide, urea, guianidine and creatine, etc. are also decomposed to ammonia, carbon dioxide and other products.

Changes in Carbohydrates: Carbohydrates are preferred by the microorganisms as energy yielding foods. They hydrolyse the polysaccharides to monosaccharides before utilization such as to glucose which is then, oxidized to CO_2 and H_2O. Anaerobically, these undergo decomposition involving one or more types of fermentation.

- Alcoholic fermentation by yeast with ethanol and CO_2 as products.
- Lactic fermentation by homofermentative lactic acid bacteria with lactic acid or by heterofermentative lactic acid bacteria with lactic acid, acetic acid, ethanol, glycerol and CO_2 as chief products.
- Coliform type of fermentation by coliform bacteria with lactic acid, formic acid, ethanol, CO_2, hydrogen and perhaps aceton and butanediol as likely products.
- Propionic acid fermentation by propionoic bacteria producing propionic acid, acetic and succinic acid and CO_2.
- Butyric- butyric isopropyl fermentation by anaerobic bacteria producing butyric acid, acetic acid, CO_2, H_2 and in some cases, butylenes glycol, butanol and 2-propanol.

They are present as salts and are oxidized by the microorganisms to carbonate and cause the food medium to become alkaline. Organic acid aerobically are oxidized to carbon dioxide and water as is done by the film yeast.

Changes in other compounds: Other compounds also undergo changes as detailed here:

- Ethyl alcohol is oxidized to acetic acid.
- Glycoside is hydrolysed to sugars.
- Acetaldehyde is oxidized to acetic acid or reduced to ethanol.
- Protopectin are acted upon by pectinesterase – pectic acid + methanol (water soluble) by hydrolysis of methyl ester. Polygalacturonases destroys the linkage between galactouronic acid unit of pectin or pectic acid to yield smaller chain and ultimately, free D-galacturonic acid, which may be degraded to simple sugar.

Changes in Lipids: Fats present in the media are hydrolysed by lipase into glycerol and fatty acid.Phospholipids may be degraded to their constituents phosphate, glycerol, fatty acid, and nitrogenous base e.g. chlorine.

One or more such changes can be produced in the food undergoing spoilage. The physical and sensory qualities of the food also undergo changes, thus making the product unfit for human consumption.

4.6 MICROBIOLOGY OF FRESH FRUITS, VEGETABLES AND THEIR PRODUCTS

4.6.1 Spoilage of Fruits and Vegetables

In general, fruits and vegetables are bulky, easily damaged mechanically, consist largely of water which is readily lost and above all, are living entities and must be kept so for their longivity. Thus, they are sensitive to their environment viz., temperature, level of oxygen, carbon dioxide and ethylene etc. Spoilage of fresh fruits and vegetables usually occurs during storage and transport and while waiting to be processed into various products. These also get contaminated with spoilage organsims either from each other or when they are laid into the baskets, lugs, boxes etc. during harvesting. Mechanical injuries during transportation further aggravate the deterioration process. The decay of perishables may occur due to the physical factors, action of their own hydrolytic enzymes or microbial contaminants etc as discussed earlier. Since fruits and vegetables after picking are alive for certain time thus, are sensitive to their environment, their rate of metabolism is temperature dependent and they may be damaged by heat or cold or even by levels of different gases in the atmosphere. Oxygen is taken in during respiration and CO_2 heat and water vapours are given-off. As fruits or vegetables are detached from the mother plant, the continuity of the flow of sap is totally disrupted but the respiration and water loss continues leading to exhaustion of food reserve and moisture. The irreparable losses are caused leading to deterioration and eventually spoilage. Spoilage is mainly of 2 types: Abiotic spoilage and Biotic spoilage.

Abiotic spoilage: It is due to the different physical (wilting, caking and melting etc.) and chemical changes in the product (hydrolytic action of enzymes, oxidation of fats, putrefaction of proteins, browning reaction between proteins and sugars). Temperature control is the major factor to provide longevity to the fruits and vegetables.

Biotic spoilage: This includes the microbial action associated with bacteria, yeasts and molds on vegetables and fruits and the normal processes of aging. The species of microorganisms causing food spoilage largely depend upon different factors e.g. kind and variety of fruits/vegetables, environmental condition e.g. storage, temperature, relative humidity of the atmosphere and various gas contents of the atmosphere etc. There are two types of microbial spoilage: (a) Spoilage caused by plant pathogens which attack various parts of the plant used as foods, (b) Spoilage caused by saprophytes. The most common and general type of spoilage in fruits and vegetables are mildew are listed in Table 4.4. Dry rots often lead to darkening and discoloring, and hardening of the surface of vegetables and fruits. In microbial spoilage, the vegetables often develop water soaked musky areas while the fruits generally have brown or white colored patches.

Table 4.4: The chief market diseases of some vegetables and fruits

Item	Market diseases
Onions	Bacterial soft rot, black mold rot, gray mold rot
Garlic	Bacterial soft rot, black mold rot
Green beans	Bacterial soft rot, mold rot, *Rhizopus*
Carrots	Bacterial soft rot, black rot, *Fusarium* rot, gray mold rot, watery soft rot
Beets	Bacterial soft rot, black rot, blue mold rot, *Fusarium* rot
Lemons	*Alternaria* rot, anthracnose, blue mold rots, stem-end rots
Peaches	*Alternaria* (or green mold rot), gray mold rot, black mold rot
Apricots	Blue mold rot, brown rot, *Cladosporium* rot, *Rhizopus* rot
Bananas	*Anthracnose, Fusarium, Gleoporium, Pestalozia*
Grapes	Black mold rot, gray mold rot, *Rhizopus* rot, blue mold rot
Strawberries	Gray mold rot, leather rot (*Phytophthora cactorum*) *Rhizopus* rot
Pears	Black rot, blue mold rot, brown rot, gray mold, *Rhizopus* rot
Potatoes	*Fusarium* tuber rot, bacterial ring rot, bacterial soft rot
Cucumber	*Rhizopus* soft rot, bacterial soft rot, blue mold rot, gray mold rot
Cabbage	Bacterial soft rot, gray mold rot, black rot, watery soft rot
Cauliflower	Bacterial soft rot, gray mold rot, black rot, watery soft rot
Tomatoes	*Alternaria* rot, bacterial canker, bacterial spot, gray mold rot, green mold rot, *Rhizopus* rot

The composition of the fruit/vegetable, its pH and moisture content affect their type of spoilage. Moisture content is usually expressed in terms of water activity ‘aw’. Various microorganisms have different requirements for moisture level (Figure 4.2). Amongst the microorganisms, spoilage can be caused by bacteria, molds/yeasts etc. depending upon the pH of food.

Bacteria: Various groups of bacteria can attack different fruits and vegetables, depending upon their composition such as lactic acid bacteria, acetic acid bacteria, coliform bacteria and sporeforming bacteria. The food can be preserved for longer time by prolonging the lag phase. This can be obtained by avoiding the contamination of the food and turning the environmental conditions e.g. temperature, moisture and pH unfavourable for the growth of contaminants (microorganism). Thus, by lowering the storage temperature of the fruits/vegetables, filling up the storage chamber with the inert gases will definitely lead to longer shelf- life of the vegetables and fruits. pH is another important factor governing the bacterial growth which range between pH 4-8. Growth rate is lowered by a decrease in pH.

Yeasts: Yeasts are widely found in the environment. The yeast growth depends largely upon the nature of fruit product. These are generally fermentative in nature.

Molds: Molds are frequently associated with food products. Some of the molds secrete toxic compounds (mycotoxins) like aflatoxins, patulin etc. Aflatoxin has been detected in dried figs and fig paste while patulin is the most common mycotoxin detected in the processed fruits. The mold *Penicillium expansum* which causes apple rot and some other molds produce patulin. The mycotoxins are deleterious to various animals and presumably the human beings also.

4.7 SPOILAGE OF PROCESSED FRUIT AND VEGETABLE PRODUCTS

The spoilage of processed fruit and vegetable products is also of two types: Abiotic spoilage and Biotic spoilage.

a) **Abiotic spoilage:** It is due to the different physical and chemical changes in the product viz. putrification of proteins, browning reactions between sugars and proteins and the physical changes of colour, caking and melting etc. The temperature and humidity are the main factors responsible for causing this type of spoilage. There is a relationship between moisture content and relative humidity with respect to different causes of spoilage in food products.

b) **Biotic spoilage:** It includes the actions associated with microorganisms, damage caused by insects, rodents etc.

Manifestation of spoilage: The microbial deterioration of a processed food product usually is manifested by alterations in the appearance, texture, colour, odour, flavour or slime formation. The appearance includes colour changes, visible growth of microorganisms, formation of pockets of gas or swelling of cans and microbial growth especially that of molds on the surface of food process (Plate 4.1). As some food products deteriorate, they tend to become soft or mushy. Degradation of foods results in the formation of compounds which have odours and flavours different from those of the fresh food.

Plate 4.1: Different spoiled products from fruits and vegetables. 1) Mold growth on pickle, 2) Mold growth on jam, 3) Mold growth on juice, 4) Mold growth on tomato crush, 5) Puffed can

Spoilage of Canned Fruits and Vegetables

Like other foods, canned fruit and vegetable products are also liable for spoilage for various reasons. Number of microorganisms surviving the heat process, storage temperature, suitability of the canned food to support the growth of the microorganisms, pH of the food, oxygen tension etc. may affect the spoilage of canned foods. Broadly, there are four causes for the spoilage of canned fruit and vegetable products viz., microbiological, physical, chemical and miscellaneous.

Microbiological spoilage: The spoilage caused by the growth of different kinds of microorganisms may be affected by under processing, inadequate cooling, infection resulting from leakage and pre-processing spoilage.

Under processing: Insufficient or improper heat treatment may result in survival of certain microorganisms causing spoilage of food product during subsequent storage. Some lot or a part of the lot may remain under processed or not processed at all (gross under processing) by mistake. As a general rule, only one type of microorganisms (bacteria or yeast or mold) are involved in such spoilage. Most of these are facultative anaerobes unusually heat resistant spore formers. Faulty operation during processing may also cause under processing. This type of spoilage can be avoided by ensuring proper heat transfer, proper retorting and proper stacking of cans in the retort.

Inadequate cooling: Immediately after processing, the cans are cooled using cold water. It gives a sort of shock to the surviving microorganisms and kills them. It also checks overcooking and hence, saves the food from textural disintegration. If cooling is not proper, spoilage can occur. In addition, the cans are cooled down (using fans also) upto 35-38°C only to allow the water to evaporate readily from the can surface. It will check the rusting of cans during storage, which may otherwise lead to some spoilage. It can be avoided by proper cooling after processing.

Infection due to leakage: Post-processing contamination may take place if there is leakage in the cans due to faulty seam, faulty lock seam or pinholes due to corrosion from inside of the can or rusting of can from outside. Here all the types of microorganisms can be present in the food. Lot of oxygen can enter into the can. Contents of such type of cans are not suitable for consumption. To avoid such kinds of spoilage, seam tests should be carried out regularly while in operation, proper hygiene should be maintained and handling should be proper. The cooling water should be chlorinated using 5-7 ppm of chlorine.

Pre-process spoilage: If the raw material is already heavily contaminated many microorganims may survive heat treatment and also the finished product may not be of desirable flavour or quality. It may also be due to faulty procedure during washing (of raw materials, cans and equipment) blanching and filling of cans. Many respiratory gases can develop causing swelling of cans during storage. To avoid such type of spoilage, proper testing of raw materials, proper washing of raw material as well as equipment, chlorination of water and proper sterilization of cans should be practiced.

Thermophillic spore forming anaerobic spoilage: The microbiological spoilage of canned fruits and vegetables can be of different types.

Flat sour: It derives its name from the fact that the ends of the can of food remain flat but the contents become sour. It is mostly found in non-acid foods like canned vegetables by the action of microorganisms (flat sour bacteria). So it cannot be detected without opening of can and culturing the microorganisms. *Bacillus stearothermophilus* and *Bacillus coagulans* are the thermophilic spore-forming bacteria responsible for flat sour type of spoilage. The latter are found in tomato juices. The immediate source of the flat sour bacteria is usually the plant equipment besides sugar, starch or soil.

TA spoilage: It is the short name for spoilage caused by thermophilic anaerobes which do not produce H_2S e.g. *Clostridium thermosaccharolyticum*. It is a sugar-splitting obligate thermophilic, sporeforming anaerobe which produces CO_2 and H_2, causing the swell and even bursting of cans. The spoiled food usually have sour odour and the source of contamination could be the plant equipment, sugar, starch and soil similar to that of flat source.

Sulphide or Sulphur Stinker spoilage: Such spoilage is caused by *Clostridium nigrificans*, mostly found in low acid foods like peas and corn. The spores of this bacterium are considerably less heat resistant and hence, their appearance in canned foods is indicative of gross under processing. H_2S can be detected by its characteristic odour on opening the can and the organism can also be detected in the form of black (FeS) colonies formed on iron sulphite agar at 55^{o}C.In case of peas, it is difficult to detect any marked discolouration. The source of this organism includes sugar, starch, soil, manure and the plant equipment.

Mesophilic spoilages: Some species of *Bacillus* and *Clostridium*, non-spore forming bacteria and even yeasts or molds may spoil the under-processed canned foods. The spore forming mesophilic thermoduric species of bacteria include *C. pasteurianum, C. butyricum, C. botulinum, C. sporogenes, B. sublitis, B. polymyxa,* etc. The non-spore forming mesophilic bacteria involved in the spoilage of tomato products, pears and some other fruits were found to be *Lactobacillus* and *Leuconostoc*. Other such genera may be *Pseudomonas*, *Micrococcus*, *Flavobacterium* etc. which may come from water and leaks in the cans.

Spoilage by yeasts: The yeasts have been found to spoil canned fruits, jams, jellies, fruit juices, etc. underleakage or under-processing conditions. Film yeasts like *Candida, Pichia*, *Hansenula* can grow on acid products like saurkraut and pickles osmophilic yeasts like *Saccharomyces rouxi*, *S. mellis* can spoil dry fruits, concentrated fruit juices and honey etc. Salt tolerant yeasts like *Torulopsis* and *Brettanomyces* can grow in brine solution.

Spoilage by molds: The molds are the common spoilage organisms of home canned foods like jams, jellies, marmalades. The common one are *Aspergillus, Penicillium, Byssochlamys fulva* etc.

Spoilage by physical causes: Some physical deformation of the container can lead to spoilage. Faulty technique in operation, under exhausting, over filling and panelling or buckling of the cans can cause spoilage of processed food products.

Faulty technique in operation: Just after retorting, if the pressure is released at once instead of slow release, distortion of can body can occur. Joints or seams may be distorted resulting in leakage. To avoid such kind of spoilage, the pressure in the retort should be released slowly after retorting and standard iron plates should be used for cans.

Under-exhausting: If the air entrapped in the tissues of canned fruit and vegetables, and the filling medium is not expelled properly, adequate vacuum may not develop which may consequently, impair the quality and appearance of the product.

Over-filling: Over-filling of cans does not allow proper vacuum formation after processing. It may also lead to flipper or springer type of spoilage. The proper filling is essential to avoid this defect.

Panelling or buckling: It occurs in case of big sized cans. If there is very high vacuum inside the can, atmospheric pressure can struck or force the can inwards resulting in leakage type of spoilage. To check such spoilage, proper vacuum should be created in the cans carefully.

Chemical spoilage: It includes reactions among ingredients, reactions between can and ingredients, hydrogen swell etc. Mainly, it is due to H_2S production, presence of oxygen, acids etc. H_2S is formed by the action of SO_2 (added through sugar or by decomposition of proteins) and H_2 formed by fruit acid acting on tin plate. If there is sufficient vacuum, H_2 is absorbed after storage for long time. Low acid foods have more H_2 swells. Therefore, pH of the food has important role in checking such spoilages. If the pH is near 4.0, it is favourable for many chemical reactions. To avoid the spoilage, we can assure proper vacuum (by hot filling) in the can and also adjust safe pH of the food prior to canning. Rusting and corrosion and perforation of tin plates: After cooling the processed cans in water, if some water remain on the surface of cans, rusting can take place. Similarly, the hygroscopic nature of the labels can also add to the rusting. In case of acid foods, there are more chances of corrosion and perforation of tin plates. More the oxygen in the can, more is the corrosion. Corrosion is more at higher than at lower temperatures. To avoid corrosion and perforation of tin plates, proper exhausting should be done and cans should not be cooled below 35^{o}C in water or fans should be used to evaporate water from the can body and non- hygroscopic in nature labels should be used and be stored at relatively low temperatures.

Metallic contamination: The tannins of raw materials or spices used react with exposed iron of the tin plate to form ferric tannate, a black product. Similarly, the SO_2 on reacting with H_2 forms H_2S that may further react with iron content of the can to form iron sulphide thus, causing spoilage of the processed food product. Also, on using the equipment made of copper or brass after sometime, in spite of thoroughly cleaning, small traces of copper oxide may remain there, which further form black copper sulphide on reacting with H_2S and discolour the product. To avoid such spoilage, proper exhausting and proper selection of equipment, thorough washing of the raw material as well as equipment.

External Appearance of Can

Flipper: A can with mild positive pressure is called a flipper. It may be an initial stage of swell or hydrogen swell but more frequently, it is due to over-filling or under exhausting, leakage or sealing at low temperature. The can ends remain flat but when the sides of can are struck with some hard structure or if the temperature of the contents is increased, bulging of ends take place.

Springer: A mild swell at one or both ends of a can is called a springer. One end may also remain permanently bulged and other flat. Pressure on the bulged end will bring it to normal but it will go to other end. Generally, the food in such cans remains fit for consumption. The reasons are similar as for flipper can.

Swells: In this case, both ends remain bulged. It may be a soft swell or hard swell. In case of soft swell, the ends are not so hard. On applying some pressure, the ends may go inward (normal) but do not remain normal on the removal of pressure. Obviously, in hard swell, can ends are rigidly hard and there is no effect of pressure except bursting or leakage of the can. The swell occurs due to the production of H_2 (formed by action of acids of food and tin plate), CO_2 or other gases (as a result of decomposition of contents by microorganisms) involving both thermophiles or mesophiles. The food is not fit for consumption and may even contain toxins produced by *Clostridium botulinum*.

Leaker: A very small leak may appear in the can due to faulty seam, faulty lock seam or pinholes resulting from corrosion from inside of the can or rusting of the can from outside.

Breather: Tiny leak in the can may allow air to pass back and forth into the can but not the microorganisms. The inside pressure of the can equals outside pressure. The contents may be spoiled due to rusting of can caused by oxygen in air passing through the tiny leak.

Buckled cans: Sometimes, the vacuum in big sized cans is so high that atmospheric pressure can strike the can body resulting in deformation of can leading to leakage of contents or contamination.

Spoilage of Fruit and Vegetable Juices

Fruit juice/squashes: The fruit juices are more spoiled by yeasts and molds than by bacteria since they have lower pH while vegetable juices are spoiled more by bacteria than yeasts and molds because of very high pH. If the fruit and vegetable juices are not processed after extraction, they are spoiled because of enzymatic changes and microbial actions. Apple and grape juices are spoiled by bacteria if the temperature of storage goes above 25^{o}C. Molds can grow on the surface of fruit juices if exposed to air. Most fruit juices have sufficient sugar to favour the growth of yeasts. Deficiency of B group vitamins discourages some bacteria. Concentrates of fruit and vegetable juices favour the growth of yeasts and of acid bacteria and sugar tolerant (*Zygosacharomyces)* species because of increased acidity and sugar concentration. Fruit juice concentrates are fermented almost exclusively by *Saccharomyces rouxi*, *S. mellis*, *Torulopsis* and *Hansenula*. Typical fermentation products are ethanol and CO_2. Heat treatment during canning of these concentrates usually kills these microorganisms and freezing prevents the growth of such organisms. In fruit squashes, if presevatives are not added in proper concentration, some yeasts (e.g. *Zygosaccharomyces*) can spoil such products.

Spoilage of canned fruit juices: The acidity is the single most important factor affecting microbial spoilage of fruit juices. Most bacteria have an optimum pH near 6.8 but may grow at pH values ranging from 4-8. Yeasts and molds can grow at pH <2.

In canned foods, a pH of 4.5 is used as a borderline between acid and low acid foods, that is foods not requiring and those requiring respectively, the minimum botulinum cook (12 D). The typical spoilage flora of fruit juices is represented by some Clostridia, *Bacillus*, members of Enterobacteriaceae, lactic acid bacteria, *Acetobacteriaceae*, yeasts and molds. The spoilage is characterised by lowering of pH (0.2-0.4 units), development of very high volumes of hydrogen and CO_2, and strong cheesy (butyric) odour. Three types of Bacilli are usually involved in spoilage of fruit juices i.e. *B.coagulans* (flat sour), *B. macerans* and *B. polymyxa* (both by storage at temperature < 46^{o}C).

The spoilage by enterobacteriaceae is characterised by the production of lactic acid, acetic acid, formic acid, H_2 and CO_2. Lactic acid bacteria causing spoilage of fruit juices include *Lactobacillus, (L. plantarum, L. fermenti) Leuconostoc mesenteroides, Streptococcus viscosum*. Among the yeasts, the most often involved species in juice fermentation belong to *Saccharomyces, Torulopsis, Candida, Pichia, Hansenula* and *Hanseniaspora.*

Molds require O_2 for development and so usually do not grow at the surface of processed fruit products. However, *Byssochlamys fulva* and *Penicillium expansum*, have been found in canned foods and the latter can grow under vacuum also.

Carbonated beverages are usually not spoiled because of inhibitory effect of CO_2 on microorganisms. The acidity (resulting from carbonation and addition of acids) also inhibits microorganisms. Since molds require air, they do not grow on the carbonated beverages.

Spoilage of Jams, Jellies, Marmalades and Preserves

Jams and jellies have usually low water activity (0.75-0.86). In addition, due to added acid, the pH is lowered and sometimes may have preservatives such as benzoic acid. All these factors lower down the risk of spoilage. Also due to heating, spoilage causing organisms (yeasts, molds) are eliminated until the package is opened whereupon recontamination could be expected (Plate 1).

Usually, osmophilic yeasts such as *Torulopsis*, *Xeromyces* and many other have been reported to spoil jams, jellies and preserves.

Spoilage of Frozen Fruits

Many fruits and fruit products are preserved by freezing including cherries, fruit juice concentrates, purees (^{o}B>45) and some sliced fruits. Usually, dry sugar or syrup is added to fruit prior to freezing. The predominant microorganisms are usually yeasts and molds besides lactic acid bacteria (in orange juice concentrate).

Spoilage of Dried Fruits and Vegetables

In dried fruits (apples, apricots, dates, figs, peaches, prunes, resins etc.), a number of microorganisms can be expected. Due to decreased water activity (<0.65 in case of sun dried products), heat treatment during dehydration and fumigation, the microorganisms may be killed or unable to cause spoilage. But, spores of bacteria and molds are likely to be the most numerous. Dried fruits may be spoiled due to the development of rancidity as concentrated flavonoids may undergo oxidation. Dried or partially dried fruits (dates, figs and prunes) are also susceptible to yeast spoilage i.e. *Zygosaccharomyces*.

4.8 PREVENTIVE MEASURES

While the fresh fruits and vegetables are spoiled by biological (microbiological) and non-biological causes, their spoilage is checked by adopting suitable preservative techniques. But the processed products do not normally spoil unless the preservative technique applied is not proper or is not applied properly or the product is stored improperly. There are a few generalized preventive measures which can be adopted to avoid their spoilage.

- It is desirable to keep the initial microbial contamination as low as possible. The commodities should be handled and stored to avoid further contamination and create conditions to check the growth of microorganisms.
- All efforts be made to apply the preservative technique, keeping in view the various steps to avoid spoilage.
- Mechanical disruption of the processed product tissue should be prevented. Equipments used for handling should be clean and free from contamination and contamination from the soil microflora should be avoided. Dipping of fruits and vegetables in solution of chlorine (50-125 ppm) removes the adhering microflora.
- Inhibition of microbial growth can be achieved by storing the food at low temperature or in inert atmosphere packaging.
- While packaging the processed product, it is absolutely essential that the environment of packing should be microbes free or least contaminated and away from stores to minimize the post-processing contamination.
- The chemical and microbiological quality of water is the single most factor which can control the quality of the finished processed product. It should conform to the prescribed standards of microbiological (indicator microorganism) and chemical quality.

- The spoilage of canned products can be minimized especially leakage by regularly checking the equipments used in canning (reformers, flanger, double seamer, retort).
- The quality of raw material is controllable factor which have profound influence on the spoilage behaviour of processed product.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Why the food can get spoiled?

4.9 LET US SUM UP

The foods especially fruits and vegetable are a living commodities and are therefore, liable for spoilage. The nature and kind of spoilage, however, depend upon the type of food and the environment where it is kept or how it is handled and stored. The causes of spoilage include contamination with microorganisms, activity of microorganisms or their enzymes, activity of native enzymes of food, infestation with rodents and influence of various external conditions where the food is stored. Decomposition of food constituents such as proteins, fats and carbohydrates and their interactions result into production of chemicals with different quality and hence, not acceptable as a food. To prevent spoilage, the foods are preserved either by giving low temperature during storage, or heated in appropriate media, irradiated, dehydrated or preserved with chemicals or made into fermented products. If such methods are not properly employed the foods can get spoiled even when they are processed.

4.10 KEY WORDS

Spoiled food : A food is said to be spoiled if it has been damaged or injured making it unsuitable for human use.

Perishable foods : There are the foods which spoil readily unless special preservation methods are used such as meat, fish, most of fruits and vegetables, egg, poultry and milk etc.

Non-perishable or stable foods : These foods do not spoil until and unless they are handled carelessly such as cereals, sugar etc.

Putrefaction : The anaerobic decomposition of the protein, peptide or amino acid resulting in the production of obnoxious odour is called as putrefaction.

Psychrophiles : Those microorganisms which have affinity for low temperatures (8-10^{o}C).

Mesophiles : Are the microorganisms which grow best at medium temperatures (25-40^{o}C).

Thermophiles : These microorganisms appear at higher temperatures (50-55^{o}C).

Under processing : It denotes insufficient or improper heat treatment that may result in survival of certain microorganisms causing spoilage of food product during their subsequent storage.

Water activity (aw) : Moisture content is usually expressed in terms of water activity.

Under-exhausting : If the air entrapped in the tissues of canned fruit and vegetables and the filling medium is not expelled properly, is called under-exhausting.

Panelling or buckling	:	It occurs in case of big sized cans when there is very high vacuum inside the can, atmospheric pressure can struck or force the can inwards resulting in leakage type of spoilage.
Flipper	:	A can with mild positive pressure is called a flipper.
Springer	:	A mild swell at one or both ends of a can is called a springer. One end may also remain permanently bulged and other flat.
Swells	:	In this case, both ends remain bulged. It may be a soft swell or hard swell.
Leaker	:	A can with a very small leak due to faulty seam, faulty lock seam or pinholes resulting from corrosion from inside of the can or rusting of the can from outside is called leaker.
Breather	:	It denotes tiny leak in the can that may allow air to pass back and forth into the can but not the microorganisms. The inside pressure equals outside pressure.
Buckled cans	:	Sometimes, the vacuum in big sized cans is so high that atmospheric pressure can strike the can body resulting in deformation of can which may further cause leakage of contents or contamination.

4.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

1. Your answer should include the following points:

   A food is a living commodity and respire and undergo various metabolic changes which if unchecked can spoil the food or if it is not harvested at proper maturity, is contaminated with dirt, or the microorganisms.

2. Your answer should include the following points:

   The major causes of spoilage are: the microorganisms or their enzymes, the native enzymes of food, rodents, environmental factors and purely chemical reactions.

3. Your answer should include the following points:

   - Delay or prevention of microbial decomposition of food.
   - Delay or prevention of self decomposition of food.
   - Prevention of damage to food caused by insects, rodents, birds and mechanical causes.

4. Your answer should include the following points:

   - Microbiological spoilage
   - Spoilage by physical causes

5. Your answer should include the following points:

   Dried fruits can have a number of microorganisms but due to decreased water activity, heat treatment during dehydration and fumigation, the microorganisms may be killed so unable to cause spoilage, but, spores of bacteria and molds may survive and cause spoilage.

6. Your answer should include the following points:

   Acetification: It is the process of conversion of ethanolic liquid into acetic acid by the activity of acetic acid bacteria.

   Putrefaction: The anaerobic decomposition of the protein, peptide or amino acid results in the production of obnoxious odour which is called as putrefaction.

   Fermentation: It is the process in which the organic compounds are converted into other organic compounds with generation of energy.

   Rancidity: It implies the oxidation of fatty substances giving specific off-odour.

7. Your answer should include the following points:

   In hard swells, both the ends of can remain bulged and rigid. In case of soft swell, the ends are not so hard. On applying some pressure, the ends may go inward (normal) but do not remain normal on the removal of pressure.

8. Your answer should include the following points:

   Water activity (aw): Moisture content is usually expressed in terms of water activity.

9. Your answer should include the following points:

   Jams and jellies have usually low water activity (0.75-0.86) so have lower risk of spoilage. However, if package is opened chances of recontamination could be expected or if there is leakage the product could be spoiled by osmophilic yeasts such as *Zygosaccharomyces Torulopsis*, *Xeromyces*.

10. Your answer should include the following points:

   Fungi

   Mucor,
   Rhizopus,
   Penicillium,
   Aspergillus,
   Alternaria, Cladosporium,
   Byssochlamys

Bacteria

Clostridium butyricum
B. coagulans (flat sour)
E. coli
Lactobacillus,
Leuconostoc mesenteroides
Streptococcus viscosum

Yeast

Saccharomyces

11. Your answer should include the following points:

    Carbonated beverages are usually not spoiled because of inhibitory effect of CO_2 on microorganisms. The acidity (resulting from carbonation and addition of acids) also inhibits microorganisms. Since molds require air, they do not grow on the carbonated beverages but may develop at the surface of uncarbonated soft drinks which contain air above the liquid surface.

12. Your answer should include the following points:

    Following are some of the factors responsible for spoilage: Number and kind of microorganisms, Suitability of temperature, Suitability of food, pH of food and Presence of air

13. Your answer should include the following points:

    Perishable foods: are the foods which spoil readily unless special preservation methods are used (meat, fish, most of fruits and vegetables, egg, poultry milk).

    Semi-perishable foods: Semi-perishable foods like waxed potatoes and some varieties of apple, if handled and stored properly, shall remain unspoiled for a fairly long period.

    Non-perishable foods: are the foods that do not get spoiled until and unless they are handled carelessly such as cereals, sugar.

14. Your answer should include the following points:

    Psychrophiles: These have affinity for low temperatures (8-10^{o}C).

    Mesophiles: These microorganisms grow best at medium temperatures (25-40^{o}C).

    Thermophiles: These microorganisms appear at higher temperatures (50-55^{o}C).

15. Your answer should include the following points:

    Bacillus coagulans

16. Your answer should include the following points:

    The initial number of microorganisms present on the food has a direct relationship with its spoilage. More the number of microorganisms present, rapid is the spoilage.

17. Your answer should include the following points:

    1) Keep the initial microbial contamination as low as possible and create conditions to check the growth of microorganisms.

    2) All efforts be made to apply the preservative technique.

    3) Mechanical disruption of the processed product tissue should not occur.

    4) Inhibit microbial growth by storing the food at low temperature or in inert atmosphere packaging of dried fruits and vegetable products.

    5) Equipments used for handling should be clean and free from contamination.

UNIT 5 CONCEPT, DETERMINATION OF PROCESS LETHALITY REQUIREMENTS AND IMPORTANCE

Structure

5.0 OBJECTIVES

After studying this unit, you should be able to understand:

- kind of foods based on their acidic reaction;
- relationship between pH of foods and heat resistance of microorganisms;
- difference in heat resistance of vegetative cells and spores of microorganisms;
- what is thermal death time and how it is determined?;
- how microorganisms behave under freezing and refrigeration conditions?; and
- the basic principle involved in various methods for controlling microorganisms.

5.1 INTRODUCTION

The foods, which we eat or drink are also excellent substrates (food) for microorganisms, which are present in air, water, soil, utensils and even in raw foods. Under suitable conditions of growth, particularly temperature and moisture, the microorganisms multiply using these food items and produce luxuriant growth. Many foods serve as carrier of various pathogenic and non-pathogenic microorganisms, which may spoil the food by their growth, change of chemical nature of food, release of unpleasant odour, production of various harmful enzymes and toxins. Such foods are unfit for human consumption. For these reasons, it is essential to prevent the entry and growth of microorganisms in our food if present, by suitable processing. Before using a suitable process, we should understand various factors which may influence the effectiveness of a process.

5.2 CLASSIFICATION OF FOODS ACCORDING TO pH

Most foods are derived either from plants or from animals. In this course, we are concerned with foods of plant origin and are known as vegetables or fruits based on their use. These foods have different pH and are classified as low acid foods, medium acid foods, acid foods and high acid foods.

a) Low acid foods

The foods having pH above 5.3 are called low acid foods. For example: peas, corn, lima beans etc.

b) Medium acid foods

The foods which have pH between 4.3 and 5.3 are called medium acid foods. For example: asparagus, beets, pumpkin, spinach etc.

c) Acid foods

Foods which have pH between 3.7 and 4.5 are called acid foods. For example: pears, pineapple, tomatoes etc.

d) High acid foods

Foods having pH 3.7 or lower are included in this category. For example: Berries and sauerkraut.

You must have noted that in general vegetables are low or medium acid foods while fruits are acid or high acid foods.

Most foods are subjected to heat treatment or cooked before use. The heat process is essential in the canning of foods to eradicate the microorganisms, which may be present in the raw food or may enter from the environment during processing; and may spoil the food if not eradicated.

The effect of pH of the food is complicated as the heating at high temperature causes decrease in the pH of low or medium acid foods. Higher the original pH, the greater the drop of pH by heating. Foods artificially adjusted to more alkaline pH give increasing protection to spores against heat as pH increases towards 9.

5.3 RELATIONSHIP BETWEEN pH OF FOOD AND HEAT RESISTANCE OF MICROORGANISMS

The pH of the foods influence the heat resistance of microorganisms. In general cells or spores are most heat resistance in a substrate that is at near neutrality. An increase in acidity or alkalinity hastens killing by heat. However, a change towards acidic pH is more effective than a corresponding change in alkalinity. This will be more clear from the Table 5.1, which shows the effect of pH on heat resistance of spores of *Bacillus subtilis.* Therefore low acid foods are heated under pressure (i.e. temperature above 100^{o}C) while the high acid foods are heated up to 100^{o}C for making free from microorganisms.

Table 5.1: Effect of pH on heat resistance of spores of *Bacillus subtilis* in 1:15 M phosphate buffer (100^{0}C)

pH	Time of survival (min)
4.4	2
5.6	7
6.8	11
7.6	11
8.4	7

5.4 HEAT RESISTANCE OF MICROORGANISMS AND SPORES

The heat resistance of microorganisms varies widely within the species and their forms:

- Thermophiles are more resistance than mesophiles and psychrophiles are least resistance.
- Spores formers are more resistant than non-spore formers. Cocci are usually more resistant than rods.
- The bacteria that clump considerably or form capasules are more resistant to heat than those which do not.
- Cells high in lipid content are difficult to kill than cells having low lipid.

However, there are many notable exceptions to the above mentioned general statements.

Higher the optimal temperatures for growth, the greater the resistance to heat. Thermal death time of bacterial cells of a few microorganisms are exemplified in Table 5.2.

Table 5.2: Thermal death time of bacterial cells

Bacteria	Time (min)	Temperature (^{o}C)
Gonococcus	2 – 3	50
Salmonella typhosa	4.3	60
Staphylococcus aureus	18.8	60
Escherichia coli	20-30	57.3
Streptococcus thermophilus	15	70-75
Lactobacillus bulgaricus	30	71

The heat resistance of microbial spores is much higher than the vegetative cells, and vary with the species of microorganism and conditions during sporulation. Resistance may vary from <1 min to 20 h at 100^{o}C. Similar to non-spore forming species, the spore forming species which have higher optimal temperature for growth are more resistant to heat than those spore forming species having lower optimal growth temperatures.

Simultaneous growth of two spores formers enhances the resistance of spores having lower heat resistance, e.g. *Clostridium perferingens* growing with *C. sporogenes*. Thermal death times of spores of a few microbial species are given in Table 5.3.

Table 5.3: Thermal death times of bacterial species

Species	Thermal death at 100^{o}C (min)
Bacillus anthracis	1.7
Bacillus subtilis	15-20
Clostridium botulinum	100-300
Clostridium calidotolerans	520
Bacillus coagulans (flat sour bacteria)	> 1030

Above examples of thermal death times of vegetative cells as well as of spores are at various concentrations of cells or spores in different substrates. These values may change to lower or higher under different conditions.

What happens to enzymes in food by heat treatments?

Most foods and microbial enzymes are destroyed at 79.4^{o}C, however some may withstand higher temperatures, especially if high temperature for short duration is employed. This is called **pasteurization**, which you will learn later in this course.

5.5 THERMAL DEATH POINT (TDP)

Thermal death point is the lowest temperature at which all microorganism in a liquid suspension are killed in 10 minutes.

5.6 THERMAL DEATH TIME (TDT OR t_D)

The thermal death time is defined as the time required, at a given temperature, for heat killing of a population of a single species of microorganism in aqueous suspension. t_D depends on the size of the population and on the pH of the suspension. It is an important factor for controlling the microorganisms by heat treatment or to determine the heat resistance of a microorganism.

5.7 DETERMINATION OF THERMAL DEATH TIME (t_D)

The description of all the procedure and equipments/apparatus, used in the determination of thermal death time is beyond the scope of this course. However, a simple glass-tube method, used in canning industry is discussed here.

5.7.1 Glass Tube Methods

A known population of cells of an axenic culture in a small volume (1 ml) of buffer solution is sealed in small glass tube. The tubes are heated in a thermostatically controlled bath to a selected temperature. The tubes are selected periodically, cooled immediately to 0^oC and the population of viable cells is determined. In case of spores, the suspension is first pasteurized to kill the vegetative cells, if present, before subjecting the spore suspension to d_T test. This is necessary as the lysed vegetative cells may have protective effect on spore-population.

Care is also taken to break up the clumps and remove the growth medium by centrifuging and washing. The volume of microbial suspension added to the buffer is kept 1-2 percent to avoid the change in the composition of heating substrate and the vials containing the suspension are brought to constant temperature, usually 0^oC before subjecting to heat treatment. If temperature above 100^oC is selected, oil bath instead of water bath is used. The test is always made in multiple tubes. Viability of the surviving organism after heat treatment should be checked on appropriate medium containing all the nutrients, which support maximum growth of that organism.

5.7.2 Decimal Reduction Time

When a microbial population is heated, the cells die at a constant rate. For example, suppose a population of 1 million (10^6) cells has been heated to a high temperature for 1 minute and 90% has died. We are now left with 100,000 (10^5) cells. If the leftover population is heated for another 1 minute, 90% of the population leaving 10000 (10^4) survivers. Thus the each one minute of heat treatment will reduce 90% of the remaining population. This is shown in Table 5.4 and is known as decimal reduction time (DRT) and represented by *D*. It can be defined as the time of heating at a temperature to cause 90% reduction in the population of viable cells or spores.

Table 5.4: Microbial death rate at constant temperature

Time (min)	Death min^{-1}	Number of survivors
0	0	1,000,000
1	900,000	100,000
2	90,000	10,000
3	9,000	1,000
4	900	100
5	90	10
6	9	1

The D value (Decimal reduction time) may also be defined as the 'time at given temperature for the surviving population' to be reduced by 1 log cycl. Please refer Figure 5.1, if we extrapolate the times from 10^3 and 10^2, the time difference is (3.5 – 2.5 = 1min is D). It means within 1 min initial population will decrease by 90 per cent (from 1000 to 100, Difference 1000 – 100 = 900).

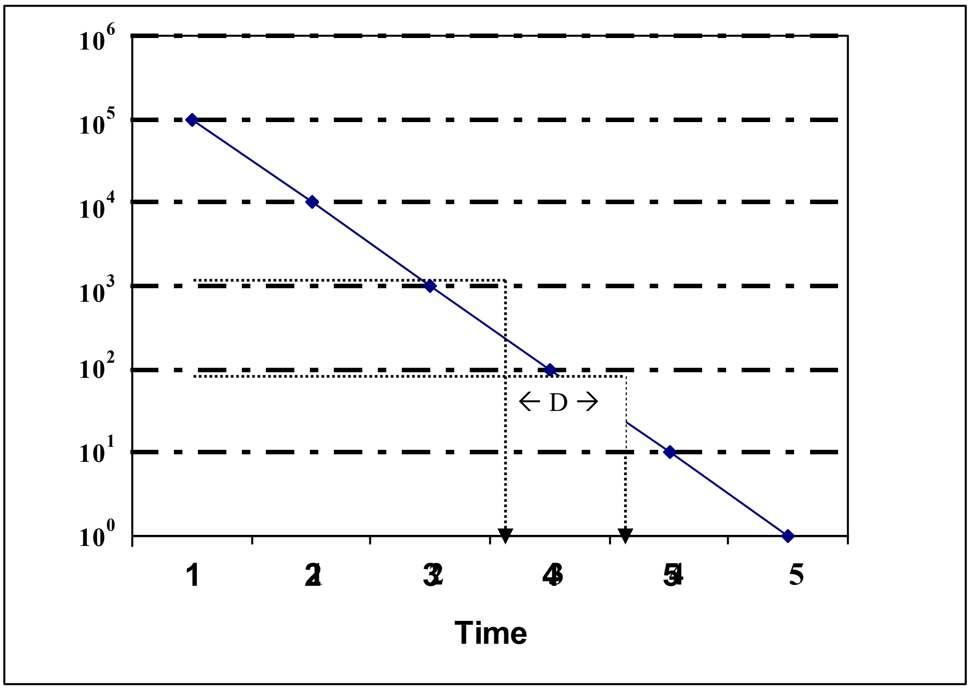

Figure 5.1: A microbial death curve showing constant death rate of cells i.e. 90% per minute D value may be calculated from the curve by extrapolating lines from the Y axis and calculating the time difference.

5.7.3 Thermal Death Time Curve (TDT Curve)/Kinetics

The methods to construct TDT curve are: (i) The growth – no growth method (ii) classical end point method and (iii) based on *D* values. We shall here discuss the method based on *D*-values. D values can be calculated at different temperatures (refer 5.7.2). As the temperature is increased, the D value decreases. It means if we heat the sample at high temperature, it will take less time to kill the microorganism in a given food sample. If we plot log D values against temperature, we will get a straight line. From this we can derive another important parameter in heat processing Z, the temperature change which results in a ten fold (1 log) change in D.

$$Z = (T2 - T1)$$

D value for a known population of cells or spores of a microbial species at several temperatures can be estimated. By plotting D values on the logarithmic scale against temperature TDT curves can be constructed (Figure 5.2).

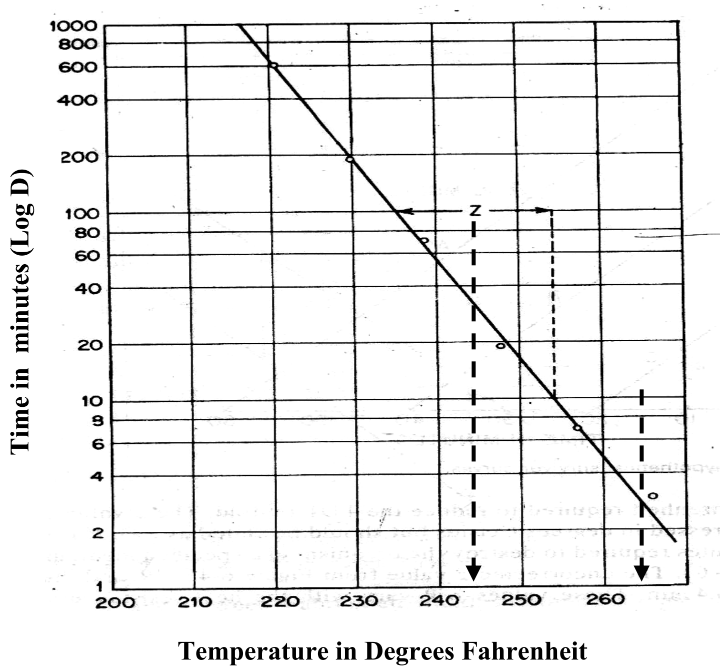

Figure 5.2: TDT curve for spores of flat sour bacteria; 115,000 spores per ml in corn at pH 6.1 (z = 19).

If we are interested to process the food item so that it may be free from any spore or microorganisms, first we have to calculate D, Z and F values. *F* is the time in minutes required to destroy the organism in a specified medium at 121°C. These values vary with the heat resistance and concentration of the test organisms and with the medium in which it is heated. From the *Z* and *F* values process times can be calculated.

5.7.4 12D Concept

Canned foods are susceptible to the spores of the organism *Clostridium botulinum*, this organism causes botulism. As a safety measure, the canning industry use the 12*D* heat treatment for low acid foods. In this process enough heat is provided to reduce 10^{12} spores of *C. botulinum* to 1 spores per ml. It can be explained as follows.

Assuming that *D* has a value of 0.21 minutes for spores of *C. botulinum* at 121°C and that out of 12 cans of food contains 1 spore. A heat process at 121°C for 2.52 min would reduce the spores to 1 spore in 10^{12} cans. The value of 2.52 min has been arrived by the following formula:

$$F_o = D_{121} (\log a - \log b)$$
$$= 0.21 (\log 1 - \log 10^{-12})$$
$$= 0.21 \times 12$$
$$= 2.52$$

5.8 DETERMINATION OF PROCESS LETHALITY REQUIREMENTS AT LOW AND HIGH TEMPERATURE

5.8.1 Heat Penetration

In heat/thermal processing of foods, the ratio of penetration of heat into a food is very important, because every part of food in a container must get adequate heat to prevent spoilage. The part which heats most slowly is the critical one; and this is near the centre of container. Solids are heated by conduction while liquids by convection. Foods which are semisolid are heated by combination of both conduction as well as convection. Conduction is slow in foods and rapid in metals.

The factor that determine the time required to bring the centre of the container of food upto the sterilizing temperature are as follows:

i) Material of which the container is made

Glass has slower rate of penetration than metal (tin can).

ii) Size and shape of container

Large container takes long time than small container. Less the radius of container faster the heating. For example: long slim cylinder will heat faster than compact wide cylinder of the same volume.

iii) Initial temperature of food

For the foods with the higher initial temperature the average temperature during heating is higher than in foods having lower initial temperature. A high initial temperature is important in processing canned foods that heat slowly. For example: pumpkin, cream style corn etc.

iv) Initial temperature of retort (steam sterilizer)

Fastest heating takes place in initially hot retort than retort having initially low temperature. Therefore, preheated retort should be used.

v) Consistency of food, size and shape

Consistency of food, size of food pieces and even their shapes affect the penetration of heat. The changes that takes place during heating (cooking effect) also affect the heat penetration. Penetration of heat in large pieces takes more time than in small pieces. This is applicable in foods, which retain their shape and even size during heating. For example: peas, plum, beats, whole grain corn etc.

Some foods become mushy or viscous during heating. In such foods penetration is slow. For example: Sweet potatoes, pumpkin, etc.

Pieces that layer like asparagus layers or spinach layers interfere with convection current

Sauces added on baked beans slow down heat penetration more than plain sauce. Starch interferes increasingly as the concentration is raised. Sodium chloride is never added in high concentration as it slows down rate of heating. Rate of heat penetration also decreases with increasing concentration of sugars; however this effect is counteracted some what by the marked decrease in the viscosity of sugar solutions. *(Addition of sugar and salt slow down the rate of heating)*

vi) Rotation and agitation

The rotation and agitation of the container of food during heat processing hasten heat penetration, if food is in form of fluid. However, in some food such operation may cause undesirable physical changes.

5.8.2 Cooling of Food after Heat Processing

The cooling operation involves the same principles of heat transfer as the heating process. Rapid artificial cooling is recommended as slow cooling may cause overcooking of the food and may allow the growth of thermophiles.

5.8.3 Determination of Thermal Processes

To determine the thermal processes data on the following two aspects are required:

i) TDT curve for most heat-resistant organism likely to be present in food. For example in low acid foods spores of *Bacillus coagulanse* (flat sour organism), which is a thermophile, may be present.

ii) Heat penetration and cooling curves for the food when packed in specific type of container of fixed size.

There are three methods to determine thermal processes:

- Graphical methods
- Formula method
- Nomogram method

The principle is similar for all the three methods; however the graphical method is most simple and therefore explained here:

Graphical method to determine thermal processes

1. The TDT curve for the most heat resistance organism likely to be encountered is determined in food being canned.

   TDTs from this curve are converted to **lethal rates** for the various heating temperatures. The lethal rate for a temperature is the reciprocal of the TDT. If TDT is 400 min at 126.7^{o}C to kill the spores in a food, the lethal rate would be 1/400 i.e. 0.0025.

2. Heat penetration and cooling curve for the food and can size involved are determined.

3. The lethal rates for different temperatures at the centre of can during the length of heating and cooling process are plotted on the heat penetration or cooling curves (see Fig. 5.3). In this figure the lethal rates are 0.01 units and times are 10 minutes for a square. An area equivalent to 10 squares under the lethality curve is unity. This means that the destruction of all the spores or cells has been accomplished. If this area is less than unity (i.e. less than 10 squares), the process is inadequate, and if more than 10 squares, it is greater than needed. The area beneath the curve is

measured by planimeter. In Figure 5.3 the heat treatment of 56 min at 126.7°C and 78 min at 121°C are adequate.

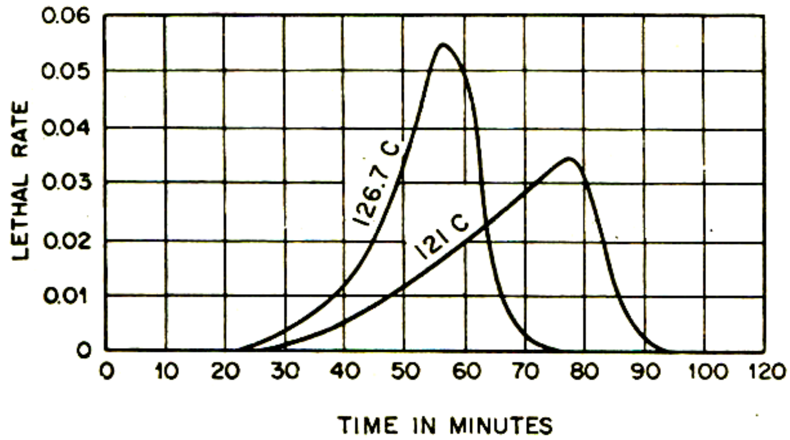

Figure 5.3: Equivalent lethality curves with retort at 126.7°C. (50,000 spores per ml)

5.9 BEHAVIOUR OF MICROORGANISMS UNDER FREEZING AND REFRIGERATION ENVIRONMENTS

Low temperatures are used to retard chemical reactions, and actions of food enzymes and to reduce slow down or stop growth and activity of microorganisms in food. The lower the temperature, the slower will be the chemical reactions, enzyme and microbial growth; and temperature below certain level will prevent the growth of a microorganism. Each microorganism has a specific **Cardinal temperature** i.e. the minimal temperature and maximal temperature at which it can grow and optimal temperature at which the growth is fastest in the shortest time. As the temperature drops below the optimal temperature towards the minimal, the rate of growth of organism decreases and is slowest at the minimal temperature. Below minimal temperature, the growth will stop but slow metabolic activity may continue. Therefore cooling down of a food from normal temperature has different effects on various microorganisms and slow down the growth of others; however the extent would vary with different species and even strains of microorganisms. A further decrease of 10°C would stop growth of more organisms, and make still slower the growth of the others. Therefore storage at low temperature influence the type of spoilage microorganisms which may predominate as illustrated in Table 5.5.

Table 5.5: Growth rate of Pseudomonas fragii at various temperatures

Temperature (°C)	Exponential growth rate (generation h^{-1})
0.0	0.09
2.5	0.13
5.0	0.20
7.5	0.29
10.0	0.38
20.0	0.92

5.9.1 Growth of Microorganisms at Low Temperature

In general, freezing prevent the growth of most food born microorganisms and refrigeration slow down growth rates except for *Clostridium botulinum* type E. Temperature below 5-6°C or less, effectively retard the growth of most food spoilage microorganisms. However, some of the microorganisms may survive at subfreezing temperature in frozen food. (Table 5.6 and 5.7)

Table 5.6: Microorganisms able to grow at subfreezing temperatures

Organisms	Temperature (°C)
Molds	
Claedosporium	–6.7
Sporotrichum	–6.7
Penicellium	–4.0
Monilia	–4.0
Yeast	
Yeast (one strain)	–34.0
Yeast (two strains)	–18.0
Bacteria	–5.0 to –17.8

Table 5.7: Different microorganisms able to grow in different frozen foods

Organisms	Food	Temperature (°C)
Bacteria	Meat	– 5.0
	Cured meats	–10.0
	Fish	–11.0
	Vegetables	–12.2
	Ice cream	–10.0
Yeast	Meat	– 5.0
	Oysters	–17.8
Molds	Meat	– 7.8
	Vegetables	– 7.8
	Barries	– 6.7

5.9.2 Effect of Freezing and Subfreezing Temperature on Microorganisms

Feezing usually results in a considerable reduction in the number of viable organisms in a food. The reduction in recoverable numbers can be the result of lethal or sublethal effects.

a) Lethal effects

Though several cells of microorganisms are killed by freezing, a few may remain viable with little or suspended metabolic activity. The lethal effects are due to denaturation or flocculation of essential cell proteins or enzymes possibly as a result of the increased concentration of solutes in the unfrozen water or perhaps in part because of physical damage by ice crystal. Rapid cooling of cells from an optimal temperature to 0^oC is most injurious and may lead to cell death due to cold shock. It is probably due to crystallization of the liquids in the membrane which damage to the permeability of the cell or due to the release of repair enzyme inhibitors, e.g. **ribonuclease inhibitors.**

b) Sublethal effects

Freezing of food may cause cryo injury to the microorganisms present on food. Such injured cells are referred as freeze injured, frost injured, cryo-injured or metabolically injured. Such cells are not really dead and may recover to start refunctioning, if repair time is permitted or additional nutritional factors are added to the enumeration media. This fact of cryoinjury is of great significance in the microbiological examination of foods.

5.9.3 Factor Affecting Microorganisms during Freezing

1. The resistance or sensitivity of microorganisms vary with the kinds of microorganisms, their form and growth phase. For example:
   a) Thermophiles are most sensitive and psychrophiles most resistance.
   b) Spore formers are more resistance than non-spore formers.
   c) Bacteria in logarithmic phase are more sensitive than in stationary phase.
   d) Rods are more sensitive than cocci.
2. Microorganisms are classified on the basis of sensitivity to freezing:
   i) **Susceptible:** Gram negative bacteria and vegetative cells of yeast and molds.
   ii) **Moderately resistant:** Gram positive streptococci and enterococci.
   iii) **Insensitive:** Spore formers.
3. Freezing parameters:
   i) ***Freezing rate***

      Rapid cooling upto 0^oC is injurious to microbial cells.

   ii) ***Freezing temperature***

      Freezing temperature between -4 to -10 is more injurious than -15 to -30^oC.

   iii) ***Times of frozen storage***

      Maximum death of microorganisms occur during the freezing process. Once the temperature is stabilized, the death is less and very low.

   iv) ***Kinds of food***

      The composition of food influence the rate of killing of microorganisms during freezing and storage. Sugar, salt, protein, colloids, fats and other substance in foods provide protection to the microorganisms while low pH and high moisture hasten the death.

v) ***Slow defrosting of food cause death*** of microorganisms.

vi) ***Freezing and thawing***

Maximum casualty of microorganisms occur if foods are repeatedly frozen and thawed.

5.9.4 Effect of Freezing on Constituents of Microbial Cells

With the lowering of temperature, water in cell gets frozen. As a result the unfrozen fluids in cell gets concentrated with solutes (salts, proteins, nucleic acids, etc). This may change the pH of cellular matter, concentrate electrolytes, alter colloidal states, denature proteins and increase viscosity. Ice crystals also form outside the cell due to the freezing of water molecules in food. These extracellular ice crystals draw water from the cell causing dehydration or concentration effect. Intracellular ice crystals due to the freezing of water may rupture cell membrane and alter the permeability of cell membrane. Intracellular ice crystals are more injurious than the extracellular ice crystals to the microbial cells.

5.10 CONTROL OF MICROORGANISMS BY VARIOUS MEANS

Most foods are either of plants or animal origin. Their spoilage is prevented by controlling microbial growth on them by using various methods. Some important methods are listed below:

1. Asepsis or preventing contacts with microorganisms.
2. Killing the microorganisms by heat treatment.
3. Keeping away from the microorganism e.g. maintenance of anaerobic conditions in sealed or evacuated container.
4. Storage at low or ultra low temperature
5. Drying.
6. Increasing osmotic concentration in foods.
7. Mixing with preservative.
8. Change of pH
9. Mechanical destruction in industry: grinding or high pressure.

Usually a combination of more than one method is used to control the microbial spoilage of food. For example: canned foods are preserved by heat treatment followed by evacuation and sealing of can. Similarly, many processed foods involve heating, mixing with preservative, evacuation of air and sealing.

5.11 PRINCIPLES INVOLVED IN VARIOUS METHODS TO CONTROL MICROBIAL SPOILAGE OF FOOD

The basic principle involved in various methods to control microbial spoilage of foods are prevention or delay of microbial decomposition. These are achieved by followings methods:

a) By keeping out microorganisms. For example: Aseptic condition during processing of food.

b) By the removal of microorganisms: For example

- By removing the microbially infected portion of food, covering, skin etc.
- Washing of raw food.
- Filteration.

c) By hindering the growth and activity of microorganisms by low temperature, drying, anaerobic condition or chemical.

d) By killing the microorganisms: sterilization by heat or radiation.

5.12 LET US SUM UP

Human foods are excellent substrate for various microorganisms, which are present in air, water, soil, raw foods, on the body of living and non-living organisms. These microorganisms may harm the body if enter in the body/tissue due to rupture or injury of outer covering layer. Many of these microorganisms may enter the food during the processing and remain either dormant for long time till get the right conditions for multiplication, if consumed, cause unpleasant odour or taste making the food unfit for consumption. Such spoilage is called microbial spoilage of food.

Prevention of microbial spoilage of foods depend upon the kind of foods. The acidity or pH of the food influence heat resistance of microorganisms. Microbial cells are more resistance to heat at pH near to neutrality and therefore, low acid foods are heated under pressure to kill the microorganisms, where as the high acid foods are heated upto 100^{o}C for short duration to make free from organisms.

The thermal death time (TDT) which is defined as the time required to kill a known population of microorganisms at a certain temperature by heat. This value differ for different microorganisms and also on various environmental factors. TDT values are of great significance in heat control of microorganisms.

The death of microbial cells is at constant rate and is expressed in *D*-value i.e. decimal reduction time. *D*-values of a microbial species at several temperatures are estimated and plotted against temperature to construct curve, which are used to determine the actual time required for killing microbes in a food at a particular temperature. In practice 12*D* concept is used in canning industry. This is based on the reduction of 10^{12} spores ml^{-1} of *Clostridium botulinum* in low acid food to 1 spore ml^{-1} by heat treatment.

Low temperature under freezing and refrigeration reduce microbial growth and at 0^{o}C most of the microorganisms stop the growth. However a few exceptions of molds, yeast and bacteria, which may grow up to –6 to –38^{o}C have been encountered.

Freezing may have lethal or sub-lethal effect on microbial cell. In sub-lethal effect the freezing injury makes the microbial cell unable to multiply, however under favourable conditions, such cells may get repaired and grow.

The various method for controlling microorganisms are asepsis, heat treatment, anaerobic conditions, storage at low temperature, drying, increasing osmotic concentration, mixing with preservatives, change of pH, irradiation and mechanical destruction by grinding or high pressure. The basic principle involving in these methods are; prevention or delay of microbial decomposition by keeping out or removing the microorganisms or creating suboptimal conditions for survival and growth of microorganisms or by killing the microorganisms.

5.13 KEY WORDS

TDP : Thermal death point is the lowest temperature at which all microorganisms in a liquid suspension are killed in 10 minutes.

TDT : Thermal death time is defined as the time required, at a given temperature, for heat killing of a population of a single species of microorganism in aqueous suspension.

D Value : Decimal reduction time is defined as the time of heating at a temperature to cause 90% reduction in the population of viable cells or spores.

12D Concept : A process in which enough heat is provided to reduce 10^{12} spores of *clostridium botulinum* to 1 spores per ml in canned food.

5.14 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   Food which have pH between 3.7 and 4.5. Example: pear, pineapple and tomatoes.

2. Your answer should include the following points:

   Low acid foods.

3. Your answer should include the following points:

   Clostridium botulinum as it is spore former.

4. Your answer should include the following points:

   Thermal death time is the minimum time required to kill a population of microorganisms in liquid suspension at certain temperature.

5. Your answer should include the following points:

   Thermal death point is the minimum temperature required to kill population of microorganimsm in liquid in 10 min.

6. Your answer should include the following points:

   By any killing agent, the death of microorganisms is at a constant rate. Suppose a population of 10^6 cells are subjected to heat treatment, 90% of them will die in first minute. Of the remaining population, 90% will die in next one minute and so on until all the population die.

7. Your answer should include the following points:

   TDT curves are constructed to determine the thermal process time at different temperature to kill the microorganisms in a food.

8. Your answer should include the following points:

   It is a concept of time required to reduce 10^{12} spores of *Clostridium botulinum* in 1 ml suspension to 1 spore by heating to certain temperature. It is used in canning industry.

9. Your answer should include the following points:

   Thermal processing is affected by the **consistency** of food.

10. Your answer should include the following points:

    Graphic method.

11. Your answer should include the following points:

    No; psychrophiles will continue growing.

12. Your answer should include the following points:

    Injury to microbial cells during freezing.

13. Your answer should include the following points:

    Yes.

14. Your answer should include the following points:

    Rupture of cell membrane leading to the leakage of cell constituent.

15. Your answer should include the following points:

    Sterilization

16. Your answer should include the following points:

    Vegetative cells

17. Your answer should include the following points:

    Clostridium botulinum

18. Your answer should include the following points:

    Reducing or suspending the metabolic activity and growth.

19. Your answer should include the following points:

    Pasteurization

20. Your answer should include the following points:

    Thermophiles

UNIT 6 THERMAL CONTROL OF MICROORGANISMS

Structure

6.0 OBJECTIVES

After studying this unit, you should be able to:

- make you understand the principals of food preservation using high temperatures;
- explain various processes for thermal preservation;
- describe the terms associated with heat preservation; and
- discuss the causes of spoilage of heat processed products and common spoilage organisms.

6.1 INTRODUCTION

The minute living organisms, not visible to the naked eye and classified as microorganisms, are virtually everywhere. Those of primary medical interest are bacteria, viruses, spirochetes, rickettsia, molds, and yeasts. They flourish in the soil of the farms that grow our grains, fruits and vegetables, on the hides and feathers of our meat animals and on the fins and organs of the seafood we eat. Though there are innumerable genera and species of each class of microorganisms, not all are of medical significance or involved in disease processes. Many of these organisms can be beneficial. In fact the predominance are composed of those that are necessary to food production, friendly environments, and metabolic processes, examples being cheese/wine production, decomposition of organic matter, and digestion of food. Lactic acid bacteria in the dairy industry, yeasts in the baking and brewing industries, molds for specialty cheeses are examples of "domesticated" microorganisms. But in a many cases these microscopic flora create serious problems in our food supply. These problems fit into two categories. **Food spoilage** occurs when the food becomes unpalatable as the result of microbial growth. Products develop undesirable flavors, odors, appearances or textures via microbial action. The other, more dangerous problem is **food poisoning**, which occurs when the organisms present in food cause human illness or death. The microorganisms either produce a toxin or cause an infection, generally intestinal, when consumed. Those organisms that spoil product are typically called **spoilage organisms**, while those that can make people sick are referred to as **pathogens**. Therefore, to avoid both of these problems we need to understand the techniques which prevent their growth.

Food preservation has been around for a long time. The technique of food preservation may vary but the goal of food preservation has been the same **i.e. to keep the food in a stable condition over a period of time so that it will not spoil or make people sick.** There are various ways of food preservation, including chemical preservation, modified atmospheres, irradiation, low temperature preservation, preservation by drying and high temperature preservation.

6.2 THERMAL PRESERVATION OF FOODS

The most common method of killing microorganisms is to subject them to a heat treatment. High temperatures act by killing vegetative cells and also spores and denaturing the food enzymes. It may also act to destroy toxins produced by certain microorganisms.

The heat treatment used depends on the following factors. In order to safely preserve foods using heat treatment, the following must be known:

- What time-temperature combination is required to inactivate the most heat resistant pathogens and spoilage organisms in one particular food? The higher the temperature, the less time needed and vice versa. Heat destruction of microorganisms is a gradual phenomenon the longer is the treatment time at lethal temperatures, the larger is the number of microorganisms killed. As higher is treatment temperature the shorter is the time required to kill microorganisms and lower is heat induced damage to food products.

- What are the heat penetration characteristics in one particular food, including the can or container of choice if it is packaged?

- What are the types of micro-organisms present in the food material? The thermal death time of different microorganisms vary widely with the species. Different foods will support growth of different pathogens and different spoilage organisms so the target will vary depending upon the food to be heated.

- What is the concentration of the microorganisms? The higher the concentration, the more time is needed.

- What is the state of the microorganism? Spores are more resistant than vegetative cells. Organisms that have been stressed are more susceptible to heat.

- What is effect of heat on the product? Obviously, the temperatures required to kill microorganisms affect most food products.

- The degree of heat penetration also must be considered. Preservation processes must provide the heat treatment which will ensure that the remotest particle of food in a batch or within a container will reach a sufficient temperature, for a sufficient time, to inactivate both the most resistant pathogen and the most resistant spoilage organisms if it is to achieve sterility or "commercial sterility", and to inactivate the most heat resistant pathogen if pasteurization for public health purposes is the goal

- What is the effect of various environmental factors, such as pH and salts or solutes. Food acidity / pH value has a tremendous impact on the target in heat preservation/ processing.

6.3 HEAT PRESERVATION PROCESSES

The most common type of food preservation by high temperatures is cooking. However, there are many more processes that involve the use of temperature above that of ambient air.

6.3.1 Sterilisation

By sterilisation we mean complete destruction of micro-organisms. Because of the resistance of certain bacterial spores to heat, this frequently means a treatment of at least 121° C (250° F) of wet heat for 15 minutes or its equivalent. It also means that every particle of the food must receive this heat treatment. If a can of food is to be sterilized, then keeping it at 121° C or retort for the 15 minutes will not be sufficient because of relatively slow rate of heat transfer through the food in the can to the most distant point. In such cases time needs to be increased.

6.3.2 Commercially Sterile Food Products

Sterile means free of life of every kind and is actually achieved under very limited conditions. The control of microorganisms in medicine, industry, sanitation, food, and feed service involves the acceptance that sterilization is most often not achievable without destroying or severely damaging the product. Only Low Acid Foods [LAF], having pH higher than 4.6, must be sterilized, because all microorganisms are able to grow in LAF. More acid products [pH equal/lower than 4.6] do not allow the growth of pathogenic spore forming bacteria. Then Sterilization is not required. Hence **Commercial Sterility** is a term commonly used in the canning industry meaning the condition achieved by the application of heat sufficient to render the processed product free from viable microorganisms (including those of known public health significance), capable of growing in the food under normal non-refrigerated temperatures at which the food is likely to be held during distribution and storage.

The process was developed by Nicolas Appert and published in 1810. All vegetative organisms that could grow in the food and cause spoilage under normal handling and storage conditions are destroyed. However **commercial sterile** foods may contain a small number of heat resistant bacterial spores, but they will not multiply under normal handling and storage conditions. Types of commercially sterile processes include canning, bottling, and aseptic processing. Commercial sterilization must make sure the numbers of surviving spores are at an acceptable level. The acceptable number of spores will depend on what type of damage they are capable of causing if they start to grow.

6.4 PASTEURIZATION

In the previous section you have read about strerilzation and commercially sterile foods. Now we will discuss milder heat treatment i.e. pasteurization. It is one type of preservation by heat that most people are familiar with. It is process of heating a liquid, particularly milk, to a temperature between 55 and 70 degrees C (131 and 158 degrees F), to destroy harmful bacteria. This process is named after the French chemist **Louis Pasteur**, who devised it in 1865 to inhibit fermentation of wine. Pasteur's aim was to destroy bacteria, molds, spores etc. He discovered that the destruction of bacteria can be performed by exposing them to certain minimum temperature for certain minimum time and the higher the temperature the shorter the exposure time required. Through this process, all of the bacteria (such as *E.coli, Lysteria*, and *Salmonella)* are not destroyed, it still exists in pasteurized products, but in very low concentrates. Refrigeration keeps the bacteria from further growth, very low. There are other bacteria that aren't harmful to humans, but they produce acids that turn the milk sour. They are called lactophilic because they consume the lactose in milk and produce acids. The extent of the pasteurization treatment required is determined by the heat resistance of the most heat-resistant enzyme or microorganism in the food. For example, milk pasteurization is based on *Mycobacterium tuberculosis* and *Coxiella burnetii*. These two organisms are the most heat resistant of pathogens that are not spore forming. Milk is a product that most people know is pasteurized. It is pasteurized by heating at a temperature of 63 degrees C (145 degrees F) for 30 minutes, rapidly cooling it, and then storing it at a temperature below 10 degrees C (50 degrees F).

Pasteurization is a comparatively low order of heat treatment, generally at a temperature below the boiling point of water. The more general objective of pasteurization is to extend product shelf-life from a microbial and enzymatic point of view. Pasteurization is frequently combined with another means of preservation - concentration, chemical, acidification, etc. Blanching is a type of pasteurization usually applied to vegetables mainly to inactivate natural food enzymes. Depending on its severity, blanching will also destroy some microorganisms.

Depending upon time and temperature treatment there are three kinds of pasteurization processes.

6.4.1 Low Temperature Long Time (LTLT)

Where pasteurization time is in the order of minutes and related to the temperature used; two typical temperature/time combinations are as following: 63°C to 65°C for 30 minutes or 75° C over 8 to 10 minutes. Pasteurization temperature and time will vary according to:

- nature of product; initial degree of contamination;
- pasteurized product storage conditions and shelf life required.

In LTLT pasteurization it is possible to define three phases:

- heating to a fixed temperature;
- maintaining this temperature over the established time period (= pasteurization time);
- cooling the pasteurized products: natural (slow) or forced cooling.

This is a typical batch method where a quantity of milk is placed in an open vat and heated to 63°C and held at that temperature for 30 min. Sometimes filled and sealed bottles of milk are heat-treated in shallow vats by that method and subsequently cooled by running water.

6.4.2 High Temperature Short Time (HTST)

HTST pasteurization is characterized by a pasteurization time in the order of seconds and temperatures of about 85° to 90° C or more, depending on holding time. Typical temperature/time combinations are as follows:

- 88° C for 1 minute
- 100° C for 12 seconds
- 121°C for 2 seconds.

While bacterial destruction is very nearly equivalent in low and in high pasteurization processes, the 121°C/2 seconds treatment give the best quality products in respect of flavour and vitamin retention. This is the most widely used process. The “hold time” is typically 125°C to pasteurize milk. This process is a continuous method and a “hold tube” is used. The “hold tube” is the tubing in the system that transports the milk after the point where the product is heated. The tubing is sized so that it takes 15-20 seconds for the product to travel all the way through it. When it reaches the end, if the temperature is at 125°C or hotter, it is considered pasteurized. It is then cooled and put in storage. The warm milk passes through the cooling section where it is cooled to 4° C or below by coolant on the opposite sides of the thin, stainless steel plates. The cold, pasteurized milk passes on to a storage tank filler for packaging.

6.4.3 Ultra High Temperature (UHT) Processing Treatments

In this method, milk is exposed to a brief, intense heating, normally to temperatures in the range 135-140 °C but for a very short time, a second or less. The treatment kills all microorganisms that would otherwise spoil the product. The process depends upon a fairly complicated *sterilizer/aseptic filling* design. The two stages of effective heat sterilization followed by aseptic filling represent an integral system. Frequently the packaging material for UHT milk is cardboard which must be chemically sterilized prior to the filling operation

This method is used mainly for coffee creamers and boxed juices with the exception of Europe. They pasteurize milk in this way. After this is done, there is no need to refrigerate, because it sterilizes the product. Sometimes the products can have a "cooked" taste that can be detected after being brought to such a high temperature.

Industrial applications of pasteurization process are mainly used as a means of preservation for milk and fruits and vegetable juices and specially for tomato juice.

6.5 PRESERVATION BY MOIST HEAT

Moisture levels of the food material are a definite influencing factor in the shelf life of food. Moist heat readily kills viruses, bacteria, and fungi by denaturing enzymes whereas dry heat kills by oxidation of cell contents. There is a correlation between the percent of water and the effectiveness of heat to kill microorganisms. Moist heat is a more effective sterilizing agent than dry heat because the moisture increases the rate of heat penetration. Moist heat requires less heat (temperature or time) than dry heat (121°Cfor 10 min of moist heat is equivalent to about 30 min at 200°C dry heat).

For this reason a lot of sterilization procedures use super heated steam that provides moist heat. Temperature over 100^0C requires heating under elevated pressure, (like in a pressure cooker) 121^0C require 100 kpa extra pressure. It is important that no air pockets are allowed to develop when a product being sterilized with steam. In air pockets food is exposed to dry heat and thus the time /temperature is not enough. Moist heat denatures proteins which destroys essential enzyme activities.

Endospores are much more resistant to heat than are vegetative cells. For this reason, moist heat sterilization is aimed at ensuring that endo spores are killed.

Terms Associated with Heat Preservation

Scientists use different terms to refer the effect of moist heat on the preservation of food. These terms include thermal death time, D-value, and z-value.

6.5.1 Thermal Death Time (TDT)

Thermal death time is the amount of time that is necessary to kill a specific number of microbes at a specific temperature. This value is obtained by keeping temperature constant and measuring the time necessary to kill the amount of cells specified.

6.5.2 D-Value

The term D-value refers to decimal reduction time. This is the amount of time that it takes at a certain temperature to kill 90% of the organisms being studied. Thus after an organism is reduced by 1 D, only 10% of the original organisms remain. The population number has been reduced by one decimal place in the counting scheme. When referring to D-values it is proper to give the temperature as a subscript to the D. For example, a hypothetical organism is reduced by 90% after exposure to temperatures of 149°C for 2 minutes, Thus the D-value would be written as D_{300F} = 2 minutes. Several parameters help us to do thermal calculations and define the rate of thermal lethality. The D-value is a measure of the heat resistance of a microorganism. It is the time in minutes at a given temperature required to destroy 1 log cycle (90%) of the target microorganism. (Of course, in an actual process, all others that are less heat tolerant are destroyed to a greater extent). For example, a D-value at 72°C of 1 minute means that for each minute of processing at 72°C the bacteria population of the target microorganism will be reduced by 90%. D-values vary according to the temperature, species of microorganisms, number of initial population, and other factors that may affect thermal resistance. In the illustration below, the D-value is 14 minutes (40-26=14 min.) and would be representative of a process at 72°C.

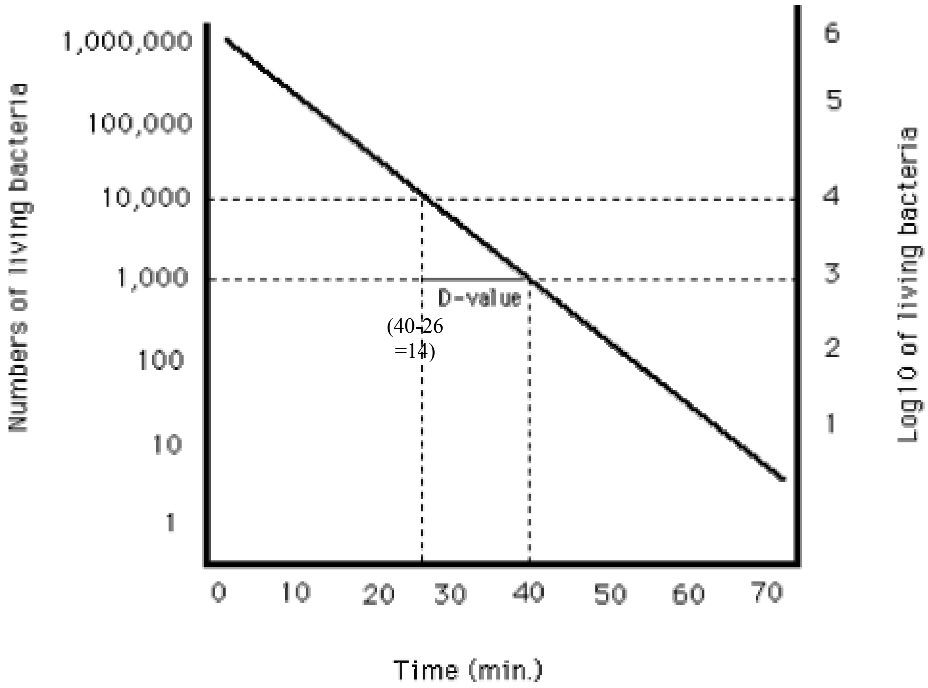

Figure 6.1: The D-value

6.5.3 Z-Value

The Z-value reflects the temperature dependence of the reaction. It is defined as the temperature change required to change the D-value by a factor of 10. While the D-value gives us the time needed at a certain temperature to kill an organism, the Z-value relates the resistance of an organism to differing temperatures. In the illustration below the Z-value is 10°C.

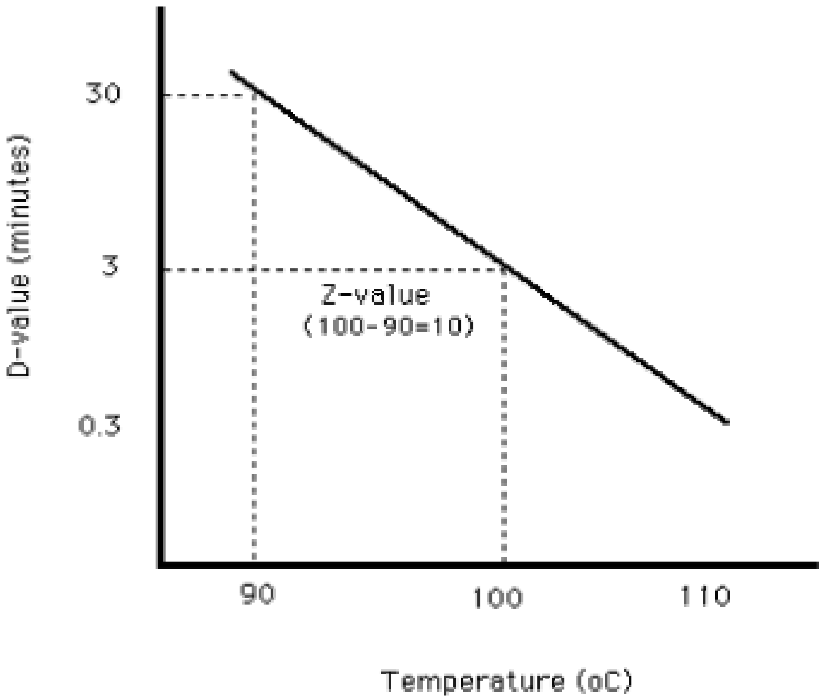

Figure 6.2: The Z-value

The Z-value allows us to calculate a thermal process of equivalency, if we have one D-value and the Z-value. So, if it takes an increase of –12°C to move the curve one log, then our Z-value is 10. So then, if we have a D-value of

4.5 minutes at 66°C, we can calculate D-values for 71°C by reducing the time by 1 log. So, our new D-value for 71°C is 0.45 minutes. This means that each -12°C increase in temperature will reduce our D-value by 1 log. Conversely, a -12°^{0}C decrease in temperature will increase our D-value by 1 log. So, the D-value for a temperature of 60°^{0}C would be 45 minutes.

Reactions that have small Z-values are highly temperature dependent, whereas those with large Z-values require larger changes in temperature to reduce the time. A Z-value of 10°C is typical for a spore forming bacterium. Heat induced chemical changes have much larger Z-values that microorganisms, as shown below:

	Z (°C)	**D121(min)**
bacteria	5-10	1-5
enzyme	30-40	1-5
vitamins	20-25	150-200
pigment	40-70	15-50

Figure 6.3 illustrates the relative changes in time temperature profiles for the destruction of microorganisms. Above and to the right of each line the microorganisms or quality factors would be destroyed, whereas below and to the left of each line, the microorganisms or quality factors would not be destroyed. Due to the differences in Z values, it is apparent that at higher temperatures for shorter times, a region exists (shaded area) where pathogens can be destroyed while vitamins can be maintained. The same holds true for other quality factors such as colour and flavour components. Thus in milk processing the higher temperature, shorter time (HTST) process (72°C/16 sec) is favoured compared to a lower temperature longer time (batch or vat) process since it results in a slightly lower loss of vitamins and better sensory quality.

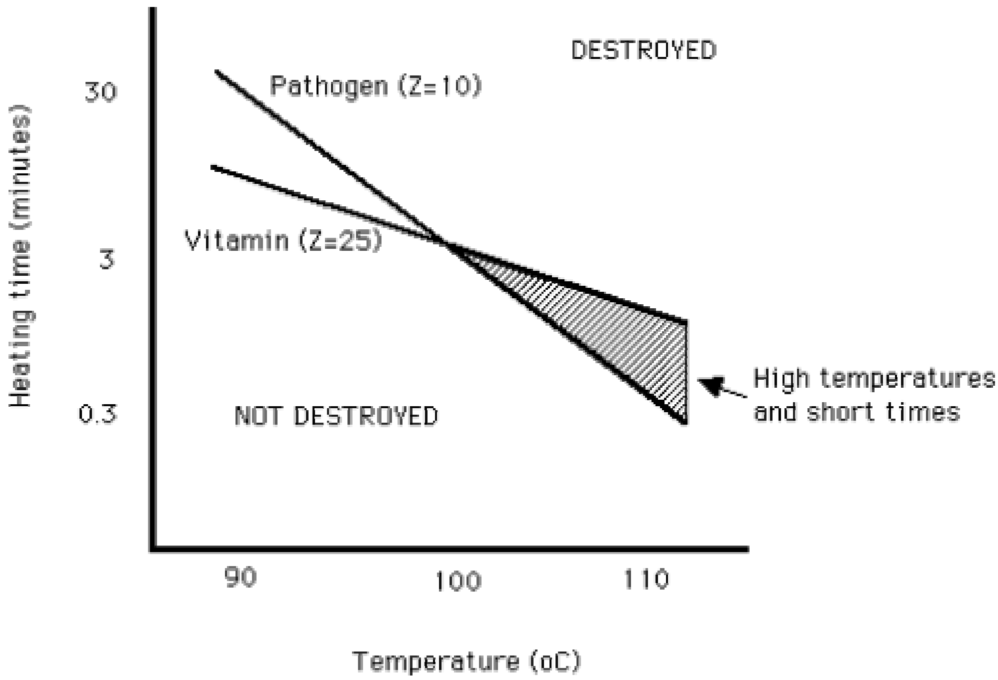

Figure 6.3: The relative changes in time temperature profile

Alkaline phosphatase is a naturally-occurring enzyme in raw milk which has a similar Z value to heat-resistant pathogens. Since the direct estimation of pathogen numbers by microbial methods is expensive and time consuming, a simple test for phosphatase activity is routinely used. If activity is found, it is assumed that either the heat treatment was inadequate or that unpasteurized milk has contaminated the pasteurized product.

6.5.4 12-D Concept

Canned foods are susceptible to the spores of the organism *Clostridium botulinum*. This is the organism that causes botulism. Their bacterial spores can survive many heat treatment processes. However, in modern food production, canned foods are subjected to a time/temperature process that will reduce the probability of the survival by the most heat-resistant *C. botulinum* spores by 12 logs or 12-D at 250F (the temperature used in the calculation of most commercial 12-D processes is 250F, and the D-value for this organism at 250F is 0.21 minutes). This process is based on the assumption of the number of surviving spores in one can. If it is assumed that a container had one million spores per can the heat treatment needed to reduce the number to one in one million i.e. from 10^6 to 10^{-12} involves a reduction of twelve decimal places i.e. from 1,000,000 to 0.0000001

6.5.5 F-Value

If we assume that there are 10 surviving spores in one can, then we can calculate the time for a 12-D process to occur by using the following formula:

- $F_0 = D_{250F}$ (log a – log b), where a = initial population and b = final population.
- So F_0 = (0.21min.) (log 10^1 – log 10^{-11}), we move down 12 log values (1 – (–11)) = 12.
- So, F_0 = (0.21min.) (1 – (–11)), or 0.21 × 12 = 2.52 minutes.

Simply put, (D-value at 250F) × (12) results in a 12-D process.

The killing effect of a time / temperature combination is referred to as the **F-value.**

F = 1 is heat killing effect equivalent to 1 min at 121°C.

The F-value required to achieve a 12D cook depends on the resistance of the particular type of bacteria. One of the most resistant species is *Bacillus stearothermophilus* which is 5 or 6 time more resistant than *C. botulinum.*

A 12-D cook for *Cl. botulinum* may require an F value of 2.52
A 12-D cook for *B. stearothermophilus* may require F = 18

From food safety angle, the microorganisms of greatest concern are *Salmonella* sp., *Clostridium perfringens*, *Staphylococcus aureus*, *Listeria monocytogenes*, *Campylobacter sp*., and *E. coli*, all of which have much lower z values and consequently should achieve a 12D process in a shorter time. *Bacillus* of the most heat resistant strains of bacteria known.

6.6 MICROBIOLOGY OF THERMALLY PROCESSED FOOD

As you can now very well understand the heat is an important way of preserving foods. Still some thermally processed foods undergo spoilage due to chemical or biological reasons. The most important chemical spoilage of canned foods is the hydrogen swell produced as a result of action of food acids with the metals. Biological spoilage of thermally processed foods by microorganisms may result either from the survival of organisms after the heat treatment or leakage of the container permitting entrance of the microorganisms. Surviving organisms may be vegetative cells or spore formers depending upon the heat treatment. Acid foods are processed at temperature around 100^{O}C which result in the killing of all vegetative cells of bacteria, yeasts and molds. Only bacterial spores may survive *stearothermophilus* is a non-pathogenic organism that has been shown to be one but these do not grow in acid foods. On the other hand, meat, vegetables and milk are processed at low temperatures. This may eliminate vegetative cells but not the spores, which germinate later and cause spoilage. Microorganisms that enter through leaks during cooling need not necessarily be heat resistant.

6.6.1 Spoilage by Thermophilic Bacteria

Under processing of low acid foods result in spoilage by thermophilic (microorganisms which require high temperature, more than 45°C for their growth) bacteria such as *Bacillus coagulance, Bacillus stereothermophilus*. These microbes produce heat resistant endospores than can survive 121°C for 4-5 minutes. These organisms produce acid without gas. This is known **as flat sour spoilage**. Some times In Low and medium acid foods the cans swell due to production of carbon dioxide and hydrogen by *Clostridium thermosaccharolyticum*. This is known as **thermophilic spoilage**. **Sulphide spoilage** is caused by *Clostridium nigrificans* in low acid foods. Spores of this bacterium are not very heat resistant and their presence is indicative of under processing. Spoilage is indicated by the the presence of H_2S and blackening of material. Sources of all these material are generally, the plant equipment, sugar, starch, soil etc.

6.6.2 Spoilage by Mesophilic Organisms

Mesophilic microorganisms are those microorganisms which grow best at temperature 25-45°C. Spoilage of canned foods by mesophilic organisms is indicative of under processing and is caused by species of Bacillus, Clostridium, Yeast and fungi. *Clostridium butyricum* and *C. pasteurianum* produce a butyric acid type of fermentation in acid or medium acid foods with swelling of the container by the production of CO_2 and H_2. Other species of *Clostridia* may produce H_2S causing can to swell. These putrefactive anaerobes (Micro organism that grow in the absence of oxygen) generally grow in low acid foods such as peas corn, meat, poultry etc. but some times may also spoil medium acid foods.

Some *Bacilli* such as *Bacillus subtilis* and *B. mesentroides* have been found to grow in poorly evacuated cans of sea foods, meat and milk. The gas forming Bacilli (B.polymyxa, B. macerans) are also reported to cause spoilage of canned peas, spinach, peaches and tomatoes.

The presence of non spore forming bacteria in canned food is an indicative of leak or under processing. *Streptococcus thermophilus*, *Pseudomonas*, *Micrococcus* and *proteus* have also been reported to cause spoilage of thermally processed products. Molds, yeast and their spores are destroyed at pasteurization temperature. Their presence is indicative of under processing or leakage. Spoilage of canned fruits and fruit products by yeasts may result in CO_2 production and spoilage of cans. Film yeast and fungi grow on the surface and cause degradation of the product.

6.7 LET US SUM UP

Thermally processed foods are those that have been i) heated in hermetically sealed container ii) have been filled hot into a container which is then closed and cooled. The purpose of these processes is to destroy pathogenic microorganisms and those that might grow and cause spoilage of the particular food. The food that are commercially sterile are those that will not support microbial growth when exposed to the usual temperatures during storage, transport and marketing. However, they may not be completely free of microorganisms. Pasteurization is heat treatment to inactivate some microorganisms. Thermally processed foods may get spoiled due to under processing or leakage.

6.8 KEY WORDS

Thermophilic : Microorganisms which grow at temperature above 45°C.

Mesophilic : Microorganisms which grow at temperature 25-45°C.

Under processing : Lower time or temperature treatment.

6.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check You Progress Exercise 1

1. Your answer should include the following points:

   - Microorganisms that spoil product are typically called **spoilage organisms**.
   - Microorganisms that can make people sick are **pathogens**.

2. Your answer should include the following points:

   - to keep the food in a stable condition over a period of time
   - to prevent it from spoilage or making people sick.

3. Your answer should include the following points:

   - chemical preservation
   - modified atmospheres
   - irradiation
   - low temperature preservation
   - preservation by drying
   - high temperature preservation.

4. Your answer should include the following points:

   - Time-temperature combination
   - heat penetration characteristics of particular food
   - the type of micro-organisms present in the food material
   - the thermal death time of different microorganisms
   - type of food
   - concentration of the microorganisms
   - state of the microorganism
   - effect of heat on the product
   - the degree of heat penetration
   - food acidity / pH value.

Check You Progress Exercise 2

1. Your answer should include the following points:

   - complete destruction of micro-organisms.

2. Your answer should include the following points:

   - the condition achieved by the application of heat sufficient to render the processed product free from viable microorganisms
   - capable of growing in the food under normal non-refrigerated temperatures at which the food is likely to be held during distribution and storage

- Unlike sterilization here the food is not completely free of microorganisms.

Check You Progress Exercise 3

1. Your answer should include the following points:

   - process created by Louis Pasteur
   - aimed to destroy bacteria, molds, spores etc.
   - discovery about the destruction of bacteria by exposing them to certain minimum temperature for certain minimum time
   - the higher the temperature the shorter the exposure time required.
   - process applied to milk.

2. Your answer should include the following points:

   - Public Health Aspect – to make milk and milk products safe for human consumption by destroying all bacteria that may be harmful to health (pathogens)
   - Keeping Quality Aspect – to improve the keeping quality of milk and milk products. Pasteurization can destroy some undesirable enzymes and many spoilage bacteria. Shelf life can be 7, 10, 14 or up to 16 days.

3. Your answer should include the following point:

   - extent of microbial inactivation depends on the combination of temperature and holding time.

4. Your answer should include the following points:

   - Through pasteurization all of the bacteria are not completely destroyed, it still exists in pasteurized products, but in very low concentrates.
   - Refrigeration keeps the bacteria from further growth, very low.

5. Your answer should include the following points:

   - thermal death time studies for the most heat resistant pathogens found in milk
   - *Coxiella burnetii* and *Mycobacterium tuberculosis* are the most heat resistant non spore forming pathogens.

6. Your answer should include the following points:

   - bacterial destruction is very nearly equivalent in LTLT and in HTST pasteurization processes but
   - HTST treatment give the best quality products in respect of flavour and vitamin retention.

Check You Progress Exercise 4

1. Your answer should include the following points:

   - moisture increases the rate of heat penetration.
   - Moist heat requires less heat (temperature or time) than dry heat
   - 121°C for 10 min of moist heat is equivalent to about 30 min at 200°C of dry heat.

2. Your answer should include the following points:

   - D-value is the amount of time that it takes at a certain temperature to kill 90% of the organisms being studied.
   - Z value is defined as the temperature change required to change the D-value by a factor of 10.
   - D-value gives us the time needed at a certain temperature to kill an organism
   - Z-value relates the resistance of an organism to differing temperatures.

3. Your answer should include the following points:

   - process based on the assumption of the number of surviving spores in one can.
   - canned foods subjected to a time/temperature process that will reduce the probability of the survival of the most heat-resistant *C. botulinum* spores by 12 logs i.e. from 1,000,000 to 0.0000001.

4. Your answer should include the following point:

   - killing effect of a time / temperature combination.

Check You Progress Exercise 5

1. Your answer should include the following point:

   - Under processing or leakage may be the cause of spoilage of thermally treated foods.

2. Your answer should include the following point:

   - *Bacillus coagulance* and *Bacillus stereothermophilus.*

3. Your answer should include the following point:

   - In Low and medium acid foods the cans swell due to production of carbon di oxide and Hydrogen by *Clostridium thermosaccharolyticum*.

4. Your answer should include the following points:

   - caused by *Clostridium nigrificans* in low acid foods.
   - Spores of *Clostridium nigrificans* are not very heat resistant and their presence is indicative of under processing.

- Spoilage is indicated by the the presence of H_2S and blackening of material.
- Sources of all these material are generally, the plant equipment, sugar, starch, soil etc.

5. Your answer should include the following points:

- *Clostridium nigrificans*
- *C. pasteurianum*
- *Bacillus subtilis*
- *B. mesentroides*
- *B.polymyxa*
- *B. macerans*
- *Streptococcus thermophilus*
- *Pseudomonas*
- *Micrococcus* and *Proteus.*

UNIT 7 DRYING – CONTROLING OF MICROORGANISMS

Structure

7.0 OBJECTIVES

After studying this unit, you should be able to:

- know the importance of dehydrated fruits and vegetables;
- have an idea about the drying/dehydration theories of fruits and vegetables;
- have the knowledge about the microorganisms evolved in dried products;
- know the different kinds of microorganism associated with dried foods; and
- know about the microbial spoilage of dried fruits and vegetable products.

7.1 INTRODUCTION

Drying or dehydration is accomplished by the removal of water from the fruits and vegetables below a certain level at which enzyme activity and growth of microorganisms is affected adversely. The dried fruits and vegetable are called as high sugar high acid foods or high value low volume foods. These dried or concentrated products save energy, money and space in shipping, packaging, storing and transportation. Dehydration or drying process usually involves heating, in which water is removed from solid or near solid substances. The term **drying** is generally used for drying of the produce under the influence of non-conventional energy sources like sun and wind. **Dehydration** on the other hand refers to the process of removal of moisture by the application of artificial heat under controlled conditions of temperature, relative humidity and air flow. The sun drying is a slow process and thus, not suitable for many high quality products. Generally, it lowers the moisture contents below about 15% which is too high for storage stability of numerous products.

7.2 PRINCIPLES

The basic principle in the process of drying or dehydration is the removal of sufficient moisture to protect the product from spoilage. The process reduces the amount of available moisture i.e. the water activity (a_w) and hence, product becomes shelf-stable and is preserved for quite a long period. Moisture-solid, relationship in fruits and vegetables are more complex than in inorganic materials as the matter in fruits and vegetables exhibits an energetic retention of moisture and the moisture is bound to the solid. The solid skeleton consists essentially of numerous cells joined together to provide a network of capillaries, some of them are very fine. First the moisture in the larger capillaries has to be evaporated then only the moisture in the finer capillaries can be removed. The cell walls act as semi-permeable membranes for the diffusion of moisture which is mainly held osmotic ally. Finally, there is a small amount of moisture adsorbed on the skeletal frame in multi molecular layers. In order to dehydrate any product specific requirements need to be fulfilled so that the product retains as much as possible, its original characteristics.

……………………………………………………………………………

7.3 MECHANISM OF DEHYDRATION

The changes during dehydration can be largely explained in terms of heat and mass transfer phenomena. A cue of food in the course of dehydration loses moisture from its surface and develops dried layer with remaining moisture confined to its centre. From the centre to the surface a moisture gradient will be stabilized. The outside dried layer acts as an insulation barrier against rapid heat transfer into the food pieces, this is further decreased by air voids formed by evaporating water. In addition to less driving force from decreased heat transfer, the centrally remaining water also now has further to travel to get out of the food piece than did surface moisture at the start of drying. In addition, as the food dries it approaches its normal equilibrium relative humidity, as it does; it begins to pick up molecules of water vapour from the drying atmosphere as fast as it loses them. When these rates are equal drying ceases.

7.4 THEORY OF DRYING

There are two steps involved in drying & dehydration.

7.4.1 Heat Transfer Theory

Transfer of heat consists of transferring of molecular or atomic motion from one region to another. There are three broad mechanisms by which such transfer can occur, conduction, convection, and radiation. In conduction, the energy is transmitted from particle to particle by a process of direct contact. Transfer of heat by convection involves bulk mixing of fluids of different temperatures. Radiation is the transfer of energy from a radiating source through space which may or may not be occupied by matter. It is by radiation that we receive all our energy from the sun.

7.4.2 Mass Transfer Theory

The removal of moisture from a food product involves simultaneous heat and mass transfer. Heat transfer occurs within the product structure and is related to the temperature gradient between the product surface and the water surface at some location within the product. As sufficient thermal energy is added to the water to cause evaporation, the vapours are transported from the water surface within the product to the product surface. The gradient causing moisture –vapour diffusion is vapour pressure at the liquid water surface, as compared with the vapour presser of air at the product surface. The heat and the mass transfer within the product structure occurs at the molecular level, with heat transfer being limited by thermal conductivity of the product structure, while mass transfer is proportional to the molecular diffusion of water vapour in air. The rate of moisture diffusion can be estimated by the expression for molecular diffusion. The mass flux for moisture movement is a function of the vapour pressure gradient as well as the mass diffusion for water vapour in air, the distance for water vapour movement within the product structure and temperature. The transport of vapour from the product surface to the air and the transfer of heat from the air to the product surface is a function of the existing vapour pressure and temperature gradients, respectively, and the magnitude of the convective coefficient at the product surface.

7.5 IMPORTANCE OF WATER ACTIVITY (a_w)

Water activity (a_w) is defined as the ratio of the vapour on the aqueous solution to that of pure water at the same temperature i.e.

a_w = Vapour pressure of solution at T°C

Vapour pressure of pure water at T°C.

Water activity is also equal to the equilibrium relative humidity (ERH);

$$a_w = \frac{\text{Equilibrium relative humidity}}{100}$$

The a_w has a major role to play in microbiological spoilage and chemical changes produced in the food. The principles of water and microorganisms relation includes:

1) Water activity, rather than water content, determines the lower limit of available water for microbial growth. Most bacteria do not grow below a_w 0.91 and most molds cease to grow at water activity of 0.80. Some xerophylic fungi have been reported to grow at water activities of 0.65, but the range of 0.70 – 0.75 is generally considered their lower limit.

2) Environmental factors affect the level of water activity required for microbial growth. The less favourable the other environmental factors (nutrients, pH, oxygen pressure, temperature) the higher becomes the minimum a_w at which microorganisms can grow.

3) Some adaptation to low water activities occurs, particularly when a_w is depressed by addition of water soluble substances (principle of IMF – Intermediate Moisture Food), rather than by water crystallization (frozen foods) or water removal (dehydrated foods).

4) When water activity is depressed by solutes. The solutes themselves may have effects which complicate the effect of a_w per se. For instance, at a given a_W microbial growth is less effectively depressed by glycerol than by sodium chloride. More recent (IMF – Intermediate Moisture Food) have resulted in the following additional findings.

   a) Water activity modifies sensitivity of microorganisms to heat, light and chemicals. In general organisms are most sensitive at high water activities (i.e. in dilute solution) and minimum sensitivity occur in an intermediate moisture. Minimum water activities for production of toxins are often higher than those for microbial growth. The phenomenon may represent an important safety factor in the distribution of dehydrated and intermediate moisture foods.

   b) The effect of water on chemical reactions in foods are more complicated than are its effect on microbial growth. It plays one or more of the following roles; a) as a solvent for reactant and for products, b) as a reactant (e.g. in hydrolysis reactions) c) as a product of reactions and d) as a modifier of the catalytic or inhibiting activities of other substances (e.g. water in activities some metallic catalysts of lipid per oxidation).

All microorganisms have an optimal and minimal water activity for growth. Adjusting the a_w of a product by addition of solutes or the removal of water, to a point below the minimal a_w of the normal spoilage flora results in a microbiological stable product. Many of the products contain viable microorganisms and spores, which are not able to germinate because of the restrictative a_w. In fabrication of a product with a reduced a_w other factors which would affect the growth of microorganisms present need to be considered, since the a_w on microorganisms is influenced by pH, oxygen level, temperature, nutrient content, and possibly food preservative, either natural or added.

Water activity (a_w) influences the physical, chemical and microbiological properties of many substances. The shelf life of foods, their colour, stability, taste, texture, vitamin content, aroma, mold formation and microbiological growth properties are influenced directly by the a_w value. a_w measurement is required to meet standards like FDA – Food Drug Act, USDA – United State Department of Agriculture, GMP – General Manufacturing Practices, HACCP – Hazard Analysis and Critical Control Points, and BIS 15000 – Bureau of Indian Standards: The foods types and range of a_w is discussed as given below.

A_w range	**Upper limit values for micro-organisms**	**Foods in this range**
1.00-0.95	*Pseudomonas, Escherichia, Proteus, Shigella, Clesiella, Bacillus, Clostridium, perfringens*, some yeast	Perishable (fresh) food and fruit in tins, Vegetables, meat, fish and milk, cooked sausage, backed bread, food with a content up to 40% weight sucrose or 7% common salt.
0.95-0.91	*Salmonella, Vibrio parahaemoliticus, C. botulinum*, Serratia, *Lactobacillus, Pediococcus*, some mold, yeast	Some cheese (cheddar, Swiss, Muenster, and Provolone) smoked meat (ham) some fruit juice concentrates, food with a 55% weight sucrose (saturated) or 12% common salt.
0.91-0.87	Many types of yeast *(Candida, Torulopsis, Hansenula), Micrococcus*	Matured sausages (salami), cake, dry chesses, margarine, and food with a 65% weight sucrose (saturated) or 15% common salt.
0.87-0.80	Most types of mold (mycotoxic *Penicillia*), *Staphylococcus aureus*, most *Saccharomyces* (bialii) spp. , *Deboryamyces*	Most fruit juice concentrates, sweetened milk, chocolate syrup, maple and fruit syrup, flour, rice, pulses with a water content 15-17%, fruit cakes traditional smoked hams.
0.80-0.75	Most types hallophilic bacteria, mycotoxic aspergilli	Marmalade, jam, fruit jelly, marzipan, glace fruit, some types of marshmallow.
0.75-0.65	Xerophylic mold *(Aspergillus chevalier, A. candid us, Wallemia semi), Saccharomyces bisporus*	Rolled oats with a 10% water content, naught, fondant, marshmallows, grouts, molasses, raw sugar, some dried fruit, and nuts.

0.65-0.60	Osmophyilc yeast *(Saccharomyces rouxi)*, some mould *(Aspergillums echinulatus, Monascus bisporus)*	Dried fruit with 15-20% water content, some types of toffee, caramel, honey
0.5		Noodles, Spaghetti, pasta. etc. with about 12% water content, spices with about 10% water content
		Egg powder with about 5% water content
0.4	No microbial growth	
0.3		Biscuits, crackers, bread crust, cookies, etc. with about 3-5% water content
0.2		Powder milk with about 2-3% water content, dried vegetables/ fruit with about 5% water content, cornflakes with about 5% water content fruit cake, rustic, crackers, biscuits

7.6 MICROORGANISMS ASSOCIATED WITH DRIED FRUITS AND VEGETABLES

Microorganisms are associated, in a variety of ways, with all of the food we eat. They may influence the quality, availability, and quantity of our food. Naturally occurring foods such as fruits and vegetables normally contain some microorganisms, and may be contaminated with additional organisms during handling. Food serves as a medium for the growth of microorganisms, and this growth may cause the food to undergo decomposition and spoilage. Food may also carry pathogenic microorganisms and as a result transmit diseases. Dried foods has been used for centuries and they are more common throughout the world than frozen foods. Growth of all microorganisms can be prevented by reducing the moisture content of their environment below a critical level. The critical level of moisture is determined by the characteristics of the particular organisms and the capacity of the food item to bind water so that it is not available as free moisture.

7.7 MICROBIOLOGY OF FRUITS AND VEGETABLE

7.7.1 Microbiology of Fresh Fruits and Vegetables

Fruits and vegetables are normally susceptible to infection by bacteria, fungi and viruses. Microbial invasion of plant tissue can occur during various stages of fruits and vegetables development and hence to the extent that the tissues are infected the likelihood of spoilage is increased. A second factor contributing to the microbial contamination of fruits and vegetables pertains to their post harvest handling. Mechanical handling is likely to produce breaks in the tissue which facilitates invasion by microorganisms. The pH of fruits is relatively acid ranging from 2-3 for lemons to 5.0 for bananas. This resists bacterial growth but does not retard fungal growth. The range for vegetables is slightly higher pH 5.0 to 7.0 and hence they are more susceptible than fruits to attack by bacteria.

7.7.2 Microbiology of Dried Fruits and Vegetables

The microorganisms on most of the dried fruits vary a few hundred per gram of fruits to thousands, and in whole fruits they are mostly on the outer surfaces. Spores of bacteria and molds are likely to be most numerous. When part of the fruit has supported growth and sporulation of mold before or after drying, mold spores may be present in large numbers. The number on the vegetable just before drying may be high because of contamination and growth after blanching and the percentage killed by the dehydrating process usually is less than with the more acid fruits. If drying trays are improperly loaded, souring of such vegetables as onions or potatoes by lactic acid bacteria with marked increase in number of bacteria which may take place during the drying process. The risk may be grater of the fruits and vegetables which are not blanched before drying like onion. Microbial counts on dried vegetables range from negligible to millions per gram. A number of genera of bacteria found on dried vegetables includes: *Escherichia, Enterobactor, Bacillus, Clostridium, Micrococcus, Pseudomonas, Streptococcus, Lactobacillus and Leuconostoc*. Of these, *Lactobacillus* and *Leuconostoc* species are predominant in many samples of dehydrated vegetables.

Dried fruits become musty of molds and dried vegetables soft or slimy if kept in a damp atmosphere in unsealed containers. Hence, proper sealing and storing of containers at ambient temperature and in a dry place is important. Dried fruits and vegetables should be packed in moisture proof containers. Higher density polythene (HDP) package of multiple aluminium foil are utilized for packing of dried vegetables.

The bacteria, such as *Bacillus* sp., *Clostridium* sp., *Micrococcus* sp, *Streptococcus* sp., and *Pseudomonas* sp. are common as soil and water born. Bacteria capable of causing food poisoning such as *Salmonella* sp. and *Clostridium botulinum*, are not found in dehydrated foods as in case of dehydrated onion where the microbial load is influenced by the following factors:

1. The load and types of microorganism present on the raw material.
2. Pre-treatment given to the material
3. Time lag between preparation and dehydration
4. Drying time and temperature
5. Moisture content of the finished product
6. In plant sanitation,
7. Packaging and storage conditions of the finished product.

One of the important types of microbiological spoilage in onion during dehydration is fermentation and souring, which are undesirable and make the product sub-standard. Sour onions have characteristics sour taste commonly associated with vegetable tissues undergoing lactic acid fermentation. Onion slices do not dry properly. Pink discolouration and off taste are indications of spoilage. Bacteria which predominate in fresh onions include representatives of the genera: *Lactobacillus*, and *Aerobactor*. Fresh onions juice sterilized by filtration suppressed the growth of *Bacillus* subtilis and *E. coli*. but did not prevent the growth of *Lactobacillus brevis* and *Aerobactor aerogens*. In good quality of dehydrated onion many aerobic bacilli and other soil and water born bacteria are not found which may be due to the toxicity of constituents present in fresh onions.

To check the souring and fermentation as well as to reduce the microbial load to the minimum the following points should be closely watched:

1. Onion bulbs selected for dehydration should be free from disease and blemish

2. Onions should be thoroughly washed after peeling in 3-5 ppm chlorine water.

3. The cut slices should be dried immediately under controlled conditions so that the finish product can be obtained in the minimum time having moisture at 6-7 percent.

4. Sanitary conditions and workers hygiene in the factory should be controlled and

5. Proper packing room facilities and nitrogen gas packaging are important for the storage of finished product

The number of microorganisms and their kinds vary at different stages of processing such as

7.7.3 Before Reception at the Processing Plant

The microbiology of foods before their reception at the processing plant is likely to be similar whether the foods are to be dried, chilled, frozen, canned or otherwise processed. Fruits and vegetables have soil and water organisms on them when harvested, plus their own natural surface flora and spoiled parts contain the microorganisms causing the spoilage. Growth of some of these organisms may take place before the foods reach the processing plant if environmental conditions permit. Thus piled vegetables may raise temperature and stimulate the growth of slime- forming, flavour harming, or even rot-producing organisms.

7.7.4 In the Plant before Drying

Growth of microorganisms that begun on foods before they have reached the drying unit may continue up to time of drying. Also equipment and workers may contaminate the food. Some of the pre-treatment reduce number of organisms while other may increase them, but the foods may be contaminated after these treatments. The grading, selection, and sorting of fruits and vegetables, influences kinds and number of microorganisms. The elimination of spoiled fruits and vegetables or of spoiled parts reduced number of organisms in the product to be dried.

Washing of fruits and vegetables removes soil and other adhering materials and serves to remove microorganisms. There also possibility of adding organisms if the water is of poor quality.

Peeling fruits or vegetables, especially with steam or lye, and slicing or cutting reduces the number of organisms if equipment is adequately cleaned and sterilized.

Dipping in dilute alkali as applied to certain fruits before sun drying may reduce the microbial population.

Blanching or scalding vegetables reduces the bacterial numbers greatly, as much as 99 percent in some instances. Sulphuring of fruits and vegetables also causes a great reduction in number of microorganisms and serves to inhibit growth in the dried product.

7.7.5 During the Drying Process

Heat applied during a drying process causes a reduction in total number of microorganisms, but the effectiveness varies with the kinds and numbers of organisms originally present and the drying process employed. Usually all yeasts and most bacteria are destroyed, but spors of bacteria and molds commonly survives, as do vegetative cells of a few species of heat resistant bacteria, improper conditions during drying may even permit the growth of microorganisms. More microorganisms are killed by freezing than by dehydration during the freezing- drying process.

7.7.6 After Drying

If the drying process and storage conditions are adequate there will be no growth of microorganisms in the dried foods. During storage there is a slow decrease in number of organisms, the microorganisms that are resistant to drying will survive best: therefore the percentages of such organisms will increase. Especially resistant to storage under dry conditions are the spores of bacteria and molds, some of the micrococci, and micro bacteria. There may be some opportunity for contamination of the dried food during packaging and other handling subsequent to drying.

Special treatment given to some dry foods will influence microbial numbers e.g. sweating of dry fruits to equalize moisture may permit some microbial growth. Pasteurization of dry fruits will reduce number of microorganisms. Some products are re-packaged for retail sale, e.g. figs in the near east, are subjected to contamination. The microbial content and the temperature of water used to rehydrate for dried foods also affect the number of microorganisms if rehydration done in water at 50°C the number of microorganisms will be more and number of microorganisms is almost eliminated when the product is rehydrated at 85 to 100°C.

7.8 SURVIVAL OF MICROORGANISMS IN DRIED FOODS

The survival of microorganisms in dried foods can be markedly affected by a_w level. There are important interaction between a_w and such factors as pH, oxygen and food composition. For many foods, deterioration during storage in the dry state is least at the relatively low a_w levels. Survival of pure cultures of vegetative bacteria equilibrated to a range of a_w levels after freeze drying have shown clearly the increase in survival that accompanies reduction in a_w level to 0.1 -0.2. Survival of *Salmonella newport* at 0.0 a_w, after freeze –drying in papain digest, was nearly maximum in vacuum, but was very poor when stored in air. Although *Pseudomonas fluorescense* proved more susceptible to death on storage, the qualitative response to a_w was similar. Death of bacteria during storage at reduced a_w levels is greatly influenced by the nature of solution from which they had been dried.

7.8.1 Survival at Freezing Temperatures

Freezing and frozen storage may reduce greatly the viability of populations of sensitive microorganisms. The latter include the vegetative cells of yeasts and molds and most gram negative bacteria. Gram positive bacteria, especially cocci, are more resistant, and for these reasons enterococci are frequently claimed to be more suitable than *Escherichia coli* as indicators of fecal contamination in frozen foods. Many fungal spores also show this level of resistance, however bacterial spores are least affected by freezing.

The rate of freezing influences the survival, because of it influence the size of ice crystals and hence the degree of mechanical damage caused to cellular structures. Rapid freezing is less damaging than slow freezing. It is the range of temperature between freezing point of a food and its eutectic, influences the a_w of food, but not its overall solute concentration. The eutectic means that the solute remain in equilibrium in frozen food. A frozen food held at -20^{o}C has an a_w of 0.823, irrespective of its composition. Although composition of food does not control a_w, it can have a marked influence on survival of microorganisms frozen in food. Sugars, sugar alcohol, glycols, and proteins, may have protective effect. The added sucrose have effect on the survival of *Torula* sp. in frozen orange juice.

7.8.2 Survival at Moderate Temperatures

Many sterile foods are microbiologically stable in the moderate or room temperature range. The majority of dried or concentrated foods, owe their stability to reduced level of a_w. However, if rehydrated before consumption, regain the ability to support microbial growth, so that the capacity of contaminating organisms to survive the period of low a_w storage is of obvious relevance. Studies on survival of pure cultures of vegetative bacteria equilibrated to range of a_w levels after freeze drying have shown clearly the increase in survival that accompanies reduction in a_w level to 0.1-0.2. In dried foods the bacteria during storage at reduced a_w levels is greatly influenced by the nature of solution from which they had been dried. While non-reducing sugars are protective, and reducing sugars accelerate bacterial inactivation.

7.8.3 Survival at Elevated Temperatures

Microorganisms vary in heat resistance, the more resistant bacteria (e.g. *Bacillus stearothermophillus*) producing spores with decimal reduction times in neutral foods as long as 4 minutes at 121°C. or 40 minutes at 110°C. Yeast ascospores are only slightly more heat resistant than vegetative yeast cells. The qualitative effect of moisture upon microbial heat resistant is well known-moist heat is a much more effective sterilizing agent than dry heat and, wherever, practicable, steam sterilization is preferred as being much more rapid than hot air (dry) sterilizing. Water activity is also likely to be significance in the heat treatment of foods in the intermediate moisture range, Pasteurization temperature for salmonellae, staphylococci, and yeast (50-60°C) death rates are lowest in the a_w range 0.75- 0.85 in glycerol adjusted solutions. Osmophilic yeasts respond similarly to salmonellae when heated in sucrose solution with decimal reduction times increasing as a_w decreases from 0.995 to 0.85. These organisms are more heat sensitive than salmonellae.

7.9 MICROBIAL SPOILAGE OF DRIED FOODS

Spoilage of dried fruits and vegetables by insects

The presence of water in fruits and vegetables is mandatory to undergo microbial spoilage. All organisms require water for carrying on their life processes. If the microorganisms cannot acquire the water it either dies or its further growth is arrested. Potential spoilage of a dried fruit, then depends upon how available water is to the spoilage microorganisms, It is therefore the thin demarcation line of water activity which establishes dehydration as a good preservative techniques. The degree to which water is available to the microorganisms is expressed by the term water activity, (a_w,) that is the vapour pressure of the solution divided by the vapour of the solvent.

Removing the water from the fruit and vegetables is to reduce its availability to the microorganisms. In a moist solid substance , the water vapour pressure is lower than the vapour pressure of free water at the same temperature because, in a solid substance, water reacts with polar group such as –CO -, -NH, -OH. Still further vapour pressure inside of capillaries (between plant cells) is lower than the vapour pressure of a plane surface of water. As the solutes present in the fruit are dissolved in water the vapour pressure is depressed. Certain osmophilic yeasts and certain xerophilic molds and fungi are able to live and proliferate at water activities of low values. These are the microorganisms responsible for the spoilage of dried fruit and vegetables. Bacterial growth of generally impossible when a_w is reduced below 0.90. The growth of normal yeast is generally impossible when the a_w is reduced below 0.88. The growth of normal molds is generally impossible below 0.80. Each organism has its own characteristics optimum a_w at which growth will occur. Molds are the most troublesome group of microorganisms will grow at a_w values below 0.70.

Dried fruits and vegetables are also subjected to insect attack when not dried and stored properly. Insect not only consume food stuffs but also leave much debris which spoils the appearance of the product. These insect can be killed either by heating or by fumigation. In heat treatment, dried fruits are dipped in boiling water or in dilute solution of salt (NaCl) –$NaHCO_3$) and then, redried at 54-65°C. Dried vegetables may be heated directly without preliminary dipping. Fumigation with ethylene oxide inside the storage chamber also reduces attack by insects.

Dried fruits become musty or moldy and dried vegetables soft or slimy if kept in a damp atmosphere in unsealed containers. Hence, proper sealing and storing of containers at ambient temperature and in a dry place is important.

Dehydrated fruits and vegetable potential defects and means to prevent them are given below:

Defects	**Causes**	**Prevention**
Molding	High product moisture, above equilibrium relative humidity corresponding to water activity a_{w} = 0.70.	Reduce water content down to optimum values, pack in hermitic air tight package.
Infestation	Presence in dried products of larva or insects.	Storage room disinfection with toxic gases. Fumigation of packed products and of packages. Disinfection

		by heat (60-65°C) of products before packing.

Considering the variety of natural food substances and the methods by which each is handled during processing , it is apparent that practically all kinds of microorganisms are potential contaminants. The type of food substance and the method by which it processed and preserved may favour contamination by certain groups of microorganisms. Most foodstuffs serve as good media for the growth of many different microorganisms, and microorganisms' changes in appearance, flavour odor, and other qualities of foods. These degradation processes may be descrived as follow;

Putrefaction

Protein foods + proteolytic microorganisms → amino acids + amines = ammonia + hydrogen sulphide.

Fermentation

Carbohydrate foods + carbohydrate-fermenting microorganisms → acids = alcohol = gases.

Rancidity

Fatty foods + lipolytic microorganisms→ fatty acids = glycerol.

Some microorganisms discolour foods as a result of pigment production. Slimes may be developed in or on foods by microorganisms capable of synthesizing certain polysaccharides.

7.10 LET US SUM UP

The reduction in weight and bulk by drying and dehydration of the commodity can result in economies in cost of containers, shipping and distribution of dehydrated products. The dehydration also result in the production of convenience products e.g. instant coffee instant milk and instant mashed potatoes. The production of dried fruits and vegetable products are less costly as there is a minimum of labour and processing equipment required. These products also require less space for storage then fresh canned or frozen fruits and vegetables.

Microorganisms are associated, in a variety of ways, with all of the food we eat. They may influence the quality, and availability of our food. Naturally occurring foods such as fruits and vegetables normally contain some microorganisms, and may be contaminated with additional organisms during handling. Food can serve as a medium for the growth of microorganisms, and this growth may cause the food to undergo decomposition and spoilage. The microorganisms on most of the dried fruits vary a few hundred per gram of fruits to thousands, and in whole fruits they are mostly on the outer surfaces. Spores of bacteria and molds are likely to be most numerous. When part of the fruit has supported growth and speculation of mold before or after drying, mold spores may be present in large numbers. Microbial counts on dried vegetables range from negligible to millions per gram. A number of genera of bacteria found on dried vegetables includes: *Escherichia, Enterobactor, bacillus, Clostridium, Micrococcus, Pseudomonas, Streptococcus, Lactobacillus* and *Leuconostoc*. Of these, *Lactobacillus* and *Leuconostoc* species are predominant in many samples of dehydrated vegetables.

Water activity (a_w) influences the physical, chemical and microbiological properties of many substances. The shelf life of foods, their colour, stability, taste, texture, vitamin content, aroma, mold formation and microbiological growth properties are influenced directly by the a_w value. The survival of microorganisms in dried foods can be markedly affected by a_w level, there are important interaction between a_w and such factors as pH, oxygen and food composition. Certain osmophilic yeasts and certain xerophilic molds and fungi are able to live and proliferate at water activities of low values. These microorganisms are responsible when water activity (a_w) is reduced below 0.88, and the growth of normal yeast is generally impossible below the water activity (a_w) of 0.88.

7.11 KEY WORDS

Water activity : Water activity (a_w) is the ratio of vapour pressure of food (P) and pure water (p_o) and expressed by aw = p/p_o.

Dehydration : Removal of moisture under controlled conditions of temperature, air flow and humidity.

Drying : Drying of the product under the source of non-conventional energy sources like sun and wind.

Blanching : Partial pre-treatment in which vegetables are heated in water or in steam to inactivate enzyme before processing.

Sulphuring : Exposing the fruits to the fumes of burning sulphure inside of closed chamber.

In-package desiccant	:	Packaging of the dried products with a material like calcium oxide or silica gel.
Sorption isotherms	:	Water sorption isotherms is a graphical presentation of data which shows the water relationship of food.
Preservation	:	Methods to hold food for a longer period than generally kept at ambient conditions. Food is safe, nutritive and free from and microbial infection.
ERH	:	Equilibrium Relative Humidity.
Osmotic dehydration	:	Removal of water through a membrane from higher concentration to lower concentration.
Sweating	:	Process for holding the dried fruits and vegetables in to bins or package for equalization of moisture
Pasteurization	:	Pasteurization of fruits and vegetable products by heat process below 100°C.
Rancidity	:	Discolouration of food products.
Processing	:	The application of heat to the fruit and vegetables after hermetic (air tight) sealing in containers is called the processing.
Spoilage	:	The food which has been damaged or injured which make the food undesirable for human use.
Rehydration ratio	:	Reconstitution ratio is the quantity of water replaced by dehydrated foods.
Reverse osmosis	:	Reverse osmosis means movement of water through the membrane by applying pressure on the solute side of the membrane in excesses of the osmotic pressure.

7.12 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - Drying of commodity in the sun with non conventional sources of energy like sun and wind is called drying.
   - Drying the commodity under controlled conditions like temperature, relative humidity and air flow is called dehydration.

2. Your answer should include the following points:

   - To reduce the weight and bulk.
   - To reduce the water activity.

3. Your answer should include the following points:

   - To convey the heat to the product.
   - To let out the moisture from the product.

4. Your answer should include the following points:

   - They exhibits an energetic retention of moisture.
   - They bound the moisture to the solid content.

Check Your Progress Exercise 2

1. Your answer should include the following points:

   - Due to heat transfer to the product.
   - Due to mass transfer out the product.

2. Your answer should include the following points:

   - Heat transfer through conduction.
   - Heat transfer through convection.
   - Heat transfer through radiation.

3. Your answer should include the following points:

   - By addition of thermal energy to the product.
   - By transfer the heat to the product and water surface.

4. Your answer should include the following points:

   - Transfer of vapour from product surface to the air.
   - Transfer of heat from the air to the product.

Check Your Progress Exercise 3

1. Your answer should include the following points:

   - Dried fruits
   - Some types of toffee
   - Honey

2. Your answer should include the following points:

   - Osmophyile yeast
   - *Aspergillus echinulatus*
   - *Monascus bisporus*

Check Your Progress Exercise 4

1. Your answer should include the following points:

   - In the form of quality
   - In the form of availability
   - In the form of quantity

2. Your answer should include the following points:

   - By reduce the moisture content of the product.
   - By reduce the moisture content of their environment below critical level.

Check Your Progress Exercise 5

1. Your answer should include the following points:

   - Some of bacteria
   - Some of fungi
   - Some of viruses

2. Your answer should include the following points:

   - Load and types of microorganisms in raw material.
   - Time leg between preparation and drying.
   - Moisture content in the finished product.

3. Your answer should include the following points:

   - Bulbs should be free from diseases and blemish
   - Dried the cut slices immediately under control condition
   - Pack and stored under proper conditions

4. Your answer should include the following points:

   - Grading
   - Selection
   - Sorting

5. Your answer should include the following points:

   - Sweating
   - Pasteurization

Check Your Progress Exercise 6

1. Your answer should include the following points:

   - By arrest the growth of the microorganisms.
   - By destroys the microorganisms.

2 Your answer should include the following points:

   - Osmophilic yeast
   - Xerophilic molds
   - Fungi

3. Your answer should include the following points:

   - For bacterial growth a_w below, 0.90

- For yeast the a_w below , 0.88
- For mold growth the a_w below, 0.80

4. Your answer should include the following points:

   - Changes in appearance
   - Changes in flavour
   - Changes in odor
   - Changes in quality

UNIT 8 CHEMICALS FOR CONTROLING MICROORGANISMS

Structure

8.0 OBJECTIVES

This unit introduces you to the concept of preservation of food with chemicals. After going through this unit you will be able to know how chemical reactions causing spoilage are prevented or delayed by use a wide range of chemical additives.

After studying this unit, you should be able to:

- know the various classes of chemical additives used in the food industry;
- explain how these chemicals help to prevent the spoilage of food;
- know the permitted and non permitted chemical additives;
- discuss the general considerations required in the selection of food preservatives; and
- that apart from certain added preservatives there are some naturally occurring preservative factors in food.

8.1 INTRODUCTION

In Unit 1, you read about the various types of microorganisms that are important in the food industry. In this unit, we shall tell you how the spoilage of food can be prevented or delayed which are caused due to these microorganisms or some other chemical reactions. This unit highlights the various classes of chemical preservatives that have been approved for the use in food and their use. The various aspects to be considered for the selection of chemical additives (food additives), their mode of action and the adverse reactions resulting due to the consumption of the additives is also elaborated in this unit. The unit also deals with the developed additives, namely acids, alcohol and bacteriocins.

8.2 USES OF VARIOUS FOOD ADDITIVES AND CHEMICAL PRESERVATIVES

For centuries, man has recognized the effects of food additives and has used whatever was available-marigold for colour, wood ashes for leavening, the lining of calf stomachs for cheese making etc. today, thousands of compounds are used as food additives, whose chemical identity and structure are known. The use of food additives is imperative in the complex and integrated society in which we live. Additives have provided protection against food spoilage during storage, transportation, distribution or processing. Also, with the present degree of urbanization, it would be impossible to maintain food distribution without the processing and packing and packing with which many additives are involved.

Additives permit the variety of foods that we deem desirable and which certainly are objectively important in maintaining important nutrition. Vitamins and minerals are important in maintaining good nutrition. Many of these chemical additives can be manufactured so that foods can be “fortified” or “enriched”.

There is then the need for the use of food additives to maintain the nutritional quality of food, to enhance the stability with resulting reduction in waste, to make food more attractive and to provide efficient aids in processing, packing and transport. The amount of food additives used should be kept to a minimum and it should conform to a standard of purity and be safe. Over 3000 different chemical compounds are used as food additives. They are categorized into different groups which will be discussed below.

According to WHO a food additive is defined as a substance or mixture of substances other than the basic foodstuff, which is present in food as a result of any aspect of production, processing, storage and packaging. The term does not include chance contaminants- thus the former refers to intentional food additive while latter is incidental un-intentional food additive.

Intentional food additives could be nutritive, freshness maintenance, sensory and processing aids; preservatives, antioxidants, emulsifiers, stabilizers, maturing agents, colours, special sweeteners, nutrient supplements, flavouring compounds and natural flavouring materials.

8.2.1 Types of Additives

- ***Acidity regulators***, used to alter and control the acidity or alkalinity levels for different desired effects, which can include preservation, added/altered tartness, colour retention and to assist raising agents.

- ***Acids***, used to control to what degree other substances function and/or to impart a sharp taste. Assists in the release of carbon dioxide in raising agents and can have a preservative effect.

- ***Anti-caking agents***, used to ensure the free flow in products such as dried milks, icing sugar and table salt.
- ***Anti-foaming agents***, used to reduce or prevent foaming (frothing) on boiling and to reduce scum forming.
- ***Antioxidants***, used to protect food against deterioration caused by exposure to air (oxidation), such as fat rancidity, flavour deterioration or colour changes.
- ***Bleaching agents***, used to artificially whiten flour.
- ***Buffers***, see acidity regulators.
- ***Bulking agents***, used to increase volume without significantly adding to the energy levels of the food. Normally used in diet foods but can also be used to pad out expensive ingredients. Not usually digested and acts as a source of dietary fibre (roughage).
- ***Carriers and carrier solvents***, used to modify a food additive (by dissolving, diluting or dispersing etc.), without changing its function, to enable easier use or handling.
- ***Emulsifiers***, used to aid in the formation and maintenance of the dispersion of two or more substances which would normally separate and not normally mix, such as oil and water. Milk, mayonnaise and salad dressings are typical oil in water emulsions, butter and margarine water in oil emulsions.
- *E*mulsifying salts, used to disperse protein so reducing the stringiness in cooked cheese.
- ***Firming agents***, used to make or retain firmness or crispness in fruit and vegetables and to strengthen gels.
- ***Flour improvers***, used to enhance the elastic properties and aid the development of dough. Also accelerates the effect of bleaching agents.
- ***Foaming agents***, used to provide a uniform dispersion of gas in a food.
- ***Gelling agents***, used to form a jelly so providing texture to a product.
- ***Glazing agents***, used to produce a protective coating or to impart a polish/sheen on the surface of a food such as confectionery or citrus fruit.
- ***Humectants***, used to retain moisture in foods by absorbing water from the air to prevent drying out.
- ***Modified starch***, used for various functions including adding texture, adding bulk, stabilizing and as a thickener.
- ***Packaging gases***, used to replace air in the packaging of foodstuffs susceptible to oxidation but not necessarily shown on food labels.

- ***Preservatives***, used to extend the shelf-life of products by preventing the growth of microorganisms which could otherwise cause food decay and, in some cases, food poisoning.

- ***Propellants***, a gas or volatile liquid used to expel foodstuffs from aerosols.

- ***Raising agents***, used to increase the volume of doughs and batters by promoting gas release (aeration).

- ***Releasing agents***, used to prevent foodstuffs sticking to machinery, molds, packaging etc. but not necessarily shown on food labels even though some may remain in the food.

- ***Sequestrants***, used to combine with trace metals in the environment to render them inactive.

- ***Stabilizers***, used to maintain the physical state of a food and to stabilize, retain or intensify the existing colour of a food, particularly emulsions, and therefore often used with emulsifiers.

- ***Sweeteners***, there are two different types of sweeteners:

  1. **Intense sweeteners** – these have a sweetness many times that of sugar and are therefore used at very low levels. They are used in products such as diet foods, soft drinks and table top sweeteners;

  2. **Bulk sweeteners** – these have a similar sweetness to sugar and are used at comparable levels. Unlike intense sweeteners they also provide bulk (although their main function is to provide sweetness). They are used in products such as sugar-free confectionery and foods for diabetics.

- ***Thickeners***, used to increase viscosity, modify texture and impart stability.

8.2.2 Role of Food Additives

Food additives help to enhance the consumer acceptability, help in maintaining or improving the nutritional quality, enhance stability or keeping quality by acting as antimicrobial agents with the resulting reduction in waste and prevention of chemical and biological deterioration, make food more attractive and provide sufficient aids in the food products for improving texture, colour and flavour, check spoilage by inactivating microorganisms and maintain safety of foods, facilitate preparation and help to improve palatability of the product.

It helps to enhance the shelf life of food or food products. It has been estimated that we consume about 5 kilograms of food additives as preservatives, colours, bleaches, flavours, emulsifiers and stabilizers every year in the food we eat. This not only results in extra work for our body to remove them, but frequently trigger asthma attacks; rashes; respiratory disturbances; hyperactivity in children, and in some people, an abnormal sensitivity to prescribed medications, particularly aspirin. Below are some common additives found in refined foods, and well-worth avoiding by those susceptible to their effects.

Acceptable daily intake (ADI) for various preservatives

Preservative	ADI (mg/kg body wt/day)
Acetic acid including its Na/K salts	No limit
Sodium diacetate	0-15
Benzoic acid including its Na/K salts	0-5
Formic acid	0-3
Hexamethylene tetramine	0-0.15
Para hydroxy benzoic acid esters	0-10
Lactic acid and its salts	No limit
Propionic acid and its salts	No limit
Natamycin/pimaricin	0-0.3
Na NO_3 and KNO_3	0-5
$NaNO_2$ and KNO_2	0-0.2
Sorbic acid including its Na/K/Ca salts	0-2.5
SO_2, Na_2 SO_3, $NaHSO_3$, Na/K metabisulphite	0-0.7

8.2.3 Preservatives

Preservatives are substances which are capable of inhibiting, retarding or arresting the process of fermentation, acidification or other decomposition of food or of masking any of the evidence of putrefaction but it does not include salt, sugar, vinegar, glycerol, alcohol, spices, essential oils etc. Sulphur dioxide (including sulphites) and benzoic acid (including benzoates) are among the principle preservatives used in the food processing industry. The permitted quanitity of sulphur dioxide and benzoic acid is given in the following tables.

Food additives and their usage concentrations

Food additives	Concentration (%)	Foods
Antioxidant : Butylated Hydroxy Anisole (BHA)	Not exceeding 0.02% of the total fat content and 0.01% of the finished product 0.02	*Rasogolla* and *Vadas* Whole and partially skimmed milk powder Margarine
Colours	0.02	Most foods
Flavour : Monosodium glutamate	0.05	Meat product, soup powder
Anticaking agent: Aluminum silicate	2	Table salt, onion powder, garlic powder, soup powder
Sweetening agent : Saccharin	100 ppm	Carbonated non-alcoholic drinks
Sequestrant : Ethylene Diethyle Tetra Amino Acetic Acid (EDTA)	33-800 ppm	Canned carbonated beverages, salad dressings and margarine

Classes of preservatives

CLASS I:

Common salt, sugar, dextrose, spices, vinegar or acetic acid, honey

CLASS II:

Benzoic acid and its salts, sulphur dioxide and the salts of sulphurous acid, nitrites and nitrates, sorbic acid and its salts, propionic acid and its salts, lactic acid and its salts.

Sulphur dioxide

Sulphur dioxide and its derivatives have been extensively used in foods as a food preservative. It acts both as an antioxidant and reducing agent and prevents enzymatic and non-enzymatic reactions, leading to microbial stability. The common used forms are sulphur dioxide gas and sodium, potassium and calcium salts of sulphite, bisulphite or metabisulphite. It is like a biocidal and biostatic agent and is more active against bacteria than molds and yeasts.

Sulphite or metabisulphite sprays or dip with or without added citric acid provides effective control of enzymic browning in pre-peeled and pre-sliced potatoes, carrots, mushroom and apples.

Sodium benzoate

It was the first chemical preservative permitted in foods by the FDA, and it continues in wide use today in a large number of foods. Benzoates have greatest activity at low pH. As used in acidic foods, benzoates act essentially as a mold and yeast inhibitor.

In foods such as fruit juices, benzoates may impart disagreeable tastes at the maximum level of 0.1 per cent. The taste has been described as being 'peppery 'or burning.

Permitted quantity of benzoic acid in food

Processed food	Permitted quantity of Benzoic Acid (ppm)
Non-alcoholic wines, squashes, crushes, fruit syrups, cordials, fruit juices and barley water (to be used after dilution)	600
Jams, marmalades, preserves, canned cherry, fruit jelly	200
Sweetened mineral water and sweetened ready to serve beverages	120
Brewed ginger beer	120
Pickles and chutneys	250
Tomato and other sauces	750
Danish tinned caviar	50
Tomato puree and paste	750
Syrups and sherbets	600
Fat spread	1000

Quantity of sulphur dioxide permitted in food

Processed food	Permitted quantity of SO_2 (ppm)
Sausages and sausage meat containing raw meat, cereals and condiments	450
Fruit, fruit pulp or juice (not dried) for conversion into jams or crystallized glace or cured fruit or other products	
a) cherries	2000
b) straw berries and raspberries	2000
c) other fruits	1000
Fruit juice concentrate	1000
Dried fruits	
Apricots, peaches, apples, pears and other fruit	2000
Raisins and sultanas	750
Other non-alcoholic wines. squashes, crushes, fruit syrups, cordials, fruit juices and barley water (to be used after dilution)	350
Jams, marmalade, preserves, canned cherry and fruit jelly	40
Crystallized glaced or cured fruit (including candied peel)	150
Fruit and fruit pulp not otherwise specified in the schedule	350
Plantation white sugar, cube sugar, dextrose, *gur*, jaggery or *misri*	70
Khandsari(s) and *Bura*	150
Refined sugar	40
Corn flour and similar starches	100
Corn syrup	450
Canned *rossogullas*	100
Gelatin	1000
Beer	70
Cider	200
Alcoholic wines	450
Sweetened mineral water/ready to serve beverages	70
Pickles and chutneys made from fruits or vegetables	100
Dehydrated vegetables	2000
Syrups and sherbets	350
Dried ginger	2000
Hard boiled sugar confectionery	350
Dry mixes of *rossogullas*	100

8.2.4 Acidulants

Sour or acidic taste of a food is attributed to the acidic components present in the food. Many processed foods and beverages, however, need the addition of acids to impart characteristic taste and flavour to the final food product. The intensity of sourness and ability to reduce pH vary among the organic group of acidulants in the decreasing order as follows:

Fumaric > tartaric > malic > acetic > citric > lactic > gluconic acid

Commonly used acidulants include acetic, adipic, citric, fumaric, lactic, malic, phosphoric and tartaric acids. Citric acid is the most versatile and widely used food acidulant.

Main foods in which acidulants occur or added to food

Acid	Main food
Acetic acid	Pickles, sauces, relishes, fermented vegetables and fruits, vinegar, wheat bread, cheeses and creams, apple juice, grapefruit juice.
Adipic acid	Beet juice, guava, papaya, raspberry, pork fat, dairy foods, gelatin and desserts, puddings, beverages, jams and jellies, snack foods, condiments
Citric acid	Oranges, lemons, grapefruit, black currants, gooseberries, pineapple, raspberries, strawberries
Fumaric acid	Confectionery, powdered gelatins, desserts, cheese cake, jams, and jellies
Glucono-delta-lactone	Cured meats, frankfurters, salami, sausages, dessert mixes, bakery mixes, processed cheese, fish products, spice preparation
Lactic acid	Fresh meat, yogurt, cheese, bread, pickles, sauces, relishes, fermented foods, buttermilk, wines, beer
Malic acid	Watermelon, plum, apple, cherry, peach, pear, grape, gooseberry, pineapple
Phosphoric acid	Cola beverages, jams and jellies, bread dough, cake, flour
Tartaric acid	Grapes, tamarind, pineapple, mulberries, gherkins, wines

8.2.5 Control of Psychotropic Contamination in Food

Increasingly all types of consumers are demanding minimally processed foods that are high in quality, nutritionally superior and easy to prepare. Food processors have met this demand by developing refrigerated foods with extended shelf life. The most important bacteriological problem in processed food products today is deterioration due to contamination by psychotropic microbes, as storage at low temperature is favourable for the growth of high levels of psychrotrophic microorganisms. Psychotrophs are bacteria, yeasts and molds that grow although slowly, at refrigeration temperature (below 7°C) but grows optimally at temperatures above refrigeration, e.g. 25-30°C. Their maximum growth temperature is 30-35^{o}C. Several pathogens such as Aeromonas hydrophila, Clostridium botulinum, Listeria spp., Yersinia enterocolitica, some strains of Bacillus cereus, enteropathogenic Escherichia coli and Vibrio parahaemolyticus can grow at refrigeration temperature. These bacteria may enrich in food during cold if storage times are long enough. Some of these pathogens can cause illness when even few cells are ingested.

The control of psychrotrophs in food products should start from the very beginning of raw material procurement up to processing and storage of the finished product. The following steps are of considerable importance. Processors need to select high-quality raw materials with low levels of microorganisms, especially psychrotrophs. Fabrication of raw materials by using clean and sanitized machinery and equipments into finished products under hygienic conditions is also important. Apart from this regular check on quality of water supply and proper chlorination of water used in the food industry should be done. Appropriate use of salt and other ingredients which reduces the a_w to 0.98 or below will lengthen the lag phase of most bacteria and will further reduce the rate of any subsequent growth. Most recent studies have shifted to the use of lactic acid bacteria that produces bactericidal chemicals called bacteriocins to slow or inhibit the growth of psychrotrophic organisms. By lactic acid bacteria a wide variety of food borne pathogens are either inhibited or killed, and many spoilage organisms are affected in similar ways, especially Gram-negative psychrotophs.

Thus the effective control of microbial contaminants must begin on the farm and be followed through to the retail store. Clean equipment and packages, use of approved food additives and chemical preservatives of Generally Recognized As Safe (GRAS) status in proper concentration, limited time of storage, low holding temperatures for raw materials and the finished product, effective laboratory control and attention to good manufacturing practices which will slow the outgrow of psychrotrophs will help the food plant to produce with good yield, good flavour, long shelf –life and high sales appeal.

8.3 GENERAL CONSIDERATIONS IN THE SELECTION OF CHEMICAL FOOD PRESERVATIVES

Antimicrobial preservatives added to foods can be grouped as follows:

1. *Those added preservatives not defined as such by law:* natural organic acids (lactic, malic, citric etc.) and their salts, vinegar, sodium chloride, sugars, spices and their oils, woodsmoke, carbon dioxide and nitrogen
2. *Substances generally recognized as safe (GRAS) for addition to foods:* propionic acid and sodium and calcium propionate, caprylic acid, sorbic acid and its salts, sulphur dioxide, sodium nitrite
3. *Chemicals considered to be food additives*, which would include all that are not included in the first two categories
4. *Chemicals proved safe and approved by the Food and Drug Administration*

8.3.1 Desirable Properties of Food Preservatives

There are seven requirements for food preservatives:

- No toxicity problems.
- Microbiocidal rather than microbiostatic properties.
- Must be stable in foods (especially if only microbiostatic).
- The spectrum of activity should correspond to the spectrum of micro-organisms likely to appear in the food.
- Must not stimulate the development of resistant strains of microorganisms.
- Chemicals used therapeutically are not recommended as food additives.
- An assay procedure should be available.

Categories of Antimicrobial Food Additives Added to the Food:

Following chemicals and biochemicals are used in food preservation:

- Naturally present or formed in the food, chemicals added to the food, bacteriocins e.g. lactoperoxidase enzyme, lysozyme, lactoferrin, nisin etc.

- Chemicals with antimicrobial properties of salts of organic acids, like citric, benzoic, propionic and ascorbic. Chemical preservatives (sulphur dioxide and sulphites, parabens etc.), nitrites and nitrates.

- Chemicals with multifunctional properties added to the food, one property being antimicrobial e.g. spices and essential oils, salt, sugar, antioxidants, vinegar etc.

8.3.2 Mode of Action of Food Additives

- Alteration of cell wall permeability.
- Alteration of colloidal nature of protoplasm.
- Damage of the cell wall.
- Damage of proteins.
- Inhibition of enzyme activity.
- Disruption of cytoplasmic membrane.
- Bacteriostatic or bactericidal action (toxicity of the antimicrobial agent towards microorganisms).
- Interference with synthetic processes.

8.3.3 Factors Affecting the Antimicrobial Activity of Food Additives

Many factors must be considered for the selection of a specific antimicrobial food additive for a specific food. These factors are as follows:

- Physical and chemical properties of the antimicrobial agents (such as water solubility, hydrophobic lipophyllic balance, boiling point, ability to ionize and potential interaction with food constituents). The activity of the antimicrobial is reduced as a result of reaction with lipids, proteins or carbohydrates.

- Composition of food, its pH/ acidity and nutritional value.

- Type of preservation system other than chemicals used in the food.

- Characteristics and number of microorganisms.

- Initial contamination by microbes prior to preservation/processing.

- Type and concentration of chemical used.

- Time and temperature of food storage.

- Cost and toxicity of the antimicrobial.

8.3.4 Precautions to be taken for Using Food Additives

- Food additives must be thoroughly tested before use. Foods containing physical hazards such as stones, seeds, glass fragments or metal pieces must be thoroughly checked.

- FDA approved food additives should be used. Improper use of some of them may prove to be harmful to human health.

- Use of additives should not be permitted if:
  - They fail to serve the interest of consumers.
  - They are used to mark the effect of faulty processing and handling techniques.
  - They are used to deceive the consumers.
  - Their use results in a significant reduction in the nutritive value of the foods.
  - Additives should be used in a controlled way so as to maximize benefits and prevent abuses.

Status of some additives and acceptable dietary intake (ADI)

Material	**Status**
Amaranth (red ozo dye)	Carcinogenic, but still WHO/FAO-prescribed an ADI* for Amaranth
Saccharin	Bladder cancer. However, still permitted in soft drinks to the extent of 100ppm. WHO/FAO-prescribed ADI from 2.5-5.0 mg/kg of body weight.
Cyclamate	Bladder cancer. WHO/FAO-prescribed ADI of 4 mg/kg of body weight for cyclamate.
Brominated vegetable oil	Banned in India and UK
Hydrogen peroxide	Used for extending shelf-life of milk, is repeatedly turned down on grounds that it would have undesirable consequences on milk collection practices.
Gallate, Phenols	Permitted in most countries, but in India there use required specific permission which is not granted.
Nitrates and nitrites	Give rise to nitrosamine which are carcinogenic but still used in our country within the permissible limit.
Sulphites	Banned in USA

*ADI-Acceptable Daily Intake (mg/kg body weight/day)

8.3.5 Adverse Effects of Using Food Additives

Although these additives are regarded as GRAS (generally recognized as safe), their increased used may also lead to various health problems viz. acidity, dyspepsia, digestive disorders etc.

Food additive name	Often used in	Common reactions
Tartrazine (colour)	drinks, cakes, snacks, ice-cream, confectionery	asthma; hyperactivity; aspirin sensitivity
Sunset yellow (colour)	drinks, packet soups, dessert, biscuits, confectionery, ice-cream	hyperactivity; allergies; aspirin sensitivity
Cochineal (colour)	cakes, confectionery, ice-cream	hyperactivity
Azorubine (colour)	packet soups, sauces, jams, desserts (jellies)	asthma; hyperactivity; asprin sensitivity
Indigotine (colour)	tablets, capsules, ice cream, biscuits	nausea; skin rashes; allergies; high blood pressure
Brilliant blue (colour)	tinned peas, bacon-flavored snacks	hyperactivity
Caramel (colour)	drinks, sauces, soups, cakes, pickles, vinegar	hyperactivity
Benzoic acid (preservative)	confectionery, cheeses,	asthma; hyperactivity;
Sulphur dioxide (preservative)	beer, wine, soft drinks, dried fruit, cordials	asthma; hyperactivity
Sodium bisulphite (preservative)	wine, beer, soft drinks, juices, cordials	asthma; destroys vitamin B1; hyperactivity
Sodium nitrite (preservative)	cured meats, some cheeses	hyperactivity; adverse reactions in children; potentially carcinogenic
Propyl gallate (antioxidant)	oils, margarine, salad dressings	gastric and skin irritant
Tert-butyl hydroquinone (antioxidant)	fats, oils, margarine, packet chips	nausea; delirium
Butylated hydroxyanisole (antioxidant)	fried snacks, soft drinks, edible oils, margarine, chewing gum	hyperactivity; asthma; adverse reactions; allergies; increases cholesterol levels
Carageenan (thickener) (emulsifier)	ice-cream, jellies, cake decorations, cheese, salad dressings	allergies; intolerances
Mannitol (emulsifier)	icecream, confectionery, low calorie foods	allergies; diarrhoea, nausea
Monosodium glutamate (MSG) (flavour enhancer)	prepacked meals, snacks, Chinese cooking	hyperactivity; asthma; adverse reactions; allergies; aspirin sensitivity

Disodium 5' ribonucleotide (flavour enhancer)	flavoured crisps, instant noodles, party pies	skin rashes; not easily broken down by body
Aspartame (sweetener)	diet drinks, diabetic confectionery, ice cream	allergies; headaches; nervous disorders

8.4 DEVELOPED AND ADDED PRESERVATIVES

Developed preservatives include those synthesized naturally, by various microorganisms during fermentation and growth and metabolism.

8.4.1 Acids Produced during Fermentation

Food fermentations may serve either or both of two purposes: (1) to produce new and desired flavours and physical characteristics and hence a different food product and (2) to help preserve the food. The preservatives produced in foods by microbial action are the most part acids (chiefly lactic) and alcohol. The preservative effect of these substances nearly always is supplemented by one or more additional preservative agents, such as low temperature, heat, anaerobic conditions, sodium chloride, sugar or added acid.

Developed acidity plays an important part in the preservation of sauerkraut, pickles, green olives, fermented milk, cheese and certain sausages and in various fermented foods of plant origin. Development of full amount of acidity from the sugar available may be permitted in the pickle and green olive fermentations, or the fermentation may be stopped by chilling or canning before the maximum acidity is attained in other fermentations. The approximate acidity developed in some of these products, expressed as lactic acid, is sauerkraut, 1.7 per cent: dill pickles and green olives, 0.9 per cent and fermented milks, 0.6 to 0.85 per cent.

8.4.2 Alcohol

The alcohol content of beer, ale, fermented fruit juices and distilled liquors has a preservative effect but was not produced primarily for that purpose.

8.4.3 Bacteriocins

Many natural products have been found to have efficient preservative effect and their application in food is catching up fast due to the increased awareness about their nutritional and health benefits. These are termed as bio-preservatives as they act on harmful spoilage and pathogenic microbes and prevent their growth in foods.

Bacteriocins constitute an important segment of these biopreservatives. Technically speaking, the bacteriocins are proteinaceous antimicrobial compounds that kill or inhibit closely related bacteria and also are capable of exhibiting a wide inhibitory spectrum against spoilage and pathogenic bacteria. Various microorganisms such as the lactic acid bacteria (comprising species of *Lactobacillus, Lactococcus, Leuconostoc* and *Pediococcus*) and species of *Corynebacterium, Propionibacterium, Enterococcus, Bacillus* and *Escherichia* have been reported to produce bacteriocins or bacteriocin-like inhibitory substances. Lactic acid bacteria have been shown to produce sufficient quantities of bacteriocins in various cultured and fermented food preparations (*dahi*, yogurt, cheese etc.) to prevent the growth of harmful bacteria. Alternatively the purified bacteriocin preparation can also be added directly to the food. So far, researchers have extensively tried out only two bacteriocins, namely nisin and pediocin as biopreservatives in various food systems of which nisin is the only bacteriocin that has been approved as a GRAS food additives.

Nisin is a well known and most widely used bacteriocin produced by *Lactococcus lactis* subsp. *lactis* (formerly *Streptococcus lactis*). It has been used in processed cheese, pasteurized milks, flavored milk and various other dairy products, in addition to canned foods and alcoholic beverages. The recommended doses of nisin used varies from 100-150 IU/g depending on the type of food. Nisin has sporostatic activity. This results in significant energy savings in canning processes by way of low heat application. So it is useful for the non-thermal preservation of foods. Nisin also has a great potential for use in brewing industry. It also finds application in low pH foods. In many European countries nisin has affirmed GRAS status in 1998 by Food and Drug Administration (FDA) for use as an antimicrobial agent.

Besides nisin, several other bacteriocins produced by lactic acid bacteria include pediocin PA-I and pediocin AcH produced by Pediococcus *acidilacti*, sakacin A from *Lactobacillus sake*, plantaricin from *Lactobacillus plantarum*, acidophilicin LA-I from *Lactobacillus acidophilus* and helveticin J produced by *Lactobacillus helveticus* and so on. The Pediococci which are used as starter cultures in certain vegetable and meat fermentations have also been the subject of recent investigation with regard to their bacteriocin-producing ability.

Advantages of using bacteriocins: The bacteriocins offer several advantages over the preservatives that are presently being used in several foods. They do not have any ill effect on the health of the consumer so they are safe to use and the inhibitory effect of bacteriocins on the growth of microorganisms exhibits the potential to inactivate microorganisms in foods.

8.5 LET US SUM UP

Chemical additives that control microorganisms are not only a technological and functional tool in hands of food technologists but also aid in restoring the nutrients lost through processing. The availability of chemical/food additives has allowed the production of numerous out-of-season foods and a variety of new food products. Additives have increased the development of convenience foods, snack foods, low-calorie and health promoting (functional) foods, exotic foods and a variety of food substitutes. The present day consumer demands high quality, convenient and minimally processed foods. Some products can be formulated with ingredients such as organic acids, chemical preservatives, nitrite, bacteriocins, high concentrations of salt, carbon dioxide etc. that are barriers to microbial growth and can also inhibit there growth due to their antibacterial and antifungal properties. The role of chemical additives thus, becomes all the more important, hence to be selected judiciously, keeping in view their toxicological and biochemical role in food, before they are recommended and they have become an integral part of food industry for day to day life for the production of various processed products. They help to assure a food supply with the safety, variety, appeal, wholesomeness and affordability we have become accustomed to.

8.6 KEY WORDS

Food Additive	:	Food additive is defined as a substance or mixture of substances other than the basic foodstuff, which is present in food as a result of any aspect of production, processing, storage and packaging. The term does not include chance contaminants.
Bacteriocin	:	Proteinaceous antimicrobial compounds that kill or inhibit closely related bacteria and also are capable of exhibiting a wide inhibitory spectrum against spoilage and pathogenic bacteria.
Nisin	:	Widely used bacteriocin produced by *Lactococcus lactis* subsp. *lactis* (formerly *Streptococcus lactis*).
GRAS	:	Substances generally recognized as safe
ADI	:	The Acceptable Daily Intake (ADI) is defined as an estimate of the amount of a food additive, expressed on a bodyweight basis that can be

ingested on a daily basis in the diet over a lifetime without appreciable risk to health. "Without appreciable risk" means the practical, in view of the actual level of knowledge, certainty that no harm will result, even after a lifetime of exposure to the chemical additive concerned. The ADI is usually given as a range of 0-x milligrams per kilogram of bodyweight per day.

8.7 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. - Food additive is a substance or mixture of substances other than the basic foodstuff, which is present in food as a result of any aspect of production, processing, storage and packaging.
   - Intentional food additives are added deliberately to food and could be nutritive, freshness maintaining, sensory and processing aids; preservatives, antioxidants, emulsifiers, stabilizers, maturing agents, colours, special sweeteners, nutrient supplements, flavouring compounds and natural flavouring materials.
   - Unintentional food additives are chance contaminants which may get incorporated into food during any step of processing and are not desirable.
2. Food additives help to:
   - Enhance consumer acceptability.
   - Help improve or maintain the nutritional quality.
   - Enhance stability and prevent deterioration.
   - Make food more attractive and palatable.
   - Maintain the safety of foods.

Check Your Progress Exercise 2

1. - Bacteriocins are proteinaceous antimicrobial compounds produced by bacteria, that kill or inhibit closely related spoilage and pathogenic bacteria eg: Nisin, Pediocin, Acidophillin etc.
   - They are used in processed cheese, pasteurized milks, flavored milks and various other dairy products, canned foods and alcoholic drinks, brewing industry etc.
2. Food additives should be non-toxic, economical, must be stable in foods, should be microbiocidal rather than microbiostatic, should have broad antimicrobial spectrum, must prevent growth of resistant strains and an assay procedure should be available to detect them.

3. Action of food additives is by:
   - Altering cell wall permeability of bacteria.
   - Altering its protoplasm.
   - Damaging proteins and cell wall.
   - Inhibition of enzyme activity of cell.
   - Disruption of cell membrane and interfering with cell synthesis processes.

UNIT 9 FOOD BORN DISEASES

Structure

9.0 OBJECTIVES

After reading this unit, you will be able to:

- know the food borne diseases;
- learn to differentiate between food borne intoxications and food borne infections;
- explain that the food borne diseases may be caused due to microorganisms, both bacterial and non bacterial or chemicals;
- explain why investigation of food borne disease outbreak is necessary; and
- describe how the investigation of food borne disease outbreak is carried out.

9.1 INTRODUCTION

Food borne disease (FBD) is caused by consuming contaminated foods or beverages. In addition poisonous chemicals or other harmful substitutes can cause food borne diseases if they are present in food. More than 250 different food borne diseases have been described. A classification of food borne diseases is given in Figure 9.1. Food borne diseases may be intestinal diseases but can be other type as well.

9.2 TYPES OF FOOD BORN DISEASES

With regard to their epidemiology, they can be divided into two major categories (Figure 9.2):

i) **Food borne Intoxication:** Examples include botulism or staphylococcal food poisoning, the causative microorganism produces an exotoxin in food: when a person consumes the food, the toxin is ingested and gives rise to disease.

ii) **Food borne Infections:** the causative organisms are ingested: these subsequently grow within the body and cause damage.

Both infections and intoxications often cause diarrhoea. Severe diarrhoea accompanied by blood or mucus is called dysentery. Both types of digestive system diseases are also frequently accompanied by abdominal cramps, nausea and vomiting. Diarrhoea and vomiting are both defensive mechanisms designed to rid the body of harmful material.

The general term gastroenteritis is applied to disease causing inflammation of the stomach and intestinal mucosa.

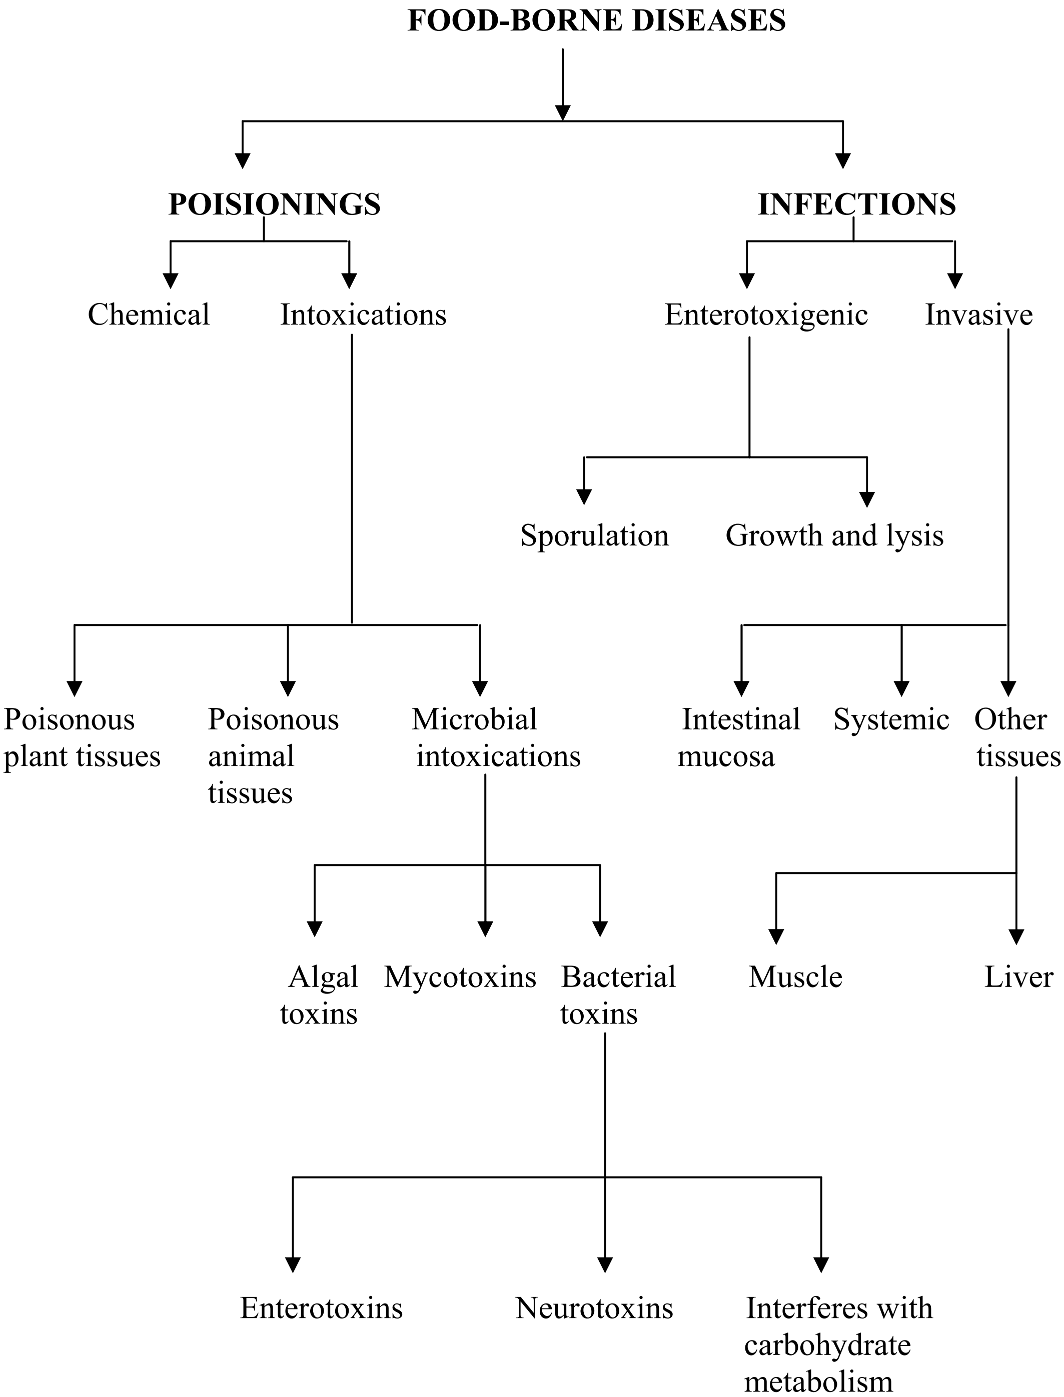

Figure 9.1: Classification of food borne diseases

FOOD-BORNE DISEASES: BACTERIAL

Intoxications

1. Staphylococcal intoxication (staphyloccocal enterotoxicosis): an enterotoxin produced by *Staphylococcus aureus*
2. Botulism: a neurotoxin produced by *Clostridium botulinum*

Infections

1. Salmonellois: enterotoxin and cytotoxin of *Salmonella* spp.
2. *Clostridium perfrigens* illness: an enterotoxin released during sporulation of *Clostridium perfringens* type A in the intestinal tract
3. *Bacillus cereus* gastroenteritis: an exo-enterotoxin released during lysis of *Bacillus cereus* in the intestinal tract
4. *Enteropathogenic Escherichia coli* infection: Several serotypes of *E. coli,* some invasive and some enterotoxigenic
5. *Others:* Yersiniosis, Shigellosis *Vibrio parahaemolyticus*

Figure 9.2: Bacteria responsible for food borne intoxications and infections

9.3 HUMAN DISEASES

Microorganisms that produce infectious diseases in human are categorized as pathogens, because they have the ability to injure body tissues and/or alter body functions.

In general, pathogenic microorganisms express their disease-producing properties through two kinds of mechanisms: (1) invasion of tissues (invasive microorganisms) and (2) production of toxins (toxigenic microorganisms).

Invasive pathogens have the ability to produce and excrete one or more kinds of extracellular enzymes resulting in injury to host tissues. Toxigenic microorganisms produce toxins of two types:

- Exotoxins – produced within certain kinds of bacteria and excreted into their surrounding environment. They are proteins in chemical composition and are relatively specific in terms of damage to the host.
- Endotoxins – are complex polysaccharides cell wall components of certain kind of bacteria. They are not released until the cell disintegrates. They are relatively heat stable, less specific in their actions and less potent than exotoxins.

The severity and distribution of any infectious disease are influenced by the manner in which the agent, the host and factors within the environment interact.

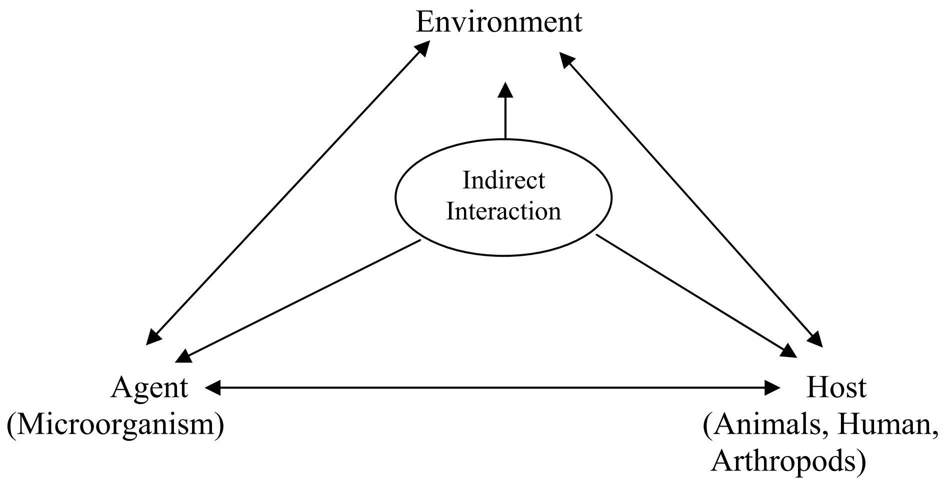

Figure 9.3: Generalized version of the triangle of causation for any kind of communicable disease

The main causes of reported food borne diseases are due to foods being mishandled. Foods that are implicated are usually "potentially hazardous" which are capable of supportive growth of disease-causing microorganisms. The various factors leading to FBD are listed in Table.

Table 9.1: Factors leading to reported food borne diseases (Ranked by % number of outbreaks)

40%	Improper cooling of foods
21%	Time lapse between preparing to serving
20%	Infected persons touching foods
16%	Inadequate cooling
16%	Improper hot storage
12%	Inadequate reheating
11%	Contaminated raw food
7%	Cross-contamination
7%	Improper cleaning
4%	Use of leftovers

9.4 CHEMICAL CONTAMINANTS OF FOOD

Poisoning by consumption of chemicals is rather uncommon and usually is characterized by appearance of the symptoms within a short period of time after the poisonous food is eaten. Various chemical contaminants include:

i) Fumigants are used to sterilize food under conditions in which steam heating is impractical. Ethylene oxide is a commonly used fumigant, which reacts with food constituents and destroys essential nutrients. It reacts with inorganic chloride to form ethylene chloro hydrine, which is toxic.

ii) Various solvents are used for the extraction of oil from oilseeds. But solvents like trichloro ethylene react with the foodstuff being processed with the formation of toxic products.

iii) Smoking of meat and fish for preservation and flavouring is an old practice. This processing contaminates the food with polycyclic hydrocarbons such as benzopyrene, many of which are carcinogenic.

iv) Metals are one of the many unintentional contaminants of food. When present beyond small quantities they are toxic. They find their way into food through air, water, soil, industrial pollution and other routes. Antimony, arsenic, cadmium, chlorinated hydrocarbons, copper, cyanide, fluoride, lead, selenium, mercury and zinc in foods have been blamed for food poisoning. Poisonous chemicals may enter foods from utensils e.g. from cheap enamelled utensils which contain antimony. Lead and arsenic residues from fruit sprays maybe on the surface of fruits but usually in harmless amounts, especially after washing. Symptoms of lead poisoning include weakness, dental caries, nausea, pains and paralysis. A major source of tin contamination is tin plate, which is used for containers of all types of processed foods. Canned foods if acidic and foods stored in tins after opening, change in colour, or develop a metallic flavour that is unacceptable. Insecticides, pesticides, growth regulators, fungicides and growth stimulators are essential in modern agriculture for the production of adequate quantities of sound food. They include insecticides like lead arsenate, organophosphate compounds (malathion), dinitro compounds. Toxicity levels for human vary.

Table 9.2: Toxicity of some metals in different foods

Metal	Type of Food	Toxic Effect
Arsenic	Fruits sprayed with lead arsenate	Dizziness, chills, cramps, paralysis leading to death
Barium	Foods contaminated with rat poison (barium carbonate)	Violet peristalsis, muscular twitching and convulsions
Cadmium	Fruit juice, soft drinks in contact with cadmium plated vessels	Excessive salivation and kidney damage, prostrate cancer, multiple fractures
Cobalt	Water, beer	Cardiac failure
Copper	Acid foods in contact with tarnished copper ware and brass utensils	Vomiting, diarrhea, abdominal pain
Lead	Processed foods	Paralysis, brain damage
Mercury	Mercury fungicide treated seed grains or mercury contaminated fish	Paralysis, brain damage and blindness
Tin	Canned foods	Colic, vomiting. Photophobia
Zinc	Foods stored in galvanized iron ware	Dizziness, vomiting

Table 9.3: Toxicity in food due to various pesticides and chemicals

Name of Pesticide	Type of Food	Toxic Effect
Pesticides	All type of raw, cooked, processed, canned foods	Acute or chronic poisoning causing damage to liver, kidney, brain, nerves leading to death
Diethylstil bestrol	Meat of still bestrol fed animals	Teratogenesis, carcinogenesis
Antibiotics	Meat of animals fed antibiotics	Drug resistance, hardening of arteries, heart diseases

Table 9.4: Permissible limits of some metals in foods

Name of metal	Foodstuff	PPM
Arsenic	1. Milk	0.10
	2. Beverages	0.50
	3. Soft Drinks	0.50
	4. Ice creams and frozen confections	0.50
	5. Dehydrated onions	2.0
	6. Dried spices and herbs	5.0
Copper	1. Beverages, soft drinks	7.0
	2. Tomato ketchup	50.0
	3. Cocoa powder	70.0
	4. Tomato puree, paste, juice powder	100.0
	5. Sugar confectionary	5.0

	2. Hard boiled sugar confectionary	5.0
Zinc	1. Beverages	5.0
	2. Fruit products	50.0
	3. Hard boiled sugar confectionary	5.0

9.5 NON-BACTERIAL MICROBIOLOGICAL CONTAMINATION OF FOOD

Microbiological contamination of food may include food borne illness due to bacteria or non bacterial sources such as mycotoxins, viruses, rickettsias, parasitic worms or protozoa or from the consumption of food contaminated with toxic substances. The food borne infections caused by bacteria will be dealt with in Unit 3 in detail.

9.5.1 Viruses

Much less is known about the incidence of viruses in foods than about bacteria and fungi because they do not grow in culture media as do bacteria and fungi, they do not replicate in foods thus found in low numbers. It is noted that virtually any food can serve as a vehicle for virus transmission. The most common food source of gastroenteritis causing virus is shellfish.

Hepatitis A virus

There are more documented outbreaks of hepatitis A traced to foods than any other viral infection. The virus causes hepatitis (jaundice) and leads to inflammation of liver. The incubation period for infectious hepatitis ranges from 15 to 45 days and lifetime immunity usually occurs after an attack. The fecal-oral route is the mode of transmission, and raw or partially cooked shellfish from polluted waters is the most common vehicle food. Shellfish are able to concentrate the numbers of bacteria or viruses during their normal feeding, which is to filter and remove particles from the water. The infectious hepatitis virus has been shown to be stable during refrigerated storage of shellfish. In addition to shellfish, raw milk, potato salad, sandwiches and cold meat cuts are also probable sources of the virus. Symptoms of jaundice include loss of appetite, yellowing of eyes, nails and skin (due to presence of bile pigments) and gastrointestinal disorder. Proper cooking, hygiene, sanitation and personnel cleanliness help to prevent virus attack.

Polio Virus

There are a large number of reported food-borne outbreaks of polio in India. It is most common in children up to 5 years. Milk is the most probable food there causes spread of polio virus. The virus reproduces in the intestinal tract, from there it invades the motor cells of the central nervous system. Initial symptoms are gastrointestinal, headache, muscle pain and paralysis. The paralytic symptoms range from sub clinical to fatal. Preventive measures include immunization of children, proper processing (pasteurization) of milk, hygienic conditions and use of potable water.

Norwalk Virus and Norwalk-like Viruses

These viruses, also known as small round structured viruses or caliciviruses, are an important cause of gastrointestinal illness throughout the United States. Members of this category of viruses are typically named for the location in which they were first identified, for example, Hawaii, Snow Mountain, Montgomery County and Oklahoma. The Norwalk virus is the prototype for this group of viruses – there are at least 11 other related viruses – hence the name “Norwalk-like virus.”

Symptoms: The signs and symptoms of Norwalk-like viruses include nausea, vomiting, diarrhea, abdominal pain, muscle aches, headache, tiredness and low-grade fever. Symptoms typically last 24 hours to 48 hours and subside on their own. There are no known long-term effects after recovery from this infection.

Transmission of viruses: Humans are the only source for these viruses. These viruses do not multiply outside the human body. The viruses are present in the feces of infected persons and can be transmitted to others when hands are not thoroughly washed after having a bowel movement.

9.5.2 Rickettsias

Rickettsias maybe considered as degenerative bacteria since they represent a form of life closely resembling bacteria except that they cannot be cultivated outside of living cells. Like the viruses they are obligate parasites. Many of the major human rickettsial diseases are by bites from fleas, lice or ticks. Examples of human rickettsial diseases include epidemic typhus, rickettsial pox, Rocky mountain spotted fever and Q fever. Cows infected with rickettsia of Q fever, *Coxiella brunettii* excrete contaminated milk which result in human infections. Hence milk is pasteurized at a minimum temperature of 62.8ºC for 30 minutes to ensure its destruction.

9.5.3 Food Borne Parasites

Trichinosis

Trichinella spiralis causes trichinosis, which results from the consumption of raw or incompletely cooked pork containing the encysted larvae.

Symptoms: One or two days after ingestion of heavily encysted meat, trichinae penetrate the intestinal mucosa, producing nausea, abdominal pain, diarrhea and sometimes vomiting. The symptoms may persist for several days. The larvae then attack the skeletal muscles, muscle pain (paralysis) is the universal symptom accompanied in difficulty in breathing, chewing and swallowing. After six months of initial infection, pain, swelling and fever occur.

Prevention and control: Chief method for prevention of trichinosis is the treatment of pork (or other meat) to ensure the destruction of any trichinae that maybe present by cooking of pork till at least 58.3ºC, quick freezing or storage at -15ºC or lower for not less than 20 days, irradiating or processing of sausage and similar meat products properly by salting, drying, smoking and refrigeration. Also trichinosis can be controlled by avoiding feeding of infected meat scraps to swine and by preventing the consumption of infested tissue by other animals.

Amoebiasis

Entamoeba histolytica is a single celled parasitic animal – a protozoa, that infects predominantly humans and other primates and causes amoebiasis. Diverse mammals such as dogs and cats can become infected but usually do not shed cysts (the environmental survival form of the organism) with their feces, thus do not contribute significantly to transmission. The active (trophozoite) stage exists only in the host and in fresh feces; cysts survive outside the host in water and soil and on foods, especially under moist conditions on the latter. When swallowed they cause infections by excysting (to the trophozoite stage) in the digestive tract (amoebiasis).

Symptoms: Infections that sometimes last for years may be accompanied by 1) no symptoms, 2) vague gastrointestinal distress, 3) dysentery (with blood and mucus). Most infections occur in the digestive tract but other tissues may be invaded. Complications include 4) ulcerative and abscess pain and, rarely, 5) intestinal blockage. Onset time is highly variable. It is theorized that the absence of symptoms or their intensity varies with such factors as 1) strain of amoeba, 2) immune health of the host, and 3) associated bacteria and, perhaps, viruses. The amoeba's enzymes help it to penetrate and digest human tissues; it secretes toxic substances.

Diagnosis: The ingestion of one viable cyst can cause an infection. Human cases are diagnosed by finding cysts shed with the stool; various flotation or sedimentation procedures have been developed to recover the cysts from fecal matter; stains (including fluorescent antibody) help to visualize the isolated cysts for microscopic examination. Since cysts are not shed constantly, a minimum of 3 stools should be examined. In heavy infections, the motile form (the trophozoite) can be seen in fresh feces. Serological tests exist for long-term infections. It is important to distinguish the *E. histolytica* cyst from the cysts of nonpathogenic intestinal protozoa by its appearance.

Transmission: Amebiasis is transmitted by fecal contamination of drinking water and foods, but also by direct contact with dirty hands or objects as well as by sexual contact.

Giardiasis

Giardia lamblia (intestinalis) is a single celled animal, i.e., a protozoa, that moves with the aid of five flagella. Organisms that appear identical to those that cause human illness have been isolated from domestic animals (dogs and cats) and wild animals (beavers and bears). A related but morphologically distinct organism infects rodents, although rodents may be infected with human isolates in the laboratory. Human giardiasis may involve diarrhea within 1 week of ingestion of the cyst, which is the environmental survival form and infective stage of the organism.

Symptoms: Normally illness lasts for 1 to 2 weeks, but there are cases of chronic infections lasting months to years. Chronic cases, both those with defined immune deficiencies and those without, are difficult to treat. The disease mechanism is unknown, with some investigators reporting that the organism produces a toxin while others are unable to confirm its existence. The organism has been demonstrated inside host cells in the duodenum, but most investigators think this is such an infrequent occurrence that it is not responsible for disease symptoms. Mechanical obstruction of the absorptive surface of the intestine has been proposed as a possible pathogenic mechanism, as has a synergistic relationship with some of the intestinal flora.

Diagnosis: *Giardia lamblia* is frequently diagnosed by visualizing the organism, either the trophozoite (active reproducing form) or the cyst (the resting stage that is resistant to adverse environmental conditions) in stained preparations or unstained wet mounts with the aid of a microscope. A commercial fluorescent antibody kit is available to stain the organism. Organisms may be concentrated by sedimentation or flotation; however, these procedures reduce the number of recognizable organisms in the sample.

Associated foods: Giardiasis is most frequently associated with the consumption of contaminated water. Outbreaks have been traced to food contamination by infected or infested food handlers, and the possibility of infections from contaminated vegetables that are eaten raw cannot be excluded. Cool moist conditions favor the survival of the organism.

Prevalence: Giardiasis is more prevalent in children than in adults, possibly because many individuals seem to have a lasting immunity after infection. This organism is implicated in 25% of the cases of gastrointestinal disease and may be present asymptomatically. This disease afflicts many homosexual men, both HIV-positive and HIV-negative individuals. This is presumed to be due to sexual transmission. The disease is also common in child day care centers, especially those in which diapering is done.

Ascariasis

Humans worldwide are infected with *Ascaris lumbricoides* and *Trichuris trichiura*; the eggs of these roundworms (nematode) which are "sticky" and may be carried to the mouth by hands, other body parts, fomites (inanimate objects), or foods. Ascariasis and trichuriasis are the scientific names of these infections. Ascariasis is also known commonly as the "large roundworm" infection and trichuriasis as "whip worm" infection.

Diagnosis: Infection with one or a few Ascaris sp. may be unapparent unless noticed when passed in the feces, or, on occasion, crawling up into the throat and trying to exit through the mouth or nose. Infection with numerous worms may result in a pneumonitis in the lungs, where the larvae break out of the pulmonary capillaries into the air sacs, ascend into the throat and descend to the small intestine again where they grow, becoming as large as 31 × 4 cm. Vague digestive tract discomfort sometimes accompanies the intestinal infection, but in small children with more than a few worms there may be intestinal blockage because of the worms' large size. Not all larval or adult worms stay on the path that is optimal for their development; those that wander may locate in diverse sites throughout the body and cause complications. Both infections are diagnosed by finding the typical eggs in the patient's feces; on occasion the larval or adult worms are found in the feces or, especially for *Ascaris* sp., in the throat, mouth, or nose.

Associated foods: The eggs of these worms are found in insufficiently treated sewage-fertilizer and in soils where they embryonate (i.e., larvae develop in fertilized eggs). The eggs may contaminate crops grown in soil or fertilized with sewage that has received nonlethal treatment; humans are infected when such produce is consumed raw. Infected food handlers may contaminate a wide variety of foods.

Prevention: Both infections may self-cure after the larvae have matured into adults or may require anthelmintic treatment. In severe cases, surgical removal may be necessary. Allergic symptoms (especially but not exclusively of the asthmatic sort) are common in long-lasting infections or upon reinfection in ascariasis.

9.6 INVESTIGATION OF FOOD BORNE DISEASE OUTBREAK

Analysis of an outbreak involves field analysis as well as laboratory analysis and is undertaken by Ministry of Health. From public health point of view the objectives of the investigation of outbreak are:

1. *Prevention and control*

   Identification of contaminated foods

2. *Knowledge of disease causation*

   Observe the track record of various illnesses-causing agents

3. *Administration guidance*

   Assessment of trends to justify regulations, decisions/actions

This requires the location and the identification of the causative agent, establishing of the means of transmission, demonstration of opportunity for growth of the pathogen.

Personnel Involved in Investigation

The team to investigate an outbreak of food borne disease consists of a person in charge, a field group and a laboratory group. The field group interviews persons, both ill and healthy, who consumed the suspected foods, physicians and nurses who are treating the victims, and personnel at the place of exposure to the disease; collects samples of suspected foods and transits them to the laboratory, collects specimens from patients or food handlers when such sample is indicated; inspects the premises where the foods were stored, prepared and served; fills out appropriate reports on these activities, and makes it available for laboratory staff. The laboratory group makes microbiological and chemical tests as indicated by reports of the field group and the nature of the suspected food and records its findings on appropriate report blanks. The person in-charge or a qualified epidemiologist then can interpret the data from all sources to determine the cause and source of disease outbreak.

Steps of Investigation

Field Analysis

a) Gathering information

The field group inspects the place or places where the suspected meal, meals or beverages were prepared and consumed and then record the results in appropriate forms. Information sought includes the menu for meals, source and method of preparation of each item on the menu, methods of storage of perishable foods, health of employees serving or preparing foods and their health history. The information obtained is recorded on a form entitled "Case History Questionnaire" as given.

Performa

Name of Person affected	Age	Time of First Symptom	Foods Consumed

The Performa indicate the most likely age group affected and the type of food being consumed by them. Also we get an idea of the type of food through which the infection could have probably been caused.

b) Sample collection

Samples of left over food and /or beverage served at suspected meal are aseptically collected by means of sterile sampling devices in sterile containers, labelled and transited to laboratory under refrigerated conditions.

c) Collection of specimens from human sources

Specimens maybe obtained from patients with food illnesses or from food handlers to ascertain the ultimate source of the pathogen that entered the food. Culture from nose, throat or skin lesions, fecal or blood samples may be done.

Laboratory Analysis

The sample received from the field are analyzed microbiologically and sometimes for chemical contamination also. The report is then sent to the in-charge, the epidemiologist (who is expert in dealing with epidemics).

Performa for Laboratory Report

Etiological Agent (Causative Agent of Spoilage)	Clinical Symptoms (of affected people)	Laboratory Investigation	Complete Investigation (Food responsible for Outbreak)	Preventive Measures
Eg: For *Bacillus gastroenteritis*		Investigation of food, stools and faeces. Isolation of the microorganism	Infection due to accidental contamination or otherwise	Asepsis, prevent inadequate treatments, proper storage conditions

Interpretation of Report

This is done by the epidemiologist and conclusion is taken out for cause of the outbreak. Complete investigation of food borne disease outbreak is given as:

i) Name of the reporting officer

ii) Name of the local authority who is analyzing the complete outbreak

iii) Area/place of outbreak

iv) Date and time when suspected meal was taken

v) Number of persons' affected

vi) Number of people at risk indicating those who have developed symptoms)

vii) Incubation Period

viii) Symptoms

ix) Occupational/age group

x) Details of suspected meal (complete analysis of food)

xi) Foods which are eaten by affected persons

xii) Number of meal sittings and time

xiii) Methods of cooking

xiv) Time and temperature of storage of cooking

xv) General notes regarding the facilities and equipments

Minimum Infrastructure/ Materials Required

- Field Kit for field analysts to collect sample, medical equipment, sterile containers, sampling device, sterilized thermometer, lamps of alcohol, sterile wrapping foil, tapes for sealing, sterile paper, towels, ice boxes, insulated boxes for carrying samples.
- Laboratory- Facility to find the total plate count and types of microorganisms, glassware, pipettes, flask, media, laminar flow, stains. Chemicals, specific test kits for enumerating specific organisms.
- Data interpretation infrastructure.

WHO'S Golden Rule for Safe Food Production

1. Choose foods processed for safety.
2. Cook foods thoroughly.

3. Eat cooked foods immediately.
4. Store cooked foods carefully.
5. Reheat cooked foods thoroughly.
6. Avoid contact between raw and cooked foods.
7. Wash hands repeatedly.
8. Keep all kitchen surfaces meticulously clean.
9. Protect foods from insects, rodents and other animals.
10. Use pure water.

9.7 LET US SUM UP

In this unit on food borne disease, we have examined what are the food borne disease and how to differentiate with food borne infections and intoxications. This includes study of various contaminants of food, namely, bacterial, non bacterial and toxic chemicals. We have also studied the importance of the investigation of food borne disease outbreak. The steps involved in the investigation were also studied. We have seen that food borne diseases maybe caused due to contaminated food and beverages. They are a common, distressing and sometimes life-threatening problem for millions of people all around the world. We also studied in the end the related golden rules for the prevention of such food borne disease outbreaks. Hence following good manufacturing practices (GMP's) and giving publicity to an outbreak and the explanation of its cause maybe helpful in educating and warning the public and avoiding further outbreaks.

9.8 KEY WORDS

Food Borne Disease : Disease caused by the consumption of contaminated foods or beverages

Food Borne Intoxication : Food borne disease caused due to ingestion of toxin already present in food.

Food Borne Infection : Food borne disease caused due to ingestion of causative organisms into the body where they multiply, grow and cause disease.

Exotoxin : Proteinaceous toxin produced by bacteria and excreted into surrounding environment

Endotoxin : Toxin produced by bacteria and excreted into surrounding environment after the cell lysis. Are mainly composed of polysaccharides.

9.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Food borne diseases are caused by consuming contaminated foods or beverages e.g., food borne infection and food borne intoxication.

2. Exotoxins are proteinaceous toxins produced by bacteria and excreted into surrounding environment.

   Endotoxins are toxins produced by bacteria and excreted into surrounding environment after the cell lysis (breaking of cell membrane), which are mainly composed of polysaccharides.

3. Chemical contaminants in food include fumigants, solvents like hexane, metallic contaminants such as antimony, arsenic, cadmium etc., insecticides, pesticides and growth regulators etc.

Check Your Progress Exercise 2

1. Non-bacterial food borne disease causing agents include viruses, rickettsias and parasites (*Trichinella, Entamoeba, Giardia, Ascaris*)

2. Jaundice is caused by Hepatitis A virus. through faecal-oral transmission. Foods associated are raw or partially cooked shellfish, raw milk, potato sandwiches and cold meat cuts.

3. Food borne parasites include:

   a) *Trichinells spiralis* (causes Trichinosis) characterized by nausea, abdominal pain, diarrhea and vomiting. Severe attack may cause paralysis, fever and severe pain.

   b) *Entamoeba histolytica* (causes amoebiasis) results in gastrointestinal distress, dysentery, ulcers and intestinal blockage.

   c) *Giardia lamblia* (causes giardiasis) results in severe gastroenteritis and intestinal problems.

   d) *Ascaris lumbricoides* causes ascariasis, resulting in digestive tract disturbance, intestinal disorder and blockage.

Check Your Progress Exercise 3

1. Objectives of food borne disease outbreak investigation are:

   - To prevent and control contamination of foods.
   - To know the disease causing agents.
   - To develop guidelines and take regulatory decisions.

2. Three steps in the investigation of any food borne disease outbreak:

   - **Field Analysis:** Collection of samples and data pertaining to the causes of outbreak in the particular area.

   - **Laboratory Analysis** dealing with the isolation of the causative organism from the various collected samples.

   - **Identification and the Interpretation of Report** involving the compilation of all facts and figures and stating the cause of outbreak and the possible causative measures to be taken.

3. WHO's Golden rule for safe food production states that:

   - Choose foods processed for safety
   - Cook foods thoroughly
   - Eat cooked foods immediately
   - Store cooked foods carefully
   - Reheat cooked foods thoroughly
   - Avoid contact between raw and cooked foods
   - Wash hands repeatedly
   - Keep all kitchen surfaces meticulously clean
   - Protect foods from insects, rodents and other animals
   - Use pure water

9.10 SOME USEFUL BOOKS

1. A manual entitled 'Procedures to Investigate Food borne Illnesses' (1976) has been written by the Committee on communicable Diseases Affecting Man in the International Association of Milk, Food and Environmental Sanitarians and provides excellent information on such food borne diseases and their outbreaks. A complete listing of diseases transmitted by foods, including etiologic agents, nature of the organism, incubation period, signs and symptoms, source or reservoir, epidemiology, foods involved and control measures can be found in Center for Disease Control (1976a).

2. Frazier, W.C. and Westoff, D.C. (1988) Food Microbiology, Tata McGraw-Hill Pub. Co., New Delhi. pp. 539.

3. Purohit, S.S. (1994) Microbiology-Fundamental and Application. 5th edn. Agro Botanical Publishers, Bikaner, India.

4. Srivastava, R.P. and Kumar, S. (1994) Fruits and Vegetable Preservation, International Book Distribution Co., Lucknow.

UNIT 10 FOOD INTOXICATIONS

Structure

10.0 OBJECTIVES

After reading this unit, you will be able to:

- discuss the causal organisms responsible for food borne intoxications;
- explain the toxins production by mold and bacteria (*Clostridium botulinum* and *Staphylococcus aureus*);
- the microbial toxins produced, the foods associated in intoxication, symptoms of the disease, diagnosis, conditions necessary for outbreak and preventive measures required will also be discussed; and
- know the naturally present toxins in the food products will also be accounted for.

After reading this unit you will be able to distinguish between food borne intoxications caused by the various microbiological agents and their preventive measures.

10.1 INTRODUCTION

We have already studied about the food borne diseases and their classification. Food borne intoxications are basically food borne illness caused due to ingestion of toxin produced my microorganisms (mycotoxins, bacterial toxins). Natural toxins present in food may also result in food poisoning in humans.

Food poisoning is also caused by consuming old, used, residual, fermented, spoiled, contaminated, toxic and bacteria infested food.

10.2 NATURAL TOXINS

Some plants and animals originate food contain toxic substances. Some pulses and legumes contain a number of toxic substances such as protease inhibitors, lathyrogens, and flavism causing agents, cyanogens, haemaglutinins and paponins which are discussed below:

a) Trypsin inhibitor is a proteinous in nature. It suppresses the release of amino acid. It thus interferes with the normal growth of animals fed with such pulses.

b) Haemglutinins are also proteins. They impair the absorption system.

c) Cynogenic glycosides cause cyanide poisoning on hydrolysis of the glycoside by the enzyme α-glucosidase, hydrogen cyanide is liberated. A cyanides content of 10-20 mg per 10 gm of pulses is considered safe. Many legumes excepting limabean (*Phaseolus lunatus*) contains cyanide within these limits.

d) Saponins are glycosides of high molecular weight. This has been reported in soyabean, swordbean and jackbean. Toxic saponins cause nausea and vomiting and can be removed by soaking the beans prior to cooking.

e) Alkaloids are known to occur in the seeds of many legumes but they are relatively innocuous.

f) Some compounds present in pulses appear to bind iodine thus producing a state of iodine deficiency in the thyroid and eventually goitre.

g) Lathyrism is a disease that paralyses the lower limbs. The disease is associated with consumption of *kesari dal* regularly as high as 300g daily. In lathyrism, the toxic substances interfere with formation of normal collagen fibers in the connective tissue.

h) A hemolytic factor in *Vicia faba* causes flavism. It is caused by eating broadbeans or by inhaling pollen of its flowers. Flavism is hemolytic anemia. In several cases, death may occur within 24-48 hours of the onset of the attack.

i) Oxalic acid, a constituent of rhubarb, spinach and beet may cause oxalic poisoning in certain individuals.

j) Some poisonous substances may also be present in some cereals and vegetables e.g. protease inhibitor in cereals and potatoes, saponins in spinach and asparagus and goitrogens in rapeseed mustard, cabbage and related species. Goitrogens cause hypothyroidism and thyroid enlargement

k) Tissues of certain marine animals contain toxic substances, which cause adverse responses when eaten. Some algae like *Gymnodinium* and *Gonyaulax* are toxic. Heating does not destroy these substances.

l) Algal or Planktonic Fish Poisonings: Fish poisoning can result from the ingestion of fish or shellfish that have fed upon algae toxic to human beings. Paralytic shellfish poisoning is caused by ingestion of shellfish such as scallops, clams and mussels which have consumed toxic dinoflagellates. Symptoms appear within 10min after ingestion and include gastrointestinal distress, parasthesia of the lips and fingertips followed by ataxia, muscular uncoordination and ascending paralysis. Death may occur within 2 to 12 hours from cardiovascular collapse or respiratory failure. The human lethal dose of toxin is considered to be 3 to 4 mg.

Prevention: Soaking, heating or fermentation of pulses can reduce or eliminate most of the toxic factors in them. Heat causes denaturation of the proteins responsible for trypsin inhibition and haemagglutination and of the enzyme causing hydrolysis of cyanogenic glycosides. Fermentation also destroys toxic factors and yield more digestible products of high nutritive value.

10.3 MYCOTOXINS

Fungi are a very diverse group of organisms and have a significant impact on the production, spoilage and safety of food. Molds have not only served to synthesize antibiotics but also to produce some foods. Fermented foods such as some cheese, soy sauce, *miso, tempeh* and other oriental delicacies are prepared with the help of molds.

It is well documented that some molds produce toxic substances. Some fungi elaborate the toxin in large macroscopic fruiting bodies; for example, the toxin produced by certain species of *Amanita*, a poisonous mushroom. Other fungi always grow and sporulate as parasites on living host plants, and sometimes will do so only on a specific host. *Claviceps* is an example of this group of fungi and it produces mycotoxins. In contrast to fungi that are parasitic on living plants another group of fungi is saprophytic and causes destruction of dead plants and animal material. There is abundance of the spores of these molds in atmosphere and are found to inhabit stored grain and dried products and hence have been referred to as "storage fungi". These molds include *Cladosporium, Fusarium, Penicillium, Aspergillus* and *Alternaria*.

Mycotoxins are secondary metabolites produced by molds on foodstuffs that causes illness or death when ingested by man or animals. The primary metabolites are those that are essential for growth whereas secondary metabolites are formed during the end of the exponential growth phase and have no apparent significance to the producing organism relative to growth. The mycotoxins commonly encountered in food are around one million times less toxic than most lethal of the botulism toxin. But long term chronic toxicity is of special concern because several of the mold metabolites are carcinogenic and influence the immune response of a number of animal species. The syndrome resulting from ingestion of toxin in a mold contaminated food is referred to as mycotoxicosis.

At the beginning of the last century, two major mycotoxicosis caused considerable suffering and mortality. They were alimentary toxic aleukia (ATA) in Russia, caused by consumption of corn contaminated with T-2 toxin produced by *Fusarium sporotrichoides* and yellow rice disease in Japan, associated with *Penicillium islandicum*. More recently, outbreaks of aflatoxicosis caused by consumption of corn contaminated with *Aspergillus flavus* were reported from India involving approximately 1000 people of whom nearly 100 died.

Several very important mycotoxins such as the sporidesmins, slaframine and tremorgens are associated with animal feeds and forages which affect the quality of meat and other animal products. It is also seen that mycotoxins present in animal feed get into human foods because they pass through the food chain in either their original or metabolized form.

When we store foods under inappropriate conditions they are susceptible to mold growth. Many mycotoxigenic species are able to produce several mycotoxins. It is likely, therefore, that contaminated foods will contain a cocktail of toxins that can interact synergistically.

Some major mycotoxins found in foods

Mycotoxin	Major Foods	Common Producing Species
Aflatoxins	Corn, groundnuts, figs, tree nuts	*Aspergillus flavus, A. parasiticus*
Aflatoxin M_1	Milk, milk products	(secreted by cow after metabolism of Aflatoxin B_1
Deoxynivalenol	Cereals	*Fusarium graminearum, F. culmorum*
Fumonisin	Corn	*Fusarium moniliforme*
Ochratoxin	Corn, cereals, coffee beans	*Penicillium verrucosum, Aspergillus ochraceus*
Patulin	Apple juice	*Penicillium expansum*
Sterigmatocystin	Cereals, coffee, beans, cheese	*Aspergillus versicolor*
Zearalenone	Corn, barley, wheat	*Fusarium graminearum*

10.3.1 Aflatoxin

Aflatoxins are the most widely studied of all mycotoxins. Knowledge of their existence dates from 1960, when more than 100,000 turkey died in England after eating peanut meal imported from Africa and South America. From the poisonous feed were isolated *Aspergillus flavus* and a toxin produced by this organism that was designated aflatoxin (*Aspergillus flavus* toxin- A-fla-toxin). These compounds are highly substituted coumarins, and at least 18 closely related toxins are known. Aflatoxin B_1 is the most important of this large family of compounds and is produced by *Aspergillus flavus, A. parasiticus* and *A.nominus*. The toxicity of the six most potent aflatoxins decreases in the following order: $B_1 > M_1 > G_1 > B_2 > M_2 \neq G_2$.

Occurrence: Aflatoxigenic molds can occur in warmer parts of the world and aflatoxicosis maybe produced in a wide range of tropical and subtropical food commodities such as figs, tree nuts and cereals. The most important crops are corn and groundnut, but it can also occur in temperate crops such as wheat. Although the production of aflatoxin initially was considered to be a problem in post harvest crops stored at inappropriate temperatures and water activities, it is now known that these compounds can be present in the field before harvest. *A.flavus* and *A. parasiticus* may infect healthy plants at a very early stage.

Biological effects: Aflatoxins are acute hepatotoxins and are known to be carcinogenic in some animal species as rat. Aflatoxin B_1 is acutely toxic to our species and is responsible for liver necrosis. The toxicological effect of the aflatoxins are influenced by their metabolism after intake into their body (Figure 10.1).

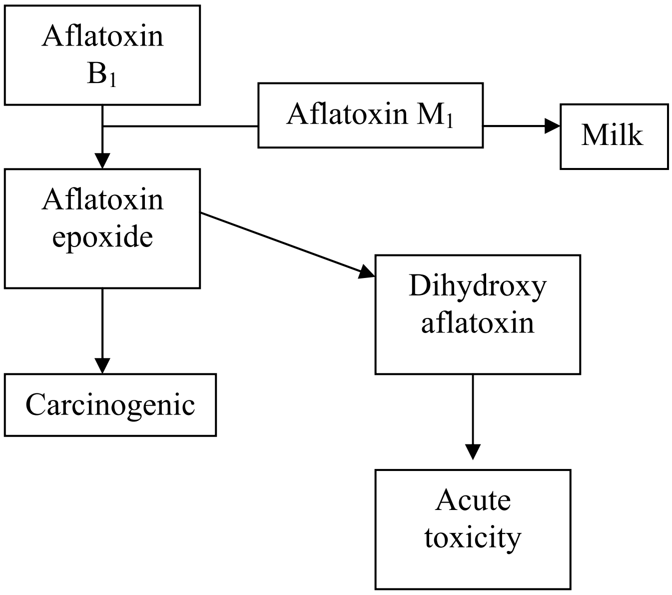

Figure 10.1: Representation of the metabolism of aflatoxin and its biological effects

When cows eat feed containing aflatoxin, aflatoxin M_1 and M_2 is excreted in the milk. Although M_1 and M_2 are less toxic than the parent compound B_1, M_1 retains its toxic and carcinogenic ability in many animals. The LD_{50} of AFB_1 for rats by the oral route is 1.2mg/kg and 1.5 to 2.0 mg/kg for AFG_1.

Control: Because aflatoxins are potentially widespread in occurrence and have an insidious combination of acute and chronic toxicity, it is prudent to control their presence in food. Many countries have legislation establishing maximum tolerance levels. Chemically treating the aflatoxin contaminated commodities like nuts maybe possible or to use technologically sophisticated equipment to sort and discard the contaminated units. It may also be possible to control the production of aflatoxin in the field by an integrated programme of agricultural management that may include plant breeding, improved irrigation and replacement of aflatoxigenic strains by non- aflatoxigenic strains of *A. flavus*.

10.3.2 Ochratoxin

Occurrence: Ochratoxin A is a phenylalanyl derivative of a substituted isocoumarin produced by *Penicillium verrucosum* in temperate climate and by several species of Aspergillus in warmer and tropical parts of the world. *Penicillium verrucosum* is especially associated with stored cereals although it has also been isolated from meat and fish, however the occurrence of ochratoxin A in meat products is usually due to transmission into muscle, kidney and blood in animal fed on contaminated animal feed such as barley. Ochratoxin may also be transferred from dietary intake into milk. *Aspergillus ochraceus* is common on coffee beans, spices, soybeans, groundnut, rice and corn. Ochratoxin is heat resistant and is not destroyed by roasting or autoclaving though the ochratoxin producing fungi are capable of growth and mycotoxin production at temperature below 10ºC.

Biological effects: It is associated with the chronic progressive kidney disease in humans known as Balkan endemic nephropathy. There is increased evidence that it can also be considered as a carcinogen with genotoxic property as well as a potent nephrotoxin. The availability of improved methods of analysis has demonstrated that ochratoxin is quite widespread in foods and its presence in human body fluids confirms that there is a significant exposure with the human population. Ochratoxin is immunosuppressive and inhibits protein biosynthesis. Ochratoxin A has been classified by the International Agency for Reseach on Cancer (IARC) as a possible human carcinogen. Low doses as 70μg/kg body weight can induce kidney tumors in male rats. Its oral LD_{50} in rats is 20 to 22 mg/kg, and it is both hepatotoxic and neprotoxic.

Control: Once ochratoxin A has been formed in a food, it is difficult to remove by most forms of food processing. Cooking with or without previous soaking removes a significant amount of ochratoxin from beans but does not lead to total destruction. Beans still contain 16% to 60% of the initial ochratoxin contamination and it seems probable that the material may have leached out rather than destroyed.

10.3.3 Patulin

It is a toxic and antibiotic metabolite produced by several species of *Penicillin, Aspergillus* and *Paeciliomyces* but the most important in the context of human food production is *P. expansum*, a soft rot pathogen of apple and pears. Patulin is an unsaturated lactose and is sensitive to sulphur dioxide and is unstable in alkali but stable in acid.

Occurrence: It is found in a range of foods based on fruits. Presence of patulin in fruit juice is a indication that the juice was extracted from poor quality fruit which is undesirable and should be avoided with good manufacturing practices. This mycotoxin has also been found in moldy bread, sausage, fruits (including bananas, pears, pineapples, grapes and peaches) and other products.

Biological activity: Patulin has an acute oral LD_{50} in rodents of about 30-50 mg/kg and has been shown to be teratogenic, immunotoxic and neurotoxic and to cause gastrointestinal disturbances in rats. Patulin is quite rapidly excreted from animals. It causes chromosomal aberrations in animal and plant cells and is a carcinogen.

Control: In apples molded by *Penicillium expansum*, most of the patulin is confined to the region of damaged tissue and simply removing the lesions reduces the toxin by 90%, but if 1cm around the lesion is also removed, no patulin is detectable in rest of the apple. Ascorbic acid has been reported to reduce levels of patulin. Although pasteurization (using high temperature, short time treatment of ten seconds at 90ºC) causes some reduction in patulin in fruit juices, it is only of the order of 20%, which is not sufficient to make a badly contaminated food product acceptable.

10.3.4 Alternaria Toxins

Several species of Alternaria (*A.citri, A. alternata, A.solani* and *A. tenuissima*) produce toxic substances that have been found in apples, tomatoes, blueberries and others. The toxins produced include alternariol, alternariol monomethyl ether, altenuene, tenuazonic acid and altertoxin-I.

10.3.5 Citrinin

This mycotoxin is produced by *Penicillin citrinum*, *P.viridicatum* and other fungi. It has been recovered from polished rice, moldy bread, country cured hams, wheat, oats, rye and other similar products. It is a known carcinogen.

10.3.6 Penicillic Acid

This mycotoxin has biological properties similar to patulin. It is produced by a large number of fungi, including many Penicillia as well as members of the *A.ochraceus*. One of the best producers is *P.cyclopium*, it has been found in corn, beans and other field crops. Its LD_{50} in mice by subcutaneous route is 100 to 300 mg/kg and it is a proved carcinogen.

10.3.7 Sterigmatocystin

These mycotoxins are structurally and biologically related to the aflatoxins, and like the latter, they cause hepatocarcinogenic activity in animals. Among the organisms that produce them are *Aspergillus versicolor*, *A. nidulans*, *A.rugulosus*. The LD_{50} for rats by intra-peritoneal injection is 60 to 65 mg/kg.

10.3.8 Fusarium Toxins

Another important genus of mycotoxin producers is *Fusarium,* many species of which produce members of the trichothecene family of mold metabolites like deoxynivalenol, neosolaniol and T-2 toxin etc.

Deoxynivalenol

Deoxynivalenol (DON) is a far more common, but much less toxic, trichothecene and is produced by species such as *F. graminearum* and *F. culmorum*. LD_{50} of DON is 70mg/kg. The trichothecenes are remarkably stable compounds, and DON will survive both dry milling and wet milling processes of corn. The baking of bread has relatively little effect on trichothecenes such as DON.

Zearalenone

It was first isolated as the agent responsible for vulvovaginitis in pigs, has very little acute toxicity, but there should be some concern about chronic exposure to a compound known to be estrogenic. It may be produced, together with DON and other trichothecenes, in a wide range of cereals including corn, barley and wheat.

Moniliformin

It was first obtained from a strain of *Fusarium moniliforme* isolated from southern leaf blight- damaged corn seed as a water soluble toxin. The LD_{50} for mice has been reported to be 20.9 mg/kg for females and 29.1 mg/kg for males. At toxic doses moniliformin causes rapid death without obvious overt cellular damage, although acute degenerative lesions in the myocardium are reported.

Fumonisins

The most recently characterized mycotoxins of any major significance in human health are the fumonisins produced by species of *Fusarium*, such as *F. moniliforme*. Like a number of mycotoxins, the fumonisins are relatively heat stable and would not be significantly destroyed by drying processes for corn or heat treatments used for the production of maize derivatives. Fumonisin B_1 is water-soluble is known to be responsible for equine encephalomalacia, porcine pulmonary edema syndrome and hepatic cancer in rats and maybe involved in the epidemiology of esophageal carcinoma in humans in southern Africa and parts of China.

The range of regulatory limits for mycotoxins

Mycotoxin	Regulatory Limit (µg/kg)
Aflatoxins in foods	0-50
Aflatoxin M1in milk	0-0.5
Deoxynivalenol in wheat	1000-4000
Ochratoxin A in foods	1-300
Patulin in apple juice	20-50
T-2 Toxin	100
Zearalenone	30-1000

10.4 BOTULISM

Botulism (Latin *botulus*, sausage) is a neuro-paralytic disease caused by the ingestion of food containing the neurotoxin produced by *Clostridium botulinum*.

10.4.1 Occurrence

Clostridium botulinum is an anaerobic, Gram-positive, spore forming, rod that produces the potent neurotoxin. The organism and its spores are widely distributed in nature and occur in both cultivated and forest soils, bottom of streams, lakes and coastal waters and in the intestinal tracts of fish and mammals and in viscera of shellfish.

On the basis of the serological specificity of their toxins, seven types of *Clostridium botulinum* are recognized: A, B, C, D, E, F and G. Types A, B, E, F and G cause disease in humans; type C causes botulism in fowls, cattle, mink and other animals and type D is associated with forage poisoning of cattle. Being a saprophyte, the organism seldom grows or produces toxic in the live animal; it can do so only by growing in food. The toxins are simple heat labile proteins and can be destroyed if heated at 80ºC for 10 minutes or longer.

C.botulinum does not produce the fully toxic molecule; instead a progenitor toxin is activated to its full toxicity by enzymes. The progenitor toxin is hydrolyzed to the highly toxic derivative toxin and is carried to target nerves where it binds to the synapses of motor neurons and prevents the release of the neurotransmitter acetylcholine. As a consequence, muscles do not contract in response to motor neuron activity and flaccid paralysis results.

10.4.2 Types and Symptoms

Different types of botulism are recognized: adult, infant and wound. A very small amount (a few nano grams) of toxin can cause illness.

Adult Botulism

Symptoms of botulism may develop anywhere between 12 and 72 hours after the ingestion of toxin containing foods. Symptoms include nausea, vomiting, fatigue, dizziness and headache, dryness of skin, mouth and throat, constipation, lack of fever, paralysis of muscles, double vision and finally respiratory failure and death. The duration of the illness is from 1 to 10 or more days depending upon host resistance and other factors.

Infant Botulism

In the adult form of botulism, preformed toxins are ingested; in infant botulism, viable botulinal spores are ingested and upon germination in the intestinal tract, toxin is synthesized. It is confined to infants under a year of age. High number of spores are found in the feces of infants during the acute phase of the disease. It appears that ingested endospores, which maybe present in honey or other baby foods, germinate in the infants intestine. *C.botulinum* then multiplies and produces the exotoxin. The infant becomes constipated, listless, generally weak and eats poorly. Death may result from respiratory failure.

Wound Botulism

It is the rarest form of botulism. The illness results when *C.botulinum* by itself or with other microorganisms infects a wound and produces toxins which reach other parts of the body via the bloodstream. Foods are not involved in this type of botulism.

10.4.3 Diagnosis

Although botulism can be diagnosed by clinical symptoms alone, differentiation from other diseases maybe difficult. The most direct and effective way to confirm the clinical diagnosis of botulism in the laboratory is to demonstrate the presence of toxin in the serum or feces of the patient or in the food which the patient consumed.

10.4.4 Foods Implicated in Botulism

The types of foods involved in botulism vary according to food preservation and eating habits in different regions. Any food that is conducive to outgrowth and toxin production, that when processed allows spore survival, and is not subsequently heated before consumption can be associated with botulism. Almost any type of food that is not very acidic (pH above 4.6) can support growth and toxin production by *C.botulinum*. Botulinal toxin has been demonstrated in a considerable variety of foods, such as canned corn, peppers, green beans, soups, asparagus, mushrooms, spinach, tuna fish ham, sausage and smoked and salted fish.

10.4.5 Conditions Necessary for Outbreak

The following conditions are necessary for an outbreak of botulism:

1. Presence of spores of *C.botulinum* of type A, B or E in foods being consumed or being processed in some other way

2. A food in which the spores can germinate and the clostridia can grow and produce toxin

3. Survival of the spores of the organism eg: because of inadequate heating in canning or inadequate processing otherwise

4. Environmental condition after processing that will permit germination of the spores and growth and toxin production by the organism

5. Insufficient cooking of the food to inactivate the toxin

6. Ingestion of the toxin-bearing food

10.4.6 Prevention and Control

The prevention and cure of botulism involves:

1. Strict adherence to safe food-processing practices by the food industry
2. Educating the public on safe home-preserving (canning) methods for foods
3. Not feeding honey to infants younger than 1 year of age
4. Not tasting any processed food having a questionable odor
5. Recommended treatment for botulism includes early administration of botulinal antitoxin and intensive supportive care (including mechanical breathing assistance).

10.5 STAPHYLOCOCCAL FOOD POISONING

Staphylococcal food poisoning results from consumption of food containing enterotoxin produced by enterotoxigenic strains of *Staphylococcus aureus*. It is caused by ingestion of improperly stored or cooked food (particularly foods such as ham, processed meats, chicken salad, pastries and ice cream) in which *S.aureus* has grown.

S.aureus is a Gram-positive coccus, very resistant to heat, drying and radiation. If the bacteria are allowed to incubate in certain foods, they produce heat-stable enterotoxin that render the food dangerous. Six different enterotoxins have been identified and are designated as A, B, C, D, E and F.

10.5.1 Occurrence

Staphylococci exist in air, dust, sewage, water, milk and food or on food equipment, environmental surfaces, humans and animals. Humans and animals are the primary reservoirs. Staphylococci are present in the nasal passages and throats and on the hair and skin of 50 percent or more of healthy individuals. A wide range of foods maybe involved in Staphylococcal food poisoning including ham, turkey, chicken and chicken salad, baked products, especially filled pastries, table ready-meats (sausage etc.), precooked frozen foods and dairy products.

S.aureus cells are relatively more resistant than many gram negative food spoilage organisms. Human intoxication is caused by ingesting enterotoxins produced in food by strains of *S.aureus,* usually because the food has not been kept hot enough (60ºC, or above) or cold enough (7.2ºC, or below). In frozen foods they may survive at –10ºC. In general, survival of *S.aureus* is best in foods that contain high concentration of sugars, eggs and buffering component such as phosphates and protein. Salt concentration less than 9.5%, temperature more than 20ºC and a pH in the range 6-8 are favourable for growth and enterotoxin formation.

10.5.2 Symptoms

A toxin dose of less than one micro gram in contaminated food will produce symptoms of staphylococcal intoxication. This toxin level is reached when *S. aureus* populations exceed 100,000 per gram. Symptoms of staphylococcal food poisoning usually develop with 1-6 hours of ingestion of contaminated food. Typical symptoms include severe abdominal pain, diarrhoea, vomiting, sweating, headache, prostration, nausea and sometimes a fall in body temperature. The mortality rate of staphylococcal food poisoning is negligible among healthy individuals.

10.5.3 Diagnosis

Diagnosis is based on the symptoms or laboratory diagnosis of the bacteria from leftover foods and from the stool cultures of victims. Enterotoxin maybe detected in foods by animal toxicity tests.

10.5.4 Foods Incriminated

Foods that are frequently incriminated in staphylococcal food poisoning include meat and meat products, poultry and egg products, egg, tuna, chicken, potato and macaroni, bakery products like cream-filled pastries, cream pies, chocolate eclairs, sandwich fillings, milk and dairy products. Foods that require considerable handling during preparation and that are frequently involved in staphylococcal food poisoning.

10.5.5 Conditions Necessary for Outbreak

The following conditions are necessary for an outbreak of staphylococcal food poisoning:

1. The food must contain enterotoxin producing staphylococci.
2. The food must be a good culture medium for growth and toxin production by the staphylococci.
3. The temperature must be favourable for growth of the cocci and enough time must be allowed for production of enterotoxin.
4. The enterotoxin bearing food must be ingested.

10.5.6 Prevention and Control

Staphylococcal food poisoning can be prevented by:

1. Avoiding contamination of food with *S.aureus.*
2. Prevention of growth of staphylococci by adequate refrigeration of foods and adjustment of more acid pH.
3. Killing staphylococci in susceptible foods by heating rapidly to 65-70ºC for 12-15 minutes.
4. Good personnel hygiene- exudates from skin lesions (pimples, boils) and nasal discharges of food handlers are rich sources of staphylococci and should be avoided.
5. Prolonged storage at room temperature of filled pastries, meat, salads and similar products that receive only a minimal heat treatment should be avoided.

10.6 LET US SUM UP

The unit deals with the food borne intoxications which are caused by ingestion of toxins produced from molds (*Aspergillus niger*, *Penicillium* sp.) or bacteria (*C.botulinum* and *S. aureus*). An effort has been made to point out the major conditions required for outbreak of the disease along with the diagnosis and the preventive measures required to prevent the outbreak of disease.

10.7 KEY WORDS

Food Borne Intoxication : It is the food borne disease caused due to ingestion of food containing the toxin.

Mycotoxins : These are secondary metabolites produced by filamentous fungi (molds) on food and feedstuffs that cause illness and death when ingested by man or animals.

Aflatoxin : This is the mycotoxin elaborated by *Aspergillus flavus*.

Ochratoxin : Mycotoxin produced by *Penicillium verrucosum*.

Patulin : Mycotoxin produced by species of *Penicillin*, *Aspergillus* and *Paeciliomyces*.

Citrinin : Mycotoxin produced by *Penicillin citrinum*.

Botulism : Food borne intoxication caused due to consumption of food containing toxin, produced by *Clostridium botulinum*.

Staphylococcal Food Poisoning : Food borne intoxication caused due to consumption of food containing toxin, produced by *Staphylococcus aureus*.

LD_{50} Dose : Lethal Dose of toxin at which minimum 50% of the population may get infected by the toxin.

Zearalenone : Mycotoxin produced by *Fusarium graminearum* and *F. tricinctum.*

10.8 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1.
   - Mycotoxins are toxins (secondary metabolites) produced by filamentous fungi on food and feedstuffs that cause illness when ingested
   - Cause hepatotoxicosis, carcinogenesis, liver cirrhosis etc.
2. Biological effects of aflatoxin include hepatotoxicosis, carcinogenesis and liver cirrhosis.
3. Natural toxins in foods: Trypsin inhibitor, haemaglutenins, cyanogenic glycosides, saponins, alkaloids, goitrogens .

Check Your Progress Exercise 2

1.
   - Botulism is caused by the bacteria *Clostridium botulinum*.
   - All low acid foods can support growth and toxin production by *Clostridium botulinum*.
   - Unheated foods are causative agents e.g.: canned foods (canned corn, peppers, green beans, soups), sausages, smoked fish etc.
2.
   - Adult Botulism is prevalent amongst adults whereas Infant Botulism is prevalent in infants of less than one year of age.
   - Caused due to ingestion of viable spores of *C. botulinum.*
   - Symptoms in adults: Nausea, vomiting, fatigue, dizziness, headache, dryness of skin and respiratory failure
   - Symptoms in infants: Constipation, weakness and loss of appetite and in severe cases death
3. Mycotoxins associated with foods are:
   - Aflatoxins (produced by *Aspergillus flavus*)
   - Ochratoxin (produced by *Penicillium verrucosum*)
   - Patulin (*P. expansum*)
   - Citrinin (*Penicillin citrinum*)
   - Alternaria toxins (*Alternaria* sp.)
   - Penicillic acid (*P.cyclopium*)
   - Sterigmatocystin (*Aspergillus versicolor*)
   - Fusarium toxins (*Fusarium* sp)

Check Your Progress Exercise 3

1. Conditions necessary for outbreak of Staphylococcal food poisoning:

- Presence of viable staphylococcal bacteria in the food
- Growth and toxin production in food
- Toxin containing food must be ingested into the body

2. To prevent and control Staphylococcal food poisoning:

- Avoid contamination of foods
- Kill organism by heating, refrigeration
- Personnel hygiene
- Adequate cooking
- Proper storage

UNIT 11 BACTERIAL FOOD INFECTIONS

Structure

11.0 OBJECTIVES

After reading this unit, you will be able to:

- describe major bacteria causes food born infections
- explain the mode of transmission of the food borne infection, symptoms and preventive measures.

11.1 INTRODUCTION

Food infection occurs when a pathogen enters the gastrointestinal tract and multiplies. Microorganisms can penetrate into the intestinal mucosa and grow there, or they can pass through other systemic organs. Infections are characterized by a delay in the appearance of gastrointestinal disturbance while the pathogen increases in numbers or affects invaded tissue. There is also usually a fever, one of the body's general responses to an infective organism.

Foodborne infections remain a major public health problem. The Council for Agricultural Science and Technology estimated in its 1994 report, *Foodborne Pathogens: Risks and Consequences*, that as many as 9,000 deaths and 6.5 to 33 million illnesses in the United States each year are food-related.

11.1.1 Zoonotic Diseases

The World Health Organization defines Zoonoses (Zoonosis, sing.) as "Those diseases and infections which are naturally transmitted between vertebrate animals and man".

Mode of transmission: Feces, urine, saliva, blood, milk, via aerosol, oral, contact with bedding or animals, etc.

Approximately 150 zoonotic diseases are known to exist. Wildlife serves as a reservoir for many diseases common to domestic animals and humans. Persons working with wildlife should be alert to the potential for disease transmission from animals. Generally, disease is more easily prevented than treated. Many zoonotic diseases are so common in nature, so rare in humans, or so mild in their symptoms, that wild animals pose a minimal health risk to people.

Zoonotic diseases include:

- Those which can be transmitted directly from animals to humans (e.g. rabies).
- Diseases that can be acquired indirectly by humans through ingestion, inhalation or contact with infected animal products, soil, water, or other environmental surfaces which have been contaminated with animal waste or a dead animal (e.g. salmonellosis, leptospirosis, anthrax). *Campylobacter* infection is mainly found in chicken meat. Listeriosis and *E.coli* gastroenteritis are two other common infections caused by zoonotic agents. All these will be discussed one by one.
- A disease which has an animal reservoir, but requires a mosquito or other arthropod to transmit the disease to humans (e.g. St. Louis encephalitis, Rocky Mountain spotted fever).

11.2 SALMONELLOSIS

Salmonellosis is the most reported zoonotic disease in European countries. Salmonellosis (*Salmonella* gastroenteritis) results from the ingestion of foods that contain significant numbers of viable cells of the members of the genus *Salmonella*. It is the most frequently occurring food borne infection.

Salmonella are small gram negative, motile, non-spore forming rods that ferment glucose, usually with gas, but usually do not ferment lactose or sucrose. They are widely distributed in nature, with humans and animals being their primary reservoir. Generally large number of salmonellae typically 10^6 to 10^9 bacterium must be ingested to cause illness.

Occurrence: The initial source of the bacteria is the intestinal tract of animals such as birds, reptiles, farm animals, humans and occasionally insects. As intestinal form, the organisms are excreted in feces from which they maybe transmitted by insects and other living creatures to a large number of places, polluted water and contaminated food. The organism may get transferred from actual infected cases of the disease or from carriers. A carrier is defined as a person or an animal that repeatedly sheds bacteria, usually through feces, without showing any signs or symptoms of the disease. Infected rodents, rats and mice may contaminate unprotected foods with their feces and thus spread *Salmonella* bacteria. Flies may play an important role in the spread of *Salmonella*, especially from contaminated fecal matter to foods. Humans acquire the bacteria from contaminated food such as beef products, poultry, eggs, egg products or water.

Symptoms: The susceptibility of humans varies with the species and strains of the organism and the total number of bacteria ingested. A longer incubation period usually distinguishes salmonellosis from staphylococcus poisoning: usually 12-36 hours for the former and about 2-4 hours for the latter. The principle symptoms of a salmonella gastroenteritis infection are nausea, vomiting, abdominal pain and diarrhoea that usually appear suddenly. This may be preceded by a headache and chills. Other evidences of the disease are watery, greenish-fowl-smelling stools, prostration, muscular weakness, faintness, usually a moderate fever, restlessness, twitching and drowsiness. The mortality is less than 1%. Intesibility may vary from slight discomfort and diarrhoea to death in 2 to 6 days. About 0.2 to 5.0% of the patients may become carriers of the *Salmonella* organism. During the acute phase of the disease, as many as one billion salmonellae can be found per gram of feces.

Associated foods: Raw meats, poultry, eggs, milk and dairy products, fish, shrimp, coconut, sauces and salad dressings, cake mixes, cocoa, peanut butter and chocolate.

Conditions Necessary for Outbreak

The food must contain or become contaminated with the *Salmonella* bacteria.

These bacteria must be there in considerable numbers i.e., food should be a good culture media, temperature favourable and enough time allowed for appreciable growth.

The viable organism must be ingested.

Prevention of Outbreak: The control of food borne salmonella infection requires the following:

1. Preventing food contamination by human carriers, especially food handlers.
2. Avoiding the use of animal products from domestic livestock that are grossly infected with salmonellae.
3. Avoiding the use of food ingredients that contain salmonellae.
4. Processing all foods susceptible to *Salmonella* contamination at time-temperature schedules sufficient to destroy the organism. Heating foods so that all portions reach 66ºC for 12-15 minutes will assure destruction of even most resistant *Salmonella* types.
5. Refrigerating all foods susceptible to *Salmonella* contamination and avoiding prolonged holding of these foods at room temperature.

11.3 ENTEROPATHOGENIC *ESCHERICHIA COLI*

Escherichia coli is generally regarded as part of the normal flora of the human intestinal tract and that of many animals. Serotypes of *E. coli* which have been implicated in human diarrhoeal diseases or food poisoning outbreaks and have been designated enteropathogenic *E. coli* (EEC). They grow over a wide range of temperatures, 20-40ºC with a minimum growth temperature at 10ºC and an optimum at 37ºC. Heating at 65ºC for 15-20 minutes is lethal. The pH range for growth is 4.2-8.50, with an optimum in the range of pH 7.2-7.5. *E. coli* will grow in the presence of 5.0% salt at 37ºC but 10% is inhibitory.

Symptoms: The *E. coli* gastroenteritis syndrome is caused by the ingestion of 10^6-10^{10} viable cells/g that must colonize the small intestine and produce enterotoxin. The syndrome is characterized primarily by non-bloody, watery diarrhoea without inflammatory exudates in stools. Incubation time of disease is around 2 days after eating the contaminated food and may last for 8 days. Common symptoms included are cramps, chills, vomiting, aches and headache.

Associated Foods: *E. coli* is the etiologic agent of food poisoning involves variety of foods such as cream pie, mashed potatoes, cream puffs and creamed fish. Other *E. coli* food poisoning outbreaks have been attributed to the consumption of milk, cheese, ice cream, meats, fish and macaroni. *E. coli* is relatively sensitive to destruction by drying or freezing but some survivors may exist for extended periods.

“Enteropathogenic” strains colonize in the small intestine and cause acute gastroenteritis in newborns and in infants up to two years of age. “Enteroinvasive” strains invade the epithelial cells of large intestine and cause diarrhoea in older children and adults. “Enterotoxigenic” (enterotoxin producing) strains produce one or both of two different toxins:a heat stable toxin (ST) and a heat labile toxin (LT). Both toxins cause diarrhoea in adults and infants. Enterotoxigenic strains of *E. coli* are often associated with Travellers’ diarrhoea, a common disease contracted by tourists when visiting developing countries. Diagnosis of travellers’ disease is based on the past travel history and symptoms. Laboratory diagnosis is by isolation of the bacteria from feces. Treatment is with fluid and electrolytes. Other strains of *E. coli* which are usually harmless in their normal habitat (the intestine) can cause disease when they gain access to other sites or tissues. These diseases include urinary tract infections, septic infections, bacteremia, meningitis, pulmonary infections, abscesses, skin and wound infections.

Prevention and Control: Involves avoiding contaminated food and water that have high coliform counts, avoiding unpasteurized juices, washing fresh fruits and vegetables thoroughly before eating raw, using adequate cooking procedures for destruction and prompt refrigeration. Most people recover from *E. coli* infection within 5-10 days without treatment. Antibiotics and antidiarrhoeal drugs are usually not helpful.

11.4 *BACILLUS CEREUS* GASTROENTERITIS

Bacillus cereus is not a common cause of food poisoning. It is a Gram positive, aerobic, spore forming rod shaped bacteria normally present in soil, dust and water. The bacterium has a minimum growth temperature around 4-5ºC, with maximum around 48-50ºC. Optimum pH range for growth is 4.9 to 9.3.

Symptoms: Extremely large numbers (10^8 per gram) of viable cells of *B.cereus* must be ingested to develop signs and symptoms of the syndrome. The bacterial cells produce intoxication characterized by acute abdominal pain, flatulence and watery diarrhoea. Headache and dizziness are common, dehydration and prostration may occur but nausea, vomiting, fever and chills are rare. The illness appears within 6-15 hours after consumption of food and the symptoms usually last less than 24 hours.

Associated Foods: Vehicle foods consist of cereal dishes that contain corn and corn starch, mashed potatoes, vegetables, minced meat, liver sausage, milk, cooked meat. Food mixtures such as sauces, puddings, soups, pastries and salads have frequently been incriminated in outbreaks.

11.5 CHOLERA

Cholera is caused by the gram negative, *V. cholerae*, which is acquired by ingesting food or water contaminated by fecal material from patients or carriers (shellfish and plankton may be the natural reservoir).

Symptoms: Once the bacteria enter the body, the incubation period is from several hours to three or more days. An infective dose of around one million organisms should be ingested to cause illness. The bacteria adhere to the small intestine wall, where they secrete the cholera enterotoxin, choleragen. As a result, there is hyper secretion of water and chloride ions, while inhibiting absorption of sodium ions. The patient experiences an outpouring of fluid and electrolytes with associated abdominal muscle cramps, vomiting, fever and watery diarrhoea. The diarrhoea can be so profuse that a person can lose 10-15 liter of fluid during the infection. Death may result from the elevated concentration of blood proteins, caused by reduced fluid levels, which leads to circulatory shock and collapse. Onset of the illness is generally sudden, with incubation periods varying from 6 hours to 5 days.

Associated Foods: Cholera is generally a disease spread by poor sanitation, resulting in contaminated water supplies. Sporadic cases occur when shellfish harvested from fecally polluted coastal waters are consumed raw.

Diagnosis: Cholera can be confirmed only by the isolation of the causative organism from the diarrheic stools of infected individuals.

Prevention: Following recommendations are there to prevent cholera outbreak:

- Drink only water that you have boiled or treated with chlorine or iodine. Other safe beverages include tea and coffee made with boiled water and carbonated, bottled beverages with no ice.
- Eat only those foods that have been thoroughly cooked and are still hot, or fruit that you have peeled yourself.
- Avoid undercooked or raw fish or shellfish.
- Make sure all vegetables are cooked, avoid salads.
- Avoid foods and beverages from street vendors.

A simple thumb rule is **“Boil it, cook it, peel it, or forget it”**.

Control: Individuals infected with cholera require oral rehydration therapy with NaCl plus sucrose, sodium bicarbonate and potassium chloride to stimulate water uptake by the intestine. The antibiotics of choice are a tetracycline or aproflaxin. The most reliable control methods are based on proper sanitation, especially of water supplies. The mortality rate without treatment is often over 50%. Medical treatment to prevent dehydration prevents all complications.

11.6 *VIBRIO PARAHAEMOLYTICUS* GASTROENTERITIS

While most other known food poisoning syndromes may be contracted from a variety of foods, *V. parahaemolyticus* gastroenteritis is contracted almost solely from seafood. It can grow in presence of 1-8% NaCl, in pH range 9.8-11.0 with 7.6-8.6 being optimum.

Symptoms: A total of greater than one million organisms may cause disease. Symptoms of intoxication which range from mild to severe and fatal, include abdominal pain, which maybe intense; a burning sensation of the stomach; vomiting and diarrhoea with watery stools and sometimes bloody discharges; fever. The mean incubation period is in range of 3-76 hours after the ingestion of the organism.

Associated foods: Vehicle foods for outbreak are raw, improperly cooked, or cooked, recontaminated seafoods, such as, oysters, shrimps, crabs, lobsters, clams and related shellfish. Cross-contamination may lead to other foods as vehicles. Improper refrigeration of seafoods contaminated with this organism will allow its proliferation, which increases the possibility of infection.

Diagnosis: Diagnosis of gastroenteritis caused by this organism is made by culturing the organism from the diarrheic stools of an individual.

Prevention: Consumption of raw or improperly cooked seafoods should be avoided as they are susceptible to infection by *V. parahaemolyticus.*

11.7 SHIGELLOSIS

Shigellosis or bacterial dysentery, is caused by facultatively anaerobic, gram-negative, non-spore forming, rod-shaped organisms belonging to the genus *Shigella* within the family enterobacteriacae. In general, shigellosis is a self-limiting disease, lasting 5 to 6 days if untreated, however in young malnourished children, the elderly and the immuno compromised (eg, AIDS patients), the disease may be fatal. It is estimated that shigellosis is responsible for the death of 500,000 children worldwide each year. There are many points of similarity between *Shigella* and *Salmonella*. They dwell primarily in the gastrointestinal tract, with optimum temperature of 37ºC, grow both aerobically and anaerobically they grow freely in warm, bland, moist foods. But unlike salmonellae, the shigellae have no flagella and thus are non-motile. The species involved are *Shigella sonnei, S. dysenteriae, S. flexineri* and *S. boydii*. As few as 10cfu of *S. dysenteriae* are known to initiate infection in susceptible individuals. The illness caused by *Shigella* accounts for less than 10% of the reported outbreaks of food borne illness in US. The organisms tolerate salt concentration of 5-6% and are relatively heat sensitive.

Occurrence: Poor personal hygiene is a common factor in food borne shigellosis, with shellfish, fruits and vegetables, chicken and salads being prominent among vehicle foods. The prominence of these foods is due to the fecal-oral route of transmission. Outbreaks have been also traced to foods such as chocolate pudding, salads.

Symptoms: Pathogenicity involves the release of lipopolysaccharide endotoxin which infects the intestinal mucosa. Shigellosis ranges from fairly mild to very severe and fatal. The onset is usually abrupt, requiring from 1-7 days of incubation, but sometimes requiring as many as 14 days. Symptoms are abdominal pain and cramps caused by inflammation of mucus surface of large intestine, nausea, diarrhoea, vomiting, elevated temperature. The mortality associated with *S. dysenteriae* infection is around 20% but it is much lower with other species. In severe instances, excessive diarrhoea leads to electrolytic imbalance in the bloodstream and ulceration in large intestine. There may be kidney failure, jaundice and persistent internal bleeding. The infection is localized and organs other than the large intestine are not invaded.

Diagnosis: Serological identification of culture isolated from stool helps to diagnose the disease.

Prevention and Control: The control of *Shigella* food borne infection is similar to that of salmonellae; avoiding contamination of foods by animal or human carriers or their excrement, thorough cooking and prompt cooling. Proper personal hygiene should be maintained. In severe cases of shigellosis, dehydration of the body may necessitate intravenous replacement of fluid with electrolytes. Ampicillin antibiotic can decrease the duration of the disease.

11.8 CAMPYLOBACTERIOSIS

It is caused by *Campylobacter jejuni*, a Gram negative rod. It is a microaerophillic organism, which means it has a requirement for reduced levels of oxygen. It is often isolated from healthy cattle, chickens, birds and even flies. It is also sometimes present in non-chlorinated water sources such as streams and ponds. The bacteria cause between 5 and 14 per cent of all diarrhoeal illnesses worldwide. C. jejuni primarily affects children under 5 years old and young adults (15-29 years old).

Symptoms: *C. jejuni* infection causes diarrhoea, which may be watery or sticky and can contain blood and fecal leukocytes (white cells). Other symptoms often present are fever, abdominal pain, nausea, headache and muscle pain. The illness usually occurs 2-5 days after ingestion of the contaminated food or water. Illness generally lasts 7-10 days, but relapses are not uncommon (about 25% of cases). Most infections are self-limiting and are not treated with antibiotics. The infective dose of *C. jejuni* is considered to be 400-500 bacteria.

Associated Foods: *C. jejuni* frequently contaminates raw chicken. Survey shows that 20-100% of retail chickens are contaminated. Many healthy chickens carry these bacteria in their intestinal tracts. Raw milk is also source of infections. The bacteria are often carried by healthy cattle and by flies on farms. Non-chlorinated water may also be a source of infection.

Prevention: the various ways to prevent campylobacteriosis are:

- Wash hands before preparing foods.
- Wash hands immediately after handling raw poultry or other meat.
- Proper cooking of chicken to internal temperature of 170ºC.
- Drink pasteurized milk and chlorinated water.
- Wash hands after handling pet feces or visiting zoos.

Control: If a person is suffering from campylobacteriosis, he can take an antibiotic such as ciproflaxin or azithromycin. Erythromycin also helps to treat the diarrhoea. Those having diarrhoea should take plenty of water.

11.9 YERSINIOSIS (*YERSINIA ENTEROLYTICA* INFECTION)

In the genus Yersinia, 11 species are recognized, including *Y. pestis*, the cause of plague. The species of primary interest in foods is *Y. enterolytica*.

Occurrence: *Y. enterolytica* is widely distributed in the terrestrial environment and in lake, well and stream waters which are sources of warm-blooded animals. It is more animal adapted and is found more often among human isolates than the other species.

Animals from which *Y. enterolytica* has been isolated include cats, birds, dogs, beavers, guinea pigs, rats, camels, horses, chickens, deer, cattle, swine, fish and oysters. It is widely believed that swine constitutes the single most common source of *Y. enterolytica* in humans.

In addition to gastroenteritis, this organism has been associated with human pseudoappendicitis, mesenteric lymphadenitis, reactive arthritis, colon and neck abscesses and cholecystis. It has been recovered from urine, blood, cerebrospinal fluid and the eyes of infected individuals. It is also recovered from the stools of gastroenteritis victims.

Associated Foods: The organism has been isolated from cakes, vacuum-packaged meats, seafood, vegetables, milk and other food products. It has been isolated also from beef, lamb and pork. Of all sources, swine appears to be the major source of pathogenic for humans.

Symptoms: Symptoms of the gastroenteritis syndrome develop several days following ingestion of contaminated foods and are characterized by abdominal pain and diarrhoea. Children appear to be more susceptible than adults and the organism may be present in stools for up to 40 days following illness. A variety of systemic involvements may occur as a consequence of the gastroenteritis syndrome.

The usual symptoms, including severe abdominal pain, fever and diarrhoea occur 24 to 36 hours after consumption of the product. The abdominal discomfort is quite specific and usually manifests itself as a sharp pain in the lower right quadrant of the abdomen. For this reason it has frequently been described as pseudoappendicitis.

Although the organism has been isolated from many foods, there have been relatively few food-borne outbreaks attributed to *Y. enterolytica*. The isolation from pasteurized milk is probably the result of post pasteurization contamination. The unique characteristic of the organism is its ability to grow at commercial refrigeration temperatures, i.e. less than 5ºC.

11.10 *LISTERIA MONOCYTOGENES* INFECTION (LISTERIOSIS)

Listeria monocytogenes is a gram-positive, motile, non-sporing rod. It is widely distributed in nature and can be found on decaying vegetation and in soils, animal feces, sewage, silage and water. In cattle it can result in abortion and mastitis and the infected animals shed the organism in milk. Other infected organisms including sheep and chicken can serve as source of the organism in the food supply.

Syndrome: Listeriosis in humans is not characterized by a unique set of symptoms since the course of the disease depends upon the state of the host. Non-pregnant healthy individuals who are not immunosuppressed are highly resistant to infection by *L. monocytogenes*. When susceptible adults contract the disease, meningitis and sepsis are the most commonly recognized symptoms. Pregnant females who contract the disease may not present any symptoms, but when they do, they are typically mild and influenza-like. Abortion, premature birth or still birth is often the consequence of listeriosis in pregnant females. When a newborn is infected at the time of delivery, listeriosis symptoms typically are those of meningitis and they begin at 1 to 4 weeks after birth, although a four week incubation has been recorded. The usual incubation time in adults ranges from one to several weeks.

Since *L. monocytogenes* can grow over the temperature range of about 1° to 45°C and the pH range 4.1 to around 9.6, it maybe expected to survive in foods for long periods of time.

Some of the ways in which *L. monocytogenes* is disseminated throughout the environment, along with the many sources of the organism to humans, are illustrated below.

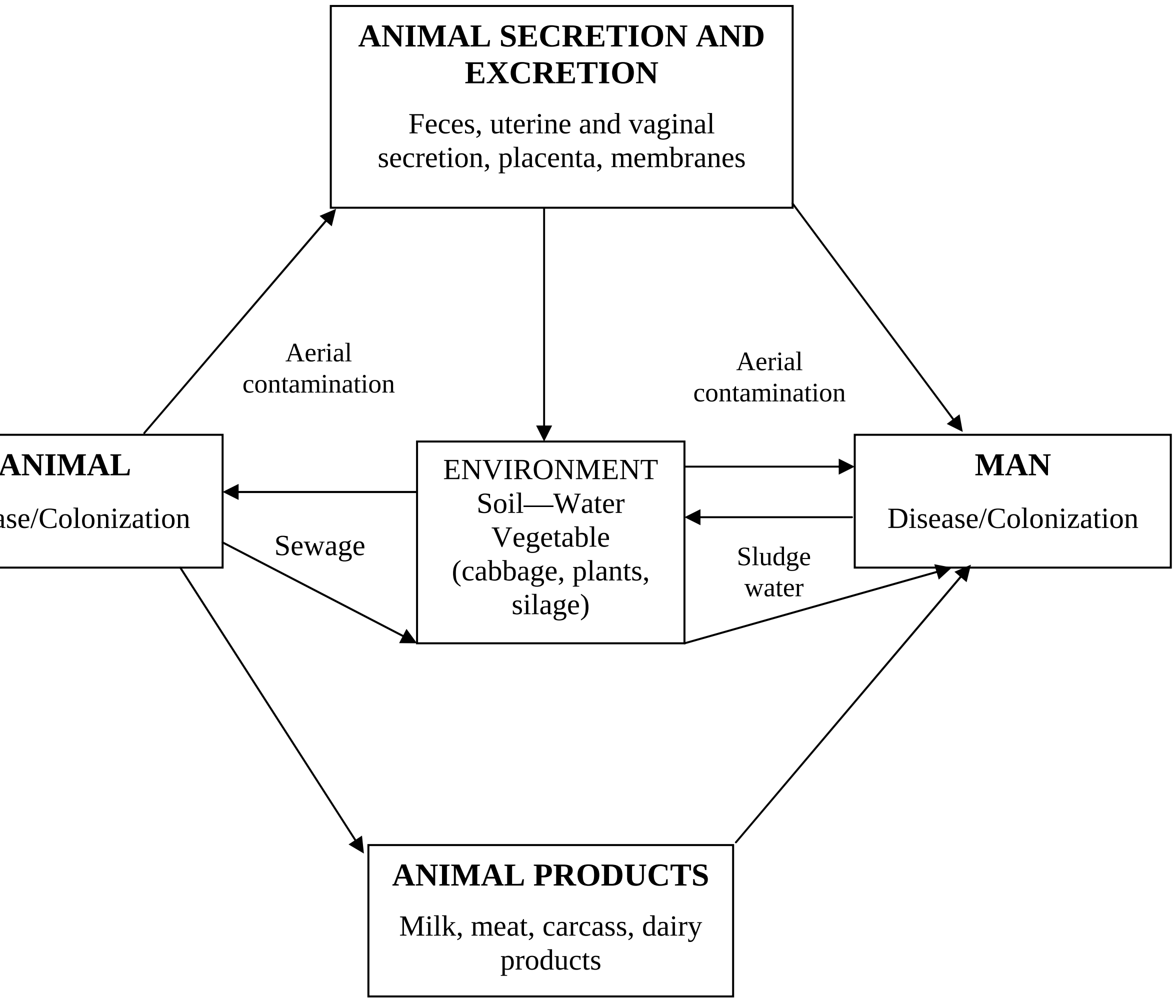

Figure 13.1: Ways in which *L. monocytogenes* is disseminated in the environment, animals, foods and humans

Tips on Foodborne Illness Prevention for Consumers

Salmonella, Escherichia coli, Shigella, Campylobacter, Listeria, and the list goes on. Interesting names for little organisms that can cause big bad health problems. Bacterial foodborne diseases have become an acute public health crisis in this country, responsible for about 6.5 to 81 million illnesses and 9,000 deaths per year. While it is unrealistic to think there would ever be a zero level of contamination in our food supply, 90% - 95% of all foodborne bacterial illness is preventable. You cannot see, taste, or smell most bacterial foodborne problems, so here's what you can do to safeguard your family.

In General:

- Don't ever consume products such as unpasteurized milk or unpasteurized apple cider or other foods made with unpasteurized products. Thoroughly cook all meat, poultry and fish products. Meats are thoroughly cooked at 71ºC, poultry at 82ºC, and fish when they easily flake with a fork.
- Break open any hamburger patties (other ground meat dishes such as meatballs, too) prior to ingestion to make sure there is no pink meat and that the juices run clear.

When Dining Out

- Hot food should be served hot and cold food should be served cold or send it back.
- Talk to the restaurant manager. Find out how much importance they place on sanitary and bacterial issues. Do they routinely use thermometers? Do

they own and routinely use a thermocouple which is a special thermometer used to accurately test temperatures of thin food? If you receive undercooked food (especially ground meat) express your displeasure and nicely inform them of the risks. Let them know how important food safety is to you.

When Shopping

- Take great care to avoid dripping raw juice from meat, poultry or fish onto your hands or other foods, especially produce. Raw juices often contain bacteria.
- Shop for cold and frozen foods last and take them immediately home to the refrigerator or freezer. Use ice chests in your car during transport, especially in the summer months or when running errands.
- Buy food only if it is in good condition. Frozen foods should be solid, refrigerated case food should be well-chilled, and canned goods should be free of dents and bulging lids. Point out any problems to the store manager.

When in your Kitchen

- Always wash your hands in hot soapy water before food preparation and after handling raw meat, poultry or fish.
- Keep your refrigerator's temperature as cold as possible without freezing your milk or produce (approximately 4°C). Keep your freezer's temperature cold enough to keep frozen food rock hard (approximately -18°C). If you are ever in doubt, temperatures can be checked with an appliance thermometer.
- After shopping, put any fresh meat, poultry, or fish, which won't be use within the next few days directly into the freezer.
- Thaw frozen food in the refrigerator or in a microwave followed by immediate cooking. ***Do not thaw food at room temperature on the counter***.
- Take great care to avoid dripping of raw meat, poultry, or fish juices onto or into other foods in the refrigerator. Use plates, platters or containers under them if necessary.
- Never put cooked food back on a plate/container which has had fresh juices on it. For example, when barbecuing take out an extra platter to put the grilled food on.
- Use non-porous plastic cutting boards for preparation and cutting of meat, poultry, and fish.
- Wash all cutting boards surfaces, platters, and containers which fresh meat, poultry, and fish have come in contact with, in hot, soapy water thoroughly before using for other foods.
- Avoid cross contamination by washing kitchen towels after contact with raw juices and by replacing sponges often. *Use paper towels wherever you can.* A good disinfectant for utensils and countertops is one tablespoon household bleach in few litres of water.

- When using eggs, cook them until firm. Don't use recipes calling for only partially cooked eggs. For example, raw cookie dough could be dangerous.

When using the microwave remember there can be cold spots, so stir and rotate food for thorough cooking.

11.11 THE MOST IMPORTANT POINT TO REMEMBER IS TO WASH YOUR HAND

Preferably with antibacterial soap for at least 20 seconds....

- ***before food preparation***
- ***after fresh meat, poultry, or fish handling and before you then touch other food, eat, or prepare baby bottles***
- ***after using the bathroom***
- ***after changing diapers***
- ***after helping toddlers in the bathroom***
- ***after cleaning the bathroom***
- ***after handling pets, cleaning litter boxes or dog runs***

PLEASE REMEMBER: Foodborne bacterial illness can be very contagious. This is called secondary transmission where a person gets ill not from ingesting the contaminated food but from coming in close contact with someone who has. Secondary transmission has been documented in the home, in day care centres, in preschools, in schools, in hospitals, and in senior citizen facilities. When someone you know has diarrhoeal illness, use extreme sanitary measures, to guard against the spread of the disease. The use of anti-diarrhoeal medication for treatment of foodborne bacterial diarrhoea is not recommended and in some cases can be harmful. If symptoms are severe, see your doctor. If food poisoning is suspected, call your local health department. Your prompt action could help prevent someone else from getting ill.

11.12 LET US SUM UP

In this unit, we attempted to familiarize you with certain outbreaks of bacteria which are responsible for food borne infections. We hope that you will be able to know the various bacteria which cause food borne infections. You will also be able to differentiate in the symptoms of the diseases caused and list the main reasons for the outbreak of the infections. This unit would also have helped you to know the information regarding the prevention of the outbreaks of the disease.

11.13 KEY WORDS

Food Infection : Food borne disease caused due to ingestion of large number of viable organisms which cause disease.

Zoonotic Diseases : Those diseases and infections which are naturally transmitted between vertebrate animals and man.

Salmonellosis	:	Food borne infection caused by *Salmonella gastroentritis*.
Enterotoxigenic *E. coli*	:	*E. coli* which produce toxins in the intestine.
Cholera	:	Food borne infection caused by *Vibrio cholarae*.
Shigellosis	:	Food borne infection caused by *Shigella sonnei*, *S. dysenteraei*.
Yersiniosis	:	Food borne infection caused by *Yersinia enterolytica*.
Listeriosis	:	Food borne infection caused by *Listeria monocytogenes*.

11.14 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. • Salmonella food infection is caused by *Salmonella gastroenteritis*.
   - Transmitted by fecal contamination of foods.
   - Incubation period 12-36 hours.
   - Symptoms: nausea, vomiting, diarrhoea, abdominal pain and green watery stools.
   - About 10^6-10^9 organisms must be ingested to cause infection.
   - *Salmonellosis* prevented by: prevention of contamination of food by Salmonella, avoiding intake of contaminated food and by destruction of organism at 66ºC for 12-15 min.

2. Prevention of Food borne infections:
   - Avoid consumption of contaminated foods and water
   - Eat properly cooked foods
   - Wash raw fruits and vegetables properly
   - Proper hygiene

Check Your Progress Exercise 2

1. • Bacillary dysentery is caused by *Shigella* sp. (*Shigella sonnei, S. dysenteraei).*
   - Incubation period is about 1 to 7 days.
   - Causes abdominal pain, cramps, inflammation of intestinal mucousa, diarrhoea, vomiting, nausea and fever.
   - In severe cases; intestinal bleeding, electrolytic imbalance, ulceration, kidney failure and jaundice.

2. • Campylobacteriosis incubation period: 2-5 days after ingestion of contaminated food.

- Symptoms: Diarrhoea containing blood, fever, abdominal pain, nausea, headache and muscle pain.
- Transmission of infection by raw chicken, raw milk and non-chlorinated water.

Check Your Progress Exercise 3

1. • Yersiniosis caused by the bacteria *Yersinia enterolytica*.
   • Causes severe abdominal pain, fever and diarrhoea.
2. • Listriosis caused by *Listeria monocytogenes* infection.
   • Transmitted by animal excretions (fecal matter) and secretions, infected vegetables, aerial contamination, sewage, sludge, polluted water, rivers and infected animal products like milk and milk products, meat, fish etc.

UNIT 12 CHEMICAL

Structure

12.0 OBJECTIVES

After studying this unit, you should be able to:

- know about different types of chemical preservatives; and
- define the essential chemical preservative limits for the various foods.

12.1 INTRODUCTION

In this unit we will make you aware about the characteristics of various chemical preservatives with special stress on antimicrobial food preservatives. We will also brief you about different chemical preservatives permitted in processed products along with maximum levels of antimicrobials permitted in foods. You will also learn about various factors which determine/ influence the action of chemical food preservatives.

12.1.1 Need for Food Preservation

Unless you grow all your food in your own garden and prepare all your meals from scratch, it's almost impossible to eat food without preservatives added by manufacturers during processing.

Food preservation is a method of preparing food so that it can be stored for future use. Because most foods remain edible for only a brief period of time, people since the earliest ages have experimented with methods for successful food preservation. Among the products of early food conservation were cheese and butter, raisins, pemmican, sausage, bacon, and grain. Scientific investigations pointed that food spoilage was mainly caused by microorganisms widely distributed in the environment. Therefore, food preservation depends on rendering conditions unfavourable for microbial growth

12.1.2 Techniques of Food Preservation

The techniques of food preservation can be separated into two groups:

- physical
- chemical

Physical methods of preservation rely on killing the microorganisms present, or at least stopping their growth for long enough to allow the food to be safely consumed. The physical methods include canning, freezing, drying, gamma irradiation, ultraviolet or high intensity white light, ultra high pressure and filtration.

Chemical food preservatives are substances which, under certain conditions, either delay the growth of microorganisms without necessarily destroying them. These are added in very low quantities and which do not alter the organoleptic and physico-chemical properties of the foods at or only very little. These work either as direct microbial poisons or by reducing the pH to a level of acidity that prevents the growth of microorganisms.

12.2 CHARACTERISTICS OF CHEMICAL PRESERVATIVES

The Food, Drug, and Cosmetic Act permit for the use of chemical preservatives in foods if the chemical is:

1. Generally recognized as safe (GRAS) for such use; or if a food additive is covered by food additive regulations prescribing conditions of safe use.
2. Not used in such a way as to conceal damage or inferiority or to make the food appear better or of greater value than it is.
3. Properly declared on the label of the food in which used.
4. It should be food grade.
5. It should perform its intended function.
6. It should be used in accordance with good manufacturing practices and, where applicable, in accord with existing food additive regulations.

According to rules, a food manufacturer must get approval from Government regulatory authorities before using a new preservative, or before using a previously approved preservative in a new way or in a different amount. In its petition for approval, the manufacturer must demonstrate that the preservative is safe for consumers, considering:

- the probable amount of the preservative that will be consumed with the food product, or the amount of any substance formed in or on the food resulting from use of the preservative
- the cumulative effect of the preservative in the diet
- the potential toxicity (including cancer-causing) of the preservative when ingested by humans or animals.

- A preservative may not be used to deceive a consumer by changing the food to make it appear other than it is. For example, preservatives that contain sulfites are prohibited on meats because they restore the red colour, giving meat a false appearance of freshness.
- The food additive regulations require the preservative to be of food grade and be prepared and handled as a food ingredient.
- The quantity added to food must not exceed the amount needed to achieve the manufacturer's intended effect.

Regulations about the use of nitrites demonstrate the scrutiny given to the use of additives. Nitrites, used in combination with salt, serve as antimicrobials in meat to inhibit the growth of bacterial spores that cause botulism, a deadly food-borne illness. Nitrites are also used as preservatives and for flavouring and fixing colour in a number of red meat, poultry, and fish products. Since the original approvals were granted for specific uses of sodium nitrite, safety concerns have arisen. Nitrite salts can react with certain amines (derivatives of ammonia) in food to produce nitrosamines, many of which are known to cause cancer. A food manufacturer wanting to use sodium nitrites must show that nitrosamines will not form in hazardous amounts in the product under the additive's intended conditions of use. For example, regulations specify that sodium nitrite, used as an antimicrobial against the formation of botulinum toxin in smoked fish, must be present in 100 to 200 parts per million. In addition, other antioxidants, such as sodium ascorbate or sodium erythorbate, may be added to inhibit the formation of nitrosamines.

12.3 CLASSIFICATION OF PRESERVATIVES

Preservatives can be categorized into following types:

1. Antimicrobials that inhibit growth of bacteria, yeasts, or molds.
2. Antioxidants that slow air oxidation of fats and lipids, which leads to rancidity.
3. Antienzymatic that blocks the natural ripening and enzymatic processes that continue to occur in foodstuffs after harvest.
4. Preservatives from natural products.
5. Traditional preservatives

We will discuss the first type of preservatives in detail but before that brief description of other types is given below for the sake of awareness.

12.3.1 Antioxidant Preservatives

As antioxidants, they keep foods from becoming rancid, browning, or developing black spots. Rancid foods may not make you sick, but they smell and taste bad. Antioxidants suppress the reaction that occurs when foods combine with oxygen in the presence of light, heat, and some metals. Antioxidants also minimize the damage to some essential amino acids--the building blocks of proteins--and the loss of some vitamins.

Antioxidant preservatives, such as butylated hydroxytoluene, butylated hydroxyanisole, *tert*-butylhydroquinone, and propyl gallate, stop the chemical breakdown of food that happens in the presence of oxygen. Unsaturated fatty acids in oils and lipids are particularly susceptible to autooxidation. In this process, a free radical initiates peroxide formation at fatty acid double bonds. The chain reaction propagates to other double bonds, and aldehyde, ketone, and acid-termination products eventually build up to create the rancid off-flavors characteristic of oils and fats gone bad. Antioxidant preservatives sop up the free radicals that help initiate and propagate these reactions.

12.3.2 Preservatives that Targets Enzymes

These are preservatives that target enzymes in the food itself that continue to metabolize after harvest. The enzyme phenolase, for example, goes to work as soon as an apple or potato is cut. It browns the exposed surface. Acids such as citric acid and ascorbic acid (vitamin C) inhibit phenolase by making the pH uncomfortably low for the enzyme. Metal-chelating agents such as EDTA (ethylenediamine tetraacetic acid) can remove the metal cofactors that many enzymes need. Chelators also make it difficult for bacterial and fungal enzymes to carry on.

12.3.3 Preservatives from Natural Products

Some of the newest antimicrobials have been found in microorganisms themselves as they form their own chemical defenses when competing with each other for space and nutrients. For example, nisin and natamycin, the cheese preservatives called bacteriocins – are harvested from microorganisms. In the U.S., nisin is used to inhibit outgrowth of *Clostridium botulinum* spores (the cause of botulism) and toxin formation in pasteurized process cheese spreads with fruits, vegetables or meats at levels not exceeding good manufacturing practice. Current good manufacturing practice in this case is the quantity of the ingredient that delivers a maximum of 250 p.p.m. of nisin in the finished product. Nisaplin-brand nisin is also approved for liquid egg products, dressings, and sauces. In other countries it is also used in fresh and recombined milk, fermented beverages like beer, canned foods, frozen desserts, and high moisture/reduced fat foods. Nisin is considered effective at controlling a wide range of gram-positive organisms including: *Listeria enterococcus*, *Bacillus sporothermodurans*, and *clostridium*. Used alone, it is not effective on gram-negative bacteria (like *E. coli*), yeasts, and molds. However, research suggests that it may be useful against some gram-negative bacteria when used in conjunction with other preservatives.

12.3.4 Traditional Chemical Food Preservatives

Traditional chemical food preservatives and their use in fruit and vegetable processing technologies are common salt and sugar.

Common salt used in brined vegetables. There is no limit for their use.

Sugars (sucrose, glucose, fructose and syrups): foods preserved by high sugar concentrations such as jellies, preserves, syrups, juice concentrates. It acts by interaction of sugar with other ingredients or processes such as drying and heating. There is no limit for their use.

12.4 ANTIMICROBIAL PRESERVATIVES

Usually accepted chemical food preservatives are detailed in Table 12.1.

Table 12.1: Commonly used antimicrobial chemical food preservatives

Agent	Acceptable Daily intake (mg/Kg body weight)	Commonly used levels (%)	Typical usage
Sorbic acid Potassium sorbate	25	0.05-0.2	fruits; vegetables; pickled products; jams, jellies
Benzoic acid Sodium benzoate	5	0.03-0.2	Vegetable pickles; preserves; jams; jellies; semi-processed products
Propionic acid Sodium propionate	10	0.1-0.3	Bakery goods, cheese spread, fruits, vegetables
Methyl paraben Ethyl paraben Propyl paraben	10	0.05-0.1	Bakery goods, fruit products; pickles; sauces
Lactic acid	No limit	No limit	Fermented meat, dairy and vegetable products, sauces and dressings, drinks.
Citric acid	No limit	No limit	fruit juices; jams; other sugar preserves
Acetic acid	No limit	No limit	vegetable pickles; other vegetable sauces, chutney
Sodium nitrite	0.2	0.01-0.02	Meat products
Sulphur dioxide	0.7	0.005-0.2	fruit juices, dried / dehydrated fruits and vegetables, semi-processed products

12.4.1 Organic Acids and Esters

Sodium Benzoate and Benzoic Acid

Benzoic acid is the compound with the antimicrobial properties, and is found naturally in cranberries, prunes, greengage plums, cinnamon, ripe cloves and apples. Sodium benzoate produces benzoic acid once it is dissolved in water.

Sodium benzoate is the sodium salt of benzoic acid and is preferred over benzoic acid in many food applications because it is 180 times more soluble in water. There is a marked pH effect for this preservative: the lower the pH, the more effective it is. Sodium benzoate will only work if the food product has a pH below 4.5; that is, if the food is naturally acidic or has been acidified.

For example, at pH 3.0 you only need approximately 0.05% of the compound to achieve the same antimicrobial effect as pH 4.0 and 0.1% benzoate. Optimum functionality occurs when the pH is between 2.5 and 4.0.

Sodium benzoate is used in fruit products, jams, relishes, beverages, dressings, salads, pie and pastry fillings, icings, olives and sauerkraut, and is effective against yeasts, some bacteria (food borne pathogens but not spoilage bacteria) and some molds. Sodium benzoate is a white granular or crystalline powder, odorless, inexpensive (at the usage level) and should be stored in a cool, dry place in watertight containers, if possible. It should be used at low levels to avoid possible off-flavours in some products. The maximum level allowable by law is 0.1%.

Sorbates

This family of compounds are available as sorbic acid, potassium sorbate, sodium sorbate or calcium sorbate. Sorbic acid is the compound with the antimicrobial properties but its salts (sorbates) are used in many cases due to differences in solubility.

Potassium sorbate is the potassium salt of sorbic acid, and is much more soluble in water than the acid. It is a white crystalline powder, inexpensive (at the usage level), with basically no noticeable flavour at normal usage concentrations. In wine processing, sorbates are used to prevent refermentation. Maximum level allowable by law is 0.1%. It produces sorbic acid once it is dissolved in water and is the most widely used food preservative in the world. It is effective up to pH 6.5 but effectiveness increases as the pH decreases. It has about 74% of the antimicrobial activity of the sorbic acid, thus requiring higher concentrations to obtain the same results that pure sorbic acid provides. It is effective against yeasts, molds, and select bacteria, and is widely used at 0.025 to 0.10 % levels in cheese, dips, yogurt, sour cream, bread, cakes, pies and fillings, baking mixes, doughs, icings, fudges, toppings, beverages, margarine, salads, fermented and acidified vegetables, olives, fruit products, dressings, smoked and salted fish, confections and mayonnaise.

It is important to know that the addition of sodium benzoate and/or potassium sorbate to a food product will raise the pH by approximately 0.1 to 0.5 pH units depending on the amount, pH, and type of product. Additional adjustment of the pH might be needed to keep the pH at a safe level.

In many food products, sorbate and benzoate are used together to provide greater protection against a wider variety of microorganisms. This only makes sense if the pH of the product is below 4.5.

Propionic acid

Propionic acid occurs naturally in strawberries, apples, violet leaves, grains. It is produced during the fermentation of some cheeses such as Swiss cheese, in concentrations as high as 1%, thus inhibiting the growth of molds. The acid is effective against bread molds and the spores of the bacterium *Bacillus mesentericus*, which cause an inedible condition in baked goods called rope. It is an oily liquid, soluble in water, with a slight pungent, disagreeable, rancid odour. It is also corrosive and flammable, thus requiring special handling.

Propionic acid and its salts, sodium and calcium propionates, are approved in the United States as GRAS (Generally Recognized As Safe) substances for food use. Their antimicrobial action is directed to molds and rope bacteria, with almost no effect on yeast, thus making them an ideal choice for products that use commercial yeast as an ingredient.

Like other preservatives, propionates effectiveness is affected by the pH of the food, with 5.5 pH being the upper effective limit. They are used mainly as mold and rope inhibitors in bread; although they are also useful in cheese, non-alcoholic beverages, confections, fillings, frostings, fresh dough, pizza crust, puddings, gelatins, jams, jellies and some meat products.

The sodium and calcium salts are transparent and white crystals with a mild cheese like flavour. The sodium form is more soluble in water than the calcium salt. Sodium propionate is recommended in baked products that use baking powder and baking soda instead of yeast as the leavening agent, because the presence of calcium ions (if you were to use calcium propionate) disrupts the leavening process. Calcium propionate is preferred in baked foods that use yeast, such as breads and rolls, because the nutritional value is increased by the added calcium.

Typical usage level of propionic acid and propionates is 0.1 to 0.4 %. Federal regulations limit the maximum level for flour, white bread and rolls at 0.32% based on the weight of the flour; for whole wheat products at 0.38% based on the weight of the flour; and for cheese products at 0.3 %.

It is important to know that the addition of sodium and calcium propionate to a food product will raise the pH by approximately 0.1 to 0.5 pH units depending on the amount, pH and type of product. Additional adjustment of the pH might be needed to keep the pH at a safe level.

Parabens

The parabens are esters of para-hydroxibenzoic acid. The two most common esters are methyl and propyl parabens, which are approved for food use in the United States under the GRAS classification. The maximum concentration allowed is 0.1 %. They are most active against yeasts and molds.

Parabens are white powders with faint odour and fair solubility in water at room temperature. The solubility is greatly increased by heating the water to 71.1°C-82.2°C. Methyl paraben is more soluble in water but less effective against molds than propyl paraben. To balance these differences, mixtures of 2 to 3 parts of methyl paraben with 1 part propyl paraben are normally used.

Important advantages of parabens are their effectiveness at higher pH values, from 3 up to 8, and stability to high and low temperatures, even to steam sterilization. Despite these properties, parabens are not as widely used as other antimicrobial agents, probably due to higher cost and flavour objections. Applications include bakery products (formulated without yeast), beverages, flavour extracts, food colours, fruit products, jams, jellies, preserves (artificially sweetened), gelatin, marinated and smoked fish, pickles, salad dressings, syrups, wine and olives.

Lactic acid

This acid is the main product of many food fermentations; it is formed by microbial degradation of sugars in products such as sauerkraut and pickles. The acid produced in such fermentations decreases the pH to levels unfavourable for growth of spoilage organisms such as putrefactive anaerobes and butyric-acid-producing bacteria. Yeasts and molds that can grow at such pH levels can be controlled by the inclusion of other preservatives such as sorbate and benzoate.

Acetic acid

Acetic acid is a general preservative inhibiting many species of bacteria, yeasts and to a lesser extent molds. It is also a product of the lactic-acid fermentation, and its preservative action even at identical pH levels is greater than that of lactic acid. The main applications of vinegar (acetic acid) includes products such as pickles, sauces and ketchup.

12.4.2 Gaseous Chemical Food Preservatives

Sulphur dioxide and sulphites

Sulphur dioxide (SO_2) has been used for many centuries as a fumigant and especially as a wine preservative. It is a colourless, suffocating, pungent-smelling, non-flammable gas and is very soluble in cold water (85 g in 100 ml at 25°C).

Sulphur dioxide and its various sulphites when dissolved in water at low pH yield sulphurous acid, bisulphite and sulphite ions. The various sulphite salts contain 50-68% active sulphur dioxide. A pH dependent equilibrium is formed in water and the proportion of SO_2 ions increases with decreasing pH values. At pH values less than 4.0 the antimicrobial activity reaches its maximum.

Sulphur dioxide is used as a gas or in the form of its sulphite, bisulphite and metabisulphite salts which are powders. The gaseous form is produced either by burning Sulphur or by its release from the compressed liquefied form.

Metabisulphite are more stable to oxidation than bisulphites, which in turn show greater stability than sulphites.

Mode of action

Sulphites inhibit microbial growth through a number of actions. They react with the energy rich compound, adenosine triphosphate; inhibit some metabolic pathways; and block cellular transport systems. Other antimicrobials alter microbial membrane or cell wall permeability or destroy the genetic material. In addition to its antimicrobial action, sulphur dioxide inhibits degradation reactions in fruits. It keeps raisins and other dried fruits from losing their light colour by blocking both enzymatic browning and a nonenzymatic browning reaction between reducing sugars and amino acids called the Maillard reaction. The reaction darkens raisins, alters their flavour, and reduces essential amino acid levels.

Uses

Sulphites are used to prevent or reduce discolouration of light-coloured fruits and vegetables, such as dried apples and dehydrated potatoes. These are added to sun-dried tomatoes, dried apricots, dried sweet potatoes, balsamic vinegar, red wine vinegar, lemon juice, and Hawaiian coconut syrup. These are also commonly used to lengthen the life of fruit juices. They are also used in wine-making because they inhibit bacterial growth but do not interfere with the desired development of yeast. Sulphites are also used in other ways, such as for bleaching food starches and as preventives against rust and scale in boiler water used in making steam that will come in contact with food. Some sulphites are used in the production of cellophane for food packaging.

Precautions

FDA prohibits the use of sulphites in foods that are important sources of thiamin (vitamin B1), such as enriched flour, because sulphites destroy the nutrient. It causes severe allergic reactions, especially in asthmatics though, for the majority of the population, they are safe.

According to FDA sulphites used specifically as preservatives must be listed on the label, regardless of the amount in the finished product. Sulphites used in food processing but not serving as preservatives in the final food must be listed on the label if present at levels of 10 parts per million or higher.

According to FDA the use of sulphites on fruits and vegetables intended to be eaten raw is banned. These were used to maintain the colour and crispness of fresh produce.

Carbon dioxide (CO_2)

CO_2 is a colourless, odourless, non-combustible gas, acidic in odour and flavour. In commercial practice it is sold as a liquid under pressure (58 kg per cm^3) or solidified as dry ice.

Carbon dioxide is used as a solid (dry ice) in many countries as a means of low-temperature storage and transportation of food products. Beside keeping the temperature low, as it sublimes, the gaseous CO_2 inhibits growth of psychrotrophic microorganisms and prevents spoilage of the fruits and vegetables, etc.

It is used as a direct additive in the storage of fruits and vegetables. In the controlled/ modified environment storage of fruit and vegetables, the correct combination of O_2 and CO_2 delays respiration and ripening as well as retarding mold and yeast growth.

The final result is an extended storage of the products for transportation and for consumption during the off-season. The amount of CO_2 (5-10%) is determined by factors such as nature of product, variety, climate and extent of storage.

Chlorine

The various forms of chlorine constitute the most widely used chemical sanitizer in the food industry. These chlorine forms include chlorine (Cl_2), sodium hypochlorite ($NaOCl$), calcium hypochlorite ($Ca(OCl)_2$) and chlorine dioxide gas (ClO_2).These compounds are used as water adjuncts in processes such as product washing, transport, and cooling of heat-sterilised cans; in sanitising solutions for equipment surfaces, etc.

Important applications of chlorine and its compounds include disinfection of drinking water and sanitation of food processing equipment.

12.4.3 Nitrites and Nitrates

Nitrites and nitrates are used mainly among the packaged meats. Sodium nitrate is added to meats such as ham, bacon, hot dogs and smoked fish. Nitrates break down in the body to nitrites and this stops the growth of bacteria, especially the bacteria that cause botulism poisoning. They are the food industry's primary chemical defense against the bacterium *Clostridium botulinum*.

It also stabilizes the red colour in cured meat and stops it turning grey. Nitrates readily convert to nitrites, which then react with the protein myoglobin to form nitric oxide myoglobin. During cooking, this is converted to nitrosohemochrome, a stable, pink pigment. They also impart a pink, fresh hue to cured meat. This chemical stabilises the red colour of the meat and gives an appearance of fresh meat. That is why nitrites are a favourite preservative of meat processors even though its excess use is restricted in many countries.

Precaution

Nitrite salts can react with certain amines in food to produce nitrosamines, which are known to cause cancer. Addition of Sodium ascorbate or sodium erythorbate inhibits nitrosamine formation and reduces the problem of nitrosamines.

The use of nitrite and nitrate has decreased greatly because of refrigeration and restrictions on the amounts used. Even though nitrite and nitrate cause only a small risk, it is always better to have fresh meat and meat product.

12.5 GENERAL RULES FOR CHEMICAL PRESERVATION

- Chemical food preservatives have to be used only at a dosage level which is needed for a normal preservation and not more.
- "Reconditioning" of chemical preserved food, e.g. a new addition of preservative in order to stop a microbiological deterioration already occurred is not recommended.
- The use of chemical preservatives MUST be strictly limited to those substances which are recognised as being without harmful effects on human beings' health and are accepted by national and international standards and legislation.

Factors which determine/ influence the action of chemical food preservatives

a) Factors related to micro-organisms:

As a general rule it is possible to take the following facts as a basis:

- Sulphur dioxide and its derivatives can be considered as an "universal" preservative as; they have an antiseptic action on bacteria as well as on yeasts and molds;
- Benzoic acid and its derivatives have a preservative action which is stronger against bacteria than on yeasts and molds;
- Sorbic acid acts on molds and certain yeast species; in higher dosage levels it acts also on bacteria, except lactic and acetic ones;
- The initial number of microorganisms in the treated product determines the efficiency of the chemical preservative.
- The efficiency is less if the product has been contaminated because of preliminary careless hygienic treatment or an incipient alteration. Therefore, with a low initial number of microorganisms in the product, the preservative dosage level could be reduced.

b) Factors related to the product:

- Chemical composition of the product.
- *pH value of the product:* the efficiency of the majority of chemical preservatives is higher at lower pH values, i.e. when the medium is more acidic.
- *Physical presentation and size which the product is sliced to:* the chemical preservative's dispersion in food has an impact on its absorption and diffusion through cell membranes on microorganisms and this determines the preservation effect. Therefore, the smaller the slicing of the product, the higher the preservative action. Preservative dispersion is slowed down by viscous foods (concentrated fruit juices, etc.)

c) Miscellaneous factors

- *Temperature:* chemical preservative dosage level will be established as a function of product temperature and characteristics of the micro-flora;
- *Time:* at preservative dosage levels in employed in industrial practice, the time period needed in order to obtain a "chemical sterilisation" is a few weeks for benzoic acid and shorter for sulphurous acid.

12.6 LET US SUM UP

In this unit you have learnt about the chemical preservatives. Herein we have discussed the characteristics of approved chemical preservatives. Various types of preservatives grouped according to their mode of action have been discussed. More stress has been laid on antimicrobial preservatives owing to their importance. Factor influencing the effectiveness of various preservatives have also been discussed. We hope that after reading this unit you will become more conscious about reading the label of processed product before consuming it.

12.7 KEY WORDS

Food Spoilage	:	Undesirable change in flavours, odours appearances or texture of food.
Preservation	:	Safeguarding
Preservative	:	Additive
Anti microbial	:	Which act against microorganisms.
Anti oxidant	:	Which removes the oxygen.
GRAS	:	Generally recognized as safe.

12.8 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   Chemical food preservatives are substances which, under certain conditions, either delay the growth of microorganisms without necessarily destroying them. These are added in very low quantities and which do not alter the organoleptic and physico-chemical properties of the foods at all or only very little.

2. Your answer should include the following points:

   i) It should have GRAS (Generally recognized as safe) status.

   ii) It should be properly declared on the label of the food in which used.

   iii) It should be used only at approved dosage level.

3. Your answer should include the following points:

   In its petition for approval, the manufacturer must demonstrate that the preservative is safe for consumers, considering:

   - the probable amount of the preservative that will be consumed with the food product, or the amount of any substance formed in or on the food resulting from use of the preservative
   - the cumulative effect of the preservative in the diet
   - the potential toxicity (including cancer-causing) of the preservative when ingested by humans or animals.

Check Your Progress Exercise 2

1. Your answer should include the following points:

   The two important antioxidant preservatives are:

   - butylated hydroxytoluene
   - butylated hydroxyanisole

2. Your answer should include the following points:

   Ascorbic acid (vitamin C) inhibit phenolase by making the pH uncomfortably low for the enzyme.

3. Your answer should include the following points:

   - nisin
   - natamycin

4. Your answer should include the following point:

   There is no limit for traditional food preservatives like salt and sugar.

Check Your Progress Exercise 3

1. Your answer should include the following points:

   The four important organic acids used as chemical preservatives are:

   - Benzoic Acid
   - Sorbic acid
   - Propionic acid
   - Acetic acid

2. Your answer should include the following points:

   1. Sulphites should not be used in foods that are important sources of thiamin (vitamin B1), such as enriched flour, because sulphites destroy the nutrient.
   2. It should not be consumed by asthmatic patients because it may cause severe allergic reactions.

3. Your answer should include the following points:

   Nitrates readily convert to nitrites, which then react with the protein myoglobin to form nitric oxide myoglobin. During cooking, this is converted to nitrosohemochrome, a stable, pink pigment. That is how they impart a pink, fresh colour to cured meat.

Check Your Progress Exercise 4

1. Your answer should include the following points:

   Chemical food preservatives have to be used only at a dosage level which is needed for a normal preservation and not more.

2. Your answer should include the following point:

   Potassium meta bisulphate

3. Your answer should include the following points:

   - The smaller is the slicing of the product, the higher is the preservative action.
   - Preservative dispersion is slowed down by viscous foods

UNIT 13 MICROBIAL

Structure

13.0 OBJECTIVES

After studying this unit, you should be able to explain:

- fresh fruits and vegetables;
- canned and processed food products; and
- drinking water.

13.1 INTRODUCTION

In this unit we will make you aware about the types of micro flora present on the surface of fresh fruits and vegetables, the sources of these microorganisms and the characteristics of pathogenic microorganisms. We will also brief you about quality standards for drinking water and the human pathogen present in contaminated water. Canning is an established way of food preservation. You will learn about the history of canning, spoilage of canned products with special reference to *Clostridium botulinum*. After that we will brief you about the microbial limits for processed foods.

13.2 MICROBIOLOGICAL PROFILE OF HARVESTED FRUITS AND VEGETABLES

The consumption of fresh fruits and vegetables is increasing as consumers strive to eat healthy diets. Global trade in fruits and vegetables and changing horticultural practices have enabled this year-round abundance to be possible, as well as adding new varieties of fresh produce to the market. During the last few decades pre-prepared minimally processed fruits and vegetables have become popular among the consumers. These products include pre-washed pre-cut salads items, grated vegetables, prepared fruit salads, or fruit combinations. Most of these products are generally eaten raw without further processing. Some products are packed in modified atmospheres to provide extension of shelf life both in relation to the potential acceptable quality and safety of the product.

Since minimum processing is required for fresh and fresh-cut fruits and vegetables, which omits any effective microbial elimination step, results in food products that naturally would carry microorganisms, some of which may be potentially hazardous to human health.

13.2.1 Sources of Microorganisms on Fresh Fruits and Vegetables

Fruits and vegetables can become contaminated whilst growing in fields, or during harvest, handling, processing, distribution and use. However, there are certain factors, which contribute to the microbiological contamination of these products with pathogens. Table 13.1 lists the sources of pathogenic microorganisms on fresh produce and conditions that influence their survival and growth.

Contamination can arise as a consequence of treating soil with organic fertilizers such as manure and sewage sludge and from irrigation water. Manure, bio-solids and irrigation water should be of a quality that does not introduce pathogens to the treated commodity. The potential of organic farming to contaminate fruits and vegetables with pathogens has to be investigated. Harvesting at the appropriate time and storing the harvested products under controlled conditions will help to retard growth of post-harvest spoilage and pathogenic microorganisms. Humid and warm storage conditions encourage the growth of microbial contaminants. The use of additional post-harvest procedures could reduce the contamination level of fruits and vegetables. Washing with water of potable quality can reduce the microbial load. Although a wide range of different agents are available for disinfecting/ sanitizing fresh produce their efficacy is variable and none is able to ensure elimination of pathogens. Fruits and vegetables carry a natural non-pathogenic epiphytic micro flora. During growth, harvest, transportation and further processing and handling the produce can, however, be contaminated with pathogens from human or animal sources. The microbial composition of the different forms of organic fertilizer will vary depending on its origin and further treatment. The quality of the water used for irrigation and as a carrier for plant protection products, fertilizers and frost protection products has to be related to the potential risk it can cause at a later stage. Technologies for irrigation are important for the control of spreading microbiological hazards. The use of drip irrigation instead of flooding or spray irrigation should reduce waterborne contamination and aerosols. However, heavy rains and wind may provide other opportunities for the transfer of microorganisms from soil to plant surfaces.

Table 13.1: Sources of pathogenic microorganisms on fresh produce and conditions that influence their survival and growth

Pre-harvest
• Soil • Irrigation water • Green or inadequately composted manure • Air (dust) • Wild and domestic animals • Human handling • Water for other uses (for example, pesticides, foliar treatments, growth hormones)
Post-harvest
• Human handling (workers, consumers) • Harvesting equipment • Transport containers (field to packing shed) • Air (dust) • Wash and rinse water • Sorting, packing, cutting and further-processing equipment • Ice • Transport vehicles • Improper storage (temperature, physical environment) • Improper packaging (includes new packaging technologies) • Cross contamination (other foods in storage, preparation and display areas) • Improper handling after wholesale or retail purchase • Cooling water (for example, hydro cooling)

13.2.2 Factors affecting Type and Number of Microorganism on Fresh Fruits and Vegetables

Fruits and vegetables normally carry a non-pathogenic epiphytic micro flora. The majority of bacteria found on the surface of plants are usually Gram-negative and belong either to the *Pseudomonas* group or to the *Enterobacteriaceae*. Many of these organisms are normally non-pathogenic for humans. The numbers of bacteria present will vary depending on seasonal and climatic variation and may range from 10^4 to 10^8 per gram. The inner tissues of fruits and vegetables are usually regarded as sterile. However, bacteria can be present in low numbers as a result of the uptake of water through certain irrigation or washing procedures. If these waters are contaminated with human pathogens these may also be introduced. The survival or growth of contaminating microorganisms is affected by intrinsic, extrinsic and processing factors. Factors of importance are nutrient composition, pH, presence of scales and fibers, redox potential, temperature and gaseous atmosphere. Mechanical shredding, cutting and slicing of the produce open the plant surfaces to microbial attack. About two thirds of the spoilage of fruits and vegetables is caused by molds. Members of the genera *Penicillium*, *Aspergillus*, *Sclerotinia*, *Botrytis* and *Rhizopus* are commonly involved in this process. The spoilage is usually associated with cellulolytic or pectinolytic activity, which causes softening of tissues, and weakening of plant structures. These structures are important barriers to prevent growth in the products by contaminating microbes.

13.2.3 Human Pathogens Associated with Fresh Fruits and Vegetables

However, risk profile surveys on the microbiological contamination of fruits and vegetables eaten raw demonstrates, potential for a wide range of these products to become contaminated with microorganisms, including human pathogens. The range of microorganisms associated with outbreaks linked to fresh produce encompasses bacteria, viruses and parasites. Most of the reported outbreaks have been associated with bacterial contamination, particularly members of the *Enterobacteriaceae*. Of these, *Salmonella* and *Escherichia coli* O157 are of particular concern. Outbreaks of illness caused by bacteria, viruses and parasites have been linked epidemiologically to the consumption of a wide range of vegetables and, to a lesser extent fruits. Surveillance of vegetables has indicated that these foods can be contaminated with various bacterial pathogens, including *Salmonella*, *Shigella*, *E. coli* O157:H7, *Listeria monocytogenes* and *Campylobacter*. Table 13.2 shows the characteristics of some microbial pathogens that have been linked to outbreaks of fresh fruits and vegetable associated illness.

Table 13.2: Characteristics of some microbial pathogens that have been linked to outbreaks of produce associated illness

Microorganism	Typical Incubation Period	Symptoms	Infectious Dose (Number of cells)	Source
BACTERIA				
Clostridium botulinum	12 to 36 h	Nausea, vomiting, fatigue, dizziness, dryness of mouth and throat, muscle paralysis, difficulty in swallowing, double or blurred vision, drooping eyelids, and breathing difficulties	Intoxication growth and toxin production in food	Soil, lakes, streams, decaying vegetation, reptiles
Escherichia coli O157:H7	2 to 5 d	Bloody diarrhoea, abdominal pain. Can lead to hemolytic uremic syndrome and kidney failure especially in children and the elderly	10 to 1000	Animal feces, especially cattle, deer and human; cross contamination from raw meat
Salmonella spp.	18 to 72 h	Abdominal pain, diarrhoea, chills, fever, nausea, vomiting	10 to 100,000	Animal and human feces; cross contamination from raw

				meat, poultry, or eggs
Shigella spp.	1 to 3 d	Abdominal pain, diarrhoea, fever, vomiting	~10	Human feces
Listeria monocytogenes	1 d to 5 or more wk	Febrile gastroenteritis in healthy adults; may lead to spontaneous abortion or stillbirth in pregnant women; severe septicemia and meningitis in neonates and immuno-compromised adults; mortality may be 20 to 40%	Unknown dependent upon health of individual	Soil, food processing environ-ments
PARASITES				
Cryptosporidium spp.	1 to 12 d	Profuse watery diarrhoea, abdominal pain, anorexia, vomiting	~30	Animal and human feces
Cyclospora spp.	1 to 11 d	Watery diarrhoea, nausea, anorexia, abdominal cramps (duration 7 to 40 d)	Unknown, probably low	Others? specific environment al sources unknown at this time
VIRUSES				
Hepatitis A	25 to 30 d	Fever, malaise, anorexia, nausea, abdominal pain, jaundice, dark urine	10 to 50	Human feces and urine
Norwalk/ Norwalk-like virus	12 to 48 h	Vomiting diarrhoea, malaise, fever, nausea, abdominal cramps	Unknown, probably low	Human feces, vomitus

However, multiplication of the pathogen is also essential for causing any damage. Some microorganisms cause illness only when ingested in high numbers (for example, *Clostridium perfringens*), while in other cases, the infectious dose is thought to be dependent upon the susceptibility of the individual (most infectious agents). Illness due to *Staphylococcus aureus*, *Bacillus cereus*, or *Clostridium botulinum* is a result of the production of toxins in the food, and it is the toxins that are responsible (sometimes in the absence of viable cells) for symptoms of the disease. These toxins are only produced by multiplying cells. This requires favourable growth conditions.

13.3 STANDARDS OF WATER FOR HUMAN CONSUMPTION

Clean water is one of the most important needs of our bodies. It is a sad fact that something as essential to life as clean drinking water can no longer be granted to us. According to research articles and news, most tap and well water now are not safe for drinking due to heavy industrial and environmental pollution. We have reached to a point that, all sources of our drinking water, including municipal water systems, wells, lakes, rivers, and even glaciers, contain some level of contamination.

13.3.1 Sources of Contaminants in Drinking Water

Several contaminants occur in nature that may present a health risk if they are found in drinking water. The various pollutant /contaminants are bacteria, viruses, uranium, radium, nitrate, arsenic, chromium and fluoride. Other sources of contamination are a result of human activity such as manufacturing or agriculture, or individual misuse. The following activities may cause harmful microorganisms and chemicals to enter the well water owner's water supply.

- Leakage from waste disposal, treatment, or storage sites.
- Discharges from factories, industrial sites, or sewage treatment facilities.
- Leaching from aerial or land application of pesticides and fertilizers on yards or fields.
- Accidental chemical spills.
- Leakage from underground storage tanks.

13.3.2 Contamination due to Harmful Microorganisms

The most common and widespread health risk associated with drinking water is microbial contamination, either directly or indirectly, by human or animal excreta and micro-organisms contained in faeces.

The pathogenic agents involved include bacteria, viruses and protozoa, which may cause diseases that vary in severity from mild gastroenteritis to severe and sometimes fatal diarroea, dysentry, hepatitis or typhoid fever. Most of them are widely distributed through out the world. Fecal contamination of drinking water is only one of the several faeco-oral mechanisms by which they can be transmitted from one person to another, or in some cases, from animal to people. The human pathogens potentially transmitted in drinking water are Bacteria viz. Escherichia coli,Salmonella, Shigella, Vibrio cholera, Yersinia enterocolitica, Campylobacter jejuni; viruses viz, Adenoviruses, Enterovirus, Hepatitis A, Hepatitis E, Norwalk virus, Rotavirus, and small round viruses; The parasites, Giardia, Cryptosporidium, Entamoeba histolytica and Drancunculus. The removal of these agents from drinking water should be given top priority.

Apart from the above said **pathogens of high health significance**, there are some more organisms that are present in environment and **not normally regarded as pathogen, may caue disease opportunistically**. When such organisms are present in water they cause infection predominantly among people whose local or general defence mechanisms are impaired. Those most likely to be at risk include the very old, the very young and patients in the hospitals,e.g. those with burns or immunosuppressive therapy, and those suffering from acquired immunodeficiency syndrome(AIDS). Water used by such patients for drinking or bathing, if it contains excessive number of these agents, may produce a variety of infections involving the skin and mucous membrane of the eye, ear, nose and throat. *Pseudomonas, Flavobacterium, Acinetobacter, Klebsiella* and *Serratia* are examples of such opportunistic pathogens. *Legionella* infects the lung. These organisms while clearly of medical importance, acquire public health significance only under certain conditions. There removal from drinking water may therefore be given moderate priority.

13.3.3 Drinking Water Standards

Microorganisms, including pathogenic organisms, may enter water supplies at every stage of the collection and distribution cycle. Emphasis should be placed on the need for an active watershed protection program, including an emergency plan for responding to major pollution events such as spills or contamination. Major quality requirements for drinking water are listed in Table 13.3.

Table 13.3: Drinking water standards

Micro-organism	Requirement
Cryptosporidium	System must remove 99% of *Cryptosporidium*
Giardia lamblia	99.9% killed
Heterotrophic Plate count (HPC)	Not more than 500 colonies per ml.
Total Coliform	Must not be detectatable in any 100 ml sample. In case of large supplies where sufficient samples are examined must not be present in 95% of the samples taken through out any 12 months period.
Fecal Coliform or *E.coli*	No fecal coliform is allowed.
Turbidity	At no time can turbidity go above 5 NTU (Nephlometric turbidity unit)
Viruses	99.99% killed / inactivated

Let us know in brief about the above contaminants.

Coliform bacteria

These are common in the environment and are generally not harmful. However, the presence of these bacteria in drinking water is usually a result of a problem with the treatment system or the pipes which distribute water, and indicates that the water may be contaminated with germs that can cause disease. **Fecal Coliform and *E.Coli*** are bacteria whose presence indicates that the water may be contaminated with human or animal wastes. Microbes in these wastes can cause short-term effects, such as diarrhoea, cramps, nausea, headaches, or other symptoms.

Turbidity has no health effects. However, turbidity can interfere with disinfection and provide a medium for microbial growth. Turbidity may indicate the presence of disease causing organisms. These organisms include bacteria, viruses, and parasites that can cause symptoms such as nausea, cramps, diarrhoea, and associated headaches.

Cryptosporidium is a parasite that enters lakes and rivers through sewage and animal waste. It causes cryptosporidiosis, a mild gastrointestinal disease. However, the disease can be severe or fatal for people with severely weakened immune systems.

Giardia lamblia is a parasite that enters lakes and rivers through sewage and animal waste. It causes gastrointestinal illness (e.g. diarrhoea, vomiting, cramps).

Hence, it is important that our drinking water does not contain any concentration of microorganisms, parasites or any other substance which constitutes a potential human health risk and it meets the minimum requirements (microbiological and chemical parameters and those relating to radioactivity) laid down by the directives.

13.4 MICROBIOLOGY OF CANNED FOODS

Foods are processed for convenience and safety. Food processing involves procedures such as: drying, canning, freezing, and pasteurization. For example, drying is a process by which water is removed from the product, causing the product to become dehydrated. Since microorganisms need water to grow, without moisture, they can't flourish. Canning is a process where foods are put into a container and given a high heat treatment to make the product sterile. The process of canning, be it vegetables, meat, or seafood, makes food safe because all dangerous microorganisms are destroyed. The canning process was developed to preserve food safely and for long periods of time.

13.4.1 History of Canning

The canning process dates back to the late 18th century in France when the Emperor Napoleon Bonaparte, concerned about keeping his armies fed, offered a cash prize to whoever could develop a reliable method of food preservation. Nicholas Appert conceived the idea of preserving food in bottles, like wine. After 15 years of experimentation, he realized if food is sufficiently heated and sealed in an airtight container, it will not spoil. An Englishman, Peter Durand, took the process one step farther and developed a method of sealing food into unbreakable tin containers, which was perfected by Bryan Dorkin and John Hall, who set up the first commercial canning factory in England in 1813. As more and more of the world was explored, and as provisioning armies took on greater importance, the demand for canned foods grew. Thomas Kensett, who emigrated to the United States, established the first U.S. canning facility for oysters, meats, fruits and vegetables in New York in 1812. More than 50 years later, Louis Pasteur provided the explanation for canning's effectiveness when he was able to demonstrate that the growth of microorganisms is the cause of food spoilage.

13.4.2 Basic Principal of Canning

The basic principles of canning have not changed dramatically since Nicholas Appert and Peter Durand developed the process. Heat sufficient to destroy microorganisms is applied to foods packed into sealed or "airtight" containers. The canned foods are then heated under steam pressure at temperatures of 116-121°C. The amount of time needed for processing is different for each food, depending on the food's acidity, density and ability to transfer heat. For example, tomatoes require less time than green beans, while corn and pumpkin require far more time. Processing conditions are chosen to be the minimum needed to ensure that foods are commercially sterile, but retain the greatest flavour and nutrition.

13.4.3 Spoilage of Canned Products

Heated canned foods may undergo spoilage either due to chemical or biological reasons. The most common spoilage of canned foods is the hydrogen swells produced as a result of action of food acid with the metal can. Such spoilage occurs mostly due to imperfect tinning and lacquering of interior of the can used for canning acidic foods. Biological spoilage of canned foods by the microorganism may result either from the survival of the organisms after the heat treatment or leakage of the container permitting entrance of the microorganisms, Surviving organisms may be vegetative cells or spore formers depending upon the heat treatment. Acid foods are processed at a temperature around $100^{O}C$ which result in killing of all vegetative cells of bacteria yeast and molds.

13.4.4 *Clostridium botulinum* a Major Threat in Canned Products

Growth of the bacterium *Clostridium botulinum* in canned food may cause **botulism –** a deadly form of food poisoning. These bacteria exist either as spores or as vegetative cells. Botulism is an **intoxication** that is caused by the ingestion of a virulent nerve toxin produced by the growth of the gram positive, obligate anaerobe, spore-former ***Clostridium botulinum***. This bacterium appears to be a normal inhabitant of the soil, hence is ready contamination of most foods. The spores can survive harmlessly in soil and water for many years. When ideal conditions exist for growth, the spores produce vegetative cells which multiply rapidly and may produce a deadly toxin within 3 to 4 days of growth in an environment consisting of:

- a moist, low-acid food
- a temperature between 4°C and 49°C
- less than 2 percent oxygen

It is able to grow in **absence of oxygen** in a wide variety of foods and in so doing produces a **protein neural toxin**, two to three grams (an amount equivalent to the quantity of salt in the average salt shaker on your table) of which would be sufficient to kill human being. However, the organism will not grow in the presence of oxygen or nitrate salts and it does not produce the toxin at a pH below 4.7. Only one strain, which is found associated with marine organisms, is able to produce the toxin at refrigerator temperature. The toxin is destroyed by boiling it at 100°C for 10 to 15 min. However, the spore requires a temperature of 121°C for 15 min to kill it. The toxin acts by binding to nerve junctions and destroying the nerve. The symptoms, which occur usually within 12 to 36 hours, but which can take up to 8 days to appear, classically consist of double vision, dizziness, inability to speak, breathe or swallow. Death often occurs due to the inability to breath. The only treatment is the injection of *antitoxin* to the several varieties of the toxin. This treatment is only effective against free toxin, as once the toxin has bound to the nerves the damage is irreversible. **The entire canning process is built around ensuring that all spores of this bacterium contaminating any canned food are destroyed in the sterilization process.** Industry has a sterling record in that deaths from commercial-botulism are very rare. This is influenced by the fact that once a product is known to contain botulism toxin none of that product is ever again purchased by a customer. **The majority of botulism poisonings occur in HOME-CANNED FOODS** prepared by grandma or your favourite aunt. A rule of thumb is “READ THE CANNING DIRECTIONS” and if you think a food might contain the botulism toxin never tastes even the smallest drop of it!

Some interesting additional information about this disease is:

- Never feed **raw honey** to a child under the age of two because the botulism spores can grow in the immature gut and produce the toxin. This can not occur in the adult due to our gut micro flora which is absent in infants.

- The botulism toxin is being used to treat certain neurological conditions where nerves that shouldn't fire do. In these cases tiny quantities of the botulism toxin is injected into the nerve, which the toxin kills and cures the condition.

- Ducks and chickens often die from botulism poisoning by eating rotting material in which the bacterium has grown. However, vultures, which as you know, eat disgusting rotten, stinking carrion, are immune to the toxin through evolution.

Botulinum spores are on most fresh food surfaces because they grow only in the absence of air, they are harmless on fresh foods. Botulinum spores are very hard to destroy at boiling-water temperatures; the higher the canner temperature, the more easily they are destroyed. Therefore, all low-acid foods should be sterilized at temperatures of 115°C to 121°C, attainable with pressure canners operated at 10 to 15 PSIG. PSIG means pounds per square inch of pressure as measured by gauge. At temperatures of 115°C to 121°C, the time needed to destroy bacteria in low-acid canned food ranges from 20 to 100 minutes. The exact time depends on the kind of food being canned, the way it is packed into jars, and the size of jars. The time needed to safely process low-acid foods in boiling-water canner ranges from 7 to 11 hours; the time needed to process acid foods in boiling water varies from 5 to 85 minutes.

13.5 MICROBIOLOGICAL STANDARDS FOR PROCESSED FOODS

By now you know that microbiological hazards are one of the biggest threats to food safety. With better understanding in microbiology and food safety, safety limits have been set for a range of pathogenic microorganisms in foods. This subunit presents the recommended microbiological guidelines for some ready-to-eat food. According to the Codex Alimentarius Commission of the United Nations, an international food standard setting authority, the functions of

microbiological guidelines include formulation of design requirements, indication of required and expected microbiological status of the food commodities, and the verification of efficacy of hygienic practice. These guidelines stipulate the safety limits of nine major food borne pathogens such as *Salmonella* species, *Listeria monocytogenes*, *E coli O157* and *Vibrio cholerae*, as well as providing a classification of microbiological quality of ready-to-eat food for reflecting the hygienic status of the food concerned.

13.5.1 Purpose of Microbiological Standards

Microbiological Guidelines are criteria indicating the microbiological condition of the food concerned so as to reflect its safety and quality. These standard lists the maximum permissible levels of food borne microorganisms that pose a risk to human health in nominated foods, or classes of foods. They can be introduced to the food industry to observe voluntarily or stipulated in legislation for compliance.

13.5.2 Sampling

The statistical validity of a microbiological examination increases with the number of field samples analysed. For regulatory purposes, **a minimum of 5 sample units** from a lot is generally specified for examination. The size of the samples taken should also be adequate to enable appropriate microbiological analyses to be undertaken. A minimum sample size of 100g or ml is commonly required. **A lot** is defined as a quantity of food or food units produced and handled under uniform conditions. This may be restricted to a food item produced from a particular production line or piece of equipment within a certain time period (not exceeding 24 hours).

13.5.3 Microbiological Assessment

There are three major components under microbiological assessment of any food.

Aerobic colony count is a count of viable bacteria based on counting of colonies grown in nutrient agar plate. This is commonly employed to indicate the sanitary quality of foods. The incubation condition of ACC used in this guideline is **30° C for 48 hours**.

Indicator organism Counts refers to the selected surrogate markers. The main objective of using bacteria as indicators is to reflect the hygienic quality of food. *E. coli* is commonly used as surrogate indicator. Its presence in food generally indicates direct or indirect fecal contamination. Substantial number of *E. coli* in food suggests a general lack of cleanliness in handling and improper storage. **Specific pathogens Counts** refer to bacteria that may cause food poisoning. Mechanisms involved may be toxins produced in food or intestinal infection. Nine specific bacterial pathogens are included in this set of guidelines. The symptoms of food poisoning vary from nausea and vomiting (e.g. caused by *S. aureus*), through diarrhoea and dehydration (*Salmonella* spp. and *Campylobacter* spp.) to paralysis and death in the rare cases of botulism. The infectious doses vary from less than 10 to more than 10^6 organisms.

13.5.4 Categories of Food based on Microbial Quality

For assessment of hygienic quality, food items are grouped into five categories taking into account the raw ingredients used, and the nature and degree of processing before sale. The microbiological assessment of ready-to-eat food on the above three components will lead to the classification of the food quality into one of the following four classes:

a) **Class A:** the microbiological status of the food sample is **satisfactory.**

b) **Class B:** the microbiological status of the food sample is **less than satisfactory but still acceptable for consumption.**

c) **Class C:** the microbiological status of the food sample is **unsatisfactory**. This may indicate a sub-optimal hygienic conditions and microbiological safety levels. Licensees of food premises should be advised to investigate and find out the causes and to adopt measures to improve the hygienic conditions. Taking of follow-up samples to verify the improvement may be required.

d) **Class D:** the microbiological status of the food sample is unacceptable. The food sample contains unacceptable levels of specific pathogens that is **potentially hazardous to the consumer**. In addition to giving advice to the licensee of the food premises as stated in (c) above, warning letters as well as other enforcement actions should be considered. Microbiological limits in respect of the above components are summarized in the table 13.4.

Table 13.4: Guideline levels for determining the microbiological quality of ready-to-eat foods

Criterions		**Microbiological Quality (CFU per gram)**			
		Class A Satisfactory	**Class B Marginal**	**Class C Unsatisfactory**	**Class D Potentially Hazardous**
Aerobic colony count (ACC)[$30^{O}C$/48 hr]					
Food Category	**1**	$<10^3$	10^3-$<10^4$	$\geq 10^4$	N/A
	2	$<10^4$	10^4-$<10^5$	$\geq 10^5$	N/A

(Food items detailed in Table 5)	**3**	$<10^5$	10^5-$<10^6$	$\geq 10^6$	N/A
	4	$<10^6$	10^6-$<10^7$	$\geq 10^7$	N/A
	5	N/A	N/A	N/A	N/A
Indicator organisms (Apply to all food categories)					
E.coli (Total)		<20	20 -< 100	≥100	N/A
Pathogens (Apply to all food categories)					
Campylobacter spp		not detected in 25g	N/A	N/A	Present in 25 g
Escherichia coli 0157		not detected in 25g	N/A	N/A	Present in 25 g
Listeria monocytogenes		not detected in 25g	N/A	N/A	Present in 25 g
Salmonella spp		not detected in 25g	N/A	N/A	Present in 25 g
Vibrio cholerae		not detected in 25g	N/A	N/A	Present in 25 g
Clostridium perfringens		<20	20<100	$100<10^3$	$\geq 10^3$
Staphylococcus aureus		<20	20<100	$100<10^4$	$\geq 10^4$
Vibrio parahaemolyticus		<20	20<100	$100<10^4$	$\geq 10^4$
Bacillus cereus		$<10^3$	10^3-$<10^4$	10^4-$<10^5$	$\geq 10^5$

N/A Not applicable

The desired microbiological quality of the some food samples is summarized in Table 13.5.

Table 13.5: Food category table for aerobic colony count assessment

Food group	Food item	Category
Meat	Beefburgers and kebabs	1
	Dim sum	2

Sushi & sashimi	Fish fillet and fish roe sashimi / sushi Sashimi other than fish fillet and fish roe	3 4

Controlling microbes

Control of microbes in processed products primarily depend upon good manufacturing practices and one of the most effective way to ensure this is by application of HACCP. HACCP stands for Hazard Analysis of Critical Control Point. HACCP is a preventive system for assuring production of safe food. It is a process that identifies food safety hazards associated with a product and process and strictly manages and monitors the Critical Control Points (CCP's) designed to control the hazard as a way of ensuring the process is in control and that the safest product possible is being produced. It requires establishment of hazard, identification of critical control points, effective monitoring follow up and evaluation. For a food processor it is necessary to know the microbial quality of the raw material, the processing environment, and the packaging component. This also requires validation of all processing stages designed to destroy both the pathogens and the spoilage agents and the efficacy of preservative system.

13.6 LET US SUM UP

In this unit you have learnt about the microbial quality limits for various foods (raw and processed). Herein we have discussed the sources of microorganisms on fresh fruits and vegetables and in drinking water. Various Food and water borne harmful microorganisms including indicator bacteria, viruses and pathogens have been discussed briefly. *Clostridium botulinum* is an important organism for canning point of view. Hence, it has been dealt in more detail. WE HOPE that after reading this unit you will become more conscious about the microbial quality of food that you are going to eat.

13.7 KEY WORDS

Spoilage microorganism	:	Microorganism which spoil the product by developing undesirable flavours, odours and changing food appearances or textures via microbial action.
Pathogenic	:	Microorganism which may infect plants, animals and man and make them sick.
Hazardous	:	Harmful
Epidemic	:	Out break of infectious disease
Gastroenteritis	:	Inflamatory change of lining of stomach caused by microorganism ingested with food and water.
Hepatitis	:	Virus Hepatitis A
Parasites	:	Life on, within or at the expense of other organisms.
Toxin	:	Poison
Intoxication	:	Toxin production

13.8 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following point:

   - Sources of microorganisms on fresh fruit are air, orchard soil, irrigation water, harvesting device, storing and packaging containers, handling personnel etc.

2. Your answer should include the following points:

- The survival or growth of contaminating microorganisms is affected by intrinsic, extrinsic and processing factors.
- Factors of importance are nutrient composition, pH, presence of scales and fibers, redox potential, temperature and gaseous atmosphere.
- Mechanical shredding, cutting and slicing of the produce open the plant surfaces to microbial attack.

3. Your answer should include the following point:

- Members of the genera *Penicillium*, *Aspergillus*, *Sclerotinia*, *Botrytis* and *Rhizopus* are commonly involved in spoilage of fresh fruits and vegetables.

4. Your answer should include the following points:

- Most of the reported outbreaks have been associated with bacterial contamination.
- Members of the *Enterobacteriaceae*. Of these, *Salmonella* and *Escherichia coli* O157 are of particular concern.

Check Your Progress Exercise 2

1. Your answer should include the following points:

- Gastroenteritis
- Diarroea
- Dysentry
- Hepatitis
- Typhoid fever

2. Your answer should include the following points:

- Microbes
- Radionuclide
- Inorganics
- Volatile organics
- Disinfectants
- Disinfection by products etc.

3. Your answer should include the following points:

- The human pathogens potentially transmitted in drinking water are Bacteria viz. *Escherichia coli,Salmonella, Shigella, Vibrio cholera, Yersinia enterocolitica, Campylobacter jejuni.*
- Viruses viz, Adenoviruses, Enterovirus, Hepatitis A, Hepatitis E, Norwalk virus, Rotavirus, and small round viruses
- Parasites viz. *Giardia*, *Cryptosporidium*, *Entamoeba histolytica* and *Drancunculus*.

4. Your answer should include the following points:

- *Pseudomonas*

- *Flavobacterium*
- *Acinetobacter*
- *Klebsiella*
- *Serratia*
- *Legionella*.

Check Your Progress Exercise 3

1. Your answer should include the following point:

   - Process where foods are put into a container and given a high heat treatment to make the product sterile.

2. Your answer should include the following point:

   - Nicholas Appert

3. Your answer should include the following points:

   - Food's acidity
   - Density
   - Ability to transfer heat.

4. Your answer should include the following point:

   - Growth of the bacterium *Clostridium botulinum* in canned food may cause **botulism –** a deadly form of food poisoning.

Check Your Progress Exercise 4

1. Your answer should include the following point:

   - Codex Alimentarius is an international food standard setting authority.

2. Your answer should include the following points:

   - Lists the maximum permissible levels of food borne micro-organisms that pose a risk to human health in nominated foods, or classes of foods.
   - Indicate the microbiological condition of the food concerned so as to reflect its safety and quality.

3. Your answer should include the following point:

   - Minimum of 5 sample units from a lot is generally specified for examination.

4. Your answer should include the following points:

   - Aerobic colony count
   - Indicator organism Counts
   - Specific pathogens Counts

5. Your answer should include the following points:

- Count of viable bacteria based on counting of colonies grown in nutrient agar plate.
- Commonly employed to indicate the sanitary quality of foods.

6. Your answer should include the following point:

   - The presence of indicator organisms in food reflect the hygienic quality of food.

7. Your answer should include the following points:

   - *Campylobacter* spp.
   - *Escherichia coli* 0157
   - *Listeria monocytogenes*
   - Salmonella spp
   - *Vibrio cholerae*
   - *Clostridium perfringens*
   - *Staphylococcus aureus*
   - *Vibrio parahaemolyticus*
   - *Bacillus cereus*

EXPERIMENT 1 PREPARATION OF MEDIA

Structure

1.1 INTRODUCTION

Microorganisms require certain basic nutrients and physical factors for the sustenance of life as do all other living organisms. However, their particular requirements may vary greatly. Nutritional needs of microbial cells are supplied in the laboratory through a variety of media to detect their presence. Microbiological media for the evaluation of spoilage and detection of bacteria, yeasts and molds in foods are mentioned in this chapter.

Objectives

After studying and performing this experiment, you should be able to:

- learn that microorganisms are ubiquitous and in nature, they do not segregate themselves by species but exist a mixture of many other cell types; and
- learn to make different media which are suitable for a particular genera of microorganisms to produce their discrete colonies.

1.2 EXPERIMENT

1.2.1 Principle

Many special purpose media are needed to facilitate recognition, enumeration and isolation of different types of microorganisms. To meet these needs, the microbiologists has developed numerous media which on the basis of their function may be classified as follows:

A) Selective media

These media provide nutrients that enhance the growth and predominance of a particular type of bacterium and do not enhance (and may even inhibit) other types of organisms that may be present. For instance, a medium in which cellulose is the only carbon source, will specifically select for, or enrich the growth of cellulose-utilizing organisms when it is inoculated with a soil sample containing many kinds of bacteria.

B) Differential media

Certain reagents or supplements, when incorporated into culture media, may allow differentiation of various kinds of microorganisms. For example, if a mixture of bacteria is inoculated on to a blood containing agar medium (blood agar) some of the bacteria may hemolyze (destroy) the red blood cells, others do not. Thus one can distinguish between hemolytic and non-hemolytic bacteria on the same media.

1.2.2 Requirements (Equipment/Machinery/Instrument/Chemicals/ Material)

- Autoclave (Portable)
- Balance
- Heating mantle/ water bath
- pH meter
- Laminar air flow
- Stirrer
- Pipettes
- Distilled water
- Media (nutrient agar, potato dextrose agar, violet red bile agar, plate count agar)
- Test tubes
- Beakers
- Cotton plugs
- pH paper
- Measuring cylinder

1.2.3 Procedure

The preparation of microbiological media usually involves the following steps:

1. Carefully weigh the proper amount of the dehydrated base medium or the correct proportion of constituent ingredients and dissolve in appropriate volume of distilled water and heat. Composition of the media is as given in Annexure-1.

2. Determine the pH of the medium, and adjust if necessary with dilute acid or alkali.

3. If a solid medium is desired, add agar (1.5-2%) and boil the medium to dissolve the agar.

4. Distribute the medium into tubes or flasks. The amount of medium distributed per container should be limited so that no point within the volume of the medium is more than 2.5 cm from the top surface of the container.

5. Autoclave at 121°C for 15 minutes. Some media (or specific ingredients) that are heat labile are sterilized by filtration.

1.2.4 Observations

Observe the pH using the pH meter or colour indicator solutions. At the next laboratory period observe for any contamination to ensure proper sterilization. Discard any contaminated flasks and wash them in disinfectant solution.

1.2.5 Results

After performing this experiment you will observe that suitable media for growth of bacteria is nutrient agar (pH 6.8-7.0) or plate count agar (pH 7.0), whereas for yeasts and moulds it is potato dextrose agar (pH 5.6) and malt agar (pH 5.4).

1.3 PRECAUTIONS

- Adjust the pH of the media accurately, to provide favourable condition of growth for the microorganisms. pH of the medium may change during sterilization and because of possible browning reactions, it is important not to exceed the recommended time and temperature.
- Prepare medium in such quantities that if stored, it will be used before loss of moisture through evaporation that becomes evident.
- To prevent contamination and excess evaporation of water from a medium in flask and tubes during storage, optionally fit aluminium foil or plastic with loose rubber bands before autoclaving in order to allow air to escape and to prevent the container from bursting.
- Avoid over loading autoclaves so that the rate of air exhaust and heating is not appreciably delayed. The autoclave should reach 121°C (15 psi) slowly but within 10 min. after starting the air exhaust operation.
- Flask or test tubes should be plugged with cotton or capped with paper.
- After sterilization gradually reduce the pressure within the autoclave (using no less than 15min) since liquids may be at a temperature above their boiling point at atmospheric pressure. If the pressure is lowered too rapidly, liquids may boil over and come out from the container.
- Used plates, pipettes, tubes etc. should be routinely decontaminated by autoclaving for 30 minute at 121°C.
- Media should be stored at 2-8°C in a dry, dust free area and should not be exposed to direct sunlight.

EXPERIMENT 2 MICROSCOPIC STAINING TECHNIQUES

Structure

2.1 INTRODUCTION

Visualization of microorganisms in the living state is most difficult, not only because they are minute but also because they are transparent and practically colourless when suspended in an aqueous medium. To study their properties and to differentiate microorganism into specific groups for diagnostic purposes, biological stains and staining procedures in conjunction with light microscopy have become major tools in microbiology. Chemically a stain may be defined as an organic compound containing a benzene ring, a chromophore (chemical group that imparts colour to benzene), and an auxochrome (chemical compound that helps in binding to cells).

Objectives

After studying and performing this experiment, you should be able to:

- learn the practical and theoretical basis of chemical staining;
- describe manipulative technique of smear preparation;
- explain procedures for simple staining and negative staining; and
- perform differential staining procedures such as the Gram's staining, acid fast staining and spore staining.

2.2 EXPERIMENT

2.2.1 Principle

Staining by various dyes provides contrast between microorganisms and their background, permitting differentiation among various morphological types and internal structure such as cell wall, vacuoles or nuclear bodies. It also enables the microbiologist to use higher magnifications.

Numerous staining techniques are available for visualization, differentiation and separation of bacteria in terms of morphological characteristics and cellular structures. A summary of commonly used procedures and their purpose is outlined in Figure 2.1.

- **Types of staining techniques**
  - **Simple Staining** Use of single stain
    - For visualization of morphological shape (cocci, bacilli and spirilli) and arrangement (chains, clusters, pairs and tetrads)
  - **Differential staining** Use of two Contrasting stains
    - Separation into groups
      - Gram's Stain
      - Acid-fast stain
    - Visualization of structures
      - Flagella stain
      - Capsule stain
      - Spore stain
      - Nuclear stain

Figure 1: Staining techniques

2.2.2 Requirements (Equipment /Machinery/Instrument and Chemicals/ Material)

- Bunsen Burner
- Microscope
- Test tube shaker
- Inoculating needle
- Cover slips
- Glass slides
- Sterilized test tubes
- Wash bottles
- Microbial cultures
- Distilled water
- Stains
- Immersion oil
- Tissue paper

2.2.3 Procedure

Preparation and fixation of bacteria for staining

Prior to staining, you must "fix" the material to be observed that is make it stick to the glass slide upon which is to be stained. If a preparation is not fixed, the film of cells will wash off during the staining procedure. Purpose of fixation is also to kill the microorganism and coagulate the protoplasm of the cell so as to fix it on glass surface (Figure 2.2).

The fixing technique, although not difficult, requires adequate care in its preparation. Follow these basic rules meticulously:

1. ***Preparation of glass slides:*** Clean slides are essential for preparation of microbial smears. Grease or oil from fingers on slides must be removed by washing the slides with soap and water, followed by a water rinse. After cleaning dry the slides and place them on laboratory towels until ready for use.

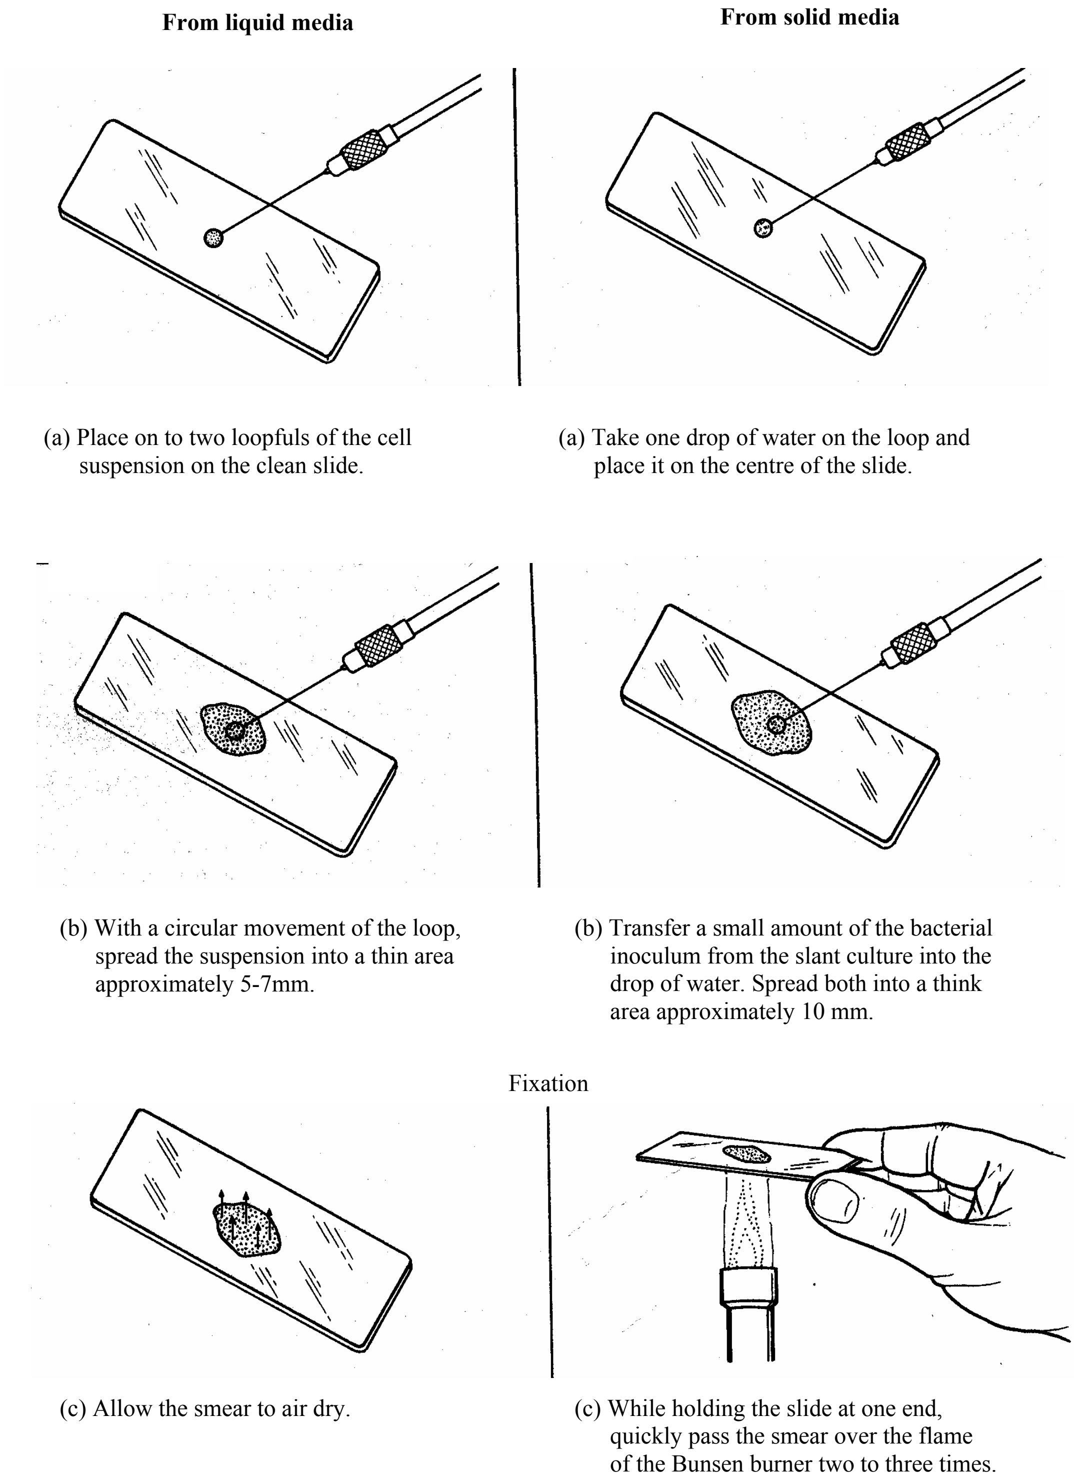

Figure 2.2: Bacterial smear preparation

2. ***Preparation of smear:*** Avoidance of thick, dense smears is absolutely essential. A good smear is one that, when dried, appears as a thin whitish layer or film. Those made from broth cultures or cultures from a solid medium require variations in technique.

   - *Broth cultures:* One or two loopful of suspended cells should be applied directly to the glass slide with a sterile inoculating loop and spread evenly over a small area.

   - *Cultures from a solid media:* Organisms cultured in a solid medium produce thick, dense surface growth and are not amenable to direct transfer to the glass slide. These cultures must be diluted by placing a loopful of water on the slide in which the cells will then be emulsified. Suspension is accomplished by spreading the cells in a circular motion in the drop of water with the needle tip. At this point, the smear must be allowed to dry completely. **Do not blow or wave it in the air.**

3. ***Heat fixation:*** Unless fixed on the glass slide, the bacterial smear will wash away during the staining procedure. This is avoided by heat fixation, during which the bacterial proteins are coagulated and fixed to the glass surface. Heat fixation is performed by the rapid passage of the air-dried smear two or three times over the flame of the Bunsen burner.

Staining with basic dyes

Herein, the bacterial smear is stained with a single basic stain. The bacterial nucleic acid and certain cell wall components carry a negative charge that strongly attract and bind to the cationic (negatively charged) chromogen. The purpose of simple staining is to elucidate the morphology and arrangement of bacteria.

The most commonly used basic stains are methylene blue, crystal violet and carbol fuchsin. Note that exposure time for staining cells to these dyes differs for each of these stains; carbol fuchsin requires 15-30 seconds, crystal violet 20-60 seconds and methylene blue 1-2 minutes for fresh cultures. For old cultures more time is required for staining.

General staining

Procedure for staining with different dyes:

1. Prepare bacterial smear of the organisms. Note: All smears must be heat fixed prior to staining.
2. Flood the smear with any one of the stains, using the appropriate exposure time.
3. Wash the stained preparation with tap water to remove excess stain. During this step, hold the slide parallel to the stream of water; in this way you can reduce the loss of organisms from the preparation.
4. Dry the slide using blotting paper.
5. Examine the stained preparation under the oil-immersion objective of the microscope.

Observe closely for significant difference in cell size, shape and arrangements.

Negative or indirect staining

1. Place a small drop of nigrosin close to one end of a clean slide.
2. Using sterile technique, place a loopful of inoculum from the mixed culture in the drop of nigrosin and mix.
3. With the edge of the second slide held at above 30° angle and placed in front of the bacterial surface, push the mixture to from a thin smear.
4. Air dry. Do not heat fixed slide.
5. Examine the slide under oil-immersion objective of the microscope.

Differential staining

Gram's stain

1. Prepare smear of the bacterial culture. Air-dry and fix these preparations with heat.
2. Flood smear with crystal violet and let stained for 30 seconds.
3. Rinse with water.
4. Cover the film with Gram's Iodine instantly and let stained for 1 min.
5. Wash with tap water.
6. Decolorize with 95% alcohol. For a thin smear, 10-20 second is long enough.
   Caution: Do not over-decolorize. Add reagent drop by drop until crystal violet fails to wash from smear.
7. Rinse with water.
8. Counter stain with safranine for 20-30 seconds.
9. Rinse with water and blot dry.
10. Examine under the oil-immersion objective.

Table 1: Steps in the gram's stain

Step	Procedure	Results	
		Gram +	Gram -
Initial Stain	Crystal Stain for 30 seconds	Stains purple	Stains purple
Mordant	Iodine for 30 seconds	Remains purple	Remains purple
Decolourization	95% ethanol for 10-20 seconds	Remains purple	Becomes colourless
Counterstain	Safranine for 20-30 seconds	Remains purple	Stains pink

Acid fast stain

1. Prepare a smear of bacterial culture.
2. Allow to air dry and heat fix in usual manner.
3. Flood smear with carbol fuchsin and place on a warm hot plate, allowing the preparation to steam for 5 minutes. **Caution**: Do not allow stain to evaporate, replenish stain as needed. Also prevent stain from boiling by adjusting the hot plate to a proper temperature.
4. Wash with tap water. Heated slides must be cooled prior to washing.
5. Decolorize with acidic alcohol (95% ethyl alcohol containing 2.5% HNO_3) for 10-30 seconds, a carbol fuchsin fails to wash from smear.
6. Wash with water.

7. Counter stain with methylene blue for 2 min.
8. Wash smear with tap water and blot dry.
9. Examine under the oil immersion objective.

Structural stain

Endospore stain

1. Prepare smear, air dry and fix with heat.
2. Flood smear with malachite green and place on a warm hot plate, allowing the preparation to steam for 2-3 minute.
   Caution: Do not allow stain to evaporate; replenish stain as needed. Prevent the stain from boiling by adjusting the hot plate at a proper temperature.
3. Cool slide and wash with water.
4. Counter stain with safranine for 30 min.
5. Wash with water and blot dry.
6. Examine under oil immersion objective.

2.2.4 Observations

In the space provided:

1. Draw a representative field for each organism
2. Describe the morphology of the organism with reference to their shape (bacilli, cocci, spirilli) and arrangements (chains, clusters, pairs)

Stain	Methylene blue	Gram Stain	Carbol Fuschin
Drawing of a representative field			
Cell morphology			
Arrangement			
Cell colour			

2.2.5 Results

Staining the microorganisms makes them contrast in colour with their surroundings so that they are more readily visible. Certain stains can also be used to identify certain structures of the cell which would otherwise be unseen.

2.3 PRECAUTIONS

- Clean, dry glass slide must be taken to prepare a smear.
- Thick dense smears should be avoided.
- The smear should be properly heat fixed on the slide to avoid its washing off during staining procedure.
- Do not heat fix in case of negative staining.
- Do not over decolorize in case of Gram's staining.
- Do not allow stain to evaporate while acid staining technique. Replenish stain as needed.

EXPERIMENT 3 CULTURING AND IDENTIFICATION OF MICROORGANISMS

Structure

3.1 INTRODUCTION

Microorganisms are ubiquitous. They are found in soil, air, water, food, sewage and body surfaces. In short, every area of our environment is replete with them. When grown on a variety of media, microorganisms will exhibit differences in the microscopic appearance of their growth. These differences, called cultural characteristics, are used as basis for separating microorganisms into taxonomic groups. The cultural characteristics for all non-microorganisms are contained in Bergy's Manual of Systemic Bacteriology with their morphological characteristics.

Objectives

After studying and performing this experiment, you should be able to:

- differentiate microorganisms into bacteria, yeasts and moulds; and
- know the different forms / shapes of microorganisms.

3.2 EXPERIMENT

3.2.1 Principle

The microorganisms can be divided into bacteria, yeasts and moulds on basis of the difference in their morphological, cultural and physiological characteristics.

Bacteria

Among the major characteristics of bacterial cells are their size, shape, structure and arrangement. These characteristics constitute the morphology of the cell. Bacteria are very small, most being approximately 0.5 to 1.0 micrometers in diameter. They are unicellular, have cell wall and cytoplasm but the nucleous is not well developed. The shape of a bacterium is governed by its rigid cell wall. Typical bacterial cells are spherical (cocci), straight rods (bacilli) or rods that are helically covered (spirilla).

Different patterns for arrangement for identification purposes are monococci, diplococci, streptococci, tetrads, staphylococci and sarcinae (Figure 3.1). Cocci generally reproduce by binary fission. Rod shaped bacteria may be sporulating type like *Bacillus* species and *Clostridium* species which produce endospores or they are non-sporulating like *Lactobacillus* species (Figure 3.2). Bacteria may be both motile (having flagella) or non-motile (no flagella).

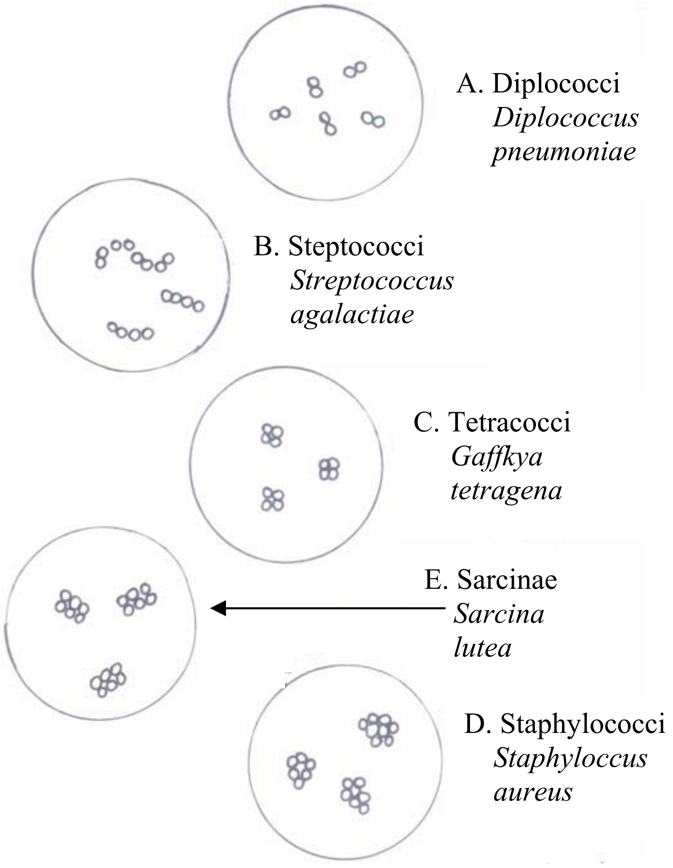

Figure 3.1: Characteristic arrangements of cocci

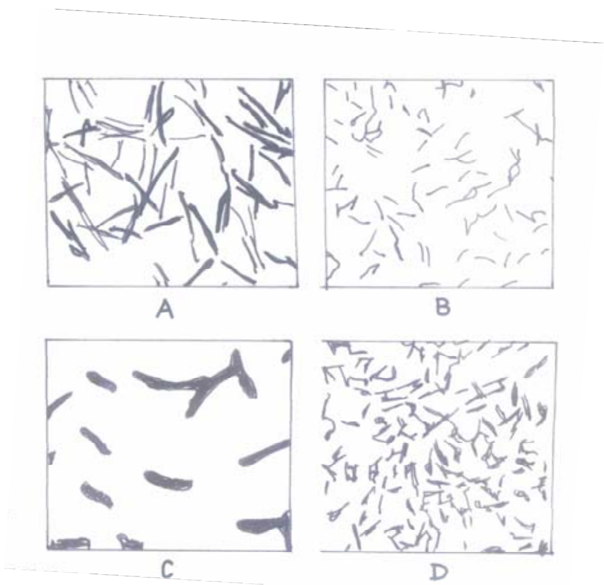

Figure 3.2: Types of rod-shaped bacteria. A) *Clostridium sporogenes*; B) *Pseudomonas sp.*; C) *Bacillus megaterium*; and D) *Salmonella typhi*

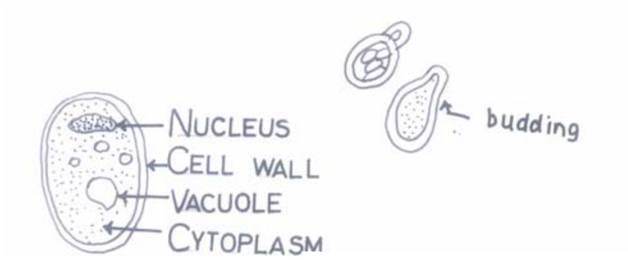
Fungi

Fungi is a group of eukaryotic organisms. They comprise of yeasts and moulds. Whereas moulds are filamentous and multicellular, yeasts are unicellular.

Yeasts

In general yeast cells are larger than most bacteria. Yeasts vary considerably in size ranging from 1-5 micrometer in width and from 5-30 micrometer in length. They are commonly egg-shaped, but some are elongated and some spherical. Yeasts lack flagella and other means of locomotion (Figure 3.3).



Saccharomyces sp. (a common bread yeast)

Figure 3.3: Yeast cell

Moulds

The thallus of moulds consist essentially of two parts: the mycelium and the spores. The mycelium is a complex of several filaments called hyphae. Filaments are made up of cells arranged end to end, branched and intertwined. Cells are like cells of higher plants in that they have visible nuclei, cell wall of varying thickness and cytoplasm. Mycelia in some fungi are divided into individual cells separated by cross walls and each cell containing a nucleus (Figure 3.4 and 3.5).

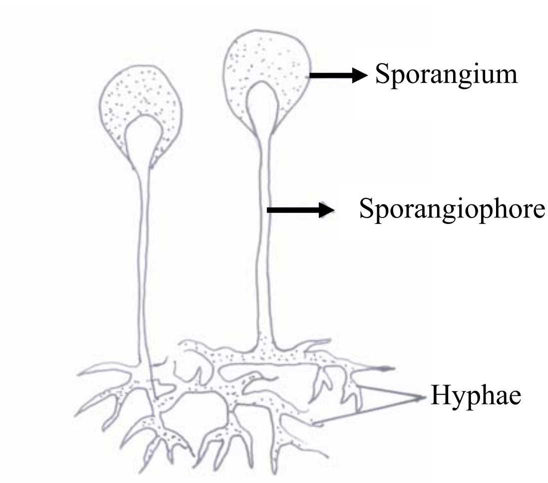


Figure 3.4: *Mucor* sp.

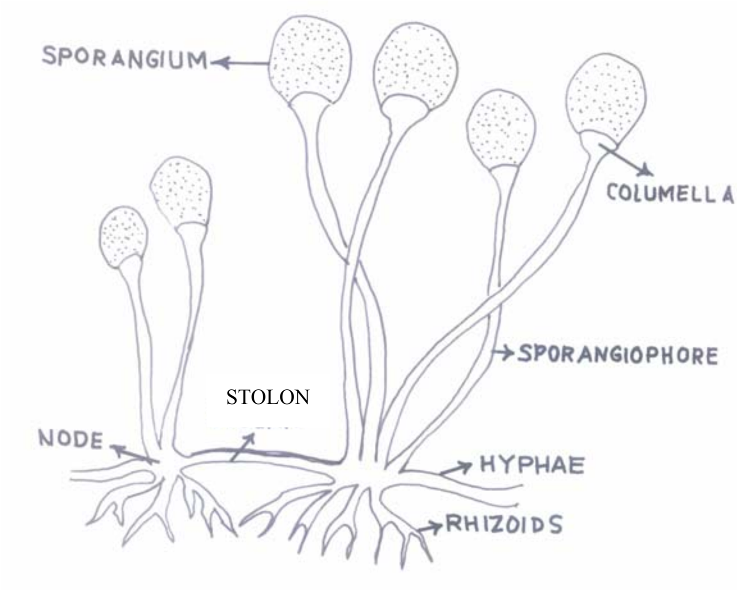

Figure 3.5: ***Rhizopus*** **sp.**

3.2.2 Requirements (Equipment/ Machinery/ Instrument and Chemicals/ Material)

- Compound microscope
- Bunsen burner
- Immersion oil
- Glass slides
- Inoculating needle
- Cover slips
- Tissue paper
- Microbial culture
- Distilled water

3.2.3 Procedure

1. Prepare the required media (broth or agar) for culturing the microorganisms
2. Place a small amount of media into test tubes, plug and sterilize them in an autoclave.
3. In case of solid media tubes, cool them in an incline position (slants)
4. When the medium is cold and solid, inoculate the surface of the medium using pre-sterilized needle. Move the needle gently on the agar surface in a snakelike motion from the butt to the top. In case of broth tubes, inoculate in the liquid media
5. Incubate both culture tubes at 30°C for few days.
6. In case of solid media, scoop out the mass of surface growth in which organism grows and put on clean, dry slide. From liquid broth, place a drop of culture on slide.
7. Observe under microscope.

3.2.4 Observations

In the chart provided:

1. Draw several cells from a typical microscopic field as viewed under each magnification.
2. Give the total magnification for each objective.
3. Observe spores or conidia and their arrangement.

	Bacteria	Yeast	Mould
Drawing of a representative field			
Magnification	---------------------	---------------------	--------------------

3.2.5 Results

Different types of spoilage have been encountered caused by various microorganisms. The type of microorganism proliferating depends on the composition of the material. The different spoilage microorganisms include bacteria, yeasts and moulds that can be observed and identified under a microscope by studying the morphological characteristics. These organisms vary in size, shape, colour, growth habit and mode of reproduction.

3.3 PRECAUTIONS

1. Use clean glass slides for smear preparation.
2. Thick, dense smears should be avoided.
3. Sterilize the inoculating needle before inoculation to avoid contamination.
4. The agar tubes should be properly sterilized.
5. Do not place the cotton plugs on ground during experiment.
6. Carefully view the characteristics of the microorganisms so as to differentiate them correctly.

EXPERIMENT 4 ASEPTIC CULTURE TECHNIQUE

Structure

4.1 INTRODUCTION

In previous experiments you learned that microorganisms thrive pretty much everywhere. It is far too easy to contaminate your lab cultures and experiments with stray microorganisms from the air, the countertop, or your tools. It is also possible to expose your surroundings or yourself to a possible pathogen. In this lab exercise, you will learn to transfer microbiological cultures from one medium to a second sterile medium without contamination of the culture, sterile medium, or the surroundings.

Objectives

After studying and performing this experiment, you should be able to:

- know how to handle microorganisms, tubed media, plated media, and inoculating tools such as loops, needles, or swabs etc.;
- learn how to transfer bacteria from test tubes or broth and agar; and
- learn how to transfer bacteria from Petri plates.

4.2 EXPERIMENT

4.2.1 Principle

Aseptic technique is a method that prevents the introduction of unwanted organisms into an environment. In order to protect sterile broth, media, plates, slants etc. from contamination we must practice aseptic i.e. sterile techniques to protect our material from contamination. By using aseptic technique only sterile surface touches other sterile surface and exposure to the non sterile environment is minimized.

Though, observing aseptic technique is the most important instruction for any microbiology experiment, some common circumstances will be discussed in this practical to make you aware of aseptic techniques.

Specific Aseptic Techniques

A) Sterilization of inoculation loop

The inoculation loop is sterilized by passing it at an angle through the flame of a gas burner until the entire length of the wire becomes orange or red hot. In this way all contaminants on the wire are incinerated. Never lay the loop down once it is sterilized or it may again become contaminated. Allow the loop to cool a few seconds to avoid killing the inoculum.

B) Transferring bacteria from broth culture to fresh broth

Requirements

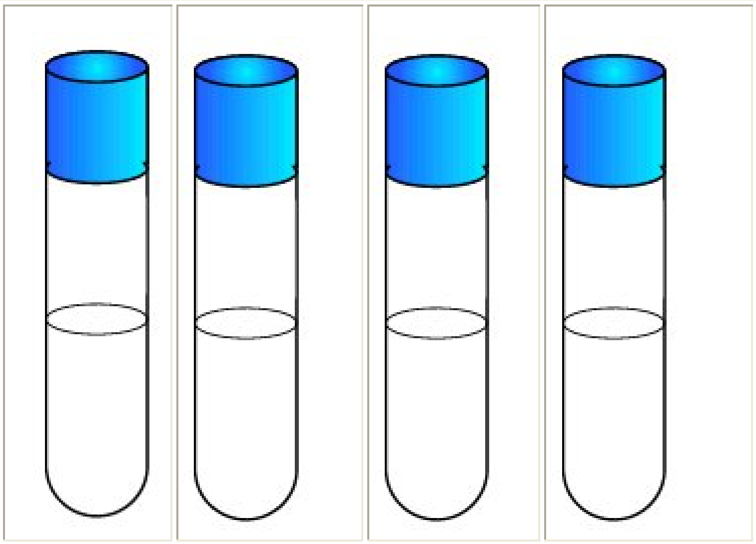
- Bunsen burner.
- Inoculation needle.
- Trypticase Soy Broth cultures of *Bacillus subtilis*, *Escherichia coli* and *Micrococcus luteus* and *Mycobacterium phlei* – referred to as Tubes A.
- Sterile Trypticase Soy Broth tubes (4 -one for each microorganism) – referred to as Tubes B.
- Glass Marking pen.

Procedure

1. Turn on the Bunsen burner.
2. Vortex culture suspensions of Bacteria given (Tubes A).
3. Place culture suspensions tube near sterile broth tubes (tubes B). Label sterile tubes with name of microorganism and date.
4. Sterilize the inoculation loop as explained above.
5. While holding inoculation loop between thumb and first two fingers of right hand, pick up tube A with left hand and open the cap/cotton plug with last two fingers of right hand.
6. Flame the lip of test tube A.
7. Place the sterile loop into culture A and take loopful of culture.
8. While still holding the inoculum in your right hand, pick up tube B with left hand and open the cap/cotton plug with last two fingers of right hand.
9. Flame the lip of test tube B gently
10. Place the loop containing droplet of culture in tube B and gently swirl it to transfer the microbes into sterile broth..
11. Take out the loop and continue to hold it in your hand.
12. Flame the lip of test tube B gently and replace the cap/plug which should be still in your right hand. Place tube B back in the test tube rack. Like wise plug the tube A and place in a test tube rack.
13. Sterilize the inoculation loop in flame.
14. Repeat the procedure with all bacterial cultures.

Results

1. Draw and describe the growth seen in each of the four broth cultures.



Bacillus subtilis Growth =	*Escherichia coli* Growth =	*Micrococcus luteus* Growth =	*Mycobacterium phlei* Growth =

Figure 4.1: Growth of bacterial culture

C) Streaking plating bacteria

a) From broth culture to sterile medium plate
b) From one petridish to fresh sterile medium plate

Requirements

- Bunsen burner.
- Inoculation needle.
- Trypticase Soy Broth cultures of bacteria (*Bacillus subtilis and Escherichia coli*) to be transferred (Tubes A).
- Trypticase Soy Agar plate cultures of bacteria (*Bacillus subtilis and Escherichia coli*) to be transferred.
- Sterile petridish having Trypticase Soy Agar medium (4 no. Two for each bacterium).
- Glass Marking pen.

Procedure

Removing inoculum from a broth culture

1. Label the plates and tubes.
2. Turn on the Bunsen burner.
3. Loosen the top of the bottle/ Tube containing the inoculum.
4. Hold the loop in the right hand.
5. Flame the loop and allow to cool.
6. Lift the bottle/test tube containing the inoculum with the left hand.
7. Remove the lid/cotton wool plug of the bottle/test tube with the little finger of the left hand.

8. Flame the neck of the bottle/test tube.
9. Insert the loop into the culture broth and withdraw. At all times, hold the loop as still as possible.
10. Flame neck of the bottle/test tube.
11. Replace the lid/cotton wool plug on the bottle/test tube using the little finger. Place bottle/test tube on bench.

Removing inoculum from a plate culture

1. Sterilize the inoculating loop in the flame of a gas burner.
2. Lift the lid of the culture plate slightly and stab the loop into the agar away from any growth to cool the loop.
3. Scrape off a small amount of the organisms and close the lid

Transferring the inoculum into a petri plate

1. Partially lift the lid of the Petri dish containing the solid medium.
2. Hold the charged loop parallel with the surface of the agar; smear the inoculum backwards and forwards across a small area of the medium
3. Remove the loop and close the Petri dish.
4. Flame the loop and allow it to cool. Turn the dish through 90º anticlockwise.
5. With the cooled loop streak the plate from area A across the surface of the agar in three parallel lines. Make sure that a small amount of culture is carried over.
6. Remove the loop and close the Petri dish.
7. Flame the loop and allow to cool. Turn the dish through 90º anticlockwise again and streak from B across the surface of the agar in three parallel lines.
8. Remove the loop and close the Petri dish.
9. Flame the loop and allow to cool. Turn the dish through 90º anticlockwise and streak loop across the surface of the agar from C into the centre of the plate
10. Remove the loop and close the Petri dish. Flame the loop.
11. Seal and incubate the plates inoculated with *Bacillus subtilis and Escherichia coli* **at 37°C upside down** (lid on the bottom) to prevent condensing water from falling down on the growing colonies and causing them to run together in inverted position.

Results

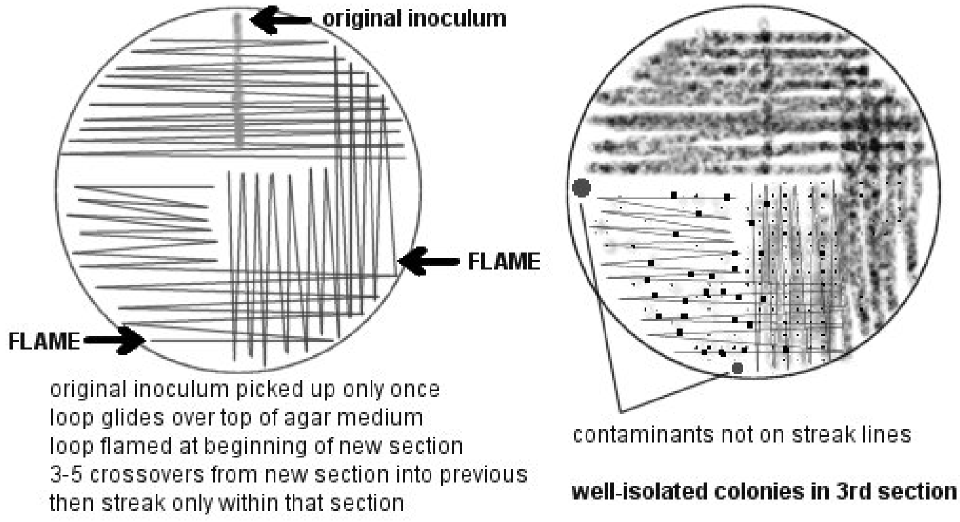


Figure 4.2: Streak plate technique

Expressing results

Bacterial colonies contain millions of cells and exhibit diverse morphologies; however, all isolated colonies produced on streak plates arise from a single bacterial cell. When evaluating colony morphology, use specific terms to describe the shape, elevation, colony margin shape, and surface texture (Figure 4.3). Colony size and colour are also useful features that are noted. All of these characteristics may be useful in the initial identification of unknown bacteria. Colonies that have different morphologies may be considered to contain different bacterial species. However, colonies that appear to be similar in morphology are not always the same bacterial species.

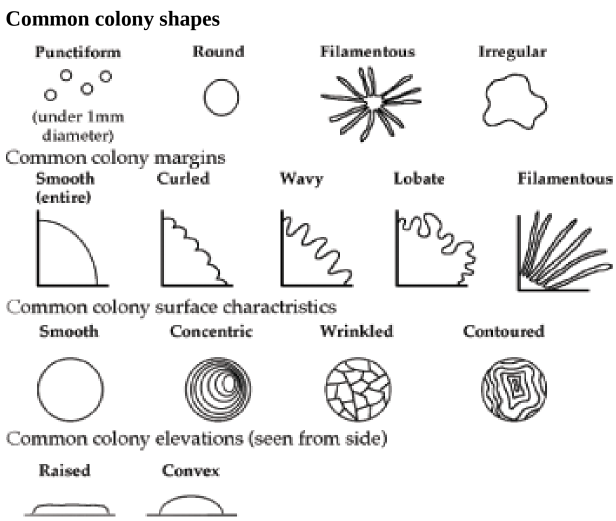

Figure 4.3: Terminology used to describe colony morphology

4.2.2 Observations

Obtain your streak plate from the incubator and visually examine the different regions:

1. Notice a dilution effect as you move from region to region.
2. Look for isolated individual colonies present.
3. Note different types of colony morphologies present.
4. Measure the size (diameter or length) and record the colony colour in Table 1.

Table 1: Colony characteristics of two bacterial colonies isolated using streak plating

Colony Size (mm)	Colour	Shape	Margin	Surface	Elevation
1.					
2.					

4.3 PRECAUTIONS

- Operations must not be started until all requirements are within immediate reach and must be completed as quickly as possible.
- Carry out all microbiological operations in a laminar flow hood.
- Wear gloves and lab coat to protect yourself but also to prevent dry skin and microorganisms from contaminating your samples.
- Use plugs made of non-absorbent cotton wool in test tubes and pipettes to prevent microorganisms from passing in or out and contaminating either the culture or the environment. The cotton wool must remain dry because this filtration property is lost if the cotton wool becomes moist – hence the use of non-absorbent cotton wool.
- For use in test tubes a plug should be properly made to ensure that it can be held comfortably without being dropped and its shape and form are retained while being removed from and returned to a test tube several times.
- Disinfect all surfaces prior to use with a disinfectant solution.
- Swab down the working surface liberally with 70% ethanol.
- Periodically spread a solution of 70% ethanol over the exterior of gloves to minimize contamination. Replace them if torn.
- In case of any spill, spread a solution of 70% alcohol and swab immediately with non-linting wipes.
- Discard gloves after use and do not wear them when entering any other lab area.
- Bring into the work area only those items needed for a particular procedure.
- Leave a wide clear space in the centre of the hood (not just the front edge) to work on. Do not clutter the area to prevent blockage of proper air flow and to minimize turbulence.
- Swab with 70% alcohol all glassware (medium bottles, beakers, etc.) before placing them inside the hood.
- Arrange the work area to have easy access to all of it without having to reach over one item to get at another (especially over an open bottle or flask).
- Use sterile wrapped pipettes and discard them after use into a biohazard waste container.

- Check that the wrapping of the sterile pipette is not broken or damaged.
- Vessels must be open for the minimum amount of time possible and while they are open all work must be done close to the Bunsen burner flame where air currents are drawn upwards.
- Discard any contaminated material immediately.
- Never perform mouth pipetting. Pipetting aids must be used.
- When handling sterile containers with caps or lids, place the cap on its side if it must be laid on the work surface.
- Make sure not to touch the tip of the pipette to the rim of any flask or sterile bottle.
- Clean the work area when finished by wiping with 70% alcohol.

EXPERIMENT 5 VISUAL AND MICROSCOPIC EXAMINATION OF RAW AND PROCESSED PRODUCT

Structure

5.1 INTRODUCTION

Isolation and identification of microbial food contaminants help to understand how infectious agents enter and spread through the food chain. There is a need to estimate the risk that food borne pathogens pose to human health in a national and international context and to identify possible interventions to reduce or eliminate these risks.

Objectives

After studying and performing this experiment, you should be able to:

- take visual observations of food samples
- visualize food-borne micro-organisms under the microscope.

5.2 EXPERIMENT

5.2.1 Principle

The potential for food to become contaminated with chemical substances or microorganisms starts from the time it is harvested and continues right through until the time it is eaten. The examination of food samples is one of the most important tasks:

Initial record of specimen as received

- Examine the specimen carefully for information such as to how it was received, condition (frozen, fresh), time, date, mode of delivery and write description of the specimen immediately.
- Examine seals for faults or damage and describe and note the details on the label.
- Weigh/ Measure the specimen as received and prior to opening.

Odour and taste

- Smell the food. The odour of a food can give clues to the nature of the complaint (volatile substances, deterioration, chemical taints etc.) Food may be required to be tasted CAREFULLY at this point.

Spoilage

- Visually observe spoilage by turbidity, gas production, bubbling etc.

Mouldy food

- Document a full description of the affected areas recording the types of colonies present, their colours and their textures. Measure the area(s) of suspect mould as soon as possible and in three dimensions if applicable. Ensure that the dimensions and numbers of individual colonies are noted.

Microscopic Examination of Foods

Principle

Microscopes are instruments that are capable of producing a magnified image of a small objects including microorganisms. In a food microbiology laboratory Compound Microscopes are most commonly used. These microscopes are light illuminated. They are used in observation and description of the microscopic morphology of bacteria, fungi, parasites and host cells in various stained and unstained preparations.

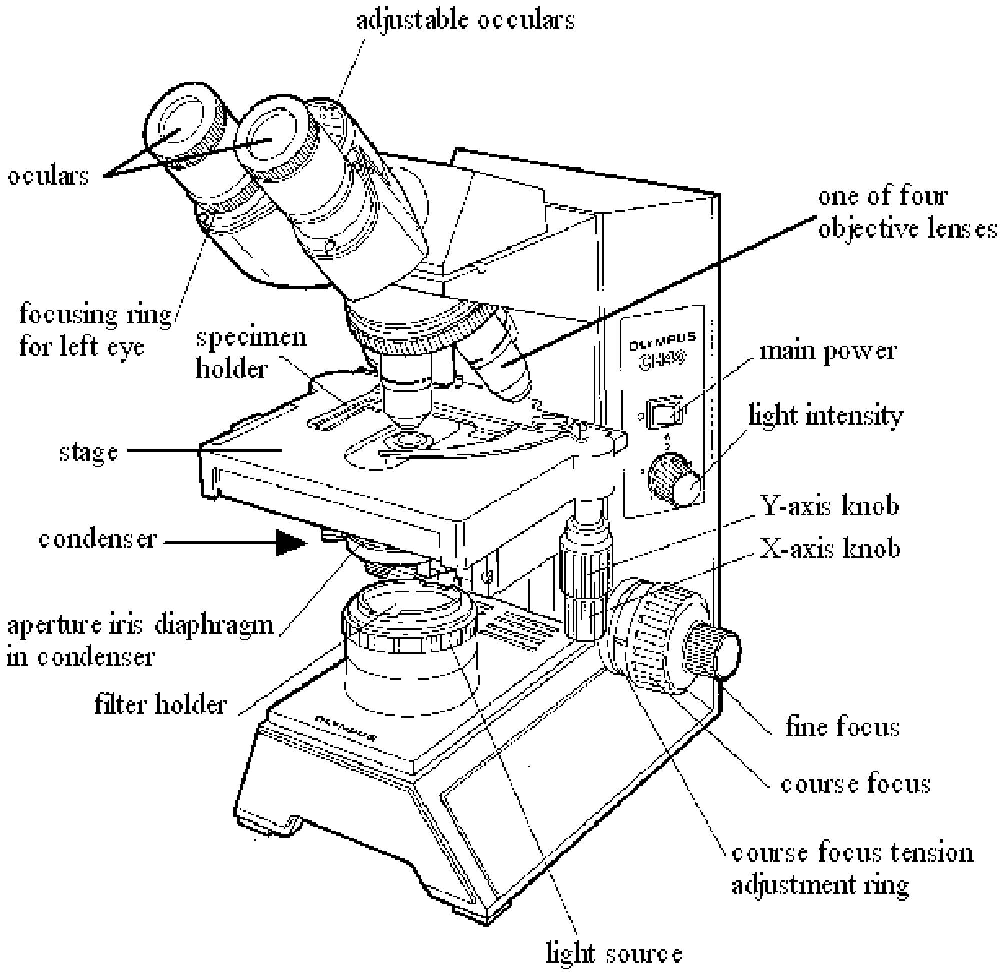

Figure 5.1: Labelled diagram of a compound microscope

Procedure to Focus the Specimen in Microscope

1. Obtain a prepared slide of contaminated food/ isolated microorganism. Mount the slide onto the stage of the microscope.

2. Start with the lowest power objective in place. Using the course adjustment knob, move the objective lens to its lowest point. Look through the ocular and focus upward with the coarse adjustment until an image comes into view. Use the fine adjustment to obtain maximum clarity. From this point on, do not use the coarse adjustment; doing so can result in damage to the lens, slide or both. Adjust the iris to allow enough light for maximum visibility and contrast. Usually, this will be about half the maximum iris opening. Too much light can wash out the details of the image.

3. Move the slide to a point of interest. Move the next objective lens into place and adjust the fine focusing knob, and adjust the iris as necessary. Repeat this step with the highest power, non-oil lens.

4. Note that as the power of the objective lens increases, the distance between the objective and the specimen (working distance) decreases. Also, as magnification increases, the field of view (visible area) and depth of field/focus (visible thickness) decrease. Moving the fine adjustment up and down allows viewing of other areas along the depth of thickness of the specimen).

5. To use the oil-immersion lens, move the turret halfway between the high-power air (non-oil) lens and the oil lens. Place a drop of immersion oil directly on the slide. Move the oil-immersion lens into place and adjust the fine focusing knob. Adjust the iris as necessary. Make sure that the immersion oil does not get on the air lenses. Make note of the differences and similarities between the organisms.

6. After using the oil lens for a specimen, wipe the lens with a piece of lens paper. Do not use anything but lens paper to clean microscope lenses. Usually, lens-cleaning fluids are not necessary unless the lens is exceptionally dirty.

For Getting the Best Possible Image

1. Use lens tissue, to clean the ocular and objective lenses; do not use any other kind of paper. You may also need to clean the slide.

2. Always begin to focus the microscope with the low power, coarse focusing knob.

3. For best viewing at high power, white light is essential. The higher the power of the objective lens, the less will be the depth of field.

Microorganism's Morphology Using the Microscope

Moulds

Mould mycelium and spores can be observed in unstained wet mounts at magnifications of x100 although direct observations of "mouldy" material through the lid of a Petri dish or specimen jar at lower magnifications with the plate microscope are also informative (but keep the lid on!). Routine identification of moulds is based entirely on the appearance of colonies to the naked eye and of the mycelium and spores in microscopical preparations.

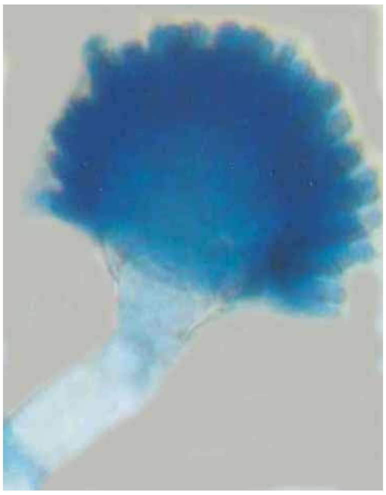

Figure 5.2: ***Aspergillus sp.*** **under microscope**

Yeast

Yeast can be seen in unstained wet mounts at magnifications ×100.

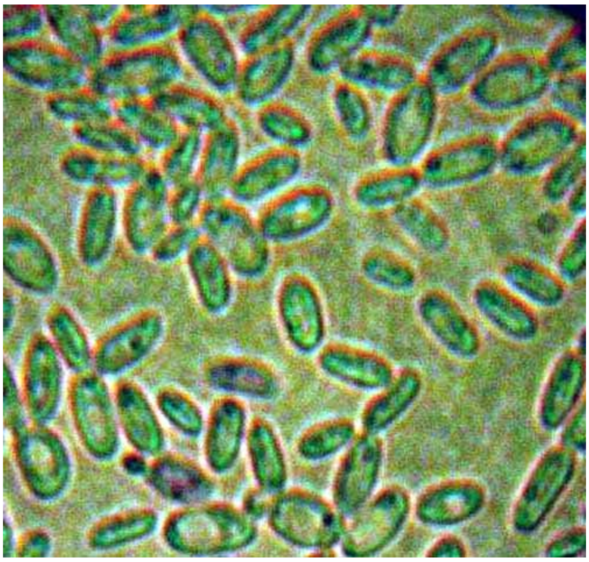

Figure 5.3: Yeast under microscope

Bacteria

Bacteria are much smaller and can be seen unstained at ×400 but only if the microscope is properly set up and all that is of interest is whether or not they are motile. A magnification of ×1000 and the use of an oil immersion objective lens for observing stained preparations are necessary for seeing their characteristic shapes and arrangements. If there is doubt that a food has caused food poisoning or has undergone microbial spoilage, the original product or a low serial dilution of it should be used to prepare a slide for direct microscopic examination. The Gram stain reaction and cellular morphology of the bacteria on the slide may indicate the need for other types of examination. A microscopic examination must be made, even though the food may have undergone heat treatment and the microorganisms involved may no longer be viable.

5.2.2 Requirements

1. Glass slides, 25 x 75 mm, with etched portion for labelling; 1 slide for each blended food sample (10^{-1} dilution)
2. Wire loop, 3-4 mm, platinum-iridium or nichrome, gauge No. 24 or 26
3. Gram stain reagents

Hucker's crystal violet

Solution A

Crystal violet (90% dye content) 2 g

Ethanol, 95% 20 ml

Solution B

Ammonium oxalate 0.8 g

Distilled water 80 ml

Mix solutions A and B. Store 24 h and filter through coarse filter paper.

Gram's iodine

Iodine 1 g

Potassium iodide (KI) 2 g

Distilled water 300 ml

Hucker's counterstain (stock solution)

Safranine O (certified) 2.5

Ethanol, 95% 100 ml

Working solution: Add 10 ml stock solution to 90 ml distilled water.

1. Compound Microscope, with oil immersion objective lens (95-100X) and 10X ocular
2. Immersion oil
3. Methanol
4. Xylene

5.2.3 Procedure

1. Prepare film of blended food sample (10^{-1} dilution).
2. Air-dry films and fix with moderate heat by passing films rapidly over Bunsen or Fisher burner flame 3 or 4 times. Alternatively, air-dry films and fix with methanol 1-2 min, drain excess methanol and flame or air-dry (this is particularly helpful for foods with a high sugar content).
3. Cool to room temperature before staining.
4. De-fat films of food with high fat content by immersing films in xylene 1-2 min; then drain, wash in methanol, drain, and dry.
5. Stain film by Gram-staining procedure.

Procedure for gram staining

1. Fix air-dried films of food sample in moderate heat. Stain films 1 min with crystal violet-ammonium oxalate solution.
2. Wash briefly in tap water and drain. Apply Gram's iodine for 1 min. Wash in tap water and drain.
3. Decolorize with 95% ethanol until blue color is no longer released (about 30 s). Alternatively, flood slides with ethanol, pour off immediately, and reflood with ethanol for 10 s.
4. Wash briefly with water, drain, and apply Hucker's counterstain (safranine solution) for 10-30 sec. Wash briefly with water, drain, blot or air-dry, and examine.
5. Examine under oil immersion and 10X ocular; adjust lighting systems to Koehlor illumination.
6. Examine at least 10 fields of each film, noting predominant types of organisms, especially clostridial forms, Gram-positive cocci, and Gram-negative bacilli.

5.2.4 Observations

- Observe the bacteria under the microscope.

	Gram positive bacterium	Gram negative bacterium

- Record the Results in table given below.

Table 1: Gram characteristic, size, shape of two bacterial as determined following Gram staining and observation using a compound microscope

Bacterium	Gram Reaction	Cell Size (µm)	Cell Shape
Unknown 1			
Unknown 2			

5.2.5 Results

- Large numbers of Gram-positive cocci on the slide may indicate the presence of staphylococcal enterotoxin, which is not destroyed by the heat treatments that destroy enterotoxigenic *Staphylococcus aureus* strains.

- Large numbers of sporeforming, Gram-positive rods in a frozen food specimen may indicate the presence of *Clostridium perfringens*, an organism that is sensitive to low temperatures. Other Gram-positive, sporeforming rods such as *Clostridium botulinum* or *Bacillus cereus* may also be present in the food.
- When the microscopic examination of suspect food discloses the presence of many Gram-negative rods, consider the symptoms and incubation periods reported for the illness under investigation and select the specific examination method for isolating one or more of the following genera: *Salmonella*, *Shigella*, *Escherichia*, *Yersinia*, *Vibrio*, or *Campylobacter*.

EXPERIMENT 6 ENUMERATION OF BACTERIA BY DILUTION AND PLATING

Structure

6.1 INTRODUCTION

The ability of microorganisms to grow and reproduce in food products is well known. Microorganisms may cause spoilage of the food product. Because of their very small size, counting the number of bacteria in a food sample can be difficult. Although direct counts are possible with a microscope, they require a lot of time and expertise. An easier method is to spread bacteria over a wide area (i.e. nutrient agar plate) and count the number of colonies that grow. If the bacteria are spread out enough, each bacterial cell in the original sample should produce a single colony. Usually, bacterial samples must be diluted considerably to obtain reasonable counts.

Objectives

After studying and performing this experiment, you should be able to:

- enumerate bacteria in food samples; and
- isolate pure colonies of bacteria.

6.2 EXPERIMENT

6.2.1 Principle

Since bacterial cell numbers are usually very high in your original sample, plating out this sample in an undiluted fashion would just lead to the creation of a bacterial lawn (a smear of many, many individual bacteria colonies that are all growing next to or on top of one another). Bacterial cell numbers need to be reduced, which is done by repeatedly diluting the amount of bacteria you have in your sample. A small amount of bacteria sample is mixed with a diluent solution (such sterile water or nutrient broth), and then successive dilutions are made. A small amount of each of the diluted bacteria samples is then spread onto an agar plate. The numbers of bacteria colonies that grow on each plate are counted. By working backwards using multiplication with the "dilution factor" (the number of times that you have diluted the bacteria sample with the diluent solution), you will be able to make a determination of the numbers of bacteria in your original sample.

For example, 10,000,000 cell per ml diluted to 100 cells per ml. It is virtually impossible to count 10,000,000 cells on the surface of the agar. However, it is much easier if we dilute the sample and only have to count 300 cells. Diluting is performed in increments because we must obtain a plate with between 30 and 300 colonies (for statistical purposes). Figure 6.1 shows how isolated colonies should look like.

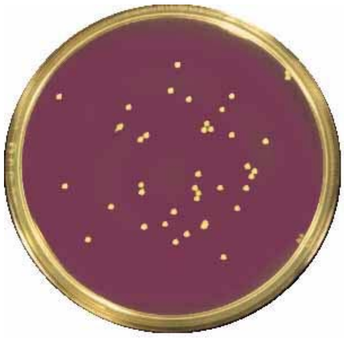

Figure 6.1: Bacterial colonies separated by spread plate method

6.2.2 Requirements

- Nutrient agar plates (6)
- Large sterile tubes (2)
- Tubes with 9 ml of sterile nutrient broth (11)
- Sterile transfer pipettes
- Sterile sticks (2)
- Micropipettor
- Bacteria spreader
- 70% alcohol
- Food samples (say Sample A has been stored in a refrigerator for 4 days;
- Sample B has been stored frozen)

6.2.3 Procedure

DAY 1

1. Label 9 dilution broth tubes as follows:

   A 10^{-2}, A 10^{-3}, A 10^{-4}, A 10^{-5}, A 10^{-6}, A 10^{-7},
   B 10^{-2}, B 10^{-3}, B 10^{-4}

2. Label 6 agar plates as follows:

   A 10^{-6}, A 10^{-7}, A 10^{-8}
   B 10^{-3}, B 10^{-4}, B 10^{-5}

3. Label one large sterile tube A and the other large sterile tube B. Weigh aseptically 1 gram of sample A, and place it in sterile tube A. Add the contents of one tube of dilution broth to the food sample, and shake the sample until the suspension appears fairly uniform. Repeat this with sample B and sterile tube B.

4. Serial Dilutions

   Precaution: You must use a new sterile pipette for each of the dilution steps.

Use a sterile pipette to transfer 1 ml of the suspension from large tube A to the culture tube labeled A 10^{-2}. Mix the contents thoroughly by pipeting up and down several times. Use a new pipette to transfer 1 ml from tube A 10^{-2} to tube A 10^{-3} and mix thoroughly as before. Continue this series of dilutions into tubes A 10^{-4}, A 10^{-5}, A 10^{-6} and A 10^{-7}.

Repeat this series of dilution using sample B. Transfer 1 ml of suspension from large tube B into tube B 10^{-2} and mix thoroughly. Serially transfer, as before, into tubes B 10^{-3} and B 10^{-4}.

5. Plating bacteria

   Use a micropipettor to withdraw 0.1 ml of liquid from tube A 10^{-5} and place it onto the surface of the agar plate labeled A 10^{-6}. (NOTE: Plating 0.1 ml of a 10^{-5} dilution will give you the same number of colonies as plating 1 ml of a 10^{-6} dilution; the agar plate cannot absorb 1 ml of liquid, so the smaller volume is used.)

   Sterilize the bacterial spreader by dipping it into a beaker of alcohol. Remove and shake off the excess. Carefully run the spreader through the flame of a Bunsen burner and allow the alcohol to burn off. Cool the spreader by holding it against the condensation on the inside of the petri dish lid. Gently spread the liquid culture onto the surface of the agar by moving the spreader in a circular manner while rotating the plate. This will ensure an even distribution of bacteria.

6. Repeat step 5 with the remainder of the A cultures:

   Spread 0.1 ml from culture tube A 10^{-6} onto plate A 10^{-7}
   Spread 0.1 ml from culture tube A 10^{-7} onto plate A 10^{-8}

7. Repeat step 5 with the B cultures:

   Spread 0.1 ml from culture tube B 10^{-2} onto plate B 10^{-3}
   Spread 0.1 ml from culture tube B 10^{-3} onto plate B 10^{-4}
   Spread 0.1 ml from culture tube B 10^{-4} onto plate B 10^{-5}

8. Allow plates to absorb the cultures, then turn plates upside-down and incubate overnight at 37° C.

Precautions

1. Before plating, be sure to label each plate with its dilution, date and "food".
2. Mix the samples thoroughly before plating.
3. After pipetting the correct amount of sample in each plate, spread the sample with a bactispreader evenly over the entire surface of the agar.
4. Remember to use aseptic technique. Invert plates. Incubate at 37°C.

6.2.4 Observations

On DAY 2, after incubating the plates, count the colonies on the plate. Each colony represents one cell initially plated. For statistical purposes, pick a plate with between 30 and 300 colonies.

PLATE # COLONIES	PLATE # COLONIES
A 10^{-6}	B 10^{-3}
A 10^{-7}	B 10^{-4}
A 10^{-8}	B 10^{-5}
Bacterial count in sample A (refrigerated food):	Bacterial count in sample B (food):

6.2.5 Calculations

Determine the number of cells/gram in the original sample of food by multiplying the number of colonies on a plate by the dilution factor of that plate.

Calculations dilutions made	**X**	**amount inoculated**	=	**"plated dilution"**
dilution factor (simply the inverse of the plated dilution)	X	# colonies	=	# CFUs/ml (or gram) of the original undiluted sample

Example

If a plate labelled 10^{-7} has 87 colonies, then the sample has $87 \times 10^{7} = 8.7 \times 10^{8}$ colonies per gram.

6.2.6 Result

Find the average number of cells/g by adding the results from all of your plates and dividing by the number of plates.

ANNEXURE-1

Composition of different media used for microbial study

1. *Standard Plate Count Agar (SPCA)*

Tryptone	-	5.0g
Yeast extract	-	2.5g
D-glucose	-	5.0g
Agar	-	15.0g
Distilled water	-	1000ml
pH	-	7.0

2. *Nutrient Agar for Bacterial count*

Beef extract	-	3.0g
Peptone	-	5.0g
Agar	-	15.0g
Distilled water	-	1000 ml
pH	-	7.0

3. *Potato Dextrose Agar for Fungal count*

Potato, peeled and diced	-	200g
D-glucose	-	20g
Agar	-	15.0g

Boil 200g of peeled and diced potato for 1 hr in a litre of water. Filter and make up the volume to 1litre and add rest of the constituents.

4. *Violet Red Bile Agar (VRBA) for coliform count*

Yeast Extract	-	3.0g
Peptone	-	7.0g
Sodium Chloride	-	5.0g
Bile Salts	-	1.5g
Lactose	-	10.0g
Neutral red	-	0.03g
Crystal violet	-	0.002g
Agar	-	13.0g
Distilled water	-	1000ml
pH	-	7.4

UNIT 1 PRINCIPLES OF HEAT AND MASS TRANSFER

Structure

1.0 OBJECTIVES

By the time you have studied this unit, you should be able to:

- define the basic principles and methods of heat transfer;
- explain the role of heat transfer in heat preservation processes;
- identify the type of food for heat processing;
- determine the heat penetration and calculate the process time in a food; and
- identify the factors affecting heat transfer and apply corrective measures to enhance the process of heat transfer.

1.1 INTRODUCTION

Heat transfer is an important operation in the food industry. Whether it is called cooking, baking, drying, sterilizing or freezing, heat transfer is part of processing of almost every food. Heat transfer is a dynamic process in which heat is transferred spontaneously from one body to another cooler body. The rate of heat transfer depends upon the differences in temperature between the bodies, the greater the difference in temperature, the greater will be the rate of heat transfer.

Temperature difference between the source of heat and the receiver of heat is, therefore, the driving force in heat transfer. An increase in the temperature difference increases the driving force and, thus the rate of heat transfer. The heat passing from one body to another travels through some medium, which in general offers resistance to the heat flow. Both these factors, the temperature difference and the resistance to heat flow, affect the rate of heat transfer.

1.2 HEAT TRANSFER SYSTEM

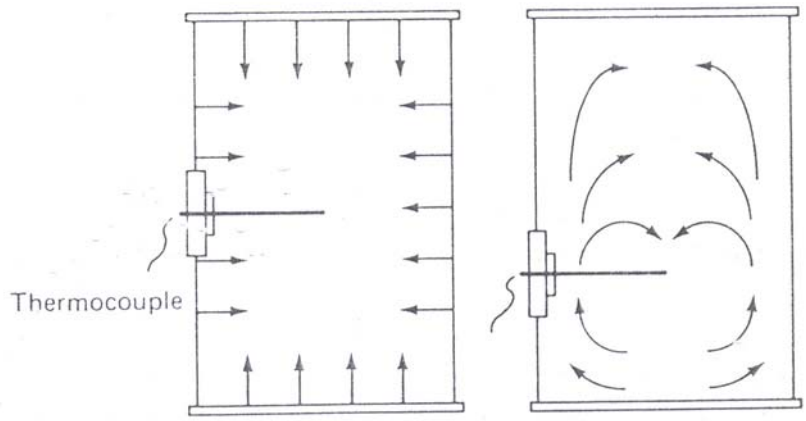
Heat can be transferred from one object to another in three ways: by **conduction,** by **convection** and by **radiation**.

Conduction is the movement of heat by direct transfer of molecular energy within solids. The molecules with greater energy communicating some of this energy to neighbouring molecules with less energy. An example of conduction is the heat transfer through the solid walls of a refrigerated store.

Convection is the transfer of heat by the movement of groups of molecules in a fluid. The groups of molecules may be moved by either density changes or by forced motion of the fluid. An example of convection heating is cooking in a jacketed pan: without a stirrer, density changes cause heat transfer by natural convection; while with a stirrer, the convection is forced.

Radiation is the transfer of heat energy by electromagnetic waves, which transfer heat from one body to another, in the same way as electromagnetic light waves transfer light energy. An example of radiant heat transfer is when a foodstuff is passed below a bank of electric resistance heaters that are red-hot (electric grill).

In general, heat is transferred in solids by conduction and in fluids by conduction and convection (Figure 1.1). Heat transfer by radiation occurs through open space, can often be neglected, and is most significant when temperature differences are substantial. In practice, the three types of heat transfer may occur simultaneously. For calculations it is often best to consider the mechanisms separately, and then to combine them where necessary.



(a) **(b)**

Figure 1.1: Heat transfer in containers by (a) conduction and (b) convection

1.2.1 Conduction

In the case of heat conduction, the equation, heat transfer rate = driving force/resistance, can be applied directly. The driving force is the temperature difference per unit length of heat-transfer path, i.e., temperature gradient. Instead of resistance to heat flow, its reciprocal, **conductance**, is used. This changes the form of the general equation to:

Rate of heat transfer = driving force x conductance, which is:

$$dQ/dt = kA\, dT/dx \qquad (1.1)$$

Where, dQ/dt (JS^{-1})is the rate of heat transfer, the quantity of heat energy transferred per unit of time, A (m^2)is the area of cross-section of the heat flow path, dT/dx (^{0}Cm^{-1})is the temperature gradient, that is the rate of change of temperature per unit length of path, and k (Jm^{-1} s^{-1} ^{0}K or Wm^{-1} ^{0}K^{-1})is the thermal conductivity of the medium. Notice the distinction between thermal conductance, which relates to the actual thickness of a given material (k/x) and **thermal conductivity**, which relates only to unit thickness. Eq. (1.1) is known as the **Fourier equation** for heat conduction.

Thermal conductivity does change slightly with temperature, but in many applications it can be regarded as a constant for a given material. Most foodstuffs contain a high proportion of water and as the thermal conductivity of water is about 0.7 J m^{-1} s^{-1}°C^{-1} above 0°C, thermal conductivities of foods are in the range 0.6-0.7 J m^{-1} s^{-1}°C^{-1}. Ice has a substantially higher thermal conductivity than water, about 2.3 J m^{-1} s^{-1}°C^{-1}. The thermal conductivity of frozen foods is, therefore, higher than foods at normal temperatures.

1.2.2 Convection

Convection heat transfer is the transfer of energy by the mass movement of groups of molecules. It is restricted to liquids and gases, as mass molecular movement does not occur at an appreciable speed in solids. It cannot be mathematically predicted as easily as can transfer by conduction or radiation and so its study is largely based on experimental results rather than on theory.

Newton found, experimentally, that the rate of cooling of the surface of a solid, immersed in a colder fluid, was proportional to the difference between the temperature of the surface of the solid and the temperature of the cooling fluid. This is known as **Newton's Law of Cooling**, and it can be expressed by the following equation.

$$q = h_s A(T_a - T_s) \qquad (1.2)$$

Where, h_s is called the surface heat-transfer coefficient, T_a is the temperature of the cooling fluid and T_s is the temperature at the surface of the solid. The surface heat-transfer coefficient can be regarded as the conductance of a hypothetical surface film of the cooling medium of thickness x_f such that

$$h_s = k_f / x_f$$

Where, k_f is the thermal conductivity of the cooling medium. It is useful at this point, however, to appreciate the magnitude of h_s under various common conditions and these are shown in Table 1.1.

Table 1.1: Approximate range of surface heat transfer coefficients

	hs (J m^{-2} s^{-1}°C^{-1})
Boiling liquids	2400-24,000
Condensing liquids	1800-18,000
Still air	6
Moving air (3 m s^{-1})	30
Liquids flowing through pipes	1200-6000

1.2.3 Radiation

Radiation heat transfer is the transfer of heat energy by electromagnetic radiation. Radiation operates independently of the medium through which it occurs and depends upon the relative temperatures, geometric arrangements and surface structures of the materials that are emitting or absorbing heat.

Radiation of wavelength 0.8-400 μm (infrared) is referred to as thermal radiation or heat rays since electro magnetic radiation with this wavelength is most readily absorbed and converted to heat energy. The infrared radiation is used primarily for surface heating as it is transmitted rapidly to the surface. It is used for dehydration of fruits and vegetables, freeze drying, baking, etc.

Radiation can be significant with small temperature differences as, for example, in freeze-drying and in cold stores, but it is generally more important where the temperature differences are greater. Under these circumstances, it is often the most significant mode of heat transfer, for example in bakers' ovens and in radiant driers.

The basic formula for radiant-heat transfer is the **Stefan-Boltzmann Law**

$$q = A\,\sigma \boldsymbol{T}^4 \tag{1.3}$$

Where, $\boldsymbol{T}$ is the absolute temperature (measured from the absolute zero of temperature at –273°C, and indicated in Bold type) in degrees Kelvin (K) in the SI system, and σ (sigma) is the Stefan-Boltzmann constant = 5.73×10^{-8} J m^{-2} $s^{-1}K^{-4}$ The absolute temperatures are calculated by the formula K = (°C+273).

This law gives the radiation emitted by a perfect radiator (a **black body** as this is called though it could be a red-hot wire in actuality). A black body gives the maximum amount of emitted radiation possible at its particular temperature. Real surfaces at a temperature T do not emit as much energy as predicted by Eq. (1.3), but it has been found that many emit a constant fraction of it. For these real bodies, including foods and equipment surfaces, that emit a constant fraction of the radiation from a black body, the equation can be rewritten

$$q = \varepsilon A\,\sigma \boldsymbol{T}^4 \tag{1.4}$$

Where, ε (epsilon) is called the **emissivity** of the particular body and is a number between 0 and 1. Bodies obeying this equation are called **grey bodies**. Emissivities vary with the temperature $\boldsymbol{T}$ and with the wavelength of the radiation emitted. For many purposes, it is sufficient to assume that for:

* dull black surfaces (lamp-black or burnt toast, for example), emissivity is approximately 1;
* surfaces such as paper/painted metal/wood and most foods, emissivities are about 0.9;
* rough un-polished metal surfaces, emissivities vary from 0.7 to 0.25;
* polished metal surfaces, emissivities are about or below 0.05.

These values apply at the low and moderate temperatures, which are those encountered in food processing. Just as a black body emits radiation, it also absorbs it and according to the same law, Eq. (1.3). Again grey bodies absorb a fraction of the quantity that a black body would absorb, corresponding this time to their **absorptivity** α (alpha). For grey bodies it can be shown that α = ε. The fraction of the incident radiation that is not absorbed is reflected, and thus, there is a further term used, the **reflectivity**, which is equal to (1 – α).

The radiant energy transferred between two surfaces depends upon their temperatures, the geometric arrangement, and their emissivities. For two parallel surfaces, facing each other and neglecting edge effects, each must intercept the total energy emitted by the other, either absorbing or reflecting it. In this case, the net heat transferred from the hotter to the cooler surface is given by:

$$q = AC\sigma\,(\boldsymbol{T}_1^{\,4} - \boldsymbol{T}_2^{\,4}) \tag{1.5}$$

where $1/C = 1/\varepsilon_1 + 1/\varepsilon_2 - 1$, ε_1 is the emissivity of the surface at temperature T_1 and ε_2 is the emissivity of the surface at temperature T_2.

1.2.4 Overall Heat Transfer Coefficients

It is most convenient to use overall heat transfer coefficients in heat transfer calculations as these combine all of the constituent factors into one, and are based on the overall temperature drop. Radiation coefficients, subject to the limitations discussed in the section on radiation, can be incorporated in the overall coefficient. The radiation coefficients should be combined with the convection coefficient to give a total surface coefficient, as they are in series, and so:

$$h_s = (h_r + h_c) \tag{1.6}$$

The overall coefficient U for a composite system, consisting of surface film, composite wall, surface film, in series, can then be calculated as:

$$1/U = 1/(h_r + h_c)_1 + x_1/k_1 + x_2/k_2 + \ldots + 1/(h_r + h_c)_2 \tag{1.7}$$

In Eq. (1.7) often one or two terms are much more important than other terms because of their numerical values. In such a case, the important terms, signifying the low thermal conductance are said to be the **controlling terms**.

1.2.5 Heat Transfer from Condensing Vapours

The rate of heat transfer obtained when a vapour is condensing to a liquid is very often important. In particular, it occurs in the food industry in steam-heated vessels where the steam condenses and gives up its heat; and in distillation and evaporation where the vapours produced must be condensed. In condensation, the latent heat of vaporization is given up at constant temperature, the boiling temperature of the liquid. Two generalized equations have been obtained:

1) For condensation on **vertical tubes or plane surfaces**

$$h_v = 0.94\,[(k^3\rho^2 g/\mu) \times (\lambda/L\Delta T)]^{0.25} \tag{1.8}$$

Where, λ (lambda) is the latent heat of the condensing liquid in J kg^{-1}, L is the height of the plate or tube and the other symbols have their usual meanings.

2) For condensation on a **horizontal tube**

$$h_h = 0.72\,[(k^3\rho^2 g/\mu) \times (\lambda/D\Delta T)]^{0.25} \tag{1.9}$$

1.2.6 Heat Transfer to Boiling Liquids

When the presence of a heated surface causes a liquid near it to boil, the intense agitation gives rise to high local coefficients of heat transfer. A considerable amount of experimental work has been carried out on this, but generalized correlations are still not very adequate. It has been found that the apparent coefficient varies considerably with the temperature difference between the heating surface and the liquid. For temperature differences greater than about 20°C, values of h decrease, apparently because of blanketing of the heating surface by vapours. Over the range of temperature differences from 1 to 20°C, values of h for boiling water increase from 1200 to about 60,000 J m^{-2} s^{-1} $°C^{-1}$. For boiling water under atmospheric pressure, the following equation is approximately true:

$$h = 50(\Delta T)^{2.5} \tag{1.10}$$

Where, ΔT is the difference between the surface temperature and the temperature of the boiling liquid and it lies between 2 and 20°C. In many applications the high boiling film coefficients are not of much consequence, as resistance in the heat source controls the overall coefficients.

1.3 TYPE OF FOOD FOR HEAT PROCESSING

There are essentially two types of food when we talk of thermal processing:

1. Acid foods
2. Low acid foods

These two categories of foods differ significantly in their behaviour when thermally processed. The acidity of the food, using the pH scale as a measure of acidity, where 1 = very high acid and 4 = very low acid; the dividing line for **acid foods** and **low-acid foods** is pH 4.6. **Acid foods** can be canned at a temperature of 100°C, while **low-acid foods** must be pressure canned (to a temperature of 115°C). The reason for this is that the toxin-producing, potentially lethal organism, *Clostridium botulinum*, will not grow and produce toxins at a pH below 4.6. Many spoilage microorganisms will not grow between pH 1 and 4.6 either. The most common spoilage microorganisms associated with **acid foods** are yeasts and moulds that can tolerate acid environments.

1. Acid foods

High acid foods contain more natural acids. Many fruits are high acid foods and the presence of these natural acids helps prevent growth of some spoilage microorganisms. If the food product has a high enough acid level, boiling-water temperatures are high enough to destroy spoilage organisms. This is a prevention method for the deadly *Clostridium botulinum* bacteria.

2. Low acid foods

Low acid foods, such as vegetables and meat products, contain very little natural acid. They must be processed at higher temperatures than boiling-water to destroy any *Clostridium botulinum* bacteria. Water boils at 100°C, at sea level, and at a lower temperature at higher elevations. Turning up the temperature under the pot or letting the water boil for a longer time does not raise the temperature of the water above its boiling point. To make water boil at a higher temperature, it has to be put under pressure, such as in a pressure canner. When a food is processed at 1.0 kg/cm^2 pressure, the water boils when it gets to 115°C, rather than at 100°C. This is high enough to kill the bacteria that causes botulism poisoning.

Adjust for Altitude to Ensure Safety

The above values of temperatures have been determined for mean sea level. As we move up the mountains, the atmospheric pressure goes down and water boils at lower temperatures as altitude increases. Lower boiling temperatures are less effective for killing bacteria. You must increase either the process time or canner pressure to make up for lower boiling temperatures.

Because altitude affects pressure and the boiling point of liquid, adjustments must be made when canning foods at altitudes of 300 m above sea level or higher. When using the boiling water bath method, processing time must be increased. Add 5 minutes to processing time for altitudes between 300 m and 1500 m above sea level. When using the pressure canner method, pressure must be increased. If using a dial-gauge pressure canner, process foods at 0.8 bar pressure for altitudes between 600 m and 1200 m and at 0.9 bar pressure for altitudes between 1200 m and 1800 m. If using the weight-gauge pressure canner, use 1.0 bar of pressure.

When you mix low-acid and acid foods, assume that the mixture remains low-acid. Although tomatoes used to be considered an acid food, some are now known to have pH values slightly above 4.6, which means they are low-acid. To safely can them as acid foods in a boiling-water canner, you must add lemon juice or citric acid.

1.4 HEAT PENETRATION

Heat penetration studies are required to be conducted for verifying the sterilizing temperature of a load (food) meant for moist heat sterilization. These studies are conducted to ensure that the coolest unit within a pre-defined loading pattern (including minimum and maximum loads) will consistently be exposed to sufficient heat lethality (minimum "F").

Heat penetration curve can be drawn by plotting the logarithmic difference between either retort temperature and product temperature (heating curve) or product temperature and cooling medium temperature (cooling curve) versus time. The purpose of a heat-penetration study is to determine the heating and cooling behaviour of a product/package combination in a specific retort system for the establishment of safe thermal processes and evaluating process deviations. The study is designed to adequately and accurately examine all critical factors associated with the product, package and process, which affect heating rates. A goal in conducting these studies is to identify the worst-case temperature response expected to occur in commercial production as influenced by the product, package and process.

Several product, process, package and measurement-related factors can contribute to variations in the time-temperature data gathered during a heat-penetration test. Establishment of a process requires expert judgment and sound experimental data for determining which factors are critical and the effect of changing those factors both within and beyond established critical limits.

A typical heat penetration curve is shown in Figure 1.2. A broken heating curve occurs when a food is initially heated by convective heating but then undergoes a rapid transition to conductive heating (for example in foods, which contain high concentration of starch, which undergoes a sol-to-gel transition).

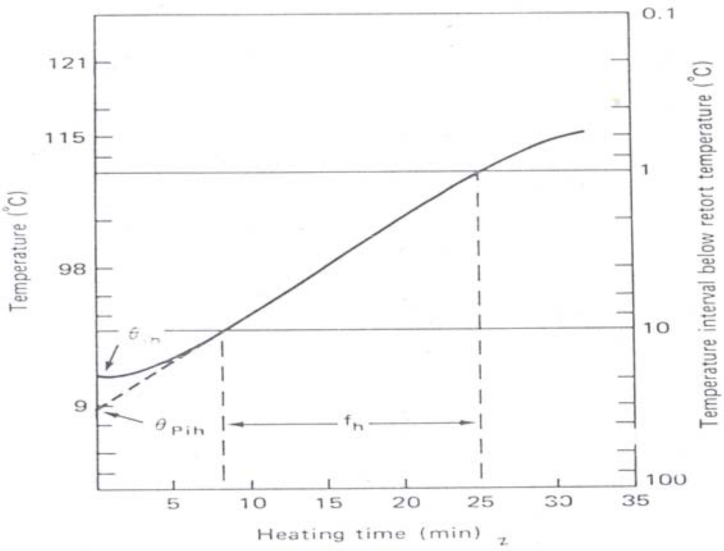

Figure 1.2: Heat penetration curve

There are a number of ways of estimating how effective heat sterilization can be. The thermal death time is the time microbes must be exposed to a particular temperature before they are all dead. Similarly, the thermal death point is the temperature at which all microbes in a sample are killed. Both are very unsatisfactory, since they depend on many factors such as number of microbes present in a sample, analytical conditions and techniques, etc.

1.5 HEAT TRANSFER CHARACTERISTICS OF FOOD

It is necessary to have information on both the heat resistance of microorganisms or enzymes and the rate of heat penetration into the food for determination of process time of a food.

Heat is transferred from steam or pressurized water through the container and into the food. Generally the surface heat transfer coefficient is very high and is not a limiting factor in heat transfer. The following factors influence the rate of heat penetration into a food:

i) Type of product
ii) Size of the container
iii) Agitation of the container
iv) Temperature of the retort
v) Shape of the container. Tall containers promote convection currents in convective heating foods.
vi) Type of container. Heat penetration is faster through metal than through glass or plastics owing to differences in thermal conductivity.

In this section, the objective is to learn as to how the thermal properties of food products affect the heat penetration and the quantity of heat. Two thermal properties of importance are thermal conductivity and thermal diffusivity in determining heat penetration. Specific heat and latent heat are important in determining the quantity of heat required for the process.

I. **Thermal conductivity** is the property indicating the rate at which heat flows through a food product. A product with high thermal conductivity lets the heat flow easily, whereas a material with low thermal conductivity, also known as an insulator, puts resistance to the flow of heat. Fourier's heat conduction equation could be used to derive the units of thermal conductivity, i.e., W/(m°C). It does change slightly with temperature, but in many applications it can be regarded as a constant for a given material. Most foodstuffs contain a high proportion of water and as the thermal conductivity of water is about 0.7 J m^{-1} s^{-1} $°C^{-1}$ above 0°C, thermal conductivities of foods are in the range of 0.6-0.7 J m^{-1} s^{-1} $°C^{-1}$. Ice has a substantially higher thermal conductivity than water, about 2.3 J m^{-1} s^{-1} $°C^{-1}$. The thermal conductivity of frozen foods is, therefore, higher than foods at normal temperatures.

Typical thermal conductivities

Metals: k = 50-400 W/m°C
Water: k = 0.597 W/m°C
Air: k = 0.0251 W/m°C
Insulating materials: k = 0.035 - 0.173 W/m°C

For foods it is represented as

$$k = 0.25\, m_c + 0.155\, m_p + 0.16\, m_f + 0.135\, m_a + 0.58\, m_m$$

Where m is mass fraction and subscripts c: carbohydrate, p: protein, f: fat, a: ash and m: moisture.

or

$$k = 0.55p/100 + 0.26(100-p)/100 \text{ J m}^{-1}\text{ s}^{-1}\text{ °C}^{-1} \text{ above freezing}$$

$$= 2.4p/100 + 0.26(100 - p)/100 \text{ J m}^{-1}\text{ s}^{-1}\text{ °C}^{-1} \text{ below freezing.}$$

Where p is the percentage of water in the foodstuff.

II. Thermal diffusivity is the actual ability of a food to conduct heat to adjacent molecules. Thermal diffusivity is a derived property that is the ratio of thermal conductivity and the product of density and specific heat. The units of thermal diffusivity, therefore, work out to be m^2/s. Higher value of thermal diffusivity means faster heat penetration and vice versa.

III. Specific heat: The specific heat is an important quantity that determines the amount of energy that must be supplied or withdrawn from a unit mass of material in order to increase or decrease its temperature by one degree. Knowledge of the specific heat of a material is, therefore, important in the design of processes such as chilling, freezing, warming, sterilization and cooking. Specific heat has the units of kJ/(kg.K) in SI system of units.

$$\text{Specific heat} = 4.19p/100 + 0.84(100 - p)/100 \text{ kJ kg}^{-1}\text{ °C}^{-1} \text{ above freezing}$$
$$= 2.1\, p/100 + 0.84(100 - p)/100 \text{ kJ kg}^{-1}\text{ °C}^{-1} \text{ below freezing.}$$

p is percentage of water in food stuff

IV. Phase transitions: It is important to determine the temperature at which transitions occur, the enthalpy change associated with a transition, the type of transition involved (exothermic or endothermic), and the quantity of material that undergoes a transition. As an example, we will consider the melting and crystallization of food components. When a material changes its physical state from solid-to-liquid (melting) or from liquid-to-solid (crystallization) it absorbs or gives out heat, respectively. A process that absorbs heat is an endothermic process, whereas a process that evolves heat is an exothermic process. Pure substances usually have very sharp melting or crystallization points and, therefore, all the heat is absorbed or evolved over a narrow range of temperature. Most foods are complex materials and, therefore, do not exhibit sharp transitions from one phase to another. The amount of heat required for the phase change is called the latent heat and has the units of kJ/kg.

$$\text{Latent heat} = 335p/100 \text{ kJ kg}^{-1}$$

This equation and the ones given earlier for thermal conductivity and specific heat represent a considerable over-simplification so they should be used with caution, particularly in the region between –18°C to 0°C. Freezing of foodstuffs occur over a range of temperatures and not at any fixed point.

Some properties of liquids and thermal data for food products are depicted in Tables 1.2 and 1.3, respectively.

1.6 DEVICES FOR DETERMINATION OF HEAT PENETRATION

There are different types of thermometers available for measuring the temperature in a thermal process and, thereby, permitting the determination of heat penetration.

I. Mercury-in-glass (MIG) thermometer

Each retort system used for the thermal processing is equipped with a MIG thermometer. Aseptic processing systems may have a temperature indicating device other than MIG thermometer as the sole temperature indicator. The MIG thermometer is the reference instrument for all temperature readings, including vent temperature, come-up temperature and process temperature during processing.

It is important that the MIG thermometer be tested/calibrated at the operating temperature of the retort system (i.e., 115□C, 120□C, 125□C etc.) and if possible in the heating medium used in the retort. If the retort is operated at more than one processing temperature or over a wide range of temperatures the MIG thermometer should be checked at all of the temperatures normally used for processing. The MIG thermometers should be tested against a thermometer that can be traced back to a BIS Standard thermometer. The accuracy of the standard thermometer should be checked at least once every 3 years depending upon how it is handled and stored.

II. Temperature recording device

Each retort system is equipped with an accurate temperature-recording device. The recording device provides a continuous record of the temperature in the retort system during thermal processing. Common systems in use are circular or strip charts, which are marked with ink pens, electrical sparks, pressure pins, or which are created by graph plotters at the time temperature readings are received. Electronic temperature monitors and recorders are now available for the purpose and should be utilized for greater accuracy and precision avoiding human errors. A band or ribbon type surface pyrometer is used by processors to monitor container surface temperatures.

III. Temperature sensors

Temperature measurement can be accomplished by essentially five basic methods: (1) liquid-in-glass, (2) resistance thermometry, (3) thermoelectric thermometry, (4) optical/radiation pyrometry, and (5) bi-metal. Investigators are most familiar with the liquid (mercury or alcohol usually) -in-glass and the bi-metal (dial gauge) types. It is possible now that investigators will encounter the use of the optical/radiation pyrometers as well.

i) Resistance thermometry

A resistance thermometer is a temperature-measuring instrument consisting of a sensor (an electrical circuit element whose resistance varies with temperature), a framework on which to support the sensor, a sheath by which the sensor is protected, and wires by which the sensor is connected to a measuring instrument, which is used to indicate the effect of variations in the sensor resistance. Resistance thermometers provide absolute calibration of temperatures in that no reference junctions are involved, and no special extension wires are needed between the sensor and the measuring instrument (as with thermocouples).

The sensors can be of two types: resistance temperature detectors (RTD's) and thermistors. The RTD sensing element is formed of solid conductors (usually in wire form) wound upon an insulating core. The insulating core is usually made of mica or ceramic. The conductors, which are wound in a helical coil to prevent mechanical restraints during thermal expansion, are generally made of platinum; however nickel and copper have been used. Platinum best meets the requirements because being a noble metal, it can be highly refined, it resists contamination, it is mechanically and electrically stable, and the relationship between temperature and resistance is quite linear.

Thermistors (a contraction for "thermally sensitive resistors") are electrical circuit elements formed of solid semi conducting materials such as oxides of nickel, manganese, iron, cobalt, copper, magnesium, titanium, and other metals. The powdered metal is formed under pressure into the desired shape, usually a flat disc. The disc is sintered, leads are attached, and encapsulated in epoxy. The finished thermistor can also be encased in a sheath of plastic, stainless steel, copper or aluminum. Both the RTD and thermistor can be obtained in various configurations.

ii) Thermoelectric thermometry

The thermoelectric thermometer is a temperature measuring instrument consisting of two continuous, dissimilar thermocouple wires extending from a measuring junction to a reference junction with copper connecting wires to a potentiometer. Unlike the resistance types, where power must be supplied to the circuit, the thermocouple circuit generates a measurable low voltage output that is almost directly proportional to the temperature difference between the "hot" junction and the "cold" junction. A unit change in this temperature difference will produce some net change in electromotive force (emf or voltage). Thermoelectric thermometry makes use of the known relationship between a difference in junction temperatures and the resulting emf developed by a thermocouple circuit. The temperature of one junction (reference junction, T1) is held at a constant known value. This is usually accomplished with an ice water (0°C) bath. The temperature of the other junction (measuring junction, T2) is determined by measuring the thermocouple circuit emf and referring to calibration tables for the particular thermocouple materials. The thermocouple junction usually is formed by twisting and fusing the two wires together or they may be butt-welded. The finished element may be used bare or enclosed in a sheath.

1.7 DETERMINATION OF COLD POINT IN A FOOD CONTAINER

In a study, determination of the cold spot was made using data collected for heat penetration curves at 5 potential cold spot locations in the jars in 18 canner loads (Table 1.4). Two levels of two procedural variations were used in testing for process calculations. Temperature profiles were compared for two fill weights (450g, 480g) and two fill temperatures (direct-fill, and after a 10 minute wait, which had means of 84.4°C and 80.4°C, respectively). Process calculation was accomplished by using thermocouples in each of six jars in different canner loads of each of the three fill methods (standard, low initial temperature, and high-fill weight). These jars were processed to 90.5°C plus an additional 5 minutes. Processing was done in a boiling water canner using the stovetop burners of a household gas range. Data were recorded using Type T copper-constantan thermocouples.

Cold Spot Location

- The cold spot for this product and jar combination was located at the geometric centre of the jar, Table 1.4.

- The D value is the number of minutes it takes the straight line portion of the heat penetration plot to pass through one logarithmic cycle.
- A larger D represents a slower rate of heat penetration.

Table 1.4: Cold spot determination of cranberry salsa in pint jars

Thermocouple height in pint jar	Average D value n = 18	Range	Standard deviation
Centre	54.86[1]	48.5-73.4	5.3
½" Below Center	53.89	48.6-64.7	3.9
1" Below Center	51.94	45.8-64.9	4.8
1½" Below Center	48.98	43.0-60.8	4.7
2" Below Center	47.00	41.4-58.0	4.5

[1]Location of cold spot, as determined by largest individual D value (worst-case scenario)

Heat penetration measures the rate at which a product heats during a thermal process. A temperature sensor or thermocouple measures temperature changes in the slowest heating region of the product or container and temperature is monitored on a recording device. The time/temperature data, and heat resistant data for the target microorganism, are used to calculate the scheduled process.

1.8 CALCULATION OF PROCESS TIME

The time/temperature relationship required for desired reduction of microbial population is based on thermal resistance characteristics of the microorganisms. The translation of this information into a form for use by the operator of a commercial system requires integration with the heating and cooling characteristics of the food product within the container. The methods to be presented lead to the establishment of a processing system operator time to ensure that the impact of the thermal process is equivalent to the desired time/temperature for a given microbial population.

One of the first concepts to be understood when establishing process times is **lethality**. The term lethality can be defined as the integrated influence of time and temperature on a microbial population. Lethality is expressed as time at a reference temperature.

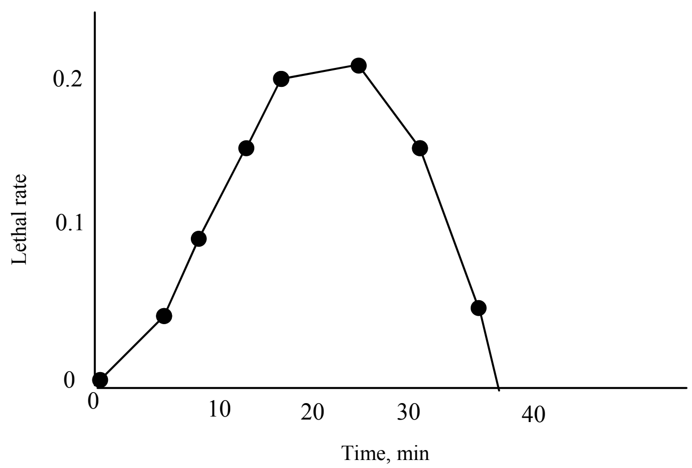

Figure 1.4: Lethal rate curve for typical process in retort

The lethal rate increases gradually with time as the temperature of the product increases. As the product temperature begins to plateau at a magnitude near the heating medium temperature, the lethal rate also plateaus and eventually decreases as the product temperature decreases during cooling. Lethality is expressed in time units for the process accomplished at the heating medium temperature.

The time/temperature relationship representing the process is compared to the process requirement needed to achieve product safety or an established spoilage rate. For example, if the process under consideration is being used to ensure the elimination of *Clostridium botulinum* as a health risk, the lethality for the process must be equal to or greater than the thermal death time for the microbial population.

The D-value or Decimal Reduction Time may be used as a measure. This is defined as the time taken under specified conditions and at a particular temperature to kill 90 per cent of the microbes in a sample. Only 10 per cent or 1/10 of the original number of microbes survive the decimal reduction time: hence its name. D-values can be determined from survivor curves when the log of population is plotted against time.

$$D_{\text{reference temperature}} = \text{Time}/(\text{Log}_a - \text{Log}_b)$$

Where a = the initial population, and b = the survivors after a time interval. F value is a mathematically calculated number that describes the total lethal effect of the process at the slowest heating point in a food container. It is the equivalent, in minutes at a given temperature, of all heat considered with respect to its capacity to destroy spores or vegetative cells of a particular microorganism.

The effectiveness of a canning process is determined from a combination of experimentation and calculation. Processing parameters are expressed in terms of a series of symbols of which D, z, and F are key. When bacterial spores are heated to a lethal temperature as during retorting of canned foods, the death of most species approximates a first order chemical reaction that can be described by a straight line on a semi-logarithmic graph paper. Figure 1.4 shows a hypothetical result from heating a species of spore at 115°C (240°F).
In Figure 1.5, one minute is required to reduce the survivors from 10,000 to 1,000 or a 90 per cent reduction (one log reduction). Similarly, one minute is required to reduce the survivors from 1,000 to 100 per gram of food and so on until only 0.01 of a spore is present in 1 gram of food-which really means that there remains only one living spore for each 100 grams of food. This time to reduce the survivors by 90% is the Decimal reduction (D) value or in Figure 1, D_{115} = 1 min. The subscript after the D indicates temperature at which the D value was determined. Many factors affect the D value, such as the species of spore, and the kind of food the spore is suspended in.

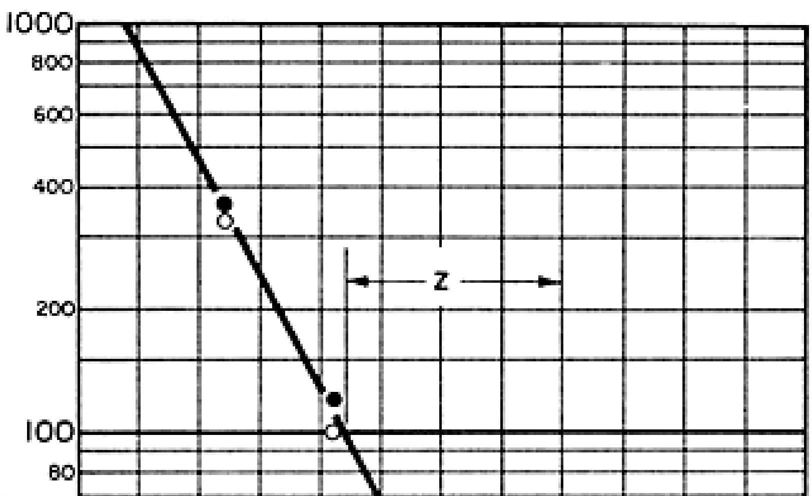

Figure 1.5: Thermal death time curve for *Clostridium botulinum*

1.9 FACTORS AFFECTING HEAT PENETRATION

There are many factors, which affect the heat transfer into the food. Generally the surface heat transfer coefficient is very high and is not a limiting factor in heat transfer. The following factors are important which influences the rate of heat penetration into a food:

1. **Type of product:** Liquid or particulate food (for example peas in brine), where natural convection current is established, heat faster than solid food (for example meat pastes and corned beef), where heat is transferred by conduction. The low thermal conductivity of food is a major limitation to heat transfer in conduction heating.

2. **Size of the container:** Heat penetration to the centre is faster in small containers than in large containers.

3. **Agitation of the container:** End-over-end agitation (Figure 1.6) and, to a lesser extent, axial agitation increases the effectiveness of natural convection curie: and thereby increases the rate of heat penetration in viscous or semi-solid foods (for example beans in tomato sauce).

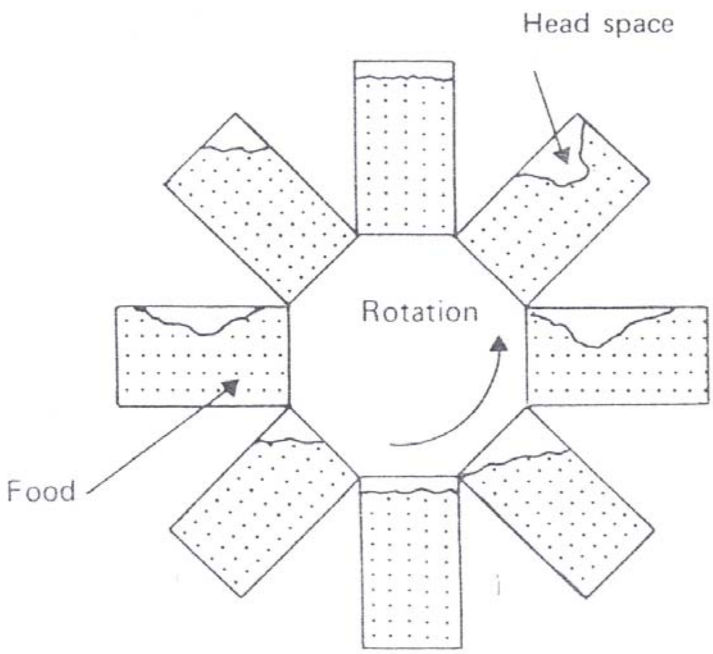

Figure 1.6: End-over-end agitation of containers

4. **Temperature of the retort:** A higher temperature difference between the food and the heating medium causes faster heat penetration.

5. **Shape of the container:** Tall containers promote convection currents in convective heating foods.

6. **Type of container:** Heat penetration is faster through metal than through glass or plastics owing to differences in thermal conductivity.

1.10 LET US SUM UP

We have in this unit learnt the basic concept of heat transfer. Heat is transferred by conduction, convection or radiation modes in a given situation. The methods of temperature measurement include mercury-in-glass (MIG) thermometers, resistance temperature detectors, thermistors, thermocouples and radiation pyrometers. Temperature measurements permit us to evaluate heat penetration rates in the thermal processes so as to determine the process durations to achieve acceptable sterilization levels. These levels differ for acid and less acid foods. If the pH level is below 4.6 the food is classified as an acid food. However, if the pH is equal to or more than 4.6, the foods are low-acid and the process temperatures would have to be more than 100°C. Temperatures more than 100°C are achievable through raising process pressure above that of the ambient. It is important to identify the cold spot in the sterilization process because the heat penetration to that spot will control the overall effectiveness of the process. Decimal reduction time at a given reference temperature is used to fix the process time. Usually, 12 logarithmic cycles are allowed for the microbial population reduction and, thus, the process time F is equal to 12 D. The factors responsible for affecting the temperature distribution and heat penetration rate need to be given due consideration for finalizing the process durations.

1.11 KEY WORDS

Conduction	:	Exchange of molecular energy directly exchanged, from the hotter to the cooler regions.
Convection	:	Transfer of heat by the movement of groups of molecules in a fluid.
Radiation	:	Transfer of heat energy by electromagnetic waves.
Black body	:	It is a body which absorbs all incident light on it.
Grey body	:	Body which partially absorbs and partially reflects incident light falling on it.
Fourier equation	:	It is the general equation guiding conduction heat transfer.
Newton's law of cooling	:	It is the guiding principle behind convective heat transfer.
Radiation pyrometers	:	Measures temperature of a distant / hot object without coming into contact with it.
Decimal reduction time	:	Time required for reducing the microbial population to one tenth of its initial number.
Microbial lethality	:	Time temperature combination to kill all microorganisms including its spores.

1.12 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answers should include the following points:

1. The different methods of heat transfer are: Conduction, Convection and Radiation.

2. The rate of conduction heat transfer increases as the temperature gradient increases.

   The equation, $dQ/dt = kA\ dT/dx$ is known as **Fourier equation** of heat conduction.

3. The basic formula for radiant-heat transfer is the **Stefan-Boltzmann Law,** $q = \in \sigma \boldsymbol{T}^4$.

   As indicated in the equation, the radiative heat flux q, is proportional to the fourth power of temperature. That means for any increase in temperature the flux increases much faster. The emissivity of the object, $\in$, indicates its capacity in relation to a black body to emit thermal radiation. The value of $\in$ is in the range of 0-1; a black body has $\in = 1$ and a perfectly reflective body has $\in = 0$. The σ is Stefan-Boltzmann constant.

4. If the temperature of one of the objects is doubled, it means the temperature difference between the two objects has increased. Since convection is directly proportional to the temperature difference, it will increase in proportion to the temperature difference. On the other hand the radiation heat transfer is proportional to the difference in the fourth power of the temperatures of the two objects, the radiation heat transfer will increase much more steeply. You can therefore, appreciate that the radiation heat transfer increases much faster than the conduction or convection when the temperature difference between two objects increases.

Check Your Progress Exercise 2

Your answers should include the following points:

1. The acid and low-acid foods are distinguished on the basis of pH. The foods with pH less than 4.6 are called acid and the foods with pH more than 4.6 are called low-acid foods.

2. The thermal process for an acid food consists of treating it in a 100°C boiling water bath, whereas the low-acid food must be pressure treated to a temperature of 115°C or higher to kill the spoilage causing microorganisms.

3. To make water boil at a temperature higher than 100°C in food processing, it has to be put under pressure, such as in a pressure canner. When a food

is processed at 1.0 kg/cm^2 pressure, the water boils when it gets to 115°C, rather than at 100°C.

4. At higher altitudes the atmospheric pressure goes down and water boils at lower temperatures. Thus, to make the thermal processing effective, either the process time or canner pressure must be increased to make up for lower boiling temperatures. That means pressure treatment may be required even for acid foods.

Check Your Progress Exercise 3

Your answers should include the following points:

1. a) Mercury-in-Glass (MIG) Thermometer
   b) Resistance temperature detector sensors

2. A thermocouple is made by joining two dissimilar metals. When one of the junctions is at a different temperature than the surrounding temperature, then a small voltage is developed which can then be measured across the two leads at the other junction. When provision is made in the circuit to take care of the reference point such as the freezing point of water, then the resultant voltage is calibrated in terms of temperature difference between the reference point and the temperature of the junction.

3. A thermistor is normally a thermally sensitive material whose electrical resistance changes with temperature. This change in resistance is calibrated in terms of temperature. It differs from a resistance temperature detection (RTD) sensor in terms of its sensitivity. As a result a thermistor is able to sense very small changes in temperature as compared to a RTD sensor.

4. K = (°C + 273), where K and C are units of temperature in Kelvin scale and Celsius scale.

Check Your Progress Exercise 4

Your answers should include the following points:

1. The Decimal Reduction Time or D-value is defined as the time taken to kill 90% of the microbes in a sample under specified conditions and at a particular temperature. D-values are determined from survivor curves when the log of population is plotted against time.

   $$D_{\text{reference temperature}} = \text{Time}/(\text{Log}_a - \text{Log}_b)$$

   Where a = the initial population, and b = the surviving population after a time interval.

2. The F value for a process is the number of minutes required to kill a known population of microorganisms in a given food under specified conditions. This F value is usually set at 12 D values and the resultant microbial population is extremely low such as one microbe in 10,000 cans (say).

3. *Clostridium botulinum* is the reference microorganism, which is used in determining the different parameters related to thermal processing.
4. Lethality is defined as the integrated influence of time and temperature on a microbial population. It is expressed in time units for the process accomplished at the heating medium temperature. For e.g., a thermal process may require 65 min at 115°C of steam temperature for a given food product to achieve full lethality.

UNIT 2 HEAT APPLICATION

Structure

2.0 OBJECTIVES

After reading this unit, you should be able to:

- enumerate processes commonly used in processing of fruits and vegetables based on heat application;
- state difference between direct and indirect method of heat transfer;
- identify various types of heat exchangers;
- describe important features of process equipment used for blanching, pasteurization, sterilization and aseptic processing; and
- explain the principle of microwave and ohmic heat transfer.

2.1 INTRODUCTION

We have studied the basic principles of heat transfer in the previous unit. Now, in this unit, we will go through the heat application aspects in relation to processing of fruits and vegetables. The subject shall be of great interest to us as processes based on application of heat form the core of food preservation and processing operations. In fact, thermally processed foods constitute a large part of the industry. As a post-harvest technician or entrepreneur or food technologists, it is essential for us to know about type of heating processes and equipment available so that the twin objectives of preservation and value addition could be achieved effectively and efficiently. Further, understanding of some of the basic thermal processing principles will help in selecting the processing parameters which would ensure maximum retention of sensory and nutritional attributes.

The important conventional as well as new processes such as blanching, pasteurization, sterilization and aseptic processing, microwave, etc., along with associated equipments have been discussed in this unit. In most of these operations, the heat transfer takes place in the form of convection and conduction. Two different principles are used in heat application. In one case, the heating medium is mixed with product to be heated. This is called direct heating and is used: (a) to heat water – steam is injected directly into the water, and (b) application of direct heating in aseptic processing either through injection or infusion. The direct method of heat transfer is efficient for rapid heating. It does, however, involve mixing of the product with the heating medium, and this necessitates strict demand on the quality of the heating medium. Indirect heat transfer is the most commonly used in food processing operations. In this method, a partition is placed between the product and the heating or cooling medium. Heat is then transferred from the medium, through the partition into the product. Most of the heat exchangers in the industry are designed on this principle. General principles governing heat transfer and response of fruits and vegetables to heat energy can be applied to all heat processes but each type of thermal processes has separate objectives. Therefore, the heat application has been delineated in this unit on basis of the objectives of the heat process after introducing heat exchangers.

2.2 HEAT EXCHANGERS

A heat exchanger is a device that transfers heat from one fluid to another without allowing them to mix, i.e., to transfer heat by the indirect method. In food processing, the purpose is to heat or cool a liquid food in bulk.

The heat exchanger has two channels separated by a partition. Hot water flows through one channel and juice through the other. Heat transfer, in connection with food products, follows general law of heat and, therefore, can be calculated by the formula:

$$Q = UA\,\Delta T$$

Q = Rate of heat transfer (Btu/hr)

U = Overall heat transfer coefficient (Btu hr^{-1} ft^{-2} $^{o}F^{-1}$)

A = Heat transfer area between medium and product (ft^2)

ΔT = Difference in temperature of medium and product (temperature of high medium and temperature of product/ low temperature medium) (^{o}F)

(A true temperature difference is given by logarithm mean difference and is represented by Δ Tm = mean differential temperature.)

From the above equation, it may be said that heat transfer is increased by:

i) Temperature difference between the “warm” and the cold “media”. This is known as driving force;

ii) Greater available surface area – this means that a greater quantity of heat can be transferred if the area of the interface between medium and product is increased;

iii) Greater overall heat transfer coefficient (U Value) – more heat can be transferred if the U value is increased. This value is determined by several factors, including the flow rates of the media, the viscosity of the product, the shape of the heat transfer surface area and the material of which the partitions are made.

2.2.1 Practical Application of Principle of Heat Transfer

We know that food products are sensitive to temperature and agitation and this affects the capacity and efficiency of heat exchangers, for example, the higher temperature difference between the product and the heating medium may cause burning of certain food solids. Some of general principles for practical heat exchangers as outlined by Farrall (1976) are:

i) Rapid movement of the film of fluids on both sides of the heat transfer surface is important.

ii) Thorough and certain mixing of the film adjacent to the heat transfer area, with the body of the fluids is essential.

iii) Make use of the counter flow principle where possible, that is having the cold inlet product adjacent to the coldest outlet of the heating medium in a continuous system.

iv) Use as great a temperature difference as possible consistent with accurate temperature control and prevention of bad effects on the product treated.

v) Use as few intermediate cooling fluids or heating fluids as possible.

vi) Use as thin a sheet of heat transfer wall as possible consistent with proper mechanical strength.

vii) Use a heat transfer surface having good heat conductivity.

2.2.2 Types of Heat Exchangers

There are many types of equipment encountered in the food industry. The most important are the plate type, tubular type, scraped surface and vat type. The heating medium is usually either hot water or steam. A brief description is given below so that we may be able to use them effectively.

I. Tubular heat exchanger

The simplest type of tubular exchangers is the double pipe which consists of two concentric tubes with one fluid passing along the centre tube and the second fluid flowing in the annular space created between the tubes. Triple tube type employs three concentric tubes, with the product flowing through the intermediate passage and the heating or cooling medium flowing with counter current system in the other two passages, so that the product is surrounded on both sides. Today the tubular exchangers are not extensively used in food processing industries. The capital cost for these are low.

II. Scraped surface heat exchanger

The scraped surface heat exchanger is designed for heating and cooling of viscous, sticky and lumping products and for crystallization. This consists of a double-pipe exchanger with a central rotating shaft inside the inner pipe. Scraper blades are attached to the shaft and remove any material which builds up on the inner pipe wall. The second fluid flows in the annular space as in a conventional exchanger. The continual scrapping of the heat transfer surface ensures that higher heat transfer coefficients are obtained with highly viscous fluids.

III. Plate heat exchanger

One of the most popular type of heat exchanger is the plate system in which thin corrugated plates are stacked together to provide passage for the product and for the heating and cooling fluid. The advantages are:

i) High heat transfer surface area within a small plant volume.

ii) High heat transfer coefficients due to configuration of the plate surface.

iii) Easily cleanable either by opening it up or by CIP (cleaning in place) method.

iv) Versatile-addition of extra plates to increase surface area, ability to arrange a wide variety of flow patterns and several different fluids can flow through separate sections of the same heat exchanger, for example, allowing heating, cooling and heat recovery to take place in a simple unit.

v) Comparatively low in cost.

IV. Vat or tank heat exchanger

The flooded jacket, vat or tank is the simplest form of heat-exchanger, which is essentially a tank within a tank, with a space between the two that is flooded with water. The vat types of heat-exchangers are mainly used for batch pasteurization. For heating, a steam injection and mixing unit is employed and the agitator is provided for movement of the product over the heat exchanger surface.

2.3 BLANCHING

As you know that blanching is a heat treatment applied to tissue systems of fruits or vegetables, primarily to inactivate natural food enzymes, prior to canning, freezing or drying. Most blanching operations are accomplished by putting the product in contact with either hot water or steam for an appropriate time. Blanching is not indiscriminate heating. Too little is ineffective, and too much damages the fruits/vegetables. The time is dependent on the objectives of the process, i.e., whether enzymes are to be inactivated or whether partial cooking is desired. It involves: i) heating food to a preset temperature, ii) holding for a preset time, and iii) cool rapidly to ambient temperature. The blanching of vegetables is most often done in hot water or steam containing calcium or magnesium salts to check chlorophyll degradation. Calcium brines or colloidal thickness are used in blanching of fruits for firming them. The blanching is not recommended for frozen fruits after thawing as it results in undesirable changes in texture and flavour. The adequacy of blanching is known through the catalase or the peroxidase test. The peroxidase system is most commonly used and we know that a negative peroxidase test is necessary to prevent the development of undesirable characteristics in the finished product.

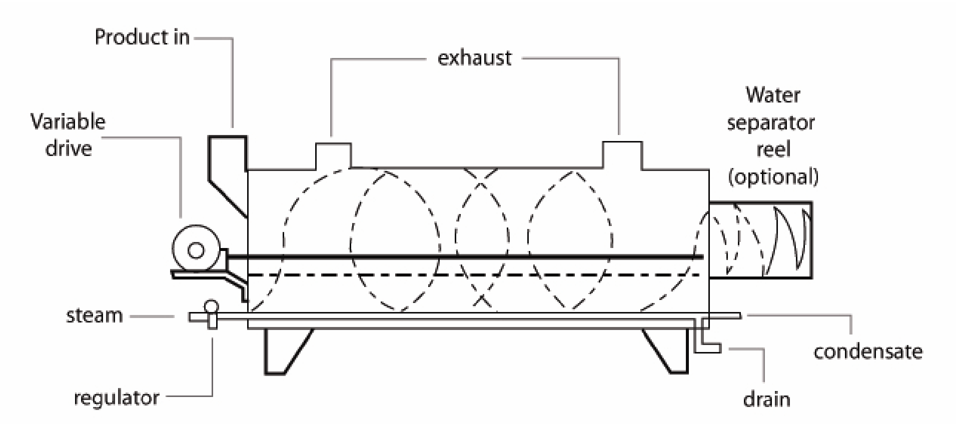
2.3.1 Process Equipment

Rotary hot water and steam blanchers are common process equipment and are shown in Figure 2.1 (a) and (b), respectively. They are available with variable speed drive. The rotary hot water blancher receives the product through a valve just above the drive end. The product is conducted into a spiral unit which conveys it to the opposite end. In the case of the hooded live steam blancher which has a perforated wire belt, the blancher serves as a conveyor making it very adoptable to the system.

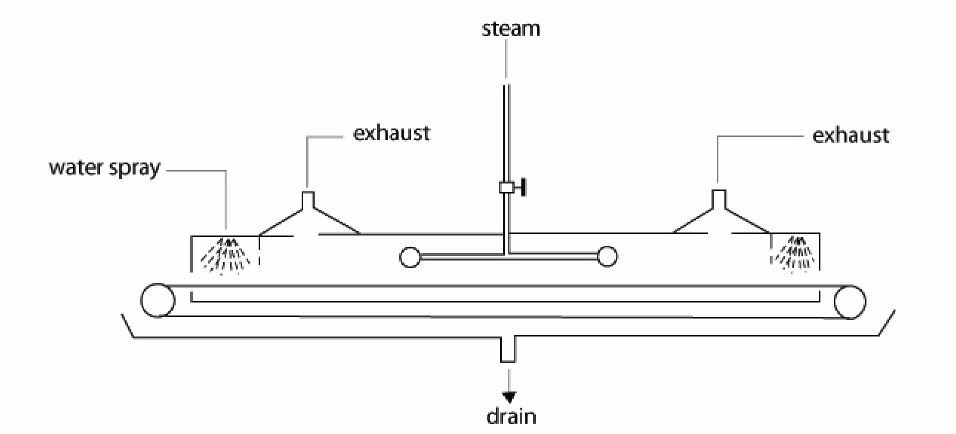
The steam blancher consists of a metal frame with galvanized sheet metal forming the steam chamber. The unit is frequently equipped with both water and steam sprays to increase its versatility as a scolder/blancher. The lower belt of the hooded chamber is pitched to a separate drain outlet for removal of condensate. A typical commercial steam blancher is approximately 20 ft. long, 4 ft. wide and 4 ft. high. A typical water blancher would be around 6 ft. in height with an overall length of 21 ft. In general steam blanching results in greater retention of water-soluble nutrients due to less leaching loss. With leafy vegetables, such as spinach, care must be taken not to overload the belt since upon heating these products tend to wet and mat. Heat transfer through this mat is very slow and under blanching could occur.

The advantages of steam blanchers are: smaller loss of water soluble components, smaller volume of waste, lower disposal charges and easy to clean and sterilize. The disadvantages associated with a steam blanchers are: limited cleaning of food, higher capital cost, uneven blanching, some mass loss in food and poor energy efficiency. At the same time, the advantages of hot water blanchers are lower capital cost and better energy efficiency. The disadvantages are loss of water soluble components, higher cost of water and disposal of effluent and risk of contamination.

A thermal screw may also be used to steam blanch products. Here, the product is conveyed in a trough by a closely fitting helical screw. Steam injected at regular interval is used to heat the product. Similar designs use hot water as the transfer medium, and this reduces abrasion and damage to sensitive products such as mushroom.



(a)



(b)

Figure 2.1: Blanchers. a) Water type rotary blancher; b) steam blancher for leafy products

We should select a size of blancher which will handle the line capacity without being over crowded. Do you know that one of the serious mistakes made by the operator is overloading. As an operator, we have to ensure maintenance of the unit on a regular basis and check that automatic controls are performing well. The use of a check thermometer to ascertain the accuracy of the one installed on the unit is a good practice.

2.4 PASTEURIZATION

Pasteurization is the term usually applied to preservation of liquid products like pulps or juices by heat. We know that this thermal treatment primarily inactivates the disease causing microorganisms present in the foods. The process i) kills non-spore forming bacteria, ii) inactivates enzymes, and iii) destroys yeasts and moulds. It is suitable for short time preservation because it reduces the number of fermentative microorganisms that contribute to the acidification of juice, at the expense of sugars. The processing details have already been discussed in earlier units and we know that the time-temperature treatment depends on i) the heat resistance of the particular vegetative or pathogenic organism, and ii) the sensitivity of product quality to heat.

2.4.1 Process Equipment

Since pasteurization is normally done at temperature less than 100° C, solid food particles can be pasteurized in the same type of equipment as that used for blanching. A water bath is the simplest pasteurization equipment for acid food products. Packaged food products are placed in steel tanks for heating with hot water. At the end of process cold water is added for cooling. A continuous water bath pasteurizer is used in pickle industry and in fruit processing. The equipment consists of a long tank through which the product moves on a belt.

Continuous water spray equipment is used for pasteurizing fruit juices. In this unit, the product is conveyed on a belt through several temperature zones where water is sprayed onto the containers. The zones are first pre-heat, second pre-heat, pasteurization, pre-cool and final cool. Do remember that glass containers be processed with care to avoid thermal shock.

For fruit, fruit juices, and tomatoes, the continuous, agitating, atmospheric cooker is widely used. Operation of the unit is similar to the continuous, agitating, pressure cooker wherein the cans are screw conveyed through the unit. The unit operates at atmospheric pressure with either steam, hot water, or a combination of steam and hot water as the heating medium. Processing rates of up to 20-250 cans/minute can be achieved.

Pasteurization of unpackaged liquid is commonly done in indirect heat exchanger and High Temperature Short Time (HTST) processing is preferred for high throughputs (Figure 2.2). The nutrient loss is less. This procedure makes use of a plate heat exchanger with three sections for heating, regeneration, and cooling, respectively, a holding tube to pasteurization temperature for the required time and a flow diversion value to ensure that liquid which has not reached the desired temperature is not discharged as finished product. It is important to ensure that rapid cooling occurs in order to prevent quality deterioration and to ensure a uniform residence time. The temperature time treatment for some of the food products is given in Table 2.1.

Table 2.1: Temperature/time treatment in pasteurization

Food Product	Temp (°C)	Time (Seconds)
Milk	72	15
Tomato Juice	118	60
Fruit Juice	88	15
Soft Drink	95	10

2.5 STERILIZATION

Sterilizing a product means exposing it to sufficiently high temperature and for a sufficiently long time that may kill all micro-organisms. In contrast to pasteurization, commercial sterilization is intended to give long shelf life (in excess of six months) to foods by destroying both microbial and enzyme activities. The products that are difficult to sterilize are low in acid and often high in protein and contain spore bearing bacteria. Sometimes severe heat treatment results in substantial changes in nutritional and sensory qualities of food. Therefore, optimum time temperature schedules are to be worked out for each product for better quality and shelf life. Sterilized products have excellent keeping quality.

There are two basic methods for sterilization (i) heating the food after it has been placed in a container (known as "in-container"), and (ii) heating and cooling the food and then packaging it aseptically (aseptic packaging). This subsection deals about sterilization process. The traditional retorting of canned foods is an example of sterilization process.

2.5.1 Process Equipment

The Batch Retort: The batch operated retorts are either horizontal or vertical. The basic feature of a vertical retort is given in Figure 2.3. It consists of a pressure vessel, usually cylindrical and a basket or grate into which individual cans are placed. The various layers of cans are separated by grids which allow thorough circulation of steam. The retort is supplied with steam, cold water and compressed air. Inlets are fitted with globe valves and the outer outlets with gate valves. At the bottom of the retort, a steam spreader is connected to the steam inlet to ensure uniform distribution of stream inside the retort. The drain is fitted to the base of the retort to remove the condensate during heating and cooling cycles. A vent, with a valve, is provided on the body of the retort. It is intended to purge the air flow between the cans during the initial part of the come-up period. The retort instrument packet is fitted with a petcock which acts as a permanent bleeder; mercury in glass thermometer; an additional place for a check thermometer; a temperature-sensing probe connecting to the recording thermometer; and a pressure gauge. An additional petcock and a pressure safety valve are on the lid. The retorts are strong enough to withstand the pressure of air, besides that of steam pressure, i.e., a working pressure of 2.8-3.5 kg/cm^2 (40-50 psig). The retorts should be located in a sufficiently large area to enable easy operation. The floor should be resistant to wear, well-drained, and impervious to water. The free space between the retort should be at least 50 cm.

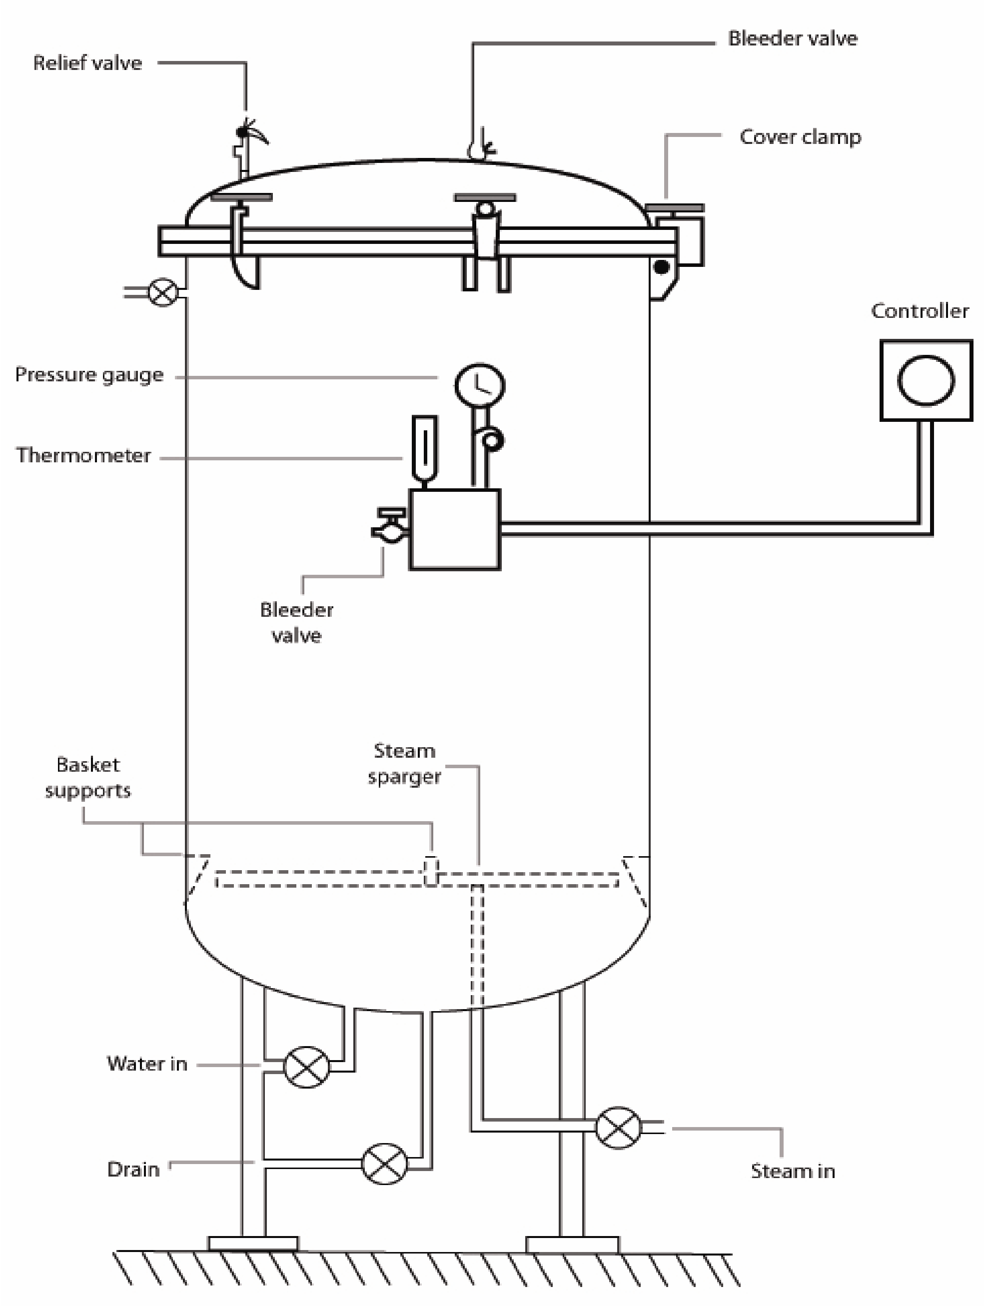

Figure 2.3: Basic layout for a vertical retort

Steam is an excellent heat medium because of its ability to condense on container surface releasing large amounts of latent heat. The main enemy of efficient heating in a closed vessel (e.g. a retort) using saturated steam is the presence of entrapped air especially that trapped in the small spaces between containers in the load. The presence of air reduces the temperature and tends to insulate the cans giving lower rates of heat transfer. This means that in order to bring about efficient and uniform heating, air must be purged, or as it is, referred to in the industry 'venting' from the retort at the start of the process. This is achieved by introducing high velocity steam into the retort. The rotary retorts ensure agitation and give adequate heating and acceptable processing times.

Retort operation is a specialized job. As a technician, you should be well trained in its operation and ensure proper processing. The basic operating procedure is as follows: The cans are placed in a basket which is lowered into the retort and then steam is introduced. Time is allowed for any condensed water to drain away before a drain valve at the base of the retort is closed.

Acidic products, for example canned fruits, require a milder heat treatment and use steam at atmospheric temperature, while the high temperature is required for less acidic foods and need heat to be supplied by steam at pressures greater than atmosphere. The steam is introduced at high speed for venting. After a short period, the vent valve is closed and the retort is brought up to temperature by allowing the steam pressure to rise to a pre-set level. After processing for the required time, the steam flow is stopped and the cooling water flow is started. As the temperature of the can's content rises the vapour pressure inside the can increases. During the heating cycle increase in pressure is balanced by the steam pressure outside the can, however, during the cooling cycle this internal pressure is balanced by admitting compressed air simultaneously. Cooling continues in retort until the temperature falls to about 40°C after which retort is opened and the cans are removed.

2.6 ASEPTIC PROCESSING AND PACKAGING

Aseptic processing and packaging is a remarkable technological advancement over traditional retort processing. It is the process by which micro-organisms are prevented from entering into the package during and after packaging. It is achieved by filling a sterilized package with a sterile food product within the confines of a hygienic environment. The packaged product could be stored without the need for refrigeration or preservatives for periods up to one year. Aseptically packaged products include milk, juices, tomato soups, sauces, broths, soy beverages, etc. The production of these products is constantly increasing in the country.

2.6.1 The Aseptic Process

The aseptic process is a technique for processing liquid food products by exposing them to brief intense heating. Sterility is the key word in the process and involves the same principles as discussed with respect to sterilization. Since very high temperatures are employed (125 °C to 145 °C), the process is also referred to as Ultra High Temperature (UHT). The holding time of the product at high temperature is very short (3 to 15 seconds) and therefore, thermal stress on the product is less while ensuring safety. This rapid heating and cooling process also reduces the energy use and nutrient losses associated with conventional sterilization. Processing at high temperature usually requires that the process be based on enzyme inactivation rather than microbial destruction. The process involves:

i) Sterilization of the product in sterile equipment;
ii) Pre-sterilized containers;
iii) Aseptic environment for filling of the sterile product into the sterile package; and
iv) Sterile packaging.

The advantages of the UHT processing are (i) higher quality (ii) increased shelf life (iii) easy adaptability to many size containers from single serving (200 ml.) to thousands of litres of bulk pack, and (iv) cheaper packaging material. The disadvantages are (i) higher cost (ii) sophisticated control and maintenance of plant, and (iii) higher skill level on the part of operators and maintenance personnel.

2.6.2 Process Equipment

UHT plants are often designed with great product flexibility in order to enable processing of a wide range of products in the same plant. Both low acid products (with pH values above 4.5) and high acid products (with pH values below 4.5) can be treated in UHT plant. However, only low acid products require UHT treatment in order to become commercially sterile as spores can grow in a low acid environment. Spores cannot develop in high acid products such as juice and the heat treatment is, therefore, only intended to kill yeasts and moulds. Normal high-temperature pasteurization is sufficient to make high end products commercially sterile. The UHT plants are classified according to the method of heating. The options are consolidated in Table 2.2.

Table 2.2: Types of UHT plants

Sl. No	Type of plant	Options available
1.	Direct Heating (Product and the heating media are in direct contact)	Steam injection (steam into product) Steam infusion (product into steam)
2.	Indirect Heating (Heat transfer surface between the product and the heating media)	▪ Plate, ▪ Tubular and ▪ Scraped surface heat exchangers

i) **Direct Heating:** There are two main methods for aseptic processing by direct methods: by injecting pressurized steam into product or by injecting product into steam (steam infusion). Both systems work on the principle that the steam comes into contact with the product, it will condense and give up some latent heat causing the product to heat up very quickly. The steam has to be of satisfactory quality, i.e., derived from drinking water. Simplified flow sheets for direct steam injection and steam infusion are shown in Figure 2.4 and 2.5, respectively. The basic principle for both systems is to pass the product from a balance tank to a pre-heating and final heating system, usually by a plate heat exchanger at 75-80°C. The product then passes through the main product pump to the steam injection or infusion system. The mixture then flows through a holding tube (2-4 seconds) which enters tangentially into the vacuum chamber. The product passes on an aseptic path – pump, homogenizer, cooler and storage tank – to aseptic package. Steam injection is most suitable for low viscosity homogeneous products such as milk and juice. Steam infusion is for more gentler and sensitive products.

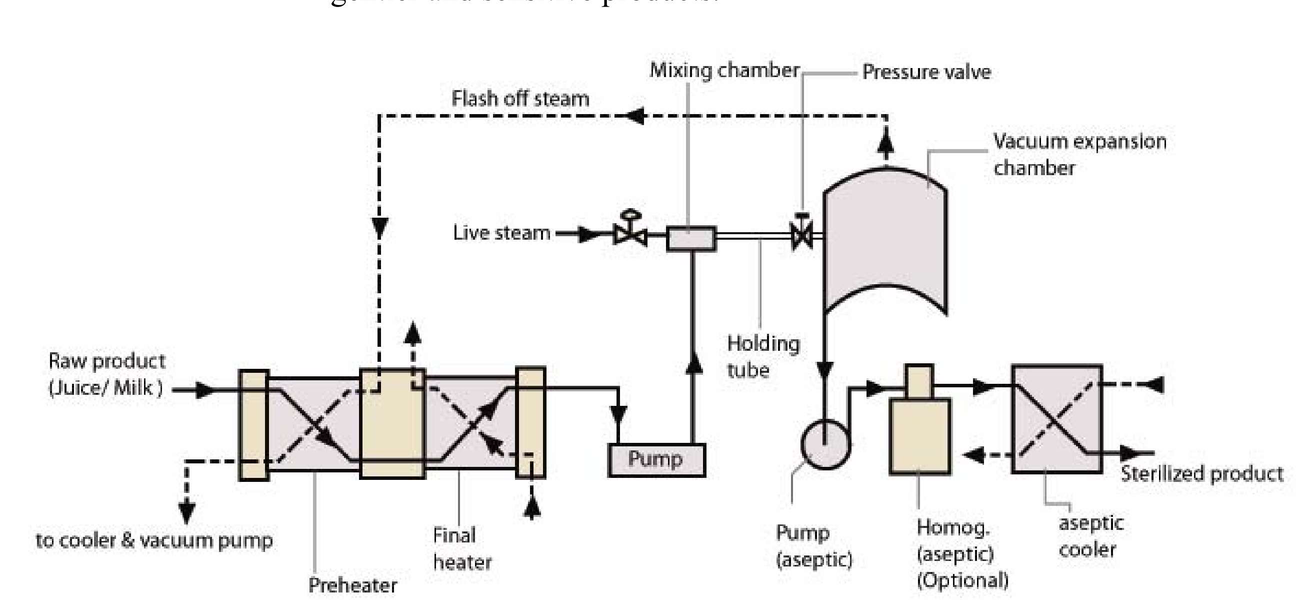

Figure 2.4: Diagram of an ultra-high temperature heating plant using direct heating (steam injection)

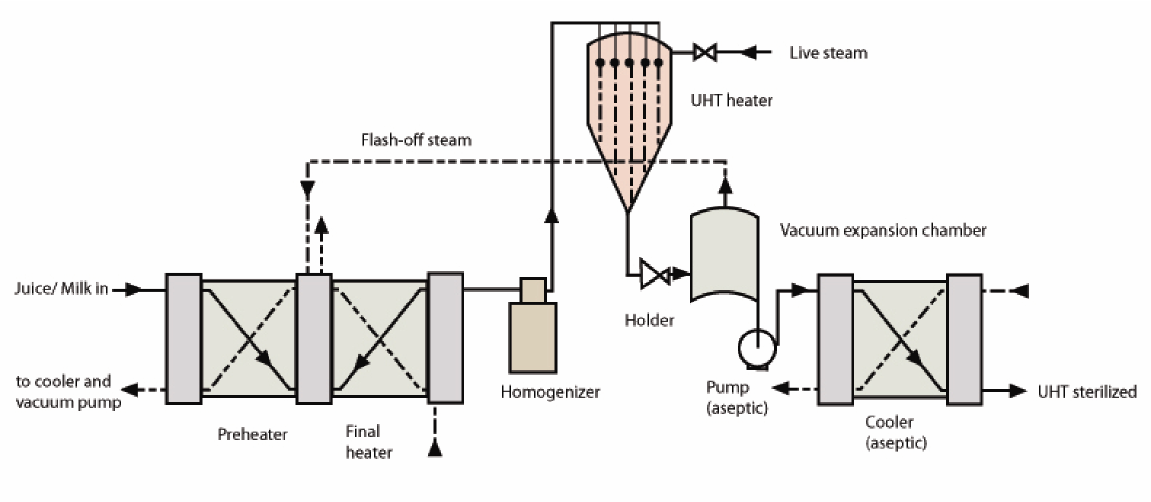

Figure 2.5: Diagram of a UHT plant using direct heating of product in a steam space (steam infusion)

ii) Indirect UHT Plant: UHT heating plants using indirect heating method rely on having a heat transfer surface between the product and the heating media. There are three main types of indirect heating system, viz. plate heat exchanger, tubular heat exchanger and scraped surface heat exchanger. Each system has benefits as well as drawbacks depending on the product process requirement. A simplified flow sheet for an indirect UHT plant is shown in Figure 2.6. UHT plants of the indirect heating types are built for capacities up to 30,000 l/h.

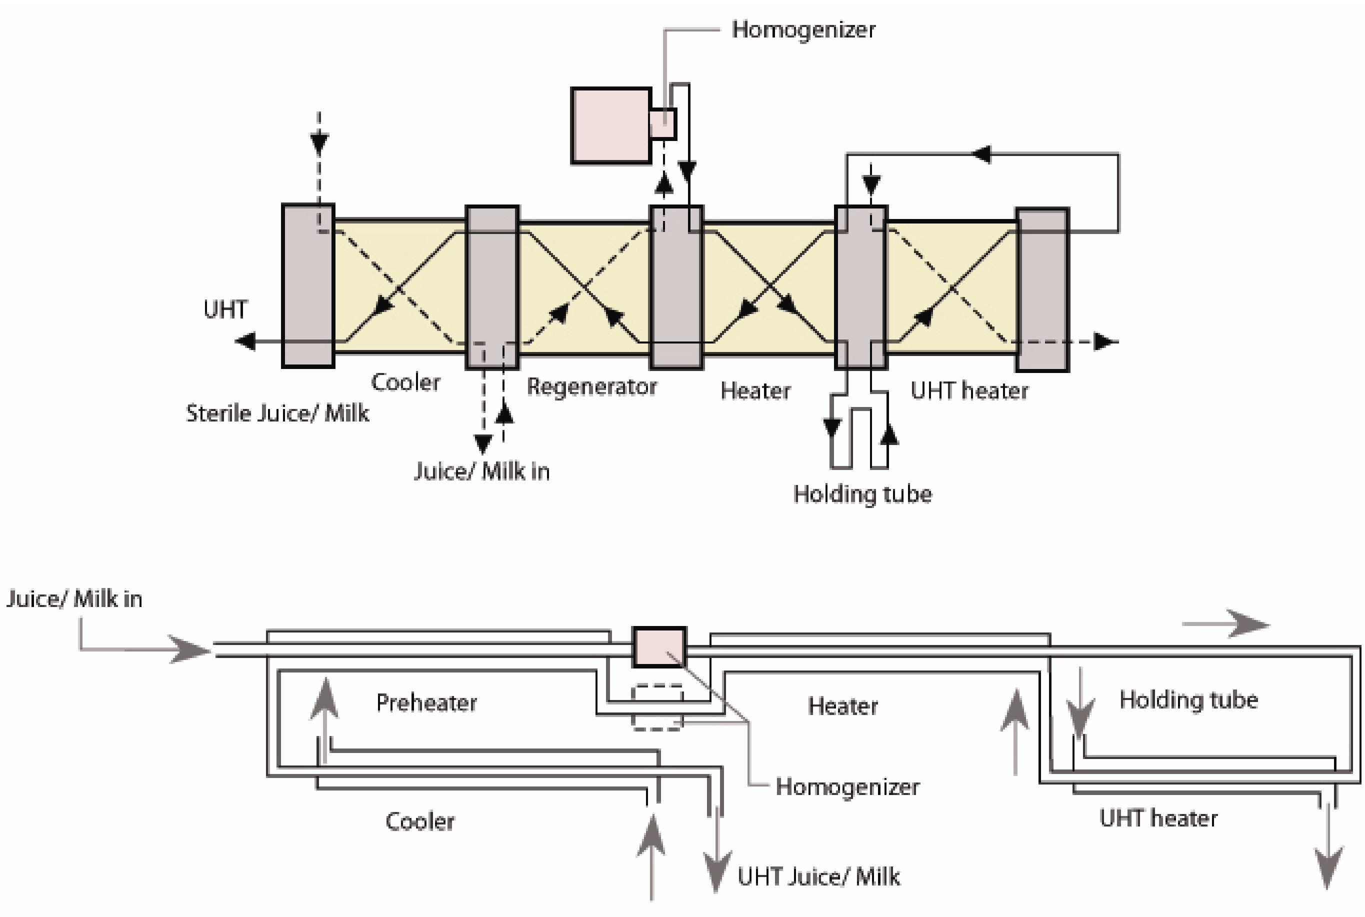

Figure 2.6: Diagrammatic representation of UHT heating plants using indirect heating methods

2.6.3 Aseptic Packages

There are several different forms of packages that are used in aseptic processing such as cans, laminates, flexible pouches, thermoformed plastic containers, tetrapack, etc. Tetrapack, a revolutionary package, is a laminate of three materials: high-quality paperboard, polyethylene and aluminium. Each material plays a critical role in achieving the unique benefits of the aseptic package. Paper (70%) provides stiffness, strength and the efficient brick shape to the package. Polyethylene (24%) on the innermost layer forms the seals that make the package liquid-tight. A protective coating on the exterior keeps the package dry. Aluminium (6%) is the silver material we see on the inside of the aseptic package. This ultra-thin layer of foil forms a barrier against light and oxygen, eliminating the need for refrigeration and preventing spoilage without using preservatives. The aseptic package contains a total of six layers in this order: polyethylene, paper, polyethylene, aluminium foil, polyethylene and polyethylene. The processing steps involved in formation of a package are: sterilization of roll and, formation of package, filling and sealing in sterile environment.

2.7 HOT PACK OR HOT FILL

The terms Hot Pack or Hot Fill or Hot-Fill-Hold-Cool Process or Flash Pasteurization refer to the filling of previously pasteurized or sterilized foods, while still hot, into clean but not necessarily sterile containers, under clean but not necessarily aseptic conditions. The hermetically sealed containers are then inverted and held for an adequate time (1-3 minutes) to sterilize the lid as well as the containers. The hot-filled containers are then cooled either in a water-spray tunnel or by immersing in a tank containing chlorinated cold water. Rapid cooling is essential to retain the colour, flavour and nutrients. In yet another practice followed in some western countries, the head space is flushed with steam or nitrogen to minimize the residual oxygen. A schematic diagram of hot-fill system is shown in Figure 2.7.

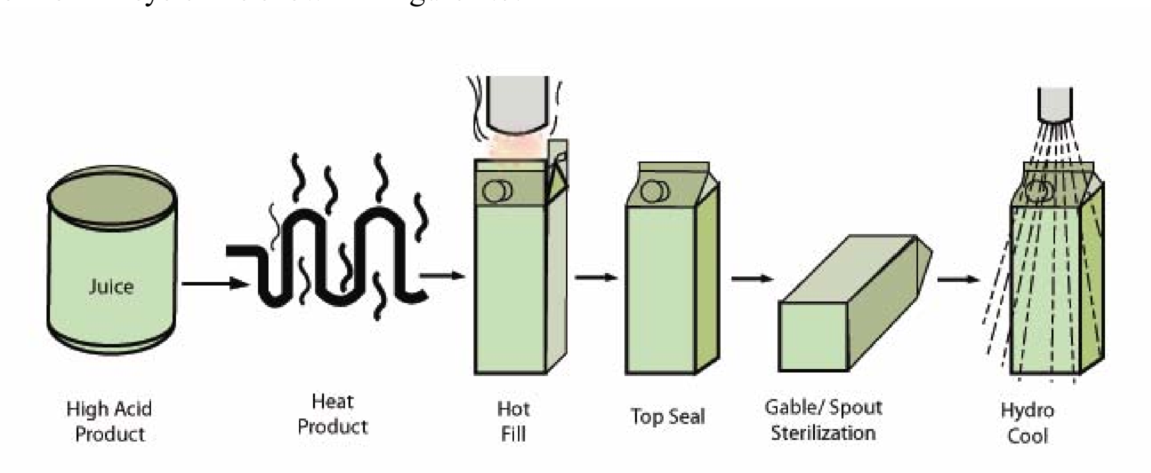

Figure 2.7: Hot-fill system – A schematic diagram

Hot-pack is more effective with acid foods, as at pH below 4.5 *Clostridium botulinum* will not grow or produce toxin. Hot pack with low acid foods (above pH 4.5) is not possible unless the product is recognized as being only pasteurized and will be stored under refrigeration. However, hot pack treatment could be combined with some additional means of preservation such as very high sugar content. The temperature and time for pasteurization and hot filling depend upon the specific product's pH and other food characteristics. It is essential that the definite temperature and time must be adhered for hot pack processing to be effective.

2.8 MICROWAVE AND OHMIC HEATING

We are familiar with microwave ovens, their use and popularity is increasing constantly. In microwave heating, a high frequency field is passed through the food, stimulating the vibrational frequencies of chemical bonds to heat the material. Microwave and ohmic heating are known as heat generation methods where heat is generated by the material *in situ* as a result of interaction with an external field.

2.8.1 Microwave Heating

Microwaves are electromagnetic waves of radiant energy, differing from such other electromagnetic radiations as light waves and radio waves primarily in wavelength and frequency. The microwave frequency ranges from 300 MHz. to 300 GHz. corresponding to wavelength in the range of 0.001-1 m, and is positioned somewhat close to FM radio and television broadcasting brands. Microwaves, like light, travel in straight lines. They are reflected by metals, pass through air and many, but not all types of glass, paper and plastic materials, and are absorbed by several food constituents including water.

When microwaves pass into foods, water molecules and other polar molecules tend to align themselves with the electric field. But the electric field reverses 915 or 2450 million times per second (MHz.). The molecules attempting to oscillate at such frequencies generate intermolecular friction which quickly causes the food to heat. In microwave, heat is generated quickly and quite uniformly throughout the mass. .

The use of microwave energy in food processing can be classified into six unit operations: heating, baking and (pre) cooking, tempering, blanching, pasteurization and sterilization, and dehydration.

The most commonly used type of microwave generator is an electronic device called a magnetron. A magnetron is a kind of electron tube within a magnetic field which propagates high frequency radiant energy. The microwave field is transmitted to the oven cavity / tunnel via an antenna placed inside the wave guide. Industrial oven is either a larger version of the domestic oven and is used for batch processing (e.g. tempering) or for continuous processes, taking the form of tunnel with food conveyed on belt inside an enclosure.

A major use of microwave in the food industry is tempering and thawing of frozen foods, especially meat, fish, butter and fruit. Tempering raises the temperature of frozen foods to around – 4°C and thus allows other operations such as cutting to be carried out much faster. Microwave tempering has a number of advantages over conventional methods as it takes minutes rather than days, reduces labour costs and requires a smaller space than the conventional refrigerated storage room. Microwaves have been used for pasteurization of ready meals, further developments are needed to use them in commercial sterilization.

2.8.2 Ohmic Heating

In ohmic heating, an electric current is passed through a food material which then heats as a result of its inherent electrical resistance. The process involves the passage of low frequency alternating current (50 or 60 Hz.) through the product. The electrical energy is transformed into thermal energy. The extent of heating depends on the uniformity of the electrical conduction throughout the product and its residence time in the heater. A typical layout of an aseptic processing system using ohmic heaters is shown in Figure 2.8.

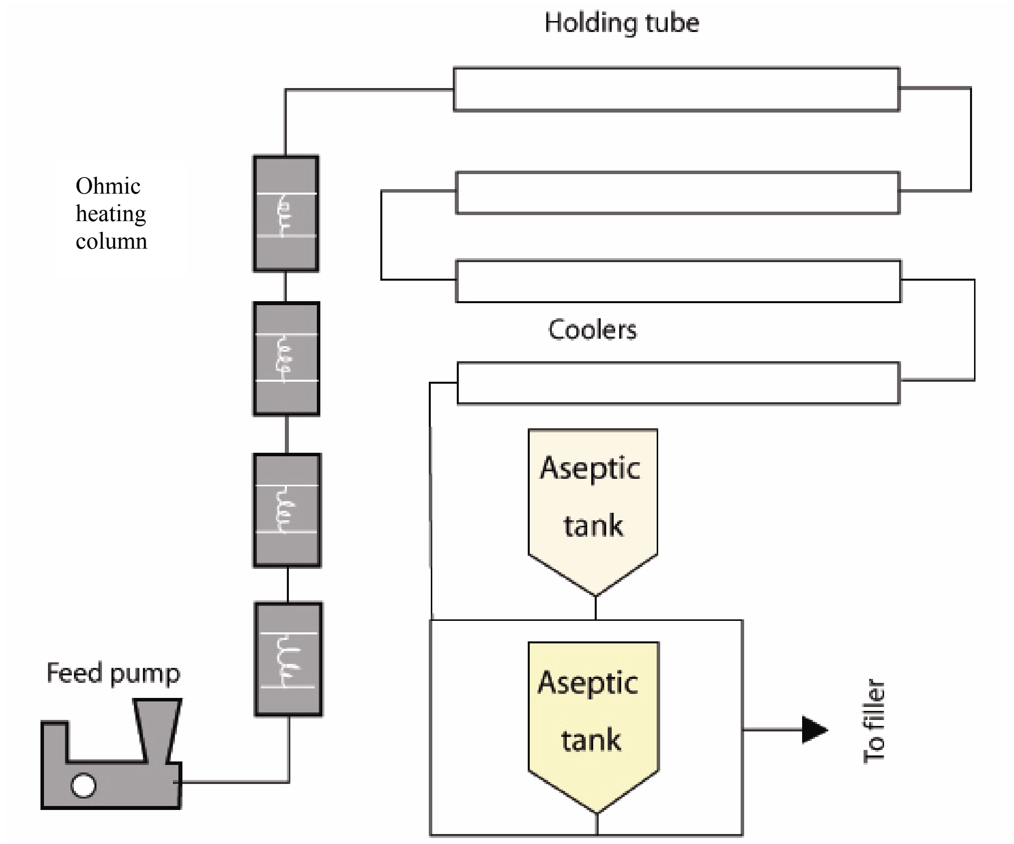

Figure 2.8: Schematic diagram of a continuous-flow ohmic heating process

2.9 LET US SUM UP

The principles of heat transfer are widely used in food processing industries. The common processes based on heat application are blanching, pasteurization, sterilization and aseptic processing. The types of heat exchangers used in these processes may include plate, vat, tubular or scraped surface. Plate heat exchangers are quite common due to various advantages such as high heat transfer surface area within a small plant volume, high heat transfer coefficient, versatility, and low cost.

Rotary hot water and steam blanchers are commonly used equipment for blanching, and size of the blancher should be in proportion to line capacity of the plant. Plate heat exchangers are usually employed for pasteurization of unpackaged liquid. The raw product passes through regeneration, heating, holding and cooling sections. After heating and holding to a stipulated temperature-time combination, the pasteurized product is chilled immediately through regeneration and cooling section. Sterilization is more severe heat treatment employed to have longer shelf life (in excess of six months) of food products and the traditional retorting of canned foods is an example of sterilization process. The entrapped air should be vented from the retort at the start of process for efficient and uniform heating. Aseptic processing and packaging is a technological advancement wherein sterilization is obtained by employing Ultra High Temperature (UHT) (125° C to 145° C) for very short time. The UHT plants could be (i) direct steam injection, (ii) direct steam infusion, and (iii) indirect UHT plant with plate/tubular/scraped surface heat exchanger. Hot pack or hot fill, effective with acid foods, involves filling of previously pasteurized or sterilized foods, while still hot into clean containers.

The new techniques microwave and ohmic heating are known as heat generation methods where heat is generated by the material *in situ* as a result of interaction with an external field.

2.10 KEY WORDS

Aseptic packaging : It is a process by which micro-organisms are prevented from entering into the package during and after packaging. An aseptic process is achieved by filling a sterilized package with a sterile food product within the confines of a hygienic environment.

Blanching : Blanching is a heat treatment applied to tissue systems of fruits or vegetables primarily to

		inactive natural food enzymes prior to canning, freezing and drying.
Commercially sterile	:	The terms are used wherein all pathogenic and toxin forming organisms have been destroyed in the product.
Heat exchanger	:	A device that transfers heat from one fluid to another without allowing them to mix.
Pasteurisation	:	A form of thermal processing, which uses moderate degree of heat treatment generally at temperatures below the boiling point of water, for short time preservation. It inactivates bacteria and disease producing organisms of importance in specific food stuff.
Sterilisation	:	Complete destruction of micro-organisms by powerful heat treatment.
UHT	:	Ultra High Temperature (UHT) is a technique for processing liquid food products by exposing them to intensive heating for a short time.

2.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answer may include the following points:

1. • Temperature difference between heating and cooling media
   • Surface area for heat transfer
   • Heat transfer coefficient

2. Important components of plate heat exchangers: Head frame, guide bar, follower, end support, carrying bar, hinged distance piece, tightening screw device, detachable ratchet spanner, bank of plates, connector grid with inlet and outlet bosses.

Check Your Progress Exercise 2

Your answer may include the following points:

1. Please refer Figure 2.1a.

2. • Smaller loss of water soluble components
   • Smaller volume of waste
   • Lower disposal charges
   • Easy to clean and sterilize

Check Your Progress Exercise3

Your answer may include the following points:

1. Please refer Figure 2.2.
2. Fruit Juice –88°C / 15 seconds
   Tomato Juice –118°C / 60 seconds

Check Your Progress Exercise 4

Your answer may include the following points:

1. Please refer Figure 2.3.

2.
   - Entrapped air tends to insulate the cans and gives lower rates of heat transfer.
   - Air is purged out from the retort at the start of process for uniform heating. This is achieved by introducing high velocity steam into the retort.

Check Your Progress Exercise 5

Your answer may include the following points:

1.
   - Higher product quality
   - Increased shelf life
   - Easily adaptable to many size containers

2. Please refer Figure 2.4.

3. The aseptic package laminate consists of (a) paper board, (b) polyethylene, and (c) aluminium.

Check Your Progress Exercise 6

Your answer may include the following points:

1. The process includes rapidly heating the juice in a heat exchanger and filling containers with the hot juice (around 95°C) followed by sealing and inverting, thus pasteurizing the container. It should be followed by rapid cooling.

2. Please refer Figure 2.6.

Check Your Progress Exercise 7

Your answers should include the following points:

1. A magnetron in the oven generates electromagnetic waves (microwave). In the electromagnetic field generated in the oven, there is a rapid reversal of change (at either 915 or 2450 mega hertz). When microwaves penetrate a food, the dipolar molecules of water that are present oscillate about their axes in response to this reversal of change. Heat is generated in the food itself as a result of rapid oscillation.

The major use of microwave in the food industry is tempering and thawing of frozen foods.

2. The ohmic heating is a process where heat is generated in the product by passing an electric current. The heat is produced due to resistance created by the product during passage of current.

UNIT 3 CANNING OF FRUITS AND VEGETABLES

Structure

3.0 OBJECTIVES

After reading this unit, you should be able to:

- state the principles of canning;
- explain the various unit operations involved in canning;
- describe the canning process of fruits and vegetables; and
- list the cans and types of spoilages of canned products.

3.1 INTRODUCTION

You know there are several methods of preservation of fruits and vegetables and canning is one of them. It is an important method of food preservation by heat. In this process, the foodstuff (fruits & vegetables) are placed in containers, and sterilized by placing them in hot water or steam. Canning is also known as appertizing in honour of its inventor. In 1804, Nicholas Appert, a confectioner in France, invented a process of sealing foods hermetically in containers and sterilizing them by heat. He had also published a book entitled, "The Art of Preserving Animal and Vegetable Substance for Many Years", which is the first known work on modern canning.

Canning is an important process of preservation of fruits and vegetables by application of heat. In this unit, we will discuss canning process for fruits and vegetables. Several unit operations are involved in the canning process. The process discusses the principles and purpose of canning, types and causes of spoilages. Tin cans are used in the canning of fruits and vegetables.

Fruits and vegetables are canned in the season when the raw material is available in plenty and at low price. The canned products are sold round the year and give better returns to the grower. Thus, canning of fruits and vegetables is an important industry.

3.2 CANNING PROCESS FOR FRUITS AND VEGETABLES

Canning is defined as the preservation of foods in the sealed containers and usually implies heat treatment as the principal factor in prevention of spoilage. Mostly the canning is done in tin cans but other containers like glass, plastics, etc. The fruits and vegetables used for canning should be as fresh as possible so that their quality could be retained. Fruits should be mature, firm ripe and free from all defects, while vegetables should be usually tender.

3.2.1 Principles

1. Destruction of spoilage organisms within the sealed containers by application of heat,
2. To improve the texture, flavour and appearance by cooking, and
3. To stop recontamination of food during storage.

You should be careful during heat application that palatability of food is least disturbed while all the microbial load is destroyed.

3.2.2 Process

Canning process includes the following steps or unit operations:

Selection of fruits & vegetables → Sorting & Grading → Washing → Peeling → Cutting → Blanching → Filling → Syruping/Brining → Lidding or Clinching → Exhausting → Seaming → Processing → Cooling → Testing for defects → Storage.

i) Selection of Fruits and Vegetables

We should select the fresh good quality fruits and vegetables for canning because quality of canned product is dependent on the quality of raw material. Fruits should be firm, mature and uniformly ripe. Over-ripe, insect infected and diseased fruits and vegetables should be rejected. Unripe and immature fruits should be rejected because they generally shrivel and toughened on canning. Vegetables should be tender. Fruits and vegetables should be free of dirt.

ii) Sorting and Grading

We should see that any spoiled, blemished, injured fruit or vegetable be discarded. Raw material should be sorted based on maturity and ripeness. Fruit and vegetables should be graded according to size and colour to obtain uniform quality of canned product. Grading can be done by hand or by machines. Screw type and roller type grader are generally used.

Fruits like berries, cherries, grape and plum are graded whole, while peach, pear, apricot, mango, pineapple, etc., are generally graded after cutting into pieces.

iii) Washing

Fruits and vegetables should be washed with water thoroughly. Washing will remove dust, dirt and any sprayed chemical residue. Any microorganism over the surface of the fruits or vegetables are also washed out. Water used for washing may be cold or hot. We may employ chlorine (150ppm) or potassium permanganate (dilute solution) in water to disinfect fruits and vegetables. Fruits and vegetables are generally soaked in water tank before washing by hand. They can be washed by spraying water, which is the most effective method.

iv) Peeling

Washed fruits and vegetables are prepared for canning. The fruits and vegetables are peeled by hand with knife or machine, heat treatment or lye solution. Lye is a solution of caustic soda. For example, peaches and potatoes are scaled in steam or boiling water and put in cold water to soften and loosen or cracking of skin. Later the skin can easily be removed by hand or pressure spray of water.

In case of lye peeling of fruits and vegetables, e.g., peaches, apricots, orange and sweet potatoes are dipped in boiling lye (1-2% caustic soda) for ½ to 2 minutes. Any trace of alkali is removed by washing fruits and vegetables in running cold water; sometimes they are also washed in water containing 0.5 per cent citric acid or hydrochloric acid.

v) Cutting

We should cut the fruits and vegetables depending upon the requirement like slice, dice, finger etc either by knife or by machine. At the same time seed, stone and core are also removed by special coring knife.

vi) Blanching

In blanching operations the prepared fruits and vegetables are kept in boiling water or exposed to steam for 2 to 5 minutes followed by cooling in running cold water. The time and temperature of blanching vary depending on the type of raw material. Inactivation of peroxidase enzyme is used as an index adequacy of blanching. The purposes of blanching are: (1) to inactivate the enzymes, which cause discolouration and off-flavour, (2) to reduce the volume by shrinkage, making their packing easier, (3) to reduce the microbial load on raw materials, (4) to enhance the green colour of vegetables like peas and spinach, (5) to remove undesirable acids and astringent taste of the peel resulting improved flavour, and (6) to remove occluded gases for reducing strain on the seam of can during processing.

vii) Filling

Tin cans are used as containers for canning. The cans can be opened from any end as they are called open top sanitary can. Cans are washed with hot water. Prepared fruits and vegetables are filled into cans either by hand or by machine. Plain cans are used generally, although in case of coloured fruits like black grapes, red plum, strawberries, etc., lacquered cans are employed.

In case of canned fruits the drained weight should not be less than 50% and for berry fruits not less than 40%. Similarly for canned vegetables the drained weight should not be less than 55% but in case of tomatoes limit is the 50%. Therefore, fruits and vegetables are filled about 60 per cent of the filling capacity of a can.

viii) Syruping

A solution of sugar in water is called syrup. Generally the fruits are covered with sugar syrup. Cans are filled with hot (79°–82°C) sugar syrup, leaving a headspace of 0.3 to 0.5cm. Syrup of 10° to 55° Brix (per cent sucrose) is generally used. We can prepare sugar syrup of 20° Brix by dissolving 250 g sugar in one-liter water and of 50^{o}Brix by dissolving one kg of sugar in one litre water. Sometimes citric acid and ascorbic acid are also mixed with the syrup to improve flavour and nutritional value, respectively. The purpose of adding syrup to fruits is (1) to improve taste, (2) to fill up the interspaces in can, and (3) to facilitate further processing.

ix) Brining

Brine is a solution of common salt in water. Brine is used in canning of vegetables. A brine of 1 to 3% salt is used at 79°-82°C, leaving a headspace of 0.3 to 0.5 cm in the can. The objectives of brining are to improve the taste of vegetables and to facilitate further processing by filling the interspaces of vegetables in the can.

x) Lidding or Clinching

Now the filled cans are covered loosely with the lid before exhausting. It has some disadvantages such as spilling of the contents and toppling of the lids. In modern canning, lidding has been replaced by clinching operation. In this case, lid is partially seamed. The lid remains sufficiently loose to permit the escape of gases, air and vapour formed during exhausting operation.

xi) Exhausting

There are respiratory gases and air remain in the cans, which are to be removed before processing. The method of removing these gases is known as exhausting. Containers are exhausted by heating or mechanically. In heat exhausting, the cans are passed through a tank of hot water or exhaust box under steam. The fruit cans are exhausted at 82 to 100°C for 7-10 minutes or until temperature at the centre of the can reaches 74°C. The vegetable cans are exhausted at 90 to 100°C for 7-10 minutes or until temperature at the centre of the can reaches 77°C. The proper exhausting reduces the strain on the seam of the can.

The time and temperature of exhausting vary with the size and contents of can, but it should be sufficient to ensure a vacuum of 12 to 15 inch Hg in processed and cooled can.

xii) Sealing or Seaming

After exhausting, the cans are sealed by double seaming machine and the method is called seaming. In sealing lids on cans, a double seam is created, and the method of sealing or closing is also known as seaming.

xiii) Processing

Process of heating and cooling of canned food to inactivate bacteria and to preserve food is also called as commercial sterilization. Many bacterial spores are heat resistant, which can only be killed either by very high or by very low temperature treatment or prolonged cooking. Such drastic treatment, however, affects the quality of food. Thus, processing time and temperature should be adequate to eliminate all bacterial growth. We must not over-cook the canned foods otherwise it will spoil the flavour, appearance and texture of the product.

All fruits and acid vegetables can be processed satisfactorily at a temperature of 100°C, i.e., in boiling water. The acid present in fruits and acid vegetables retards the growth of bacteria and spores. These bacteria and spores do not thrive in heavy sugar syrups, which are normally used in canning fruits. Vegetables, generally non acidic (except tomato and rhubarb), are processed at a higher temperatures of about 115 to 121°C.

Bacterial spores usually do not grow below pH 4.5 as you have read in previous chapters. We, generally process the canned products having pH less than 4.5 in boiling water but products with pH higher than 4.5 require processing at 115 to 121°C. The higher temperature can be obtained by processing in a retort under a pressure of 0.70 to 1.05 kg/cm^2 (10 to 15 lb/sq. inch). The centre of can should attain these high temperatures.

The temperature and time of processing vary with the size of the can, the larger the can, the greater is the processing time. Fruits and acid vegetables are generally processed in open type cookers, continuous non-agitating cookers and continuous agitating cookers.

The open cookers are galvanized iron tank of desired capacity. Sealed cans are placed in iron crates and immersed in the tank containing boiling water. In continuous cookers, the cans travel in boiling water in crates carried by overhead conveyors. In continuous agitated cookers, the cans are rotated by special mechanical devices to agitate the contents of the cans. Agitation reduces the processing time considerably.

The non-acid vegetables are processed under steam pressure in closed retorts. The sealed cans are placed in the retort, keeping the level of water 2.5 to 5.0 cm above the top of the cans. The cover of the cooker is then screwed down tightly and the cooker is heated by steam to the desired temperature. The period of processing (sterilization) should be counted from the time the water starts boiling or steaming. After heating for the required period, heating is stopped and the petcock or vent is opened. When the pressure comes down to zero the cover is removed and the cans are taken out.

xiv) Cooling

After processing, the cans are cooled rapidly to about 39°C to stop the cooking process. Cooling can be done by several methods such as (1) immersing the hot cans in tank containing cold water, (2) spraying cold water, (3) turning in cold water into the pressure cooker, and (4) exposing the cans to air. Generally the first method is practiced. Cooling water may be kept sterile with 1 or 2 per cent chlorine. If canned products are not cool immediately after processing, the quality is deteriorated, e.g., peaches and pears become dark in colour, tomatoes turn brownish and become bitter in taste, while peas become mashy with a cooked taste.

xv) Testing for Defects

Before the canned products are marketed, we should test them for any defect. The finished cans are tested for leak or imperfect seals. We should tap the top of the can with a short steel rod. A clear ringing sound indicates a perfect seal, while a dull and hollow sound shows a leaky or imperfect seal. Leaky cans should be removed from the lot.

xvi) Storage, labelling and packing

Before storage, the cans should be completely dry, small traces of moisture are likely to induce rusting. They should be stored in a cool and dry place. Storage of cans at high temperature should be avoided, as it shortens the shelf life of the product. The high temperature may lead to hydrogen swell and perforation during extended storage. The basement stores are useful, especially during summer months. The temperature in these stores is lower by about 6° to 8°C, compared to outside temperature. Before dispatch, the cans are labelled and packed either in wooden or cardboard boxes, and are ready for marketing. The cans may be stored for 1 to 2 years depending upon the type of raw materials used and the shelf life of the product.

3.2.3 Tin Containers

The cans are made of thin steel plate of low carbon content, lightly coated on both sides with tin metal. Sometimes discolouration of the product or corrosion of the tin plate takes place. In order to avoid corrosion, these cans are coated inside and or outside with lacquer, the process is known as "lacquering". There are two types of lacquers used.

1. Acid-resistant-Acid-resistant lacquer is a golden colour enamel, cans coated with it are called R enamel or A.R. cans. The lacquered cans are used for packing fruits having water soluble colour (anthocyanins) for example raspberry, strawberry, red plum, coloured grapes, pomegranate, etc. Fruits having water insoluble colour, for example pineapple, mango, grapefruit, etc., are packed in plain cans only.

2. Sulphur-resistant – This lacquer is also of a golden colour, cans coated with it are called C. enamel or S.R. cans. These cans are used for packing pea, corn, lima beans, etc.

The tin cans are supplied to the canning factory in flattened form, where they are reformed using a machine, reformer, into cylindrical shape. After that, they are flanged by using flanger, which curls the rings outwards at each end. The one end of the cylindrical can is then fixed, before filling it, using a machine known as double seamer. After filling, processing and exhausting the can, the lid is fixed using the same machine.

Table 3.1: Commercial can sizes and capacities

Sl. No.	Trade name of can	Size (mm)	Capacity (in cubic cm)
1.	A1	68 × 102	316
2.	1-1b Jam	78 × 90	356
3.	A1-T	78 × 119	479
4.	A2	87 × 114	579

5.	1-1b Butter	103 × 70	470
6.	A2-1b Jam	103 × 102	721
7.	A2½	103 × 119	848
8.	7-1b Jam	157 × 148	2543
9.	A10	157 × 178	3069

3.2.4 Spoilage in Canned Fruits and Vegetables

Canned products are liable to spoilage for various reasons. Spoilage in canned food may be caused due to two reasons:

A) Spoilage due to physical and chemical changes:

1. Swell – Swell or bulge in cans caused due to the positive internal pressure of gases formed by microbial or chemical action. Hydrogen Swell – This type of swelling is due to the hydrogen gas produced by the action of food acids on the metal of the can. The swelling ranges from flipper – springer, soft swell or hard swell.
2. Overfilling – Overfilling should be avoided.
3. Faulty retort operation – It gives cans look like swells.
4. Under exhausting – It causes severe strain during heat processing.
5. Panelling – It is seen in large sized cans that the body is pushed inward due to high vacuum inside.
6. Rust – Rust is mostly seen under the label and subsequently affects the label. Cans lacquered externally do not rust.
7. Leakage – Cans generally leak due to defective seaming and nail holes.
8. Bursting – Cans may burst due to excess pressure of gases produced by decomposition of the food.
9. Discolouration – This may be due to enzymatic and non – enzymatic browning. Enzymatic discolouration can be avoided by placing the peeled and cut pieces of fruits and vegetables in 2% salt solution.
10. Stack burning – The contents in the can if remain hot for a long time during storage result in stack burning. It may cause discolouration. To avoid stack burning cans should be cooled quickly to about 39^{o}C before storage.

B) Spoilage by microorganisms

The time gap between filling and heat processing may cause microbial spoilage. If cans are not processed properly they may result in spoilage by bacteria and the spoilage is termed as “Under processed” spoilage.

Various spoilages caused due to different microorganisms are:

1. Flat sour – The non-acid vegetables spoiled by Bacillus coagulens and Bacillus sterothermophilus.
2. Thermophilic acid spoilage – Cans swell due to production of carbon dioxide and hydrogen by Clostridium thermosaccharolyticum.

3. Sulphide spoilage – Caused by Clostridium nignificans in low acid foods.

So, we should process cans properly to avoid any type of spoilage.

3.3 CANNING OF FRUITS

The fruits are exhausted at 82 to 100°C for 7-10 minutes or until the centre of the can reaches at least 74°C temperature. The types of can, strength of covering sugar syrup and time-temperature for No.2½ and No.10 cans are summarised in Table 3.2.

Table 3.2: Canning time table for fruits and tomatoes

Sl. No.	Fruit	Type of can	Strength of syrup (Degree Brix)	Processing time (min) in boiling water at 100°C	
				No.2½	No. 10
1.	Apple	Plain	Water or light syrup	12	25
2.	Apricot	Plain	55	35	50
3.	Banana	Plain	30+0.2% citric acid	20	–
4.	Blackberry	Fruit lacquered	55	20	30
5.	Cherry (sweet)	Fruit lacquered	40	20	25
6.	Cherry (sour)	Fruit lacquered	45	20	25
7.	Fig	Plain	55	15	35
8.	Grape (coloured)	Fruit lacquered	40	12	15
9.	Grape (white)	Plain	40	12	15
10.	Grape fruit	Plain	60	30to 40	

11.	Guava	Plain	40	20	–
12.	Jack fruit	Plain	50	30	–
13.	Litchi	Plain	40	30	–
14.	Mango	Plain	40	30	–
15.	Mulberry (coloured)	Fruit lacquered	40	12	–
16.	Musk Melon	Plain	40+0.3% Citric acid	30	–
17.	Orange	Plain	50	15 to 20	
18.	Papaya	Plain	45	30	–
19.	Peach	Plain	55	30	50
20.	Pear	Plain	40	35	60
21.	Pineapple	Plain	40	30	60
22.	Plum, red	Fruit lacquered	40	20	30
23.	Raspberry	Fruit lacquered	45	12	25
25.	Strawberry	Fruit lacquered	50	15	20
26.	Tomato	Plain	Only tomato juice in the case of standard pack	30	70
27.	Fruit Cocktail (Fruit salad)	Plain	45	30	90

i) Apple

Apples are generally not canned. However, canned apples available in the large sizes of cans are used in pies. The varieties used for canning are: Golden Delicious, Yellow Newton, Baldwin, Jonathan, and Ambri.

The fruits should be washed in warm dilute hydrochloric acid (0.5%) solution to remove any residue of lead or arsenic sprays. And then washed thoroughly in cold water to remove traces of acid. The apples are peeled by hand or machine and cut into 0.3 to 0.6 cm thick slices. The prepared fruits should be kept in 2 to 3 per cent common salt solution to avoid darkening due to enzyme action. The prepared fruits are blanched in hot water at 71 to 81^o C for 3 to 4 minutes and then cooled in water. Blanching removes the air and gases and inactivates enzymes. The blanched fruits are filled into cans, covered with hot water or thin sugar syrup, exhausted, sealed and processed.

ii) Apricot

Apricots are mostly grown in Kashmir, Himachal Pradesh and Uttaranchal, where a great scope exists for their canning. Charmagz and Shakarkand are white sweet varieties which are good for canning. Apricots are either canned whole or halves.

iii) Banana

South Indian varieties of banana, viz. Pachabale, Chandrabale, Nendran, Poovan and Vannan are good for canning. Fully ripe bananas are selected for canning. Fruits are peeled by hand and then cut into long slices of 1 to 2 cm thickness. The slices are filled into cans and covered with a sugar syrup of 25 to 30° Brix containing 0.2 per cent citric acid. Then the cans are exhausted, sealed and processed.

iv) Ber

Umran and *Katha* varieties of *ber* are good for canning. Fully mature fruits are selected for canning. Peel is removed by hand with the help of stainless steel knife or by dipping in 5 per cent boiling hot caustic soda solution for 2 minutes and then washed in running tap water. Second washing is done in water containing 0.1 per cent citric acid in order to remove any traces of caustic soda solution. The fruits are cut into slices. The slices are filled into one lb Jam size can, exhausted; sealed, processed in boiling water for 20 minutes and cooled.

v) Berry Fruits

Among berry fruits, strawberry, loganberry, black berry, raspberry, mulberry and black and red currants are popular for canning. White heart cherry and red cherry having creamy white flesh, are good for canning. Maraschino cherries are canned for mixing with other fruits and for fruit cocktails.

The cherries for canning are generally decolourised during curing in brine for 4-6 weeks. During curing cherries are kept in a brine, which is made up of about 0.75 to 1.0 per cent sulphur dioxide (SO_2) and about 0.4 to 0.6 per cent slaked lime. The cured cherries are washed well in water and dyed with a red dye like Erythrosine, and the colour is fixed with citric acid. These cherries are used for canning.

vi) Citrus Fruits

Generally grape fruit and oranges are canned. Grape fruit varieties Marsh Seedless, Duncan and Foster are good for canning. The fruit is immersed in hot water (93 to 96°C) for 2 to 5 minutes. It softens the peel, which can easily be removed by hand. The peeled fruit is further hand peeled or lye-peeled to remove the white rag portion called albedo. For lye peeling, the whole fruit is immersed in hot lye solution containing 1.5 to 2.0 per cent caustic soda (NaOH) for 20 to 30 seconds. It is then washed with cold water and the segments are separated. The membranes and seeds are removed with the help of knife. The prepared segments are filled into plain cans, and then filled with 60° Brix syrup. The filled cans are exhausted for 25 to 30 minutes at 82 to 87°C, then sealed and processed for 30 to 40 minutes at the same temperature. The cans are cooled immediately after processing.

Satsuma, Mandarin and Unshu (in Japan) are employed for canning. Malta and Sathgudi, which are tight skin, and loose jacket Nagpur and Coorg oranges also yield good canned products.

The peel of loose jacket orange is removed by hand easily. The peel of tight skin oranges is removed and prepared similar to grape fruit. The filled cans are exhausted for 15 to 20 minutes at 82 to 87°C, sealed and pressed for another 15 to 20 minutes at the same temperature in open cooker. After processing, the cans are cooled immediately in cold water.

vii) Grape

Grape varieties such as Thompson Seedless and Muscat are good for canning. Only large sized berries are used for canning. Washed berries are filled into cans and covered with syrup of 20 to 40° Brix. The cans are exhausted, sealed and processed. The coloured grapes should be canned in lacquered cans.

viii) Guava

Fully ripe but firm fruit, with white flesh, are selected for canning. Fruits are peeled by knife or by lye solution as described above. Peeled fruits are cut into halves and seeds are scooped out with a spoon-shaped knife. The prepared fruit should be immersed in 1 to 2 per cent common salt solution. It helps to prevent the fruit from browning. Either halved or quarters are canned. The peel and core with seeds can be used for making guava jelly or guava cheese. Canned guava has a taste and aroma better than those of fresh fruits.

ix) Jack-Fruit

Jackfruit is mostly available in Maharashtra, Bihar, Orissa, Karnataka, Kerala and Tamilnadu. In these states, certain sections of the people use it as an important staple food. All parts of the fruit can be used in one or the other form of food. The green and immature fruit can be canned as a curried vegetable. The ripe fruit with the crisp bulb after seed removal is used for canning in sugar syrup.

The fruit is washed, cut into several large pieces and the bulbs are removed with hand. The fruit contains a white, highly sticky, latex so, a little vegetable oil such as til or gingelly oil, is smeared on the hand and the knife to prevent the latex from sticking on them. The latex is soluble in oil. The bulb after seed removal is canned as a whole, halved or quarter. Generally syrup of 50° Brix having 0.5 to 0.75 per cent citric acid is used for canning of jackfruit bulb.

x) Litchi

Litchis are mostly cultivated in Bihar, Orissa, Uttaranchal and Uttar Pradesh. Tree-ripened fruit is selected for canning. Fruit is washed, skin is removed, and aril is separated from stones. The aril is filled in cans, and aril covered with sugar syrup of about 40^{o} Brix containing 0.5 per cent citric acid. The filled cans are exhausted, sealed and then processed as mentioned earlier. After processing, cans are cooled promptly and thoroughly in running cold water to prevent development of pink colour in the product.

xi) Mango

In India, Uttar Pradesh, Tamil Nadu, Andhra Pradesh, Karnataka, Bihar, Maharashtra and West Bengal lead in mango cultivation. Dashehari, Alphonso, Badami, Baneshan, Raspuri, Neelam, Mulgoa and Totapuri or Bangalora are the most important mango varieties for canning. Juicy and fibrous varieties are not suitable for canning.

Fully developed and mature fruits are harvested and ripened. Canning ripe (just ripe but firm) fruits are selected, washed with water and peeled by hand with the help of knife. The pulp is either cut into two broad side (Chick) or quartered or 6 to 8 cm longitudinal slices.

The prepared fruit is placed in two per cent common salt solution to prevent enzymatic browning. The fruit has slightly higher pH than the critical pH of 4.2 so it is necessary to add 0.3 to 0.5 per cent citric acid in the syrup in order to process in open cookers. The trimmings of the slices, pulp adhering to the peel and stone can be used profitably for the preparation of mango juice or beverages and mango jam.

xii) Papaya

Fruit is washed, peeled, seed removed and cut into slices or cubes for canning. The fruit pulp has a high pH value so it is necessary to add 0.5 per cent citric acid in the syrup to reduce the pH below 4.5. Sometimes papaya is canned with other fruits like pineapple, mango, banana, etc., to produce fruit cocktails.

xiii) Peach

There are two types of peaches, one the clingstone, where the pulp adheres to the stone tightly, and the other freestone where the pulp adheres to the stone loosely or freely. Among the clingstone peaches, Tuscan, Palora and Philips Cling are the varieties good for canning. Among the freestone peaches, Elberta, Lovell and J.H. Hale are suitable varieties for canning.

The fruits are cut into two halves and the pits removed. In large canneries, mechanically operated knives are used to cut fruit into halves and to remove the pits. The cut halves are peeled by immersing them in boiling lye solution containing 1 to 2 per cent caustic soda for ½ to 1 minute. The loosened peel is removed by washing with water. The prepared halves are filled in cans, covered with syrup, exhausted and processed in open cooker. Sometimes peach slices are also canned. Peaches are also used as an important constituent of fruit cocktail.

xiv) Pear

Pears are cultivated in Himachal Pradesh, Kashmir, Uttaranchal and hilly areas of South India. Pears are harvested fully mature, firm but green. The fruits are ripened at room temperature (23 – 26^{o} C) and soft fruits are used for canning.

The fruit is peeled with a knife and cut longitudinally into two halves. The core is removed by coring knife. The prepared fruit is placed in 1 to 2 per cent common salt solution to prevent browning. The halves are then filled into cans, covered with hot sugar syrup, exhausted, seamed and processed as usual. The cans should be cooled immediately in cold water to prevent development of pink discolouration of the fruit during storage.

xv) Pineapple

Pineapple is mostly grown in Assam, West Bengal, the West Coast of India, Andhra Pradesh and Karnataka states. Giant Kew and Queen are the two important varieties of pineapple employed for canning.

The fully mature and just ripe fruit is selected for canning. Uniform size graded fruits are peeled, cored and sliced on a Ginaca machine in foreign countries. In India, the fruits are sliced, and then core and peel is removed by hand with the help of coring and punching knife. Slices are graded usually for size. Since the fruit contains highly active proteolytic enzymes, injurious to skin, the workers should wear rubber gloves. The slices are filled into cans, covered with syrup, exhausted, seamed, processed and cooled as usual.

xvi) Plum

The Red Victoria and the Yellow Pershore plums are important canning varieties. The Alubukhara plum generally grown in North India, also gives a fairly good canned product.

Generally whole plum with stone is canned. Since plum contains water-soluble red colour, which is due to the presence of anthocyanins, is canned in lacquered cans. Washed fruits are filled into can, either as discrete number or by weight, covered with syrup and processed as usual.

xvii) Other Fruits

There are some minor and lesser-known fruits such as. Date, Pomegranate, Mulberry, Musk melon, Water Melon, Aonla, Carambola, Tamarind, Avocado, Custard Apple, Karonda, etc. which may also be canned as usual. These fruits may be canned as slices, cubes or juice and pulp or beverages.

3.4 CANNING OF VEGETABLES

The vegetables are exhausted at 90-100°C for 7-10 minutes or until the centre of the can reaches at least 77°C temperature. The types of can, strength of covering brine and time-temperature for No.2½ and No.10 cans are summarised in Table 3.3.

Table 3.3: Canning time table for non-acid vegetables

Sl. No.	Vegetables	Type of can	Strength of Brine (common salt)	Processing time min. at 0.7 kg per cm^2 steam pressure	
				No. 2½ Can	No. 10 Can
1.	Asparagus	Plain	2.25%	24	40
2.	Bean	Plain	2.25%	40	75
3.	Beet-root	Sulphur resistant	Water or 1.5% Brine	30	40
4.	Cabbage	Plain	2%	40	60
5.	Carrot	Plain	2%	25	50
6.	Cauliflower	Plain	2%	20	–
7.	Curried vegetables	Plain	–	60 to 70	
8.	Mushroom	Plain	2% “	25	40
9.	Okra	Plain	2% “	35	–

10.	Pea, garden	Sulphur resistant	2% Brine & 2.5% sugar solution	45	60
11.	Potato	Plain	2%	45	–
12.	Turnip	Plain	2%	35	50

i) Asparagus

he asparagus shoots are green and white. The tender shoots are used for canning. Just after harvesting the shoots are washed and graded for size and cut according to the height of the can. Shoots are blanched in boiling water for 2-3 minutes then placed in cold water. The blanched shoots are filled into sulphur-resistant cans, covered with 2.0 per cent common salt solution, exhausted, seamed and processed as usual.

ii) Beans

French beans, which are tendered and stringless are used for canning. The beans are washed thoroughly with water and cut into slices about 2.5 cm in length. The slices are blanched in boiling water, drained and filled into plain cans. The beans in the cans are covered with 2 per cent brine, exhausted, closed and processed under pressure in retorts. Sometimes diced beans with diced carrots and garden peas are also canned as mixed vegetables.

iii) Beetroot

Beetroot is washed with water thoroughly. The top and roots are removed with a stainless steel knife. The vegetable is cut in the form of discs or cubes and placed in 1 to 2 per cent common salt solution to preserve the colour. The prepared pieces are filled into vegetable lacquered cans, covered with 2 per cent brine, exhausted, seamed and processed as usual.

iv) Cabbage

Cabbage head with tender yellow leaves is used for canning. After washing, the head is cut into 4 to 8 pieces or shredded into 2.5 cm thick pieces. The pieces are generally blanched in boiling water for 5 to 7 minutes. The blanching water may preferably contain 1 per cent citric acid. After blanching it is cooled in 2 per cent brine to prevent discolouration. The prepared vegetable is filled into plain cans, covered with 2 per cent brine and processed as usual.

v) Carrot

Generally yellow varieties of carrot are used for canning. Tender and small carrots are selected for canning. The carrots are washed well and skin is scrapped with a knife. For large-scale work, mechanical peeler is employed. The peeled carrot is graded for size and used as such or cut into discs or cubes for canning. The carrot is blanched in boiling water for 8 to 12 minutes and packed into plain cans. Brine is used for canning.

vi) Cauliflower

In case of cauliflower, compact flower head is selected and cut into pieces of suitable size. The pieces are canned similar to that of cabbage.

vii) Mushroom

Edible mushrooms, which are not poisonous, are selected for canning. Button mushroom is generally canned whole. Sometimes, mushroom is bleached to a pale colour in a solution of sodium sulphite and citric acid. They are washed with water and blanched in boiling water for 4 to 5 minutes and subsequently dipped in cold water to prevent discolouration. Blanched mushrooms are filled into plain cans, covered with 2 per cent hot brine, exhausted, seamed, processed as usual.

viii) Okra

Okra is also known as Lady's finger. Tender green okras of uniform size are selected. Okra is canned as a whole or as slices. These are washed and blanched in boiling water for 1 to 2 minute and then cooled in brine containing 1.5 per cent common salt. This helps in removal of mucilage. The blanched okras are filled into plain cans and covered with 2 per cent brine, exhausted, seamed and processed as usual. Sometimes, the okras are also canned with thick tomato sauce in order to overcome the mucilaginous property.

ix) Peas

Bonneville is the most popular pea variety for canning in India. We should see that the peas for canning are uniformly ripe and should retain the green colour even after processing. They should also possess good texture and flavour. Large size peas are generally preferred for canning.

Peas are shelled by pea-podding machine and graded by size using sieves with mesh ranging from 0.7 to 1.0 cm. The graded peas are blanched in boiling water for 2 to 5 minutes, and rinsed in cold water. They are filled into plain cans by hand or machine and covered with 2 per cent brine. Sometimes, 2 per cent cane sugar is also added in brine to improve the flavour of the peas. An edible and FPO permitted green colour also may be added to the brine. The cans are exhaussted, closed and processed in a retort as usual. Canned fresh peas are generally known as 'green peas' or 'garden peas'. Dried peas are also canned. The dried peas, which are soaked in water, are canned similar to fresh peas. The dried canned peas are known as 'processed' peas.

x) Potato

Potatoes are canned either whole or slices. Good starchy and firm potatoes are selected and washed to remove the adhered soil. Potatoes are peeled with a knife or by potato peeler, a machine having abrasive surface to remove peel. Peeled potatoes are kept in 2 per cent common salt solution to prevent discolouration. Peeled potatoes are blanched in boiling water for 5 to 7 minutes. Blanched pieces are filled into plain cans, covered with 2 per cent brine, exhausted, seamed, processed and cooled as usual. Some varieties of potato turn bitter after canning, which should not be used.

xi) Tomato

Tomatoes for canning should be firm ripe, medium in size, regular in shape, and of uniform red colour. Tomatoes should have plenty of pulp and free from blemishes.

Tomatoes after washing are placed in boiling water or steam for 2 to 3 minutes to crack the skin and then washed in cold water to remove peel easily. Any green patch is trimmed out. The peeled and trimmed tomatoes are filled into plain cans and covered with tomato juice; and after exhausting and seaming processed in open cooker. It's processing is different from other vegetables as it is acid food.

xii) Turnip

Turnips are red, white and yellow in colour but generally white turnips are canned. Select fibre free tender turnips. They are washed thoroughly with water and cut into about 1 cm thick slices. The pieces are blanched in boiling water for 3 to 5 minutes and cooled. The blanched turnips are filled into cans, covered with 2 per cent brine and processed in retort as usual.

xiii) Other Vegetables

There are several other vegetables, which may be canned similar to the methods given above. They are Karela, Tinda and Parwal. Spinach (Palak) is also canned as puree.

Sarson-ka-Saag (Mustard Green)

Sarson-ka-saag is generally prepared from mustard leaves and spinach in the ratio of 4:1. It has good demand as canned product in India and abroad. The tender shoots of green mustard and spinach are washed, chopped and cooked with salt for 40-45 min. Then mashing is done along with the addition of corn flour or Bengal gram flour (besan). The mass, then fried along with other ingredients and filled into cans, exhausted for 10 minutes and sealed. The cans are processed for 50 minutes in a retort at 0.7 kg/cm^2 and cooled to room temperature. A general recipe for canning of sarson-ka-saag is given below:

Mustard green chopped	800g
Spinach chopped	200g
Tomato	100g
Onion	100g
Garlic	20g
Ginger	80g
Ghee/Oil	100g
Salt (to taste)	15g
Chilli	10g
Corn flour or besan	50g

xiv) Curried Vegetables

Canning of vegetables in brine is a western way of preserving and consuming. There are certain vegetables that are canned as we cook them along with spices and condiments. Certain vegetables like potato, cauliflower, peas, tomatoes are cooked in combination or alone and canned as curried vegetables. Curried vegetables are those vegetables, which are canned along with spices and condiments such as mustard, coriander, red chilli, turmeric, common salt and vegetable oil in form of gravy. The curried vegetables are readily consumed after heating in the cans. In order to prepare the curried vegetables, the oil is heated in a pan, the mustard seed is fried in it, then other ingredients in powder form are added to taste (as done at home while cooking vegetables) and heatings continued. Then required amount of water is added and brought to boil. The curried vegetables are filled into can along with gravy, closed and processed for 60 to 70 minutes at 0.7 kg/cm^2 in a retort.

3.5 ASEPTIC CANNING OF FRUIT AND VEGETABLE PRODUCTS

Fruit and vegetable products are packed by using the latest developed technique known as aseptic canning. As you know that this system is basically a high temperature short time (HTST) sterilizing process. This method combines flash sterilization and cooling with aseptic methods of packaging for fluid and semi-fluid products, thus eliminating retorting and cooling. It is being used commercially particularly for bulk packing of products. This system has advantage that quality of the product is maintained better. The nutrient losses are minimum due to HTST processing and shelf life of the product is more.

3.6 LET US SUM UP

Canning is a method of preservation of fruits and vegetables by heat application. The main principle of canning is the destruction of spoilage microorganisms. The canning process includes several unit operations, viz. selection, sorting, grading, washing, peeling, cutting, blanching, filling, syruping or brining, lidding or clinching, exhausting, seaming, processing, cooling and storage. Fruits and vegetables differ in the canning process due to their acid value.

Tin cans of different sizes are used for packing of fruits and vegetables. For some fruits and vegetables lacquer cans are used. If cans are not processed adequately they develop some defects. The defects may be caused by physical and chemical changes, and by microorganisms. Canned products can be stored for 1 to 2 years depending on the quality of raw materials.

3.7 KEY WORDS

Blanching : Blanching is done by immersing fruits and vegetables in hot water or by exposing to steam followed by cooling.

Syruping or brining : After placing prepared fruits or vegetables in can, syrup or brine is added, respectively is called syruping or brining.

Exhausting : The vacuum in the can obtained by heat treatment or by mechanical means is known as exhausting.

Seaming : It is sealing or closing of lids on cans by double seamer. Interlocking of curl of the lid and flange of the can creates double seam.

Processing : The application of heat to fruits and vegetables after hermetic (air tight) sealing in containers is called processing.

Commercial sterilization : It is the term used for those thermally processed products in which microorganisms and their spores do not grow under normal conditions of storage.

Principle purpose of canning : Destruction of spoilage or pathogenic microorganisms and retention the original characteristics of food.

Unit operation : It is one of the steps in a complete process or a physical change in form or place, for example, peeling, cutting, grading, etc.

3.8 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answer should include the following points:

1. • Destruction of microorganisms, which may cause spoilage of foods.
   • Improve the flavour, texture and appearance of food by cooking.
   • Prevent recontamination.

2. Selection of fruits and vegetables → Sorting and Grading → Washing → Peeling → Cutting → Blanching→ Filling → Syruping → Lidding/Brining or Clinching → Exhausting → Seaming → Processing → Cooling → Testing for defects → Storage

3. • Fruits are covered with sugar syrup while vegetables are covered with brine
   • Fruits are processed at 100°C while vegetables are processed at 115° to 121°C.
   • Fruits are processed in open cookers while vegetables are processed in retort under pressure(0.7kg/cm^2)

4. i) Spoilage due to physical and chemical changes:
      • Swell – Hydrogen swell; Flipper, Springer, etc.
      • Overfilling, faulty retort operation, under exhausting, panelling, rust, leakage, bursting, discolouration and stack burning

   ii) Spoilage by microorganisms
      • Flat sour.
      • Thermophilic acid sour
      • Sulphur spoilage, etc.

Check Your Progress Exercise 2

1. Your answer should include the following points:
   • To lower the pH of canned fruit
   • To improve the palatability of canned product

2. Your answer should include the following points:
   • To prevent enzymatic browning
   • To prevent darkening
   • To prevent discolouration

3. Your answer should include the following points:

- In open cooker, normal atmosphere is maintained
- In open cooker temperature of boiling water remain & below 100°C and never increases.
- The fruits and tomato (acidic vegetables) are cooked generally in the open cooker.

Check Your Progress Exercise 3

1. Your answer should include the following points:

   - Vegetables are generally non acidic in nature
   - The pH of non acidic vegetables are above 4.5
   - Non-acidic vegetables are processed at high temperature
   - High temperature can only be attained when processed under pressure in a retort.

2. Your answer should include the following points:

   - Certain vegetables contain water soluble colour
   - Presence of anthocyanins
   - Presence of sulphur compound
   - Asparagus, Beetroot, Peas are packed in lacquered cans

UNIT 4 FORMS OF WATER IN FOODS, SORPTION AND DESORPTION OF WATER IN FOODS AND WATER ACTIVITY

Structure

4.0 OBJECTIVES

After reading this unit, you should be able to:

- state the meaning of water activity and water sorption isotherms;
- explain the properties of water in solutions;
- describe the effect of water activity on various biochemical reactions, microbial growth, food preservation, etc.; and
- discuss the water activity in packaged and stored food.

4.1 INTRODUCTION

All foods provided by nature, contain water. High water content in foods is most likely to show rapid deterioration due to biological and chemical changes. Our ancestors found that spoilage could be delayed or prevented by drying perishable foods. The water in foods serves as a solvent for many constituents. The removal of water will concentrate these constituents. The increasing concentration, rather than decreasing water content, preserves the food. Water can be removed by heat, sun's radiation, salt or sugar. Thus, any method increasing the concentration of a food's aqueous phase enhances its stability.

Therefore, study of water in foods is also a study of aqueous solution in which the solutes, by their nature and concentration, alter the physical properties of the solvent. It is the state of water in food which influences the microbial growth, enzymatic and non-enzymatic reactions. By controlling the water content, or concentrating the food solution, we may stabilize the food for a longer period. The water content influences the biological or chemical changes, and these changes affect the taste, texture and appearance of the food.

Thus, there is a water related criteria, viz. water content, solute concentration, osmotic pressure, equilibrium relative humidity (E.R.H.), and water activity (a_w). It is the water activity, which is the most useful expression of water requirements for microbial growth and enzyme activity. It becomes more important in defining the quality of food material. Thus, by controlling the water activity of fruits and vegetables, we may predict the freshness, or storability of their processed products.

4.2 PROPERTIES OF WATER IN SOLUTIONS

Water has its own property. When solutes are dissolved in water, the water molecules become oriented with respect to solute molecules. In simple word water molecules and solute molecules are engaged with each other. The water molecules become less free to escape from the liquid into the vapour phase, and the vapour pressure is lowered. There is a relationship between solutes concentration and vapour pressure of liquid or solution. It indicates that with increase in solute concentration, vapour pressure decreases, and it lowers the freezing point but it raises the boiling point of the solution.

The water activity is described as the ratio of water vapour pressure of food (solution) to the water vapour pressure of pure water (solvent) at the same temperature and expressed by

$$a_w = P/P_o$$

P = Vapour pressure of food
P_o = Vapour pressures of pure water

It is expressed as a fraction but under equilibrium condition, equilibrium relative humidity (E.R.H.) is equal to $a_w \times 100$, provided that its vapour pressure is not reduced. The pure water has the water activity of 1.00, which is equivalent to an E.R.H. of 100 per cent. Thus, a food with a water activity of 0.8 would produce an E.R.H. of 80 per cent.

Any addition of solutes in water influences the water activity. For example, an ideal solute of 1 molal concentration has a_w 0.9823, but glycerol has 0.9816, sucrose has 0.9806, while has sodium chloride 0.967. The difference in water activity may be small for non-electrolytes but for electrolytes the difference in water activity is always great. It increases with the increase in the number of ions generated per molecule.

4.3 WATER SORPTION ISOTHERMS

A percentage of total water in a food is strongly bound to specific sites, e.g. hydroxyl groups of polysaccharides. When all sites are (statistically) occupied by adsorbed water the moisture content is termed monolayer value. This monolayer value represents the moisture content at which the food is most stable.

It influences certain chemical reactions. For example, lipid oxidation rates increase at water contents below the monolayer, while rates of non-enzymatic browning increase above it. The capillary forces in foods also influence the water activity, generally it depresses water activity.

To understand the water relations of a food, the water activity levels corresponding to a range of water content must be determined. The data are plotted to provide a water sorption isotherm (Figure 4.1).

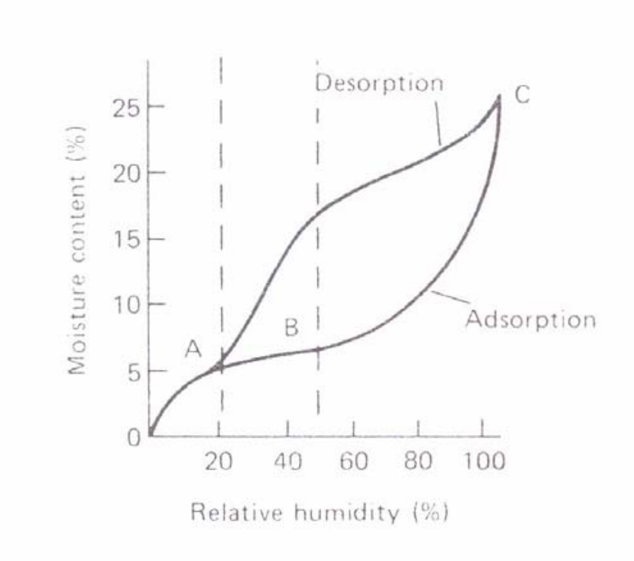

Figure 4.1: Water sorption isotherms

The graphical relationships between water content and water activity (a_w) are termed "isotherms" and the loop is fermed as hystoresis loop. Any changes in temperature affect this relation. Thus, water taken by a dry food is termed adsorption and water removed from a moist material is termed desorption. The difference is greatest at lower temperature (5°C) and not detectable at higher temperature (60°C).

There are different stages of water sorption. In theory, the course of water sorption by a dry material is first by the formation of a monolayer, followed by multiplayer adsorption, the uptake into pores and capillary spaces, dissolution of solutes, and entrapment of water at higher levels of water activity. These phases or stages vary in the food product depending upon chemical composition and structure. Thus, we find that water activity plays a great role in the study of freezing and dehydration of fruits and vegetables. By controlling water activity of the food, oxidative changes and microbial growth can be checked. The water activity can be a basis for the standard specification of food material. And it also becomes the basis of guidelines, for pickled, fermented and acidified foods.

4.4 WATER ACTIVITY AND METHODS

The water in food, which is not bound to its molecules, can support the growth of microorganisms. This unbound or free water is also termed as water activity (a_w).

The water activity and moisture content of a food are not the same. The various foods may have exactly the same moisture content but have different water activities. For example, jams, jellies and plum puddings have 0.8 $a_{w,}$ while dried fruits have 0.6 a_w.

The water activity can determine the shelf life of a food. There are several factors, including the temperature and pH, that influence the growth of the organisms in food, but water activity may be the most important factor in controlling spoilage. The water activity can predict which microorganisms will and will not be potential cause of spoilage. Hence, the water activity plays a role in determining the activity of bacteria or enzyme, which can have a major impact on the colour, taste and aroma of the product. There are several food preservation methods which to eliminate spoilage by reducing the availability of free water to microorganisms. The processes such as concentration, dehydration, freeze-drying and freezing can reduce the amount of free water in a product.

Water activity or equilibrium relative humidity of a food effects its quality during processing storage, transportation, marketing etc. Any change in the water activity of specific food may lead to the changes in its quality.

Moisture measurement techniques have been classified into three groups based on function: (i) water activity, (ii) atmospheric relative humidity, and (iii) total moisture. The first group deals with direct water activity / E.R.H. measurements as related to foods. The second group deals with relative humidity measurements, which covers food related activities, for example, ambient relative humidity in food storage areas. The third group deals with measurement of total moisture content, regardless of the condition or degree of water binding. These measurement methods are listed below.

Graphic Interpolation, Bithermal Equilibrium, Manometer, Hair Hygrometry, Isopiestic Equilibration, Electric Hygrometry, Chemical Methods, Freezing Point Depression, Dew Point Methods, Relative Humidity Methods, Thermometric Methods, Total Moisture Methods, Gravimetric, Gas Chromatography, Karl Fischer Titration, Nuclear Magnetic Resonance, Thermal Analysis, Moisture Evolution Analysis, Infrared, Vacuum Oven Drying, Solvent Extraction.

The control of water activity in processed products of fruits and vegetables is essential for maintenance of their wholesomeness, safety, texture, and for suppression of undesirable enzymatic and chemical changes. These objectives can be achieved by utilizing water activity adjustment as a legitimate means of food preservation. The water activity adjustment in a food is also affected by a large number of substances added to the food.

4.5 EFFECT OF WATER ACTIVITY ON ENZYME REACTIONS

Enzymes are proteinaceous substances that catalyze organic reactions. The enzymatic reactions may be beneficial or detrimental changes occurring in foods. For example, the addition of a proteolytic enzyme, which acts as chill proofing agent, to beer to prevent precipitation of proteins when it is refrigerated. These enzymes develop in foods through the growth of specific types of microorganisms. For example, proteases and lipases synthesize by the mould, *Penicillium roqueforti* that produces desirable flavours during ripening of blue cheese.

Certain enzymes catalyze detrimental changes in food, such as non-microbial decomposition of fruits and vegetables during handling and storage. The enzymes, viz. peroxidase may cause browning; ascorbic acid oxidase may cause oxidation of ascorbic acid. It is therefore, important to thwart the activities of these naturally occurring enzymes in foods. Blanching of fruits and vegetables by hot water or steam is one method to inactivate enzymes and prevent the deleterious changes.

The enzymes also produce free radical by hydrolytic reactions. The water participates actively in these reactions. These reactions are not limited with low moisture foods, since many enzymatic reactions cease at higher concentration than that required for hydrolysis. At low water activity levels free mobile water monolayer is not available to carry out reactions. Under such conditions the enzymatic reactions are suppressed. But, when the water activity of food increased, the enzymatic reaction rates increase. Thus, by controlling water activity, we can check the enzymatic reaction rates. In other words, we may increase the rates of beneficial reactions and reduce the rates of deleterious reactions, and maintain the desired quality of foods.

There are certain enzyme preparations, which can be used to affect desirable changes in foods, These enzyme preparations can be stabilized by use of certain substances such as sodium chloride, glycerol, or propylene glycol. There are other factors, which also affect the stability of enzymes in foods, such as temperature, pH, ionic strength, moisture level, nature of food, time of storage, presence of activators and inhibitors, etc.

The enzymatic activity virtually ceases at water activity values below monolayer value. This is due to the low substrate mobility and its inability to diffuse to the reactive site on the anzymes.

Fungal proteolytic enzymes are strongly inhibited by 2-3% sodium chloride (NaCl), as the activity is in the range of 0.6-0.8. The optimal water activity levels for invertase activity is greater than 0.997. In a glycerol / water mixture, lipoxidase and peroxidase exhibit optimal activity in the range of 0.94-0.97 water activity.

4.6 EFFECT OF WATER ACTIVITY ON NON-ENZYMATIC BROWNING REACTIONS

The water activity plays a great role in influencing the non-enzymatic browning (NEB) reactions in the processed fruit and vegetable products. The substrates for NEB are the reducing sugars such as glucose and fructose and amino groups of amino acids or proteins. Sucrose may be a substrate but does not cause browning. Hydrolysis of sucrose into glucose and fructose during processing may cause browning. A number of factors such as temperature, pH, and water activity also affect the NEB reactions. They are called the formation of browning or Maillard reaction products. These browning reactions deteriorate the quality of the processed products.

The water activity that causes the maximum rate of browning varies with different foods. At low water activity browning is reduced due to lower mobility of reactants, whereas at higher a_w browning is maximum. During browning, condensation reaction produce water and at higher moisture levels, browning is inhibited by end product inhibition. At higher moisture contents, water dilutes the reactants and the rate of browning falls.

Browning that occurs during processing or storage may either increase or decrease the acceptability of a food. For example, in a dehydrated pea soup stored at 54°C, a steady increase in browning rate occurs as the relative humidity of the system is increased. The maximal rate occurs in the 65-70%

relative humidity range. Thus, the temperature and moisture content during storage influence the browning rate in dehydrated products. NEB is a serious problem in the production of intermediate moisture food (IMF), since they are poised at 0.6-0.8 water activity, which places them well within water activity ranges for optimal browning. If the water activity is reduced to the range of 0.40 to 0.50 from 0.65 to 0.75 the browning of IMF can be reduced.

It is clear from the above discussion that maximal browning reaction rates in fruit and vegetable products occur in the 0.65-0.75 water activity range. By checking the water activity we can reduce the non-enzymatic browning.

4.7 EFFECT OF WATER ACTIVITY ON MICROBIAL GROWTH AND SURVIVAL

4.7.1 Microbial Growth

Food is spoiled by microorganisms, i.e. bacteria, yeast and moulds. There are four main phases of the growth cycle of these microorganisms, viz. the lag phase, the logarithmic phase, the stationary phase, and the death phase. Bacteria, yeasts and fungi reproduce by different methods such as binary fission, budding or by hyphal extension, respectively. But the phases through which these organisms pass are broadly similar.

The first phase, i.e., the lag phase, is the period of adjustment or adaptation. Physiologically the microorganisms are very active during this phase. The organisms are metabolizing, but there is a lag in cell division. At the end of the lag phase, each organism divides. However, since all the organisms do not complete the lag period simultaneously, there is a gradual increase in the population until the end of this period, when all cells are capable of dividing at regular intervals. The lag phase is followed by rapid growth, i.e., the exponential or logarithmic phase. During this period, the population is nearly most uniform in terms of chemical composition of cells, metabolic activity, and other physiological characteristics.

The logarithmic phase of growth is followed by a levelling off, the stationary phase. During this phase, the population remains constant for a time, perhaps because the reproduction rate is balanced by an equivalent death rate. Following the stationary phase, the organisms may die faster than new ones are produced, if indeed some organisms are still reproducing. During the death phase, the number of viable organisms decreases exponentially, essentially the inverse of growth during the lag phase.

We should understand that the important criterion in the water relations of a particular microorganism is the minimal water activity permitting growth. From the point of view of food technology and preservation of fruit and vegetable products, less extreme effects may also be detrimental. For example, at certain water activity levels, the population of a microorganism may be insufficient to produce a toxic product or an infectious dose. The reduced water activity along with another chemical or physical agent such as pH or common salt may have synergistic inhibitory effect on the growth of any microorganism. Thus, it is important to consider the effects of water activity on microbial growth and survival.

In general, the microorganisms associated with foods, moulds are more tolerant of a decreased a_w than yeasts, and yeasts are more tolerant than bacteria. In high moisture foods ($a_w > 0.90$) bacteria are mainly responsible for spoilage, food poisoning or fermentation. In intermediate moisture foods (a_w 0.90-0.60) yeasts and moulds are of significance in spoilage. However, most microorganisms re inhibited in low moisture foods ($a_w < 0.60$).

The a_w of most fresh foods is above 0.99. Most spoilage bacteria do not grow below a_w of 0.91 while spoilage moulds can grow as low as 0.80. With respect to food poisoning bacteria, *staphylococcus aureus* has been found to grow at as low as 0.86, while *clostridium botulinum* does not grow below 0.95 a_w. Just as yeasts and moulds grow over a wider pH range than bacteria, the same is true for a_w. The lowest reported values for bacteria of any type is 0.75 for halophilic bacteria, while xerophilic moulds and osmophilic yeasts have been reported to grow at a_w values of 0.65 and 0.60, respectively.

Inhibition of microorganisms in a food is frequently not caused solely by a decrease in a_w, but may also be influenced by pH, temperature, nutrition, preservatives or a competitive microflora. At any temperature, the ability of microorganisms to grow is reduced as the a_w is lowered. The range of a_w over which growth occurs is greatest at the optimum temperature for growth. The presence of nutrients increases the range of a_w over which the organisms can survive.

Factors affecting the germination of spores *clostridium batulinum* have indicated interaction or combined effects of a_w, temperature, pH, oxidation – reduction (O-R) potential, and sodium chloride and sodium nitrate concentrations. Addition of solutes such as glycerol and common salt also influences the water activity of a solution. This shows the availability of solvent or water in a solution, since it reduces with the addition of solutes. Such conditions also influence the growth of microorganisms. For example, non-osmophilic yeast, *saccharomyces*, grows at water activity levels down to 0.93-0.92 in sodium chloride and to 0.91-0.90 in sucrose media. But the osmophihlic yeast will grow in more concentrated environment, i.e., sugar rich and salt-rich foods.

Thus, depending upon the type of microorganism, water activity along with solutes and other factors can be selected to enhance or restrict their growth.

4.7.2 Microbial Survival

The survival of microflora is of concern during two stages of fruits and vegetables. Firstly for short period during processing and secondly for long periods during storage. We should adopt measures to prevent the growth of these microflora. We are concerned especially with the survival of microorganisms in commercially processed fruit and vegetable products. These may be frozen, dried or canned products.

Similar to the rate of multiplication, the rate of inactivation of microorganisms tends to be exponential. It shows that the same proportion of the viable population will be inactivated in each succeeding unit of time. If we plot, the number of viable cells against time, a linear curve would be obtained, and from it rate of death can be determined. This is generally expressed as the decimal reduction time or D-value. It is the time required to destroy 90 percent of the organisms. Mathematically, it is equal to the reciprocal of the slope of the survivor curve and is a measure of the death rate of an organism.

Storage stability of frozen and dried foods

A large number of microorganisms have been reported to grow at and below 0°C. Their growth at and below freezing temperatures depends on several factors of foods, namely, nutrient content, pH, and the availability of liquid water. The a_w of foods may be expected to decrease as temperatures fall below the freezing point. In fruit juice concentrates which contain comparatively high levels of sugars, these compounds tend to maintain a_w at levels higher than would be expected in pure water, thereby making microbial growth possible ever at subfreezing temperatures. Bacteria differ in their capacity to survive during freezing, with the cocci being generally more resistant than gram negative rods. Of the food poisoning bacteria, salmonellae are less resistant than *staphylococcus aureus* or vegetative cells of *clostridia*, while endospores and food poisoning toxins are apparently unaffected by low temperatures.

The heat resistance of microbial cells increases with decreasing humidity or moisture. The preservation of foods by drying is based on the fact that microorganisms and enzymes need water in order to be active. Although some microorganisms are destroyed in the process of drying, this process is not lethal to microorganisms, and indeed many types may be recovered from dried foods. Osmophilic yeasts such as *Saccharomyces rouxii* strains have been reported to grow at an a_w of 0.65 under certain conditions. The most troublesome group of microorganisms in dried foods are the moulds, with the *Aspergillus glaucus* group being the most notorious at low a_w values. In the absence of fungal growth, dessicated foods are subjected to certain chemical changes which may result in the food becoming undesirable upon holding.

Drying usually is accomplished by the removal of water, but any method that reduces the amount of available moisture, i.e., lowers the a_w, in a food is a form of drying. Thus, for example, dried fish may be heavily salted so that moisture is drawn from the flesh and bound by the solute and hence is unavailable to microorganisms. Sugar may be added, as in sweetened condensed milk, to reduce the amount of available moisture.

The potentials of reduced water activity in food preservation with the following considerations are:

i) an a_w of 0.85 inhibits the most common food pathogens,

ii) bacterial spore germination is inhibited at relatively high a_w values,

iii) non-sporeformers, which can grow at an aw below 0.95, are susceptible to pasteurizing temperatures,

iv) sub-optimal conditions of growth impose inhibition at higher levels of water activity,

v) organisms that will grow at low water activities multiply very slowly, and

vi) yeasts and moulds can be suppressed by antimycotics.

4.8 EFFECT OF WATER ACTIVITY ON PACKAGING AND STORAGE

The conditions during storage and transport should be maintained in such a way so that any deterioration is kept to a minimum. These problems are influenced by the temperature and relative humidity during storage and by the type of package in which foods are stored. Therefore, we should consider the water activity requirement in the packaging, storage and transportation of food products.

i) Transportation of processed products

During transportation of processed products the moisture migration may cause condensation. This has proved to be a problem in successful transportation of some commodities due to differences in climatic zones. For example, if cooling is followed by an increase in atmospheric temperature then humidity causes condensation on the inner surface of any container. This causes an increase in the relative humidity of the air above 90 per cent, but aeration can reduce it to a safe level.

Similarly, condensation of moisture on the surface of containers such as canned foods may spoil the label, corrode the can and mould attack. This type of problem can be prevented by drying the container before loading and lacquering the can from outside.

In the atmosphere of equilibrium relative humidity (ERH) a commodity at low water activity, even small decrease in air temperature may cause moisture condensation. For example, the air at 70 per cent ERH and 30^{o}C becomes saturated and hence prone to moisture condensation if its temperature falls by only 6^{o}C, such conditions may also permit the mould growth.

ii) Packaged products

Packaging generally reduces the atmosphere of a commodity to a minimum, hence protects it from outside sources, particularly the migration of moisture and variation in temperature. The quality of a food depends upon its properties, packaging material and the storage environment. We are concerned with the changes influenced by water activity, particularly appearance, taste, odour and texture, resulting from microbiological and biochemical changes. Packages are expected to provide adequate degree of protection to the product. With advances in packaging technology, packages are often expected to provide nutritional and constitutional information to sell the product. The packaging material has to provide desired water activity, which is the main concern. But, there are special requirements that include protection from light and oxygen, retention of preservatives, fragility of the product and the ease with which the package can be filled, handled and stored. Properly sealed cans and glass bottles give complete protection to the packed food against the intake of gases, moisture and microorganisms. The more attention should be given to the flexible films or packaging materials, which exhibit a very wide range of moisture (vapour) and gas permeability.

iii) Packaging materials

The basic flexible materials of importance are aluminium, plastic, regenerated cellulose and paper. The overall permeability of aluminium foil and laminate is near zero. The permeability of plastic film is governed by its thickness. Thicker films generally have lower permeability, greater strength and higher cost. In food packaging application, the materials are combined by lamination, coating or co-extrusion, and they may have properties different from the basic or individual film. Type of food product, its hygroscopicity, environment inside and outside of package, handling during storage, marketing, transportation, etc., usually govern this type of combination of packaging materials. Sometimes, microbiological problems may arise. When moist product is packed in impermeable or low permeable materials, such as glass, metal or films coated with polyvinylidene chloride or polyvinyl chloride, the food will equilibrate with the internal atmosphere of the package, and cooling may cause condensation of moisture, resulting in high water activity in which microbial growth may occur. Hence, we should see that product of relatively low water activity be packed in moisture impermeable packages and some measure of microbial control should also be used. Although, when high water activity products are packed in permeable material, then care must be taken to prevent excessive moisture loss from the product. This can be achieved by careful selection of wrapping material or by control of humidity in the surrounding atmosphere of the package.

iv) Unrefrigerated packaged products

Dehydrated vegetables, which have water activity of 0.30 or below, require protection against moisture and oxygen. Laminates of polyethylene, aluminium foil and paper have been successfully employed for packaging dehydrated vegetables. Dehydrated soups are also packaged similar to dried vegetables, which provide full protection to the product. The dried fruits have much higher water activity levels, may be stored safely in relatively permeable film, where ambient humidity is very low. The potato chips and roasted nuts which depend on their appeal and crispness are not susceptible to unsuitable storage conditions. These products have substantial amount of lipids, hence need additional protection, and therefore hence packaged with nitrogen gas. But for long storage costly items like nuts vacuum packaging in cans or glass jars require. However, for retail marketing, these products are successfully packaged in a wide variety of materials with low water vapour transmission rate, and oxygen permeability. For example, cellulose-plastic combination, poly vinylidene chloride coated-cellulose or polypropylene are used.

v) Refrigerated packaged products

Generally, fresh fruits and vegetables are kept in cool store at suitable temperatures and relative humidity (RH). For example, cured onions and garlic can be stored at 0°C with RH 65-70 per cent, whereas vegetables like cabbage, carrots, cauliflower, leafy greens, green peas, turnip require 95 per cent of RH. Apples are stored at 0-3°C with 85-90 per cent RH depending upon non-chilling and chilling sensitive varieties.

A compromise is required between packaging material of fresh fruits and vegetables that retain water and maintain crispness, but cause condensation and fogging of the films and those which permit loss in weight and crispness, but do not fog. Sometimes, adequate perforations are made in the package for minimum respiration without physiological disorders in the living tissues. Frozen vegetables are commonly packed in polyethylene or paperboard, waxed or plastic coated moisture proof film, to minimize oxygen uptake and loss of moisture. The frozen fruit juice concentrates are packaged in hermetically sealed tin cans or aluminium laminated composite containers.

1. Describe the role of water activity in packaged products during storage?

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

4.9 LET US SUM UP

The fruits and vegetables by nature contain high water; consequently they are highly perishable products. Most likely they show rapid deterioration due to biological and chemical changes. Water acts as a solvent in the food products. The solutes present in aqueous phase, by their nature and concentration, alter the properties of solvent. It is the state of water in food products, which influences the microbial, enzymatic and non-enzymatic reactions. Thus, controlling the water content or concentrating the food solution, the food may be stabilized for a longer period. The solution of food (fruits and vegetables) has its properties, and may be expressed as water activity. The water activity is certainly related with properties of food and has great importance to study its influence on microbial growth/ survival, moisture content of food, packaged food during storage, transport and preservation.

Many enzymatic reactions cease at higher water content than that is required for hydrolysis. At low water activity levels, the free moisture is not available, hence enzymatic reactions are suppressed. The maximum non-enzymatic reactions occur in food equilibrated to 0.65-0.70 water activity, but reduce at higher and lower water activity levels.

The lower level of water activity suppresses microbial growth in food products. Removal of water from foods, reduces its water activity, hence preservation is affected.

Properly prepared fruit and vegetable products, packed in appropriate packaging material and stored under controlled conditions have longer shelf life.

4.10 KEY WORDS

Water activity : Water activity (a_w) is the ratio of vapour pressure of food (p) and pure water (p_o), and expressed by $a_w = p/ p_o$

Sorption isotherm : Water sorption isotherm is a graphical presentation of data which shows the water relationship of a food.

Concentration	:	It is the removal of water from foods mostly by heat application and concentration of soluble solids or solutes.
Enzyme	:	Enzyme may be defined as proteinaceous compounds that catalyse organic reactions.
Preservation	:	Methods to hold food for a longer period than generally kept at ambient conditions. Food is safe, nutritious and free from any microbial infection.
Halophilic bacteria	:	They are salt tolerant bacteria. The extremely halophilic bacteria have evolved to grow only at low levels of water activity and only when these levels are produced by high sodium chloride concentrations.
Osmophilic yeast	:	Sugar tolerant yeast.
Adsorption	:	The taking up of one substance at the surface of another.
Desorption	:	Removal of adsorbed water from a solid. Reverse process of adsorption.
Adsorption isotherm	:	The relation between the amount of a substance adsorbed and its pressure or concentration at constant temperature.
Xerophilic	:	Microorganisms able to inhabit places where the water supply is scanty, or where conditions, e.g., excess of salt, make it difficult to take in water.

4.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercises 1

Your answers should include the following points:

1. The water activity is described as the ratio of vapour pressure of solution (food) and vapour pressure of solvent (water) and expressed by

$$a_w = p/\,p_o$$

a_w = Water Activity

p = Vapour pressure of solution (food)
p_o = Vapour pressure of solvent (water)

Under equilibrium condition, E.R.H. is equal to $a_w \times 100$. Provided that its vapour pressure is not reduced. The pure water has an a_w of 1.00, which is equivalent to an E.R.H. of 100 per cent.

2. To understand the water relations of a food, the water activity levels corresponding to a range of water contents must be determined. The data are plotted to provide a water sorption isotherm. The water sorption isotherm is a graphical presentation of data, which shows the water relationships of a food. It is useful in showing at what water contents certain desirable or undesirable levels of water activity are achieved.

3. The following methods can be used to measure the water activity:

   Graphical Inter Polation, Bithermal Equilibration Mamometry, Hair Hygrometry, Isopiestic Equilibration, Electric Hygrometry, Chemical methods, Freezing Point Depression and Dew Point Method.

4. The measurement of water activity in a food is essential for maintenance of their wholesomeness, safety, texture, and for suppression of undesirable enzymatic, and chemical changes.

Check Your Progress Exercises 2

Your answers should include the following points:

1. Enzymes are proteinaceous substances that catalyze organic reactions, which may be beneficial or detrimental, occurring in foods. The water participates actively in these reactions. Many enzymatic reactions cease at higher water content than that required for hydrolysis. At low water activity levels, the free mobile water is not available to carry out reactions. Under such conditions the enzymatic reactions are suppressed, but when water activity of food is increased, the enzymatic reactions rate gets increased. Thus, by controlling water activity we can check the enzymatic reactions.

2. The non-enzymatic browning is caused by reactions between glucose or fructose and amino group of food and influenced by water activity level. The maximum level of such reaction occurs in samples equilibrated to 0.65 to 0.70 $a_{w.}$ But reduced at higher and lower levels of water activity. Thus, by controlling water activity, we can reduce the non-enzymatic browning.

3. For microbial growth optimum moisture content in food is essential beyond this limit the growth is suppressed. The lower level of water activity does not provide free moisture whereas concentration of solutes suppresses microbial growth. At very high water content dilution of nutrients prevent their growth.

Check Your Progress Exercises 3

1. Properly dried fruits and vegetables should be packed in such packaging materials, which do not permeate moisture vapour, light and gases. These food packages should be stored at desirable relative humidity and temperature. If there are differences in temperature and relative humidity in the packaged food and its surrounding atmosphere, then the moisture migration may cause condensation, which may create problems in the successful transportation. This can be reduced by aeration. Proper packaging also protects food by maintaining desirable water activity.

UNIT 5 DRYING, DEHYDRATION AND EVAPORATION

Structure

5.0 OBJECTIVES

After reading this unit, you should be able to:

- describe the mechanisms of drying and dehydration of fruits and vegetables;
- reduce the weight and bulk, and water activity of fruits and vegetables;
- explain various methods and types of evaporation and evaporators used;
- define the microorganisms involved in spoilage of dried products;
- determine the drying and rehydration ratio; and
- evaluate the factors affecting the drying rate of fruits and vegetables.

5.1 INTRODUCTION

Drying or dehydration is accomplished by the removal of water from the fruits and vegetables below a certain level at which enzyme activity and growth of microorganisms are affected adversely. Evaporation is an important unit operation commonly employed to remove water from dilute liquid foods to obtain concentrated products. The dried or concentrated fruit or vegetable product is called as high sugar high acid food or high value low volume food. The dried or concentrated products save energy, money and space in packaging storage and transportation. Dehydration or drying process usually involves heating, in which water is removed from solid or near solid substances. Both drying and dehydration mean the removal of water. The term drying is generally used for drying in the sun, while dehydration is generally used for drying the commodities under the controlled conditions. Evaporation process also involves heating where water is removed from the liquid substance. Evaporation, sometimes also termed as concentration, is different from drying and dehydration, since the final product of evaporation process remains in liquid state. Removal of water from food provides microbiological stability and assists in reducing transportation and storage costs. Fruit juice is concentrated by evaporating water. For aromatic juice, it is desirable to heat the juice for short time and cooling rapidly. This minimizes the effect on flavour, aroma, and sugar compounds.

5.2 DRYING PHENOMENA

You are aware that the fruits and vegetables contain sufficient water which allows their spoilage by microorganism and physiological changes. So, the reduction of free water or removal of moisture becomes necessary to provide stability to a product. The drying or dehydration reduces the amount of available moisture, i.e., water activity. The relationship between moisture and solid in fruits sand vegetables is a complex phenomenon. The physiological structure of most fruits and vegetables restricts the rate of migration of water from within to the exposed outer surfaces from where it can evaporate.

Therefore, the changes during dehydration can be explained in terms of heat and mass transfer phenomena. During dehydration a food loses moisture from its surface and gradually develops a dry layer with remaining moisture confined to its centre. A stabilised moisture gradient is formed from the centre to the surface. As a result, the outside dry layer forms an insulation barrier against rapid heat transfer into the food pieces, especially since the evaporating water leaves air voids behind it. In addition to less driving force from decreased heat transfer, the centrally remaining water also has to travel further to get out of the food piece than did surface moisture at the start of drying. And, as the food dries it approaches its normal equilibrium relative humidity, as it does it begins to pick up molecules of water vapour from the atmosphere as fast as it loses them. When these rates are equal drying ceases. The cracking, shrivelling and shrinking may occur during dehydration due to the removal of moisture through diffusion from centre to outer surface. Excessively fast removal of moisture from outer layers may result in case hardening thereby sealing the surface and causing inadequate drying in the centre.

5.3 FACTORS AFFECTING DRYING

Food dehydration involves two steps (i) to get heat into the product and (ii) to get moisture out of the product. The above two steps are not always favoured by same operating conditions. For example, food may be pressed between two heated plates. This will provide close contact and improve heat transfer into the food through top and bottom, but the close contact of the plates will interfere with the escape of free moisture. Therefore, it may be better to use one bottom hot plate to get heat in and a free surface on top of the food to let moisture out. The following factors influence the drying rate.

i) Temperature

The rate of heat transfer into the food, which provides the driving force for moisture removal, is affected by the temperature difference between heating medium and the food. Greater the temperature difference, more will be the transfer of heat and moisture removal. When the heating medium is air, temperature also plays a role in carrying away the water driven from the food in the form of water vapour. However, moisture creates a saturated atmosphere at the food's surface which slows down the rate of subsequent water removal.

ii) Surface area

The heat and mass transfer is affected by surface area. Higher surface area results into increased rate of drying. Therefore, the food to be dehydrated is sub divided into small pieces or thin layers which speeds up drying for two reasons. First, larger surface area provides more surface in contact with the heating medium and thus, more surface area from which moisture can escape. Second, smaller particles or thin layers reduce the distance through which heat travels to the centre of the food and moisture in the centre of the food travels to reach the surface and escape.

iii) Air velocity

High velocity air, in addition to taking up moisture, sweeps it away from the drying food surface. It also prevents the moisture from making a saturated atmosphere around food and hence helps in subsequent moisture removal.

iv) Dryness of the air

When the food is dried in air, food drys rapidly due to higher absorption and more holding capacity of moisture by dry air than the moist air. Moist air is closer to saturation so can absorb and hold less additional moisture,

The extent of dryness of the air also determines how a low moisture content food can be dried further. Dehydrated food is hygroscopic and each food has its own equilibrium relative humidity. Equilibrium relative humidity (ERH) is the humidity at a given temperature where the food neither loses moisture nor picks up moisture from the atmosphere.

5.4 DRYING AND RECONSTITUTION RATIO

5.4.1 Drying Ratio

Drying ratio varies with the type of variety, growing conditions, time of harvest, grade of raw material and loss in preparation. It should not be expressed on the basis of moisture per cent in the material, rather it should be expressed on a dry weight basis, i.e., as the ratio of water content to dry matter. The weight of dry matter going into the dryer remains the same as that is taken out, i.e., only the amount of water changes, while the dry matter does not. Drying ratio is also known as dehydration ratio.

Knowing the water content of a fresh material entering the dryer and of the product leaving the dryer, the drying ratio, or its reciprocal drying yield, can be calculated as follows:

$$\text{Drying ratio} = \frac{\text{Weight entering dryer}}{\text{Weight leaving dryer}} = \frac{100 - M1}{100 - M0} = \frac{T0 + 1}{T1 + 1}$$

Where M0 = per cent moisture of the material entering the dryer
M1 = per cent moisture of the product leaving the dryer
T0 = lb of water per lb of bone (dry material entering the dryer)
T1 = lb of water per lb bone (dry material leaving the dryer)

For example, potatoes, prepared and ready for the dryer, have about 78 per cent moisture, when properly dried they have about 7 per cent moisture. Then

M0 = 78, M1 = 7, T0= 78/22 = 3.55, T1 = 7/93 =0.075

$$\text{Drying ratio} = \frac{100 - 7}{100 - 78} = \frac{3.55 + 1}{0.075 + 1} = 4.23 = 4.23:1$$

$$\text{Drying yield} = \frac{100 - 78}{100 - 7} = \frac{0.075 + 1}{3.55 + 1} = 40.236 \text{ or } 23.6 \text{ percent}$$

It should be noted that over all ratio between weight of raw material entering the dryer and weight of finished product leaving it must take into consideration the losses incurred during preparation and final inspection.

5.4.2 Reconstitution Ratio

Reconstitution (rehydration) means the replinishment of quantity of water replaced by dehydrated foods.

Calculation can be made to express the results in terms of "rehydration ratio", "coefficient of rehydration" and "per cent of water in the rehydrated material",

Examples of such calculations are as follows:

i) Rehydration ratio

Suppose the weight of the dehydrated sample used for the test is 10 g (W_D) and the drained weight of rehydrated sample is 60 g (WR). Then

$$\text{Rehydration} = \frac{W_R}{W_D} = \frac{60}{10} = \frac{6}{1},$$ The rehydration ratio is 6 to 1, i.e. 6:1

Coefficient of rehydration

The drained weight of the rehydrated sample is 60 g (W_R), the weight of the dehydrated sample is 10 g (W_D) which contains 5 per cent moisture, and the original material before dehydration contained 87 per cent moisture (A). Then, coefficient of rehydration is

$$\frac{W_R \times (100 - A)}{(W_D - W_M)100} = \frac{60 \times (100 - 87)}{\{10 - (10 \times 0.05)\}} = \frac{780}{9.5} = 0.82$$

Where W_M = Weight of dehydrated sample x moisture per cent
or amount of moisture present in dried sample taken

Per cent of water in rehydrated material

Knowing the drained weight of the rehydrated sample, the per cent of water in the rehydrated material can be calculated by

$$\frac{\begin{matrix}\text{Drained wt. of (WR)} \\ \text{rehydrated sample}\end{matrix} - \begin{matrix}\text{Dry matter content in sample} \\ \text{taken for rehydration}\end{matrix}}{\text{Drained wt. of rehydrated material}} \times 100$$

$$\frac{60-9.5}{60} \times 100 = \frac{5050}{60} = 84.1\%$$

Note: It is suggested that the following conditions be met for better rehydration.

1. Determine the time of soaking and boiling that is compatible with optimum quality of the product.
2. Start the test with at least enough water to submerge the pieces, but do not use so much water that excess amount are present at the end of the test.
3. Shake or stir if necessary to insure wetting of all pieces during the test.
4. Control the rate of heating so as to prevent rapid and variable losses of water while boiling.

5.4.3 Rehydration of Dried Fruits and Vegetables

Factors that affect rehydration process of the dehydrated/ dried products are time, temperature, air displacement, pH and juice strength. Rehydration rates can be accelerated by ultrasonic treatment of the product to be rehydrated in water. Gamma radiation increases the rehydration rates of freeze dehydrated apples. In addition, it can control microbial growth subsequently to dehydration and during storage. At 26°C, freeze dried mushrooms rapidly reach the maximum rehydrability. While at 98°C, the rate of rehydration is slower and the degree of rehydration is also lower.

5.5 SPOILAGE OF DRIED FRUITS AND VEGETABLES

A food is said to be spoiled if it has been damaged or injured so as to make it undesirable for human use. "A product is unfit as a food if discriminating consumer, knowing the story of its production and seeing the material itself, will refuse it as a food". Obviously the fitness of the food may be subjective but in dried fruits (apple, apricot, dates, figs, peaches, prunes, resins, etc.) a number of microorganisms can be present. In whole dried fruits, these may vary from a few hundred per gram of fruit to thousands. Due to decreased water activity (<0.65 in case of sun dried product), heat treatment during dehydration and fumigation, the microorganisms may be killed or are unable to cause spoilage. But spores of bacteria and moulds are likely to be numerous. Dried fruits may be spoiled due to the development of rancidity as concentrated flavonoids may undergo oxidation.

Dried or partially dried fruits such as dates, figs and prunes, are susceptible to spoilage by yeast, i.e., *Zygosaccharomyces*. In dates, spoilage may occur if moisture level exceeds 23-25%. In prunes (18-20% moisture), *Monascus bisporus* has been found to be the most frequent spoilage microorganism. Attempts to provide very tender and more palatable products have resulted in 26-28% moisture in prunes, which are highly susceptible to spoilage and require chemical preservative. The shelf –life of high moisture prunes may be extended by dipping them in 2% potassium sorbate or 0.1% sodium benzoate solution.

In dried vegetables, microbial counts are usually higher than fruits and can be a few millions per gram. During drying, if trays are not loaded properly, higher microbial contamination can occur. During blanching also, if the water is not properly chlorinated, infection can occur. The main genera responsible for spoilage are *Escherichia, Bacillus, Clostridium, Micrococcus, Pseudomonas, Streptococcus, Lactobacillus, Leuconostoc* etc.

Another reason for the spoilage of low moisture food (dried/ powdered fruits or vegetables, chips, etc.) is the presence of oxygen, light, relative humidity and higher temperature. At very low water activity ($a_w < 0.1$), no microbial or non-enzymatic spoilage can occur except lipid oxidation. At a_w between 0.2-0.6, only non enzymatic browning can occur. Enzymatic deterioration starts if water activity exceeds 0.3. Mould and yeast activities usually start at $a_w > 0.7$ but bacterial growth is apparent at $a_w \leq 0.8$. The rate of reaction also depends upon temperature (in general, for every 10^0C increase in temperature, the rate of reaction is doubled). Dried apricots treated with SO_2 and stored at different temperatures showed that the samples stored at 46.1°C darkened in 3 weeks but those stored at room temperature (21.1°C) did not darken for 3 months, while those stored at 0°C showed no darkening even after 6 months.

Dried fruits and vegetables are also prone to insect attack if not dried and stored properly. Insects not only consume food stuff but also leave much debris which spoils the appearance of the product. These insect can be killed either by heating or by fumigation. In heat treatment, dried fruits are dipped in boiling water or in dilute solution of salt (NaCl, $NaHCO_3$) and then, redried at 54-65°C. Dried vegetables may be heated directly without preliminary dipping. Fumigation with ethylene oxide inside the storage chamber also reduces attack by insects.

Preventive measures for spoilage

It is desirable to keep the initial microbial contamination as low as possible. To check the growth of microorganisms or prevent the dried fruit and vegetable products from spoilage, the following points should be considered.

- All efforts should be made to apply the appropriate preservative technique, keeping in view the various steps i.e., recommended quantity of preservative, suitable pre-treatments and drying temperature for specific time.
- Mechanical disruption of tissues in the processed product should not occur.
- Equipment used for handling should be clean and free from contamination. As far as possible, contamination from the soil micro flora be avoided. Dipping of fruits and vegetables in solution of chlorine (50-125 ppm) removes the adhered micro flora.
- Inhibition of microbial growth can be achieved by storing the food at low temperature or in an inert atmosphere packaging.
- Any canned product showing bulging or popping should be rejected.
- Any juice or squash or such product showing any cottony type material on the surface of juice should be discarded.

- If a product in a can after opening gives off-flavour, like rotten eggs, alcoholic smell or gas formation, contents of the can should not be consumed.
- Low temperature storage helps in restricting physiological activities.
- It is absolutely essential that the environment of packing of a processed product should be microbe-free or least contaminated.
- The quality of water (both chemical and microbial) is the single –most factor which controls the quality of the finished product. It should conform to the prescribed standards of microbiological (indicator microorganisms) and chemical quality.
- The spoilage of canned product can be minimized especially leakage by regularly checking the equipment used in canning (reformers, flinger, double seamer, retort).
- The quality of raw material used has profound influence on the spoilage behaviour of processed product, e.g. sulphur sugar which blackens the canned fruits and vegetables should be avoided.
- Use of lacquered can prevents sulphur staining or hydrogen swell encountered in canned pertinacious or high acid products, respectively.

5.6 DRYING METHODS AND EQUIPMENT

There are numerous methods of drying and accordingly large number of driers are available commercially. The method of drying and equipment depend on the food material to be dried, i.e., solid, mixture or liquid. Sometimes, drying methods is unique to a product. The factors considered for a drier include method of heat transfer, source of energy radiation and method of heat application. Most of the commercial driers are insulated to reduce heat losses, and hot air in them is recirculated to save energy. The driers and available having energy saving devices which recover heat from the exhaust air or automatically control the air humidity. Some of the driers and drying methods are described below.

5.6.1 Hot Air Driers

i) Sun and solar drying

Sun drying is the most widely practised fruit and vegetable processing operation, particularly in tropical and subtropical regions, where plenty of sunshine is available. The food material is simply laid out on flat surfaces and turned regularly until dry. In solar drying system, solar energy is collected in a chamber to heat the air, which in turn dries the material. The solar driers may be direct, indirect or mixed of energy collectors.

Both these drying methods are simple and inexpensive. However, the disadvantages of drying food material by these methods are poor control over dying conditions and lower drying rates. This results in lower quality and variability in the dried product.

ii) Kiln driers

These driers are two storey constructions. A furnace on the lower floor generates heat and the warm air rises to upper storey which has a slotted floor. The food such as apple slices or rings are spread over the slotted floor for drying. In this method drying time is relatively longer and there is no control over drying conditions. Therefore, it has limited use. However, the driers have a large capacity and are easy to maintain.

iii) Cabinet driers (tray driers)

These driers consists an insulated cabinet fitted with stainless steel trays. These trays may be of shallow mesh or perforated. A cabinet drier may contain 6 to 96 trays or more depending on use. The heat in these driers may be generated by electricity or through a furnace fired with diesel, petrol or kerosene oil. The food is spread in thin layers (2-6 cm deep) on the trays. Hot air is circulated over and / or through each tray by a system of ducts and baffles for uniform air distribution. Tray driers are used for small scale production (1-20 t/day) or for pilot scale work. They have low capital and maintenance cost.

iv) Conveyor or belt driers

In these driers fruits and vegetables are dried on a mesh belt. Initially the air flow is directed upwards through the bed of food and later on downwards. In two or three stage driers, the food material may be dried into deeper beds (15-25 cm to 250-900 cm thickness). The product is dried uniformly to 10-15 per cent moisture level. In these driers drying conditions can be controlled easily and production rates are usually higher.

v) Tunnel driers

These driers are used for large scale (up to 5000 kg) drying of food material. Thin layers of food are spread on trays and stacked on carts/trucks which move through an insulated hot tunnel. When a dry cart leaves the discharging and of the tunnel it makes room to load another wet cart into the receiving end of the tunnel. The food dehydration in these driers is a semi-continuous process. The drying of food is finished in bin driers as these driers lower the moisture content of semi dried food to 3-6 per cent level.

vi) Belt though driers

These are air convection belt driers used for small and uniform pieces of fruits and vegetables. The food is dried in a mesh conveyor belt which hangs freely between rollers, to form a shape of a trough. The heated air is blown through the bed of food. The belt moves keeping the food pieces in the trough in constant motion to expose new surfaces continuously to hot air. The mixing action moves food away from the drying air thus, allowing time for moisture to move from the interior of the pieces to the dry surface. The moisture removes rapidly. The drier operates in two stages, first to 50-60 per cent moisture and then to 15-20 per cent moisture level. Foods are finished in bin driers. These driers are not suitable for sticky foods.

vii) Bin driers

These are cylindrical or rectangular containers fitted with a mesh base. Hot air passes up through a bed of food at relatively low speeds. They are usually used for finishing (3-6% moisture level) after initial drying in other types of driers. These driers have a high capacity and low capital and running cost.

viii) Fludised bed driers

In these driers hot air is blown through a food bed contained in metal trays with mesh or perforated bases. The greater air velocities make the bed expand, and the food particles become suspended in air and vigorously agitated. The bed is said to be fludised. The air thus acts as with the drying and the fludising medium. Fludising is a very effective way of maximising the surface area of food for drying in a relatively small space. Driers may be batch or continuous in operation. These driers are compact and have good control over drying conditions, high thermal efficiencies and high drying rates. Fludised bed driers are limited to small particulate foods that are capable of being fludised without excessive mechanical damage (e.g., peas, diced or sliced vegetables, powders).

ix) Spray driers

These are air convection driers used for dehydrating liquid food products. In these driers, a fine dispersion of pre concentrated liquid food is first atomized to form droplets (10-200 μm diameter) and sprayed into a current of heated air at 150-300^{0}C in a large drying chamber. The dry particles, suspended in air stream, flow into separation equipment where they are removed from air, collected, and packaged or subjected to further treatment such as instantising. For successful drying uniform atomising is necessary which may be achieved by centrifugal or pressure nozzle or two-fluid nozzle atomizers.

5.6.2 Heated Surface Driers

In these driers heat is supplied to the food material by conduction. These driers have two advantages over hot air driers.

i) large volume of air is not required to be heated before drying commences,
ii) drying may be carried out in the absence of oxygen.

i) Drum or roller driers

The driers may have a single or double or twin hollow drums. The single drum is widely used. In these driers slowly rotating hollow steel drums are heated internally by pressurized steam (120-170°C). A thin layer of food (paste, puree or sludge) is spread uniformly over the outer surface by dipping, by spraying, by spreading or by auxiliary feed rollers. Before the drum has completed one revolution (within 3 minutes), the dried food in the form of thin layer is scraped off by a 'doctor' blade which contacts the drum surface uniformly along its length. The driers have been used successfully to dry apple sauce, purees of apple, banana, mango, papaya, etc.

ii) Vacuum band and vacuum shelf driers

These driers are used to produce puff dried foods. In vacuum band drier a food slurry is spread or sprayed onto a steel belt (or band) which passes over two hollow drums within a vacuum chamber. The food is first dried by steam heated drum and then by steam heated coils located over the band. The dried food is cooled by a second water-cooled drum and removed by a doctor blade. Vacuum shelf drier consists of hollow shelves in a vacuum chamber. Food is placed in thin layers on flat metal trays and vacuum is created in the chamber. Hot air or steam is passed to dry the food.

5.6.3 Freeze Drying

Dehydration by freezing (lyophilization) requires a product to be first frozen in a conventional freezer and then evaporating (sublimating) the water, which is in ice form, directly into the vapour phase at a very low temperature (up to –80°C) and pressure. Freeze driers consist of a vacuum chamber which contains trays to hold the food material during drying, and heaters.

Refrigeration coils are used to condense the vapours. Automatic defrosting devices are fitted alongside to keep the coils free of ice for vapour condensation. Vacuum pumps remove non condensable vapours. The types of driers depend on supply of heat to food. Commercially, conduction and radiation types are used. Different type of freeze driers are contact freeze driers, accelerated freeze driers, radiation freeze driers, microwave and dielectric freeze driers, liquid nitrogen and cryogenic freezing.

5.6.4 Osmotic Drying

The process of osmotic drying is the removal of a percentage of water from a piece of fruit or vegetable by placing it in contact with granular sugar / salt or a concentrated sugar / salt solution. About 40 per cent of the water can be removed by this process. After osmotic dehydration, the product may either be frozen, or dried in air or vacuum drier. The time and temperature of osmotic dehydration depend on the size, shape and the food material. Sometimes, sulphur dioxide treatment is required to preserve the colour. This process is comparatively costlier than conventional drying.

5.6.5 Microwave Drying

Microwave is a form of electromagnetic energy. They are transmitted as waves, which penetrate food material, and are then converted to heat. Microwaves are produced at specific frequency bands. When microwaves are passed into a food material they induce friction in water molecules and produce heat. The extent of heating depends on the water content of the food material. Domestic and commercial microwave ovens are available which may be used to dry fruit juices, pulps, fruit pieces, etc.

5.6.6 Foam Mat Drying

The process is used to dry liquid foods. They are formed into a stable foam by the addition of a stabilizer or a foaming agent and aeration with nitrogen or air. The foam is spread on a perforated belt/tray to a depth of 2-3 mm and dried rapidly in a drier. Foam drying is approximately three times faster than drying a similar thickness of liquid. The thin porous mat of dried liquid is ground to a free flowing powder. The rapid drying and low product temperatures result in a high quality product.

5.7 EVAPORATION/CONCENTRATION METHOD AND EQUIPMENT

Liquid foods are usually concentrated by partial removal of water through evaporation. Function of evaporation is to pre-concentrate the food prior to drying, freezing or sterilization. It increases the solids content and reduces the weight and volume of a food. During evaporations, latent heat is transferred from the heating medium (steam) to the food, to raise the temperature of its boiling point. The vapour pressure rises and bubbles of vapour in the liquid are formed due to latent heat of vaporization supplied by the steam. The vapour is then removed from the surface of the boiling liquid. The more common concentrated foods include fruit and vegetable juices and concentrates jams and jellies, tomato paste, fruit purees, etc. Some of the methods and equipment for evaporation or concentration of foods are described below.

5.7.1 Methods of Evaporation

i) Solar evaporation

Solar evaporation is the simplest method of evaporating water with solar energy. This was done to derivate salt from sea water from earliest times and is still practiced. However, solar evaporation is very slow and is suitable only for concentrating salt solutions.

ii) Open kettles

Some foods can be satisfactory concentrated in open kettle that is heated by steam. This is the case for some jellies and jams and for certain types of soups. However, high temperatures and long concentration times damage most foods. In addition, thickening and burn-on of product to the kettle wall gradually lower the efficiency of heat transfer and slow the concentration process. Kettles and pans are still widely used in the manufacture of maple syrup, but here high heat is desirable to produce colour from caramelized sugar and to develop typical flavour.

iii) Flash evaporators

Flash evaporators are used for subdividing the food material and bringing it into direct contact with the heating medium. Clean steam superheated at about 150°C is injected into food which is pumped into an evaporation tube where boiling occurs. The boiling mixture then enters a separator vessel in which the concentrated food is drawn off at the bottom and the steam plus water vapour from the food is evacuated through a separate outlet. Because temperatures are high, foods that lose volatile flavour constituents will yield these to the exiting steam and water vapour. These can be separated from the vapour by essence-recovery equipment on the basis of different boiling points between the essence and water.

iv) Thin-film evaporators

In thin-film evaporators, food is pumped into a vertical cylinder which has a rotating element that spreads the food into a thin layer on the cylinder wall. The cylinder wall of double jacket construction usually is heated by steam. Water is quickly flashed from the thin food layer and the concentrated food is simultaneously wiped from the cylinder wall. The concentrated food and water vapour are continuously discharged to an external separator; from which product is removed at the bottom and water vapour passes to a condenser. In some systems the water vapour temperature is raised by mechanical vapour recompression to yield steam for reuse to save energy. Product temperature may reach 85°C or higher, but since residence time of the concentrating food in the heated cylinder may be less than a minute, heat damage is minimal.

v) Vacuum evaporators

Heat-sensitive foods are most commonly concentrated in low temperature vacuum evaporators. Thin-film evaporators frequently are operated under vacuum by connecting a vacuum pump or steam ejector to the condenser.

It is common to construct several vacuum vessels in series so that the food product moves from one vacuum chamber to the next and thereby becomes progressively more concentrated in stages. The successive stages are maintained at progressively higher degrees of vacuum, and the hot water vapour arising from the first stage is used to heat the second stage. The vapour from the second stage heats the third stage, and so on. In this way, maximum use of heat energy is obtained. Such a system is called a multiple effect vacuum evaporator. System employed in grape juice industry continuously concentrate juice from an initial solids content of 15% to a final solid concentration of 72% at rate of 4500 gal of single strength juice per hour. Similar systems concentrate tomato juice from 6% solids to 30% solids at rate of 15,000 gal or more of single strength juice per hour. Use of energy-saving mechanical vapour recompression is common.

vi) Freeze concentration

When a solid or liquid is frozen, all of its components do not freeze at once, some of the water forms ice crystals in the mixture. The remaining unfrozen food solution is now higher in solid concentration. It is possible, before the entire mixture freezes, to separate the initially formed ice crystals. One way of doing this is to centrifuge the partially frozen slush through a fine mesh screen. The concentrated unfrozen food solution passes through the screen while the frozen water crystals are retained and can be discarded. Repeating this process several times on the concentrated unfrozen food solution can increase its final concentration several- fold. Freeze concentration has been applied commercially to orange juice.

vii) Ultra filtration and reverse osmosis/hyper filtration

Low-temperature separation and concentration processes employing perm selective membranes are increasingly being used in the food industry. These applications are largely dependent on membrane properties such as water permeability rate, solute and macromolecule rejection rate, and length of useful membrane life. Different membranes are required for different liquid foods.

There are two types of pressure-driven membrane separation processes, a) reverse osmosis / hyper filtration, and b) ultra filtration. In the former, macromolecular solutes are selectively removed, whereas the latter separates out relatively larger solute molecules or colloids. Ultra filtration membranes are generally " less tight" than reverse osmosis membranes, that is, they restrict macromolecules such as proteins but with moderate pressure allow smaller molecules such as sugar and salt to pass through. Reverse osmosis membranes are "tighter" and with greater pressure will permit the passage of water but hold back various sugars, salt, and larger molecules. In nature, osmosis involves the movement of water through a perm-selective membrane from a region of higher concentration to a region of lower concentration; the region of lower concentration generally contains solutes in solution and has associated with it an osmotic pressure. It is possible to reverse the normal flow of water through the membrane by applying pressure on the solute side flow of water through the membrane by applying pressure on the solute side of the membrane in excess of the osmotic pressure. This is a reverse osmosis.

viii) Plate evaporator

Plate evaporator is similar to plate heat exchanger. The fluid which is to be evaporated is passed on one side of the plate and steam flows on the other side. The fluid is superheated and passes into a flash chamber. The evaporator flashes-off and the product and vapours are separated. High viscosity fluids can be efficiently circulated in the evaporators with concentration above 60°Brix.

ix) Membrane concentration

A high quality product can be produced by membrane concentration process. The principle involved is the interposition of a membrane between the food stream and a waste or transfer stream, and the establishment conditions providing a driving force for transport of water across the membrane from the feed to the transfer stream. The possibility of obtaining high quality product depends on the use of semi-permeable membranes which means membranes with much less resistance to water transport than to transport of components that are to be retained.

Ostomek is a new process and is a cold direct osmotic concentration process, utilising a thin membrane (25-10 μm) with a molecular weight cut-off of about 100 daltons. High fructose corn syrup is used as an agent to facilitate osmotic concentration as it flows, counter-current to the juice. Heat labile juice such as strawberry would benefit from this cold process, since flavour and colour degrade with exposure to heat. Concentration of clear juice streams are also possible using a continuation of reverse osmosis and evaporation. Cross flow membrane systems are ideally suited for this application because of self cleaning turbulence effect. The reverse osmosis technology is effective in concentrating a low solids juice (7-8°B) two or three folds.

x) Centrifugal evaporators

In these evaporators, a thin film is produced by centrifugal force in single or nested cones. The cones have steam on the alternative side to provide a heat transfer surface. The system operates under vacuum. This allows the total time on the juice transfer surface to be as little as 0.5 second, with only a small increase in product temperature. They are good for extremely heat sensitive and or high viscosity products. Their major draw back is low capacity and high capital cost. These evaporators concentrate as well as distil de-gas and de-odourize the liquids that have high sensitivity to heat.

5.7.2 Types of Evaporators

Several types of evaporators are used in the food industry.

i) Batch-type pan evaporator

One of the simplest and perhaps oldest types of evaporators used in the food industry is the batch-type pan evaporator. The product is heated in a steam jacketed spherical vessel. The heating vessel may be open to the atmosphere or connected to a condenser and vacuum. Vacuum permits boiling of the product at temperatures lower than the boiling point at atmospheric pressure, thus reducing the thermal damage to heat-sensitive products.

The heat-transfer area per unit volume in a pan evaporator is small. Thus, the residence time of the product is usually very long, up to several hours. Heating of the product occur mainly due to natural convection, reducing in smaller convective heat transfer coefficients. The poor heat transfer characteristics substantially reduce the processing capacities of the batch type pan evaporator.

ii) Natural circulation evaporators

In natural circulation evaporators, short vertical tubes, typically 1-2m long and 50-100 mm in diameter, are arranged inside the steam chest. The whole calamari (tubes and steam chest) is located in the bottom of the vessel. The product when heated rises through these tubes by natural circulation while steam condenses outside the tubes. Evaporation takes place inside the tubes and the product is concentrated. The concentrated liquid falls back to the base of the vessel through a central annular section.

iii) Rising-film evaporator

In a rising-film evaporator a low viscosity liquid food is allowed to boil inside 10-15 m long vertical tubes. The tubes are heated from the outside with steam. The liquid rises inside these tubes by vapours formed near the bottom of the heating tubes. The upward movement of vapours cause a thin liquid film to move rapidly upwards. A temperature difference of at least 14°C between the product and the heating medium is necessary to obtain a well developed film. High convective heat –transfer coefficient is achieved in these evaporators. Although the operation is mostly once through, liquid can be recirculated if necessary to obtain the required solid concentration.

iv) Falling-film evaporator

In contrast to the rising- film evaporator, the falling film evaporator is used for high viscous liquids. Film moves downwards under gravity on the inside of the vertical tubes. The design of such evaporator is complicated by the fact that distribution of liquid in a uniform film flowing downwards in a tube is more difficult to obtain than an upward-flow system such as in a rising film evaporator. This is accomplished by the use of special designed distributors or spray nozzles. The falling-film evaporator allows a greater number of effects than the rising film evaporator. For example, if steam is available at 110°C and boiling temperature in the last effect is 50°C, then the total available temperature differential is 60°C. Since rising film evaporator requires 14°C temperature differential across the heating surface, only four effects are feasible. However, as many as 10 or more effects may be possible using a falling-film evaporator. The falling-film evaporator can handle more viscous liquid than the rising film type. This type of evaporator is best suited for high heat-sensitive products such as orange juice. Typical residence time in a falling film evaporator is 20-30 seconds compared with a residence time of 3-4 minutes in a rising film evaporator.

v) Rising/falling-film evaporator

In the rising /falling film evaporator, the product is concentrated by circulation through a rising-film section followed by a falling-film section of the evaporator. The product is first concentrated as it ascends through a rising tube section, followed by the pre concentrated product descending through a falling-film section, there it attains its final concentration.

vi) Forced-circulation evaporator

The forced circulation evaporator involves a non contact heat exchanger where liquid food is circulated at high rates. A hydrostatic head, above the top of the tubes, eliminates any boiling of the liquid. Inside the separator, absolute pressure is kept slightly lower than that in the tube bundle. Thus, the liquid entering the separator flashes to form a vapour. The temperature difference across the heating surface in the heat exchanger is usually 3-5°C. Axial flow pumps are generally used to maintain high circulation rates with linear velocities of 2-6 m/s, compared with a linear velocity of 0.3-1 m/s in natural-circulation evaporators. Both capital and operating costs of these evaporators are very low in comparison to other types of evaporators.

vii) Agitated thin-film evaporator

It is used for very viscous fluid foods. The feed is spread on the inside of the cylindrical heating surface by wiper blades. Due to high agitation, considerably higher rates of heat-transfer are obtained. The cylindrical configuration results in low heat transfer area per unit volume of the product. High pressure steam is used as the heating medium to obtain high wall temperatures for reasonable evaporation rates. The major disadvantages are the high capital and maintaining costs and low processing capacity.

5.8 LET US SUM UP

Removal of water from food is primarily done to lower the water activity (a_w) so that microbial growth is inhibited. It also saves energy, moisture and space in shipping, packaging, storage and transportation of dried fruit and vegetable products, which are known as high value low volume food or high acid high sugar foods. Dehydration industry is a processing industry of the future. There exists quite a good scope for the export of dehydrated fruits and vegetables as the demand for these products is on the rise in the world, particularly in European countries. It is, therefore, necessary to co- ordinate effectively and achieve all that is possible in the field of export, internal demand, right quality and variety of raw material, product promotion, new technologies, etc., with the objective of helping the grower to get remunerative returns for his produce. Evaporation is an important unit operation commonly employed to remove water from dilute liquid foods to obtain concentrated liquid products which provides microbiological stability and assists in reducing transportation and storage costs.

Due to decreased water activity (<0.65 in case of sun dried product), microorganisms may be killed or are unable to cause spoilage in dehydrated products. But spores of bacteria and moulds are likely to be the most numerous. Dried fruits may be spoiled due to the development of rancidity as concentrated flavonoids may undergo oxidation. It is desirable to keep the initial microbial contamination as low as possible and the commodities should be handled and stored in such a way that there are minimum chances of further contamination.

5.9 KEY WORDS

Water activity : Water activity (a_w) is the ratio of vapour pressure of food (p) and pure water (p_o) and expressed by aw = p/p_o.

Sorption isotherms : Water sorption isotherm is a graphical presentation of data which shows the water relationship of food.

Concentration : Removal of water from foods mostly by heat application and concentration of soluble solids or solutes.

Preservation : Methods to hold food for a longer period than generally kept at ambient conditions. Food is safe, nutritious and free from microbial infection.

ERH : Equilibrium relative humidity.

Osmosis : Osmosis means movement of water through a membrane from higher concentration to lower concentration.

Unit operation : It is a step in the complete process or a physical change in form or place, for example, peeling, cutting, grading, etc.

Drying ratio : Drying ratio is the reciprocal of fresh material to dried material.

Spoilage : The food which has been damaged or injured make the food undesirable for human use.

Rehydration ratio : Reconstitution ratio is the quantity of water absorbed by dehydrated foods.

Reverse osmosis : Reverse osmosis means movement of water through the membrane by applying pressure on the solute side of the membrane in excesses of the osmotic pressure.

Evaporation : Evaporation is a heating process in which water is removed from the liquid substance.

5.10 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:
   - Drying of a commodity in the sun with non conventional sources of energy like sun and wind.
   - Drying a commodity under controlled conditions like temperature, relative humidity and air flow.

2. Your answer should include the following points:
   - An unit operation commonly employed to remove water from liquid foods.
   - To obtain concentrated liquid products.

3. Your answer should include the following points:
   - To reduce the weight and bulk of a food.
   - To reduce the water activity.

4. Your answer should include the following points:
   - Due to loss of moisture from the surface.
   - Stabilizing the moisture gradient between surface and centre of the product.

Check Your Progress Exercise 2

1. Your answer should include the following points:
   - To get heat in.
   - To let moisture out.

2. Your answer should include the following points:
   - It provides the driving force for moisture removal.
   - It carries away water in the form of water vapour.

3. Your answer should include the following points:
   - It provides more surface in contact with heating medium.
   - Provides more surface for moisture removal.

4. Your answer should include the following points:
   - Smaller product size reduces the distance through which moisture is to travel from centre of the surface.
   - Smaller product size reduces the distance through which heat is to be transferred from the surface to the centre.

5. Your answer should include the following points:

   - It absorbs more moisture.
   - It sweeps away moisture very fast.

6. Your answer should include the following points:

   - The relative humidity at which product neither gains nor loses its moisture.

Check Your Progress Exercise 3

1. Your answer should include the following points:

   - Drying ratio is the reciprocal of fresh material to dried material.
   - Reconstitution ratio is the quantity of water replaced by dehydrated foods.

2. Your answer should include the following points:

   - Time of soaking
   - Temperature of the water
   - Air displacement
   - pH of the product
   - Juice or sugar content availability in the product.

3. Your answer should include the following points:

   - The food which has been damaged or injured.
   - The food which is not fit for consumption.
   - The food which is attacked by microorganisms.

Check Your Progress Exercise 4

1. Your answer should include the following points:

   - Drying the food material by using hot air.
   - Drying the food material by using heated surface.
   - Drying the food material by freezing.
   - Drying the food material by microwaves.
   - Drying the food material by using sugar or salt and their solutions.

2. Your answer should include the following points:

   - Dehydration by freezing means drying a food material at low temperature (up to –80°C) and low pressure.
   - At low temperature and pressure, the water in ice form in food material is evaporated directly into vapour (sublimation).

3. Your answer should include the following points:

   - Microwaves are a form of electromagnetic energy.
   - Microwaves are when passed into a food material they induce friction in water molecules and produce heat, thus drying the material.

Check Your Progress Exercise 5

1. Your answer should include the following points:

   - Removal of water from the liquid substances.
   - Removal of water to concentrate soluble solids.

2. Your answer should include the following points:

   - Solar evaporation is used for salt concentration.
   - Kettle evaporation is used for maple syrup.

3. Your answer should include the following points:

   - Osmosis means movement of water through a membrane from higher concentration to lower concentration.
   - Reverse osmosis means movement of water through the membrane by applying pressure on the solute side of the membrane in excesses of the osmotic pressure.

4. Your answer should include the following points:

   - Low capacity
   - High capital cost

5. Your answer should include the following points:

   - Batch type evaporator
   - Natural circulation evaporator
   - Rising film evaporator
   - Falling/film evaporator
   - Rising/falling film evaporator
   - Forced circular evaporator

6. Your answer should include the following points:

   - Falling film evaporator is used for high viscous liquids, while rising film evaporator is used for low viscous liquids.
   - High heat sensitive products are more suited to falling film evaporator while low heat sensitive products used in rising film evaporation.

7. Your answer should include the following points:

   - High capital and maintenance cost.
   - Low processing capacity.

UNIT 6 CHILLING

Structure

6.0 OBJECTIVES

After reading this unit, you should be able to:

- describe chilling and refrigeration cycle;
- explain chilling injury and refrigerated requirements of fruits and vegetables; and
- define evaporative cooling.

6.1 INTRODUCTION

You know that fruits and vegetables are highly perishable and more liable to spoilage than food grains. This is basically because they contain high moisture content. The spoilage of such perishable crops can be delayed by controlling the post harvest environmental conditions of temperature, humidity and atmospheric concentration of gases. Chilling is one such method of regulating temperature. More precisely, chilling mean the use of low temperature without inducing ice formation in foods. The chilling process may be considered complete when the mean temperature of the product has approximately reached the intended value for storage or processing.

The chilling operation is divided into 3 basic types based on its main purpose.

i) Chilling for preservation.

ii) Chilling for development of desired biological and biochemical processes.

iii) Chilling to facilitate some processing treatments, by temporarily changing certain physico-chemical properties.

Chilling for preservation is aimed to extend the shelf-life or keeping quality of a living produce, e.g., fruits and vegetables. This is mainly due to reduction of metabolic activity at low temperature. Chilling may also be used to extend the storage life of products such as pasteurized and sterilized canned foods.

Chilling for development of desired biological and biochemical processes includes fermentation of beer and wine, meat ageing, and processing of many dairy products such as cheeses, etc.

Temporarily changing certain physico-chemical properties to facilitate some processing treatments is used in the processing of bakery products, chocolate, butter, margarine etc. However, this is beyond the scope of the present unit and we would restrict ourselves to chilling for preservation only. In the present unit, we will focus only on the first purpose, i.e., chilling for preservation.

Refrigeration is the most common method of chilling or low temperature storage of fruits and vegetables. Refrigerated storage helps to retard the spoilage in perishable crops in the following manner:

- aging due to ripening, softening, textural and colour changes;
- undesirable metabolic changes and respiratory heat production;
- moisture loss and the wilting;
- spoilage due to invasion by bacteria, fungi, and yeasts; and
- undesirable growth, such as sprouting of potatoes.

One of the most important functions of refrigeration is to control the respiration of crops. Respiration generates heat as sugars, fats, and proteins in the cells of the crop are oxidized. The loss of these stored food reserves through respiration means decreased food value, loss of flavour, loss of saleable weight, and more rapid deterioration. The respiration rate of a product strongly determines its transit and post-harvest life. The higher the storage temperature, the higher will be the respiration rate. Apart from temperature, humidity and concentration of gases are also important. Before observing their effect let us first understand how refrigerator works.

6.2 REFRIGERATION

The refrigerator cycle is based on the principle of making cold which is done by removing heat from the system. If you are science student then you must have surely studied carnot's engine. Refrigeration is in fact the reverse of carnot's engine. The refrigeration cycle uses a fluid, called a refrigerant, to move heat from one place to another. The key to understanding how it works is recognizing that at the same pressure, the refrigerant boils at a much lower temperature than water. For example, the refrigerant commonly used in home refrigerators boils between 40 and 50°F (4.4 – 10°C) as compared to water's boiling point of 212°F (100°C). In the original home refrigerators ammonia was the common refrigerant used. Pure ammonia gas is highly toxic to people and would pose a threat if the refrigerator were to leak, so all home refrigerators don't use pure ammonia. You might have heard of refrigerants known as **CFCs** (chlorofluorocarbons). These were originally developed by Du Pont in the 1930s as a non-toxic replacement for ammonia. CFC-12 (dichlorodifluoromethane) has about the same boiling point as ammonia. However, CFC-12 is not toxic to humans, so it is safe to use in your kitchen. However, many large industrial refrigerators still use ammonia. In the 1970s, it was discovered that the CFCs then in use are harmful to the ozone layer, so as of the 1990s, all new refrigerators and air conditioners use refrigerants that are less harmful to the ozone layer. Freon is the common refrigerant used today. Now we need to study the refrigeration cycle.

Every refrigerator is made up of at least four key parts:

i) Compressor
ii) Heat-exchanging pipes (also known as a condenser)

iii) Expansion valve
iv) Refrigerant

Let's look at the process to see how boiling and condensing a refrigerant can move heat. The process is the same whether it is operating a refrigerator, an air conditioner or a heat pump. This example illustrates a closed-loop system (Figure 6.1).

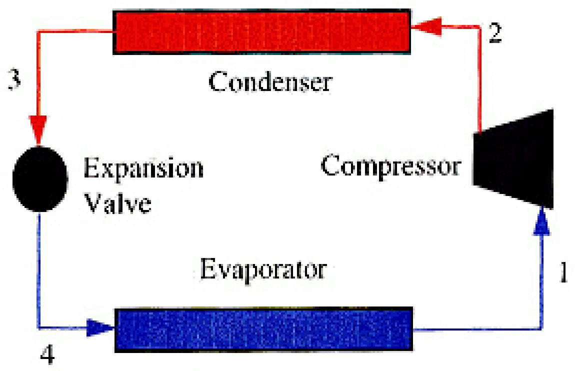

Figure 6.1: Vapour compression refrigeration cycle

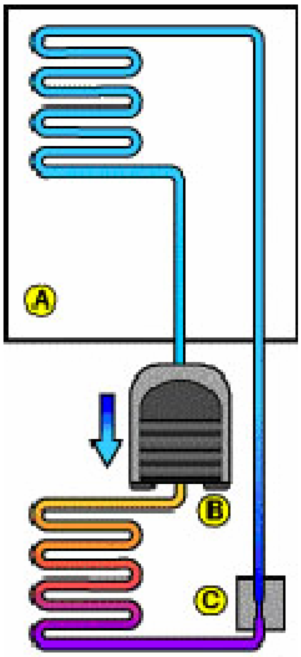
The above diagram shows the simplified, stepwise process of the refrigeration cycle, where the associated parts of the refrigerator fit into it. These four parts will now be explained in detail. Lets begin with evaporator first. As the name implies, refrigerant in the evaporator "evaporates". Upon entering the evaporator, the liquid refrigerant's temperature is between 40 and 50°F and without changing its temperature, it absorbs heat as it changes state from a liquid to a vapour. The heat comes from the warm moist room air blown across the evaporator coil. As it passes over the cool coil, it gives up some of its heat and moisture may condense from it. The cooler drier room air is re-circulated by a blower into the space to be cooled.

The vapour refrigerant now moves into the compressor, which is basically a pump that raises the pressure so it will move through the system. Once it passes through the compressor, the refrigerant is said to be on the "high" side of the system. Like anything that is put under pressure, the increased pressure from the compressor causes the temperature of the refrigerant to rise. As it leaves the compressor, the refrigerant is a hot vapour, roughly 120 to 140°F.

It now flows into the refrigerant-to-water heat exchanger, operating as the condenser during cooling. Again, as the name suggests, the refrigerant condenses here into liquid form. As it condenses, it gives up heat to the loop, which is circulated by a pump. The loop water is able to pick up heat from the coils because it is still cooler than the 120 degree coils.

As the refrigerant leaves the condenser, it is cooler, but still under pressure provided by the compressor. It then reaches the expansion valve. The expansion valve allows the high pressure refrigerant to "flash" through becoming a lower pressure cooled liquid. This pressure drop causes expansion followed by evaporation. Evaporation further causes heat absorption making refrigerant cool. The cycle is complete as the cool liquid refrigerant re-enters the evaporator to pick up room heat. In winter, the reversing valve switches the indoor coil to operate as the condenser and the heat exchanger as the evaporator.

In summary, the indoor coil and refrigerant-to-water heat exchanger where the refrigerant changes phase by absorbing or releasing heat through boiling and condensing. The compressor and expansion valve facilitate the pressure changes, increased by the compressor and reduced by the expansion valve. See a detailed Figure 6.2.



A -- Inside of refrigeration

6.3 DETERMINATION OF REFRIGERATION LOAD

If we want to cool the product then heat must be removed and brought to a specific low temperature. The heat removed is described in terms of refrigeration load. In other words, refrigeration load can be defined as that quantity of heat which must be removed in order to reduce the temperature of the products from its initial temperature to the temperature consistent with good frozen food storage. It is calculated in terms of heat unit as British Thermal Units (Btu), calories (cal) or joules (J). This has, of course, been replaced by International System of Units (SI) which employs joules and gram as units of heat and weight (One Btu = 252 calories = 1055 joules = 1.055 KJ).

One Btu or British Thermal Unit is defined as the quantity of heat which will raise or lower the temperature of one pound of water by 1°F through the range of 32°F to 212°F at normal atmospheric pressure.

A calorie is the amount of heat which will raise or lower the temperature of one gram of water by 1°C from 14.5 to 15.5°C at normal atmospheric pressure.

The specific heat of any substance is the ratio of its heat capacity to that of water. In either case, the specific heat of water is taken as one. Thus, in British system, specific heat is

$$= -\frac{\text{Heat required to raise/lower the temperature of unit mass of water by } 1^{\circ}\text{C}}{\text{Heat required to raise/lower the temperature of unit mass of water by } 1^{\circ}\text{C}}$$

(Since heat capacity of water = 1).

Or, Specific heat at any temperature = Heat required to raise or lower the temperature of unit mass of water by 1°C or in other words, amount of heat in calories required to raise or lower the temperature of one gram of the substance by 1°C.

Generally heat is of two types – Sensible heat and latent heat.

Sensible heat may be defined as the heat we readily perceive by the sense of touch and which produces a temperature rise or fall as heat is added or removed from a substance. Always remember that specific heat is different in the liquid state and in the frozen state. So, it may be different before and after freezing.

Latent heat is the quantity of heat required to change the state or condition under which a substance exists, without changing its temperature, e.g., a definite quantity of heat must be removed from water at 0°C (32°F) to change it to ice at 0°C. This is known as latent heat of fusion or crystallization.

Similarly, in going from water to steam at 100°C, it is the latent heat of evaporation. In freezing, we are interested in the latent heat of fusion, and this in the case of water is 144 Btu/1b. It is quantitatively different from 144 Btu/lb for substances other than water.

Calculation Refrigeration Load

After you have known the terms, let us see how to calculate refrigeration load. To calculate this we need to understand that to freeze a food it is necessary to bring down its temperature to freezing point. This involves the following:

i) The number of Btu required to cool the product from its initial temperature to its freezing point, or say H_1.

ii) The number of Btu required to change the food from the liquid state to the frozen state at its freezing point, or say H_2.

iii) The number of Btu required to lower the frozen food from its freezing point to the desired storage temperature, or say H_3.

Using this concept, we can calculate refrigeration load using the following equations:

$$H_1 = (S_L) \times (W) \times (T_i - T_f) \qquad (1)$$

$$H_2 = (H_f f) \times W \qquad (2)$$

$$H_3 = (S_S) \times W \times (T_f - T_s) \qquad (3)$$

$$H_{fs} = H_1 + H_2 + H_3$$

Where,

S_L = Specific heat of food above its freezing point

H_f = Latent heat of fusion

S_S = Specific heat of food below its freezing point

H_{fs} = Total heat (Btu) requirement

W = Weight in pounds

T_i-T_f = Difference between the initial temperature and the freezing point (°F).

T_f-T_S = Difference between the freezing point and the desired storage temperature (°F).

Let's take one example:

What is Btu requirement to lower the temperature of 1000 lbs of peas from 70°F to 30°F, and finally to storage given at temperature at 0°F. Given S_L =0.8, H_f = 108, S_S = 0.43.

Here we first have to calculate H_1.

From equation (1)

$$H_1 = (S_L) \times (W) \times (T_i - T_f)$$

$$= 0.8 \times 1000 \times (70 - 30)$$

$$= 0.8 \times 1000 \times 40$$

$$= 32000 \text{ Btu.}$$

Now, calculate H_2.

From equation (2)

$$H_2 = H_f \times W$$

$$= 108 \times 1000$$

$$= 108000$$

Finally, calculate H_3.

From equation (3)

$$H_3 = (H_f) \times (W) \times (T_f - T_s)$$

$$= 0.43 \times 1000 \times (30\text{-}0)$$

$$= 12900$$

$$H_{fs} = H_1 + H_2 + H_3$$

$$= 32000 + 10800 + 12900$$

$$= 152900 \text{ Btu.}$$

Refrigeration load is usually reported in terms of refrigeration. So values should be changed to tonnes by dividing Btu by 288000:

$$\frac{152000}{288000} = 0.527 \text{ tonnes}$$

One ton (2000 1b) of refrigeration is the number of Btu required to convert 1 ton of water at 32°F to 1 ton of ice at 32°F in 24 hrs. Since latent heat of fusion for water = 144 btu/lb, a ton of refrigeration = 144 × 2000 = 288,000 Btu/24 hrs.

6.4 REFRIGERATED STORAGE OF FRUITS AND VEGETABLES

The principal refrigeration requirements of fruits and vegetables are controlled low temperature, air circulation and humidity.

Relative humidity (RH): Most food stores are best at refrigeration temperatures when the relative humidity of air is between 80 and 95 per cent. This is generally related to moisture content of foods. Celery, spinach and several other crisp leafy vegetables require 90-95% RH.

Controlled low temperature: Fruits and vegetables are highly perishable because they respire and produce heat at varying rates. They, therefore, need to be stored at low temperatures. Refrigeration is the gentlest method of extending the shelf life of fruits and vegetables. By and large, it has relatively few adverse effects upon taste, texture, nutritive value and overall changes in food, provided simple rules are followed. Domestic refrigerators usually run at 4.4°–7.2°C (40-45°F). Properly designed refrigerators, refrigerated storage rooms and warehouses provide sufficient refrigeration capacity and insulation to maintain the room within about 1°C. Proper insulation is must to maintain the optimum storage temperature. Refrigeration system must be of appropriate size to handle maximum expected heat load as an undersized system will allow temperature to rise during peak heat load conditions. Different fruits and vegetables evolve different heat during respiration. (Table 6.1) As you can see from the table green beans, broccoli, sweet corn, green peas, spinach and strawberry evolve high heat during respiration. These products are difficult to store.

Table 6.1: Heat evolved from respiration of fruits and vegetables

Commodity	Btu per tonne per 24 hrs	
	32°F (0°C)	40°F (4.4°C)
Apples	300-800	590-840
Beans, green	5,500-6,160	9,160-11,390
Broccoli	7,450	11,000-17,600
Carrots	2,130	3,470
Corn (sweet)	6,500	9,390
Onions	600-1,100	1,260-1,980
Oranges	420-1,030	1,300-1,500
Peach	850-1,370	1,440-2,030
Peas	669-880	-
Peas (green)	8,160	13,220
Potatoes	440-880	1,100-1,760
Spinach	4,240-4,860	7,850-11,210
Strawberry	2,730-3,800	3,660-6,750
Tomatoes (ripe)	1,020	1,250

Based on their respiration rate, the storage requirement and shelf-life of fruits and vegetables is also different, e.g., broccoli, a highly respiring vegetable at a storage temperature of 32^{o}F has a shelf-life of 7-10 days in comparison to 6-8 months for onions at same temperature. While temperature is the primary concern in the storage of fruits and vegetables, relative humidity is also important. The relative humidity of the storage unit directly influences water loss in produce. Water loss can severely degrade quality-for instance, wilted greens may require excessive trimming, and grapes may shatter loose from clusters if their stems dry out. Water loss means saleable weight loss and reduced profit.

Most fruit and vegetable crops retain better quality at high relative humidity (80 to 95%), but at this humidity, disease growth is encouraged. The cool temperatures in storage rooms help to reduce disease growth, but sanitation and other preventative methods are also required. Maintaining high relative humidity in storage is complicated by the fact that refrigeration removes moisture. Humidification devices such as spinning disc aspirators may be used.

Air circulation: Air must be well circulated in the cold storage rooms. This will help more heat away from food surface to cooling coil. Air, that is, circulated within a cold storage must not be too moist or too dry. If it is high in humidity, moisture will condense on surface of cold foods and moulds will grow on these surfaces. On the other hand, if air is too dry, it will cause excessive drying out. Most food stores are best at refrigeration temperatures when the relative humidity of air is between 80-95% for prolonging the storage period. Foods can be protected from losing excessive moisture by using several packaging methods. This forms a barrier for migration of moisture from food to storage temperature.

6.5 CHILLING INJURY OF FRUITS AND VEGETABLES

Low temperature storage may have some deleterious effects also. One such effect is called as chilling injury. Chilling injury has variable symptoms as ripening failure in climacteric fruits, different forms of external or internal discolouration, pre-disposition to microorganism infection, etc. The exact mechanism by which chilling injury affects the crop has still not been determined. It has been shown to be concerned with loss of membrane integrity and ion leakage and changes in enzyme activity.

General symptoms of chilling injury

i) Surface and internal discolouration, e.g., internal browning in apples and brown vascular streaks in banana.

ii) Surface pitting, e.g., in tomato, papaya, mango, limes and lemons.

iii) Development of off-flavour.

iv) Failure to ripen in some climacteric fruits.

v) Incidence of surface mould growth or decay.

The chilling injury depends on storage temperature and varies with crop, e.g., chilling injury symptoms develop in banana around 12.6°C. However, some varieties may be resistant to chilling injury at this temperature. In mango, generally chilling injury occurs at 10-15°C depending upon variety.

Based on sensitivity to chilling injury, the crops are classified as

- Chilling sensitive, and
- Non-chilling sensitive.

Chilling sensitive

Fruits: banana, mango, avocado, papaya, pineapple, citrus, plantains, pomegranate, sapota, guava, olive, etc.

Vegetables: snap beans, cucumber, muskmelon, watermelon, okra, potato, tomato, spinach, sweet potato, summer squash, etc.

Non-chilling sensitive

Fruits: apple, apricot, cherry, fig, peach, pea, plum, strawberry, etc.

Vegetables: asparagus, lima beans, beet root, cabbage, broccoli and carrots.

Mechanism of chilling injury

The general mechanism of chilling injury involves following changes:

i) *Abnormal respiratory response:* This generally involves a sudden upsurge in respiratory rate and respiratory quotient leading to uneven ripening.

ii) *Changes in lipids:* Chilling injury involves irreversible disorganization of cellular membranes like mitochondrial and vacuolar membranes. A phase transition occurs in the cytoplasm and it changes from soil to gel stage. When gel formation occurs, the cytoplasm becomes viscous and its movement is restricted.

iii) *Increased membrane permeability:* This is evident by high percentage of electrolytes leached out of the cell. This further leads to increased rigidity of protoplasm and resistance to flow.

Approaches to control chilling injury in fruits and vegetables

If the tolerance to chilling in the chilling resistant tissues can be increased or if the development of chilling injury symptoms can be delayed, the storage life can be increased. The following approaches are generally recommended to control chilling injury in fruits and vegetables:

i) Temperature conditioning
ii) Intermittent warming
iii) Controlled atmosphere storage
iv) Application of growth regulators
v) Packaging, waxing and other coatings

i) *Temperature conditioning:* A cool temperature conditioning just prior to critical chilling range increases the tolerance of commodities to chilling during subsequent low temperature storage and delays the development of injury symptoms. A cool conditioning at 10°C for 10 days before storing at 4°C in peppers reduces chilling injury symptoms. Sometimes a double step-wise temperature conditioning may be more effective than single step conditions. A hot conditioning may be useful in some cases, e.g., pre-storage heating at 30°C for 17-22 hrs decrease injury.

ii) *Intermittent warming:* Interrupting low temperature storage with one or more short periods of warm temperature increases storage life of some chilling sensitive crops. Intermittent warming treatment must be given before chilling injury becomes irreversible. If applied too late, results are not seen. Intermittent warming is hypothesized to remove toxic or inhibiting substances that accumulate during chilling.

iii) *Controlled atmosphere storage:* Most products respond favourably to decrease in oxygen level and increase in carbon dioxide concentration. Pre-storage treatment of grapefruit with high carbon dioxide is effective during inhibiting pitting during cold storage.

iv) *Application of plant growth regulators:* Application of some plant growth regulators such as ABA, Triazoles and ethylene decreases chilling injury symptoms.

v) *Packaging, waxing and other coatings:* Packaging in plastic films and coatings help to maintain relative humidity and modify gas concentration and prevent chilling injury symptoms.

6.6 EVAPORATIVE COOL STORAGE SYSTEM

On-farm cooling facilities are a valuable asset for any produce operation. A grower who has on farm cooling facility for storing produce has greater market flexibility because the need to market immediately after harvest is eliminated. The challenge, especially for small-scale producers, is the set-up cost. Refrigerated storage systems are although best but expensive in terms of capital investment. Innovative farmers and researchers have thus created a number of low-cost structures. One such low cost structure is evaporative cool storage which was developed by scientists at Indian Agricultural Research Institute.

Principle

Evaporative cool storage is also called as zero energy cool chamber. It is based on the simple principle of evaporative cooling. Evaporative cooling occurs when air, that is not already saturated with water vapour, is blown across any wet surface. An evaporative cooler consists of a wet porous bed through which air is drawn, cooled and humidified by evaporation of water. The faster the evaporation, the greater is the cooling. Can you now think and tell why it is called a zero energy cool chamber? It is so called because it does not require any electricity or power to operate and all the materials required to make the cool chamber are available easily and cheaply. It can be installed at any site by even unskilled person as it does not require any specialized skill or raw material. This simple storage structure has many advantages. Let's see what are they?

- No mechanical or electrical energy is needed.
- Allows small farmers to store produce for a few days; so growers are not forced to sell at low prices, and incur losses.
- Ideal for use in packing stations and markets.
- Reduces losses and pays for itself in a short time.
- Can also be used for mushroom cultivation, sericulture and storage of bio-fertilizers.
- Raw materials required are re-usable.
- The fruits and vegetables stored do not suffer chilling injury.

Let us find out how to construct a zero-energy cool chamber at farm level. We need simple raw materials like

i) Bricks, riverbed sand, bamboo, khaskhas (or any plant material of similar nature), gunny bags/cloth, etc.

ii) A source of water like a tap, a tubewell, a well, a pond, or a canal. The water can be drawn from the source to the cool chamber with the help of a flexible tube/pipe or any suitable container.

iii) Design and construction*:* The floor of the storage space is made with a single layer of bricks. The side walls are made with a double layer of bricks leaving approximately 3" space between the bricks. The cavity between the bricks is filled with riverbed sand. About 400 bricks are required to make a chamber of the dimensions as given in Fig. 6.3. The top of the storage space is covered with khaskhas /gunny cloth in a bamboo frame structure.

The cool chamber should be constructed under a shed with a lot of aeration. The cool chamber site should be close to the source of water.

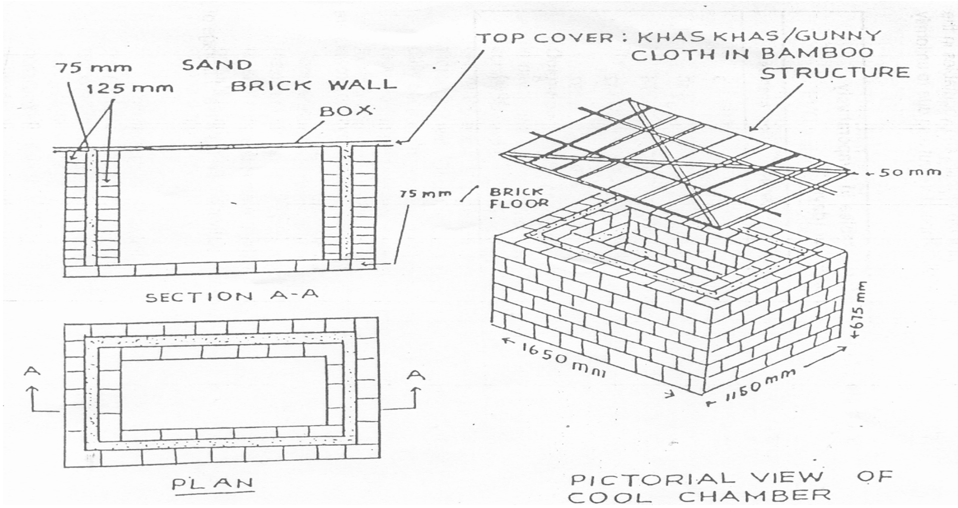

Figure 6.3: Pictorial view of cool chamber

iv) Operation: After construction, bricks of the walls and floor, the sand used in cavity and the top cover made of khaskhas /gunny cloth and bamboo are made completely wet by sprinkling water till they are saturated. It should be ensured before the actual storage of fruits and vegetables that the cool chambers are thoroughly wet. Once the cool chamber is completely wet, sprinkling of water is done once in the morning and once in the evening daily which is enough to maintain the required temperature and humidity. Alternatively, watering can be done by fixing a drip system with a source of water supply. The following precautions are to be observed for smooth functioning of cool chamber:

- Use clean unbroken bricks with good porosity.
- Sand should be clean and free of organic matter and clay.
- Keep the bricks and sand saturated with water.
- Prevent direct exposure to sun.
- Build in an elevated place to avoid water-logging.
- Try to site a place where breezes blow.

Temperature and relative humidity: It has been observed that the average maximum temperature of the cool chamber is considerably low compared to outside temperature throughout the year. During summer, when the maximum outside temperature is 44°C, the maximum cool chamber temperature is never recorded more than 28°C. Similarly, relative humidity of the cool chamber is maintained above 90 per cent practically throughout the year. The minimum relative humidity recorded in the cool chamber is 84 per cent even when the outside humidity is as low as 13 per cent. In general, it is noticed that there is a direct correlation between the outside relative humidity and the temperature difference between the cool chamber and outside. The maximum difference in temperature between cool chamber and outside is noted in the months of April, May and June. This could be attributed to low outside relative humidity during this period. The difference in temperature between the cool chamber and outside could be as high as 18-20°C when the outside humidity is extremely low.

The storage life of fresh fruits and vegetables is considerably increased by keeping them in cool chamber immediately after harvest. Its main advantage is that fruits and vegetables stored in cool chamber do not suffer chilling injury. Increased shelf life of fruits and vegetables in the cool chamber is not only because of low temperature but also due to uniformly high humidity (Table 6.2).

Table 6.2: Shelf life of fruits and vegetables in evaporative cool chamber

Produce	Shelf life (days)		Cool chamber
	Time of storage	Outside	
Leafy vegetables	Summer	< 1	3

6.7 LET US SUM UP

Fresh fruits and vegetables are perishable. They contain high moisture content and liberate heat during respiration. Storage at low temperature removes respiratory heat and extends the shelf life of fruits and vegetables. Refrigeration is best method for low temperature storage but is expensive and energy intensive. Zero-energy cool chamber is a viable option for low temperature storage of farm produce. It is relatively cheaper and can be constructed using locally available materials. During summer when the maximum outside temperature is 44°C, the maximum cool chamber temperature is never recorded more than 28°C. Similarly, relative humidity of the cool chamber is observed above 90 per cent throughout the year. Low temperature storage also has some drawbacks. Some crops are susceptible to chilling injury, a low temperature storage disorder, which manifests in number of ways like abnormal ripening, browning and pitting.

Temperature conditioning, intermittent warming and controlled atmosphere storage are some of the strategies to control chilling injury disorder.

6.8 KEY WORDS

Chilling injury : Chilling injury is a low-temperature physiological disorder or abnormality of crops where freezing is not a factor.

Specific heat : Specific heat of any substance is the heat required to raise or lower the temperature of unit mass of water by 1°C.

Latent heat : Latent heat is the quantity of heat required to change the state or condition under which a substance exists, without changing its temperature, e.g., a definite quantity of heat must be removed from water at 0°C (32°F) to change it to ice at 0°C.

Refrigeration load : It is defined as that quantity of heat which must be removed in order to reduce the temperature of the products from its initial temperature to the temperature consistent with good frozen food storage.

6.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answers should include the following points:

1. Chilling is the low temperature treatment used to extend shelf life of fruits andvegetables. It does not involve ice formation.

2. Phase change in the refrigerator takes place at two places first at the evaporator and second at the condenser.

3. Common refrigerants used in the refrigerator are ammonia, CFC (Chloro fluoro carbon) and freon.

Check Your Progress Exercise 2

Your answers should include the following points:

1. Chilling injury is a low-temperature physiological disorder observed in some crops. The crops develop some abnormalities during freezing.

2. Banana is never stored in refrigerator because it suffers chilling injury at that storage temperature.

3. Surface and internal discoloration, e.g., internal browning in apples and brown vascular streaks in banana. Surface pitting, e.g., in tomato, papaya, mango limes and lemons. Development of off-flavour and failure to ripen in some climacteric fruits.

4.
   - Temperature conditioning
   - Intermittent warming
   - Controlled atmosphere storage
   - Application of growth regulators
   - Packaging , waxing and other coatings

Check Your Progress Exercise 3

Your answer should include the following points

1. When evaporation of water occurs cooling takes place producing cooling effect. The greater the evaporation the greater is the cooling effect.

2. It is difficult to store peas and broccoli because they are high respiring crops and produce large quantities of heat during respiration.

3. Optimum humidity requirement of most fruits and vegetables is 85-95%.

UNIT 7 CONTROLLED AND MODIFIED ATMOSPHERE STORAGE

Structure

7.0 OBJECTIVES

This unit shall analyze the basic and applied aspects of controlled/ modified atmosphere storage of fruits and vegetables. Here the issues of physiological basis and problems and prospects of CA / MA storage of fruits and vegetables will be discussed. After studying this unit, you will be able to:

- describe the basic requirement of CA/ MA storage;
- explain physiological effects of CA/MA storage on fruits and vegetables;
- enumerate the methods of atmospheric modification; and
- evaluate the economic benefits of CA/ MA technology.

7.1 INTRODUCTION

The effect of gases on harvested fruits is known since ancient times. In earlier days fruits were used to be taken to temples for improved ripening. This was due to the volatiles released on burning of incense containing hydrocarbon gases that helped ripening of the fruits. In 1819 J.E. Bernard in France noticed that harvested fruits absorb O_2 and liberate CO_2.Atmosphere devoid of O_2 caused no ripening in peach, prunes and apricot for several days but ripening continued when they were placed back in air. A commercial cold storage was built in 1856 by B. Nice for apples and ice was used to maintain a temperature of 1°C. After a decade he started experimenting with modifying the cold store gases inside. In 1907 J. Foulton observed the increase in fruit damage by large accumulation of CO_2 in the storage atmosphere. In 1915 R.W. Thatcher after experiments with apples in sealed boxes containing various levels of gases concluded that CO_2 greatly inhibited ripening. The first scientific evidence on the effect of CO_2 on respiratory rates was established by Kidd and West in

1917 in seeds. In the early 1940 the term of 'gas storage' was replaced by Controlled Atmosphere (CA) storage. Now let us discuss the modern understanding of CA/ MA storage.

Atmosphere at ambient conditions comprises of 78.08% N_2, 20.98% O_2 and 0.03% CO_2. Any deviation from this normal atmosphere composition, e.g., elevated level of CO_2 and reduced levels of O_2 and N_2 or any other combination is known as '**Modified Atmosphere**'. When this deviated normal atmosphere is precisely kept under control then it is termed as "**Controlled Atmosphere**". This control can be done in package (Controlled Atmosphere Packaging) or in the storage chamber (CA-storage). Generally, O_2 below 8 per cent and CO_2 above 1 per cent are used in CA-storage. Atmospheric modification is a supplementary practice to temperature management in preserving quality and safety of fresh fruits, vegetables, ornamentals and their products throughout post-harvest handling and storage.

Essentiality of CA/MA technology should be justified only if (a) the commodities are having high market value, (b) it need longer storage life, (c) require significantly better quality, and (d) fetch better price compared to conventional cool stored produce. Retardation of ripening, reduction in decay, prevention of specific disorders and maintenance of product texture are some of the potential advantages of CA/MA storage. However, initiation or aggravation of certain physiological disorders, viz. black heart in potato, brown stain in lettuce, brown heart in apples and pears, etc., take place in CA-storage if appropriate gaseous regimes are not maintained. A concentration of less than 2 per cent O_2 or more than 5 per cent CO_2 in the storage/ package atmosphere results in irregular ripening of banana, tomato and pear. Too low O_2 or too high CO_2 can increase the susceptibility to decay causing organisms. Off-flavour development in fruits and stimulation of sprouting and retardation of periderm formation in potatoes are some of the ill effects of improper CA-condition. On the other hand, a very high concentration of CO_2 (up to 30%) is extremely beneficial in checking the *Botrytis* rot in strawberry fruits.

The quality retention in fresh horticultural produce in CA storage is mainly due to reduction in the respiratory and metabolic activities and check in ethylene liberation.

7.2 PHYSIOLOGICAL BASIS OF CONTROLLED ATMOSPHERE (CA) STORAGE

Exposure of fresh horticultural crops to low O_2 and/or elevated CO_2 atmosphere within the range tolerated by each commodity reduce their respiration and ethylene production rates. However, outside this range respiration and ethylene production rates can be stimulated indicating a stress response. This stress can contribute to incidence of physiological disorders and increased susceptibility to decay. Elevated CO_2-induced stresses are additive to and sometimes synergistic with, stresses caused by low O_2; physical or chemical injuries; and exposure to temperatures, RH, and/or ethylene concentrations outside the optimum range for the commodity.

The shift from aerobic to anaerobic respiration depends on fruit maturity and ripeness stage (gas diffusion characteristics), temperature, and duration of exposure to stress-inducing concentrations of O_2 and/or CO_2. Up to a point, fruits and vegetables are able to recover from the detrimental effects of low O_2 and/or high CO_2 stresses (fermentative metabolism) and resume normal respiratory metabolism upon transfer to air. Plant tissues have the capacity for recovery from the stresses caused by brief exposure to fungistatic atmospheres (> 10% CO_2) or insecticidal atmospheres (< 1% O_2 and/or 40 to 80% CO_2). **Climacteric fruits are less tolerant and have lower capacity for recovery following exposure to reduced O_2 and/or elevated CO_2 levels than non-climacteric fruits**. The speed and extent of recovery depend upon duration and levels of stresses, stage of maturity and metabolically driven cellular repair mechanism.

Elevated-CO_2 atmospheres inhibit activity of ACC synthase (key regulatory enzyme of ethylene biosynthesis), while ACC oxidase activity is stimulated at low CO_2 and inhibited at high CO_2 concentrations and/or low O_2 levels. Thus, elevated CO_2 atmospheres inhibit ethylene action. Optimum modified atmospheric compositions retard chlorophyll loss (green colour), biosynthesis of carotenoids (yellow and orange colours) and anthocyanins (red and blue colours), and biosynthesis and oxidation of phenolic compounds (brown colour). Controlled atmospheres slow down the activity of cell wall degrading enzymes involved in softening and enzymes involved in lignification leading to toughening of vegetables. Low O_2 and/or high CO_2 atmospheres influence flavour by reducing loss of acidity, starch to sugar conversion, sugar inter-conversions, and biosynthesis of flavour volatiles. When produce is kept in an optimum atmosphere, retention of ascorbic acid and other vitamins result in retention of better nutritional quality.

Specific responses to CA depend upon cultivar, maturity and ripeness stage, storage temperature and duration, and in some cases, ethylene concentrations. Nitrogen is an inert component of CA. Replacing N_2 with argon or helium may increase diffusivity of O_2, CO_2 and C_2H_4, but they have no direct effect on plant tissues and are more expensive than N_2 as a CA component. Super-atmospheric levels of O_2 up to about 80 per cent may accelerate ethylene-induced degreening of non-climacteric commodities and ripening of climacteric fruits, respiration and ethylene production rates, and incidence of some physiological disorders (such as scald on apples and russet spotting on lettuce). At levels above 80 per cent of O_2 some commodities and post-harvest pathogens suffer from O_2 toxicity. Use of super-atmospheric O_2 levels in CA will likely be limited to situations in which they reduce the negative effects of fungistatic or elevated CO_2 atmospheres on commodities that are sensitive to CO_2-injury.

7.3 EFFECTS OF CA STORAGE

The following are some of the beneficial effects of CA storage.

- Retardation of senescence (including ripening) and associated biochemical and physiological changes, i.e., slowing down rates of respiration, ethylene production, softening, and compositional changes.

- Reduction of sensitivity to ethylene action at O_2 levels < 8% and/or CO_2 levels > 1%.

- Alleviation of certain physiological disorders, such as chilling injury of avocado and some storage disorders, including scald of apples.

- Effects directly or indirectly on post-harvest pathogens (bacteria and fungi) and consequently decay incidence and severity. For example, CO_2 at 10 to 15% significantly inhibit development of *Botrytis* rot on strawberries, cherries, and other perishables.
- Low O_2 (< 1%) and/or elevated CO_2 (40 to 60%) can be a useful tool for insect control during storage of dried products from fruits, vegetables, flowers, nuts and grains.

The harmful effects of CA storage of fruits and vegetables are mentioned below:

- Initiation and/or aggravation of certain physiological disorders, such as internal browning in apples and pears, brown stain of lettuce, and chilling injury of some commodities.
- Irregular ripening of fruits, such as banana, mango, pear, and tomato can result from exposure at O_2 levels below 2% and/or CO_2 levels above 5%.
- Development of off-flavours and off-odours at very low O_2 concentrations and very high CO_2 (as a result of anaerobic respiration and fermentative metabolism)
- Increased susceptibility to decay when the fruit is physiologically injured by too-low O_2 or too-high CO_2 concentrations.

7.4 METHODS OF CREATING MODIFIED ATMOSPHERE CONDITIONS

MAP may be defined as the enclosure of food products in gas-barrier materials in which gaseous environment has been changed in order to inhibit spoilage agents, either by maintaining a higher quality within a perishable food during its natural life or actually extending the shelf life.

Modified atmosphere can be created ***passively*** by the respiration of commodity, also called ***commodity generated*** modified atmosphere, and ***active*** modified atmosphere generation.

7.4.1 Passive Modified Atmosphere

If commodity characteristics are properly matched to film permeability characteristics, an appropriate atmosphere can passively evolve within a sealed package as a result of the consumption of O_2 and the production of CO_2 through respiration. This atmosphere must be established rapidly and without danger of the creation of anoxic conditions on injuriously high level of CO_2.

7.4.2 Active Modified Atmosphere

Because of the limited ability to regulate a passively established atmosphere, an active modified atmosphere can be created by vacuum packaging or replacing the package atmosphere with the desired gas mixture.

- **Vacuum packaging:** It involves placing a product in a film of low O_2 permeability, the removal of air from the package and application of a hermetic seal. During packaging product compression takes place which makes it unsuitable for many products.

- **Gas packaging:** Gas packaging overcomes the limitations of vacuum packaging. Oxygen, nitrogen and carbon dioxide are gases generally used which have specific role, viz. O_2 is essential for respiration of fresh fruits and vegetables, CO_2 is a bacterial and fungal growth inhibitor and nitrogen is inert, tasteless and less prone to pass either into the product or out through the packaging material.

7.4.3 Available Films for MAP

i) Plastic films: The permeability of plastic films is an important attribute which determines their suitability for packaging of fresh fruits and vegetables. An ideal film allows more CO_2 to exit than O_2 to enter. The CO_2 permeability must be somewhere in the range of 3-5 times greater than the oxygen permeability, depending upon the desired atmosphere. Permeability characters of films commonly used for packaging are presented in Table 7.1.

Table 7.1: Gas and water vapour permeabilities of some selected films available for modified atmosphere packaging of fresh produce

Film	Permeability, cc/m^2 day. atm for 25 meq film at 25°C		Water vapour transmission g/m^2 day atm 38°C and 90% RH
	Oxygen	Carbon dioxide	
LDPE	7800	42000	18
HDPE	2600	7600	7-10
Polypropylene cast	3700	1000	10-12
Polypropylene, oriented, OPP	6000-22000	6000-22000	NA
Rigid PVC	150-350	450-1000	30-40
Plasticized PVC	500-30000	1500-46000	15-40
Ethylene vinyl acetate (EVA)	12500	50000	40-60
Microporous, OPP	50000	50000	Variable
	72000	72000	Variable
	120000	120000	Variable
	200000	200000	Variable

NA: Not available

Low density polyethylene (LDPE) and polyvinyl chloride (PVC) are the main films used in packaging of fruits and vegetables. Gas diffusion across a film is determined by: film structure, film permeability to specific gases, thickness, area, concentration gradient across the film, temperature and differences in preserve across the film.

A list of desirable characteristics of plastic films for MAP of fresh produce is as follows:

- Required permeability for the different gases
- Good transparency and gloss

- Light weight
- Heat tear strength and elongation
- Low temperature heat-sealability
- Non toxic
- Non reactant with produce
- Good thermal and ozone resistance
- Good weatherability
- Commercial suitability
- Ease of handling
- Ease of printing for labeling purposes.

ii) **Surface coatings:** These are synthetic and natural chemicals which are composed of lipids, resin, polysaccharides, proteins and composite or bilayer substances. These surface coatings help to maintain quality of fresh produce and to reduce the volume of disposable non-biodegradable packaging materials. They also act by altering the gaseous atmosphere within and surrounding the fruit.

Surface coatings have been developed to overcome the limitations of MAP and CA. The risk of condensation on the inner surface and the associated incidence of rots in plastic films is eliminated. Surface coatings are used to modify internal atmosphere composition thereby delay ripening, reduce water loss and improve the finish of skin.

Requirements for edible films and coatings

- Good sensory qualities
- High carrier and mechanical efficiencies
- Enough biochemical, physiochemical and microbial stability
- Free of toxins and safe for health
- Simple technology
- Non polluting
- Low cost of raw materials and process.

Commonly used coatings

Lipids and Resins – Natural waxes-carnuba wax, candelilla wax, rice bran wax, bees wax, Petroleum based - paraffin, polyethylene wax, mineral oil, vegetable oils (corn, soybean), acetoglycerides, oleic acid, resins (shellac, wood resin, coumarone)

Polysaccharide based – They are very effective barriers to O_2 and CO_2 but not water. Cellulose derivatives: methylecellulose (MC), hydroxy propylcellulose (HPC), and hydroxy propylmethyl celluose (HPMC). These are commercially sold under the name of Nature seal, Tal prolong, Semperfresh. Chitosan based is Nutrisave.

Proteins – Their use in restricted due to high permeability to water.

Composite and bilayer coatings: They are mostly used when both the O_2 and moisture barrier properties need to be incorporated in the surface coating materials. That means the coating should have both hydrophobic and hydrophilic substances. For example, coating materials made up of sodium caseinate.

iii) Relative tolerance of fruits and vegetables to O_2 and CO_2 concentrations

The extent of benefits from CA and MA use depend upon the commodity, cultivar, physiological age (maturity stage), initial quality, concentration of O_2 and CO_2, temperature, and duration of exposure to such conditions. Subjecting a cultivar of a given commodity to O_2 levels below and/or CO_2 levels above its tolerance limits at a specific temperature time combination will result in stress to the living plant tissue, which is manifested as various symptoms. Tables 7.2 and 7.3 include classifications of fruits and vegetables according to their relative tolerance to low O_2 or elevated CO_2 concentrations when kept at or near their optimum storage temperature and relative humidity.

Table 7.2: Classification of fruits and vegetables according to their tolerance to low O_2 concentrations

O_2 concentration (%)	Commodities
1.0	Some cultivars of apples and pears, broccoli, mushroom, garlic, onion
2.0	Most cultivars of apples and pears, kiwifruits, apricot, cherry, nectarine, peach, plum, strawberry, papaya, pineapple, olive, cantaloupe, green bean, celery, lettuce, cabbage, cauliflower, brussels sprouts
3.0	Avocado, persimmon, tomato, pepper, cucumber, artichoke
5.0	Citrus fruits, green pea, asparagus, potato, sweet potato

Table 7.3: Classification of fruits and vegetables according to their tolerance to elevated CO_2 concentrations

CO_2 concentration (%)	Commodities
2	Apples (Golden Delicious), Asian and European pear, apricot, grape, olive, tomato, sweet pepper, lettuce, Chinese cabbage, artichoke, sweet potato
5	Most cultivars of apples and peach, nectarine, plum, orange, avocado, banana, mango, papaya, kiwifruit, pea, chilli, egg plant, cauliflower, cabbage, brussels sprouts, radish, carrot

7.5 COMMERCIAL APPLICATION OF CA STORAGE

Controlled atmosphere storage systems are used commercially for long-term storage of fresh horticultural crops. Commercial use of CA storage is maximum in apples and pears. Recent researches have shown potential advantages of this method in short-term (a few days) and medium-term (a few weeks) storage of certain types of produce. Optimizing storage conditions requires facilities that allow the temperature and the composition of gases in storage rooms to be controlled precisely. Each product reacts in different way to different concentration of gases.

There are various types of CA systems used in commercial storage. These include generating nitrogen by separation from compressed air using molecular sieve beds or membrane systems. Others are ultra low O_2 (1.0 to 1.5%) storage (ULO), low ethylene (< 1 $\mu L\ L^{-1}$) CA storage; rapid CA storage (rapid establishment of optimal levels of O_2 and CO_2), programmed or sequential CA storage (e.g., storage in 1% O_2 for 2 to 6 weeks followed by storage in 2 to 3% O_2 for the remainder of the storage period), etc. Recent reports of short-term control atmosphere exposure (CAE) techniques indicate a great promise of simulated effect of continuous CA–storage system with particular reference to delay in disease development, delaying the senescence and quality assurance of CA-insensitive climacteric fruits. Other developments include use of atmospheric modification during transport and distribution, improved technologies of establishing, monitoring, and maintaining CA, using edible coatings or polymeric films with appropriate gas permeability to create a desired atmospheric composition around the commodity.

In commercial CA storage the crop is loaded into an insulated store room whose walls have been made gas tight. The temperature is controlled by mechanical refrigeration and the composition of the atmosphere is constantly analysed for carbon dioxide and oxygen levels. Usually the tolerance limits are set at, say plus or minus 0.1%. In active scrubbing, after a predetermined level of CO_2 is reached of the store the atmosphere, is passed through a chemical (CO_2 scrubber) which removes CO_2, and then it is flushed back into the store. In passive scrubbing, the CO_2 scrubber is placed inside the store.

The following factors are to be taken into account with controlled atmosphere storage:

- It is expensive, therefore, only the best fruit should be stored.
- If there is a choice, small fruit should be stored.
- Fruit should be placed in storage as soon as possible after harvest, and in any case within a day.
- The store should be closed and cooled each evening during loading.
- Only one type of crop should be stored in one room and preferably the same cultivar.

The characteristics for a fruit to be compatible with the use of CA are: a long post harvest life, resistance to chilling injury, a large range of non-injurious atmospheres, resistance to fungal and bacterial attack, adaptation to a humid atmosphere, a climacteric fruit that can be ripened during or after storage, and absence of negative CA residual effect.

7.6 ENVIRONMENTAL FACTORS INFLUENCING MA AND CA STORAGES

7.6.1 Temperature and Relative Humidity

The temperature at which a commodity is stored influences the storage life of product, more importantly in film packed commodities. The commodity will cool and warm more slowly than it would if it is exposed directly to ambient temperatures. Temperature also affects the permeability of film. In general, film permeability increases as temperature increases, with CO_2 permeability responding more than O_2 permeability. A film that is appropriate for MAP at one temperature may not be appropriate at other temperature. Relative humidity appears to have little effect on permeability of most films unless actual condensation occurs on the film.

7.6.2 Light

For many commodities, light is not an important factor which influences their post harvest handling. However, green vegetables in the presence of sufficient light, could consume substantial amounts of CO_2 and produce O_2 through photosynthesis. Greening of potatoes can be avoided by using opaque packages.

7.6.3 Sanitation Factors

Packaging of fresh fruits and vegetables in plastic films can create a high-humidity low-oxygen environment that is favourable to pathogenic microorganisms. Care must be taken to avoid conditions favourable to the growth and reproduction of such microorganisms.

7.7 CA SYSTEMS FOR TRANSPORTATION

Many CA systems have been developed for use during transportation. They should be used when transport periods are long and /or fruit is very perishable. Some of the systems in use are:

Oxytral system	Occidental Petroleum Corporation, California, USA	Highway and sea shipment of lettuce, celery, papaya, pineapple
Tectrol system	Transfresh Corporation, California, USA	Lettuce, strawberry, mango, avocado.
CONAIR-Plus System	G+H Montage GmbH, Hamburg, Germany	Apple, avocado, melon, mango.
PRISM CA	Per Mea Inc., St. Louis, Missouri, USA	Apple, pears.
Fresh tainer	Maidstone, England	Apple
NITEC	Spokane, Washington, USA	Apple.

A comprehensive list of most suitable storage atmospheres for CA or MA storage of vegetables is provided in Table 7.4.

Table 7.4: Recommended controlled atmosphere conditions during transport/storage of vegetables

Commodity	Storage temp (°C)	Optimum oxygen (%)	Optimum carbon dioxide (%)	Approximate storage life
Artichoke	0-5	2-3	2-3	29 d
Asparagus	1-5	21	5-10	21 d

7.8 LET US SUM UP

Atmosphere at ambient conditions comprises of 78.08% N_2, 20.98% O_2 and 0.03% CO_2 under normal conditions. Any deviation from this normal atmosphere composition, e.g. elevated level of CO_2, reduced level of O_2, and N_2 or any other combination is known as '**Modified Atmosphere**'. When this deviated normal atmosphere is precisely kept under control then it is termed as "**Controlled Atmosphere**". This control can be done in package (Controlled Atmosphere Packaging) or in the storage chamber (CA-storage). Generally, O_2 below 8% and CO_2 above 1% are used in CA-storage. Atmospheric modification is a supplementary practice to temperature management in preserving quality and safety of fresh fruits, vegetables, ornamentals and their products throughout post-harvest handling. Essentiality of CA/MA technology should be justified only if (a) the commodities are having high market value,

(b) it significantly enhances storage life, (c) it retains significantly better quality, and (d) it fetches better price compared to conventional cool stored produce. Elevated CO_2-induced stresses are additive to and sometimes synergistic with, stresses caused by low O_2; physical or chemical injuries; and exposure to temperatures, RH, and/or ethylene concentrations outside the optimum range for the commodity.

The beneficial effects of controlled atmosphere storage are retardation of senescence, reduction of sensitivity to ethylene action, alleviation of certain physiological disorders and direct or indirect effect on post-harvest pathogens. It can be a useful tool for insect control. The harmful effects of CA storage of fruits and vegetables are initiation and/or aggravation of certain physiological disorders, irregular ripening of fruits, development of off-flavours and off-odours and increased susceptibility to decay.

If commodity characteristics are properly matched to film permeability characteristics, an appropriate atmosphere can passively evolve within a sealed package as a result of the consumption of O_2 and the production of CO_2 through respiration. It is also called passive MA. Because of the limited ability to regulate a passively established atmosphere, an active modified atmosphere can be created by vacuum packaging or replacing the package atmosphere with the desired gas mixture. The permeability of plastic films is an important attribute which determines their suitability for packaging of fresh fruits and vegetables. Surface coatings help to maintain quality of fresh produce and to reduce the volume of disposable non-biodegradable packaging materials. They also act by altering the gaseous atmosphere within and surrounding the fruit and create a MA condition.

There are various types of CA systems used in commercial storage. These include generating nitrogen by separation from compressed air using molecular sieve beds or membrane systems. Others are ultra low O_2 (1.0 to 1.5%) storage (ULO), low ethylene (< 1 $\mu L\ L^{-1}$) CA storage; rapid CA storage (rapid establishment of optimal levels of O_2 and CO_2), and programmed or sequential CA storage (e.g., storage in 1% O_2 for 2 to 6 weeks followed by storage in 2 to 3% O_2 for the remainder of the storage period), etc. Many CA systems have been developed for use during transportation. They should be used when transport periods are long and /or fruit is very perishable.

7.9 KEY WORDS

Modified atmosphere : Atmosphere at ambient conditions comprises of 78.08% N_2, 20.98% O_2 and 0.03% CO_2 under normal conditions. Any deviation from this normal atmosphere composition, e.g. elevated level of CO_2, reduced level of O_2, and N_2 or any other combination is known as **Modified Atmosphere.**

Controlled atmosphere : When this deviated normal atmosphere is precisely kept under control then it is termed as **Controlled Atmosphere**.

Passive modified atmosphere : If commodity characteristics are properly matched to film permeability characteristics an appropriate atmosphere can passively evolve within a sealed package as a result of the consumption of O_2 and the production of CO_2 through respiration

Active modified atmosphere : An active modified atmosphere can be created by vacuum packaging or replacing the package atmosphere with the desired gas mixture.

Vacuum packaging : It involves placing a product in a film of low O_2 permeability, the removal of air from the package and the application of a hermetic seal.

Gas packaging : Gas packaging overcomes the limitations of vacuum packaging. Mixed gases or inert gas is used in the package for specific purposes.

Surface coatings : The synthetic and natural chemicals which are composed of lipids, resin, polysaccharides, proteins and composite or bilayer substances are used as surface coating materials for various purposes. These surface coatings help to maintain quality of fresh produce and to reduce the volume of disposable non-biodegradable packaging materials. Edible films and coatings are also available.

Composite and bilayer coatings : It is mostly used when both the O_2 and moisture barrier properties need to be incorporated in the surface coating materials. This means the coating should have both hydrophobic and hydrophilic substances.

7.10 ANSWERS TO CHECK YOUR PROGRESS EXCERCISES

Check Your Progress Exercise 1

Your answer should include the following points:

1. Composition of normal atmosphere is 78.08% N_2, 20.98% O_2 and 0.03% CO_2. Any deviation from this normal atmosphere composition i.e., elevated level of CO_2, or reduced levels of O_2, and N_2 or any other combination is known as **Modified Atmosphere**. When this deviated normal atmosphere is precisely kept under control then it is termed as **Controlled Atmosphere**.
2. Kidd and West (1917).
3. O_2 below 8% and CO_2 above 1%.

4. Essentiality of CA/MA technology should be justified only if (a) the commodities are having high market value, (b) need longer storage life, (c) require significantly better quality, and (d) fetch better price compared to conventional cool stored produce.

Check Your Progress Exercise 2

Your answer should include the following points:

1. i) X ii) √ iii) X iv) √ v) √
2. Initiation and/or aggravation of certain physiological disorders, irregular ripening, development of off-flavours and off-odours, and increased susceptibility to decay.
3. Active and passive modification.

Check Your Progress Exercise 3

Your answer should include the following points:

1. i) √ ii) √ iii) X iv) X
2. Temperature and relative humidity, light and sanitation factors.
3. Any three of the following: Oxytral system, Tectrol system, CONAIR-Plus System, PRISM CA, Fresh tainer or NITEC.
4. Yes, Different types of surface coatings materials are:

   i) Lipid and resin based, e.g., carnuba wax
   ii) Polysaccharide based, e.g., Tal prolong
   iii) Protein based, and
   iv) Composite and bilayer coatings

UNIT 8 FOOD IRRADIATION

Structure

8.0 OBJECTIVES

After studying this unit, you should be able to:

- describe different kinds of ionizing radiations;
- define mechanism of irradiation;
- explain applications of gamma irradiation;
- illustrate the effect of radiation on nutrients;
- describe the effect of radiation on micro organisms; and
- assess the beneficial aspects of food irradiation.

8.1 INTRODUCTION

Food irradiation is a physical process like drying, freezing, canning and pasteurization. Food can be irradiated wet, dry, thawed or frozen. It is a cold process and does not cause change in texture and freshness of food unlike heat. In fact you will not be able to differentiate between irradiated and non-irradiated food on the basis of colour, flavour, taste, aroma or appearance.

This radiation technique is very effective and due to its highly penetrating nature, it can be used on packed food commodities. It means a food commodity, which is packed, can be radiated for sterilization, disinfestation or disinfection purposes and shipped directly.

As you may be aware that many chemical fumigants / preservatives are used to preserve food commodities. Which sometimes leave toxic residues in foods that may be carcinogenic in nature. Contrary to these chemical fumigants, irradiation does not leave any toxic residue in treated foods. So, it is considered very safe. Besides, radiation-processing facilities are environment friendly and safe to workers and public around.

In spite of all its benefits, the radiation processing technique is not a magic wand. It cannot be used to make spoiled or bad food look good. It cannot eliminate already present toxins and pesticides in food. It is a need based technique and can't be applied to all foods. Amenability of a particular food commodity to irradiation needs to be scientifically established and the food commodities that are duly permitted under PFA Act should only be radiation processed.

8.2 IONIZING RADIATIONS

8.2.1 Kinds of Ionizing Radiations

Gamma rays, X-rays and electron beam are the part of invisible light waves of electromagnetic spectrum (U.V. rays are also part of this invisible range but wavelength is not as short as that of X-rays or gamma rays). These high-energy radiations can change atoms into electrically charged ions by knocking out an electron from the outer orbit and thus, are called ionizing radiations. But, at dose levels approved for food irradiation, these radiations cannot penetrate nuclei and thus, food can never become radioactive.

Other types of radiation energy with longer wavelengths are infrared and microwaves. Infrared radiation is used in conventional cooking. Microwaves, due to their relatively longer wavelength, have lower energy levels but are strong enough to move molecules and generate heat through friction.

Three types of ionizing radiations are approved to be used for food irradiation.

i) Electron beams generated from machine sources operate at a maximum energy of 10 MeV.

ii) X-rays generated from machine sources operate at a maximum energy of 5 MeV.

iii) Gamma rays are emitted from Co-60 or Ce-137 with respective energies of 1.33 and 0.67 million electron volts (MeV).

i) Electron beams

Electron beams are streams of very fast moving electrons produced in electron accelerators. For your better understanding, an electron beam generator is comparable to the device at the back of TV tube that propels electrons into the TV screen at the front of the tube. For irradiation using electron beams, only approved electron accelerators can be used. Electron beams have a selective application in food irradiation due to their poor penetration. They can penetrate only one and one half inches deep into the food commodity. As a result, shipping cartons (pre-packed bulk food commodities) are generally too thick to be processed with electron beams. Since electron beams are generated through machine sources, so they can be switched on or off at will and require shielding.

ii) X-rays

X-rays are also generated through machine sources. X-rays are photons and have much better penetration and are able to penetrate through whole cartons of food products. To produce useful quantities of X-rays, a tungsten or tantalum metal plate is attached to the end of accelerator scan horn. The electrons strike the plate and X-rays are generated which pass through the metal plate and penetrate the food product conveyed underneath. But, remember that this X-ray machine is a much powerful version to the machine used in many hospitals and dental clinics. Since X-rays are generated through machine sources, so they can be switched on or off at will and require shielding.

iii) Gamma rays

The third type of ionizing radiations approved for food processing are gamma rays that are produced from radioisotopes either Co-60 or Ce-137. Contrary to electron beams and X-rays, radioisotopes cannot be switched off or on at will and they keep on emitting gamma rays. Radioisotopes require shielding. Co-60 source is kept immersed under water when it is not in use and Ce-137 is shielded in lead. Due to their continuous operation, radioisotopes need to be replenished from time to time. Gamma rays are photons and have deep penetration ability.

8.2.2 Mechanism of Irradiation

The preservative action of ionizing radiations is due to both primary and secondary effects resulting from interaction of radiations with molecules and microorganisms present in food.

i) Primary effect

The incident radiation interacts with the atoms and molecules present in food and cause ejection of electrons. This leads to ionization and dissociation. The ejected electrons cause further excitation of molecules present in food. These are represented in the equation below:

$RH \longrightarrow RH^+ + e^-$ Ionization

$RH \longrightarrow R + H$ Dissociation

$RH \longrightarrow RH^+$ Excitation

ii) Secondary effect (Radiolysis of water)

Since water is present in almost all the foods, either in free or bound form, an understanding of chemical changes which water undergoes is important. Gamma rays excite and ionize water and other molecules along their track, giving rise to excitation, ionization and free radicals. These events contribute a great deal to the secondary effects of gamma radiation.

The summary of happenings can be represented by the equation

$$H_2O \longrightarrow \underbrace{OH^+}_{\text{Free radicals}} + \underbrace{e^-\,aq.}_{\text{Hydrated electron}} + \underbrace{H^+_{FR} + H_2}_{\text{free radicals (FR)}} + H_2O_2 + \underbrace{H_3O^+}_{\text{Hydronium ion}}$$

8.2.3 Process of Gamma Irradiation

In a typical gamma irradiation facility, irradiation is carried out inside an irradiation chamber. The later is shielded by 1.5-1.8 meter thick wall. Radiation source Co-60 is contained in slender pencil like stainless steel casings, which in turn are contained in lead shield. Food products, pre-packed or in bulk are placed in suitable containers and carried into the irradiation chamber with the help of automatic conveyor. The conveyor goes through a concrete wall labyrinth. This concrete wall serves as a shield and prevents radiation from reaching the surrounding area.

For irradiation of food products, the radiation source is raised above the water shield, after activating all safety devices. The food containers or boxes move around the source in the cell and get exposed for a specific length of time that allows them to absorb a defined radiation dose.

Gamma irradiation can be compared to switching on a light, illuminating a room and turning it off. Gamma rays pass into the food, affect the food or target organisms present in food and leave the food. Outcome of irradiation depends on type of food products, radiation dose and organisms present in food.

After radiation, proper handling and processing of food should be ensured, because irradiation cannot prevent further contamination from improper handling or processing. Irradiation cannot be used to make spoiled food good or to clean up 'dirty' food. If food already looks, tastes or smells bad, it cannot be saved by any treatment including irradiation. The bad appearance, taste or smell will remain.

Food processes such as heating, freezing, chemical treatment and irradiation are not intended to serve as substitutes to good hygienic practices. Both at national and international levels, good manufacturing practices govern the handling of specific foods and their products. They must be followed in the preparation of food, whether the food is intended for further processing by irradiation or any other means.

Irradiators are designed with several layers of overlapping protection systems / safety devices to detect any malfunctioning of the equipments and to protect working personnel from accidental exposure to the radiations. Potentially hazardous areas are regularly and meticulously monitored. A system of inter locks / checks prevents unauthorized entry into the radiation chamber when the source is out of shield.

All irradiation facilities are under strict control of regulatory agencies. In India, irradiation facilities operate under direct control of AERB (Atomic Energy Regulatory Board), Bhabha Atomic Research Centre, Mumbai. These facilities are thoroughly evaluated for their efficacy and safety before a license is issued. Further monitoring is through periodic checks and regular inspections of the facility and in case of any non-compliance, severe penalties and delicensing of facility results.

8.2.4 Units of Irradiation

The units used to measure the effects of radiation are gray and sievert in accordance with recommendations of International Organisation for Standardisation (ISO). Formerly, units used for measuring radiation were the rad and the rem.

The gray (Gy) is the unit used to measure absorbed dose of radiation and is equal to one joule of energy absorbed per kg of matter being irradiated. 1 Gy corresponds to 100 rad.

The unit used to measure the dose equivalent to one given exposure, taking into account the different biological effectiveness of different type of radiation, is the sievert (Sv). 1 Sv corresponds to 100 rem.

The unit used to measure the activity of a given source of radiation is Becquerel (Bq). The former unit was Curie (Ci). 1 Bq is equivalent to 2.7 x 10^{-11} Ci.

8.3 EFFECT OF IONIZING RADIATION ON NUTRIENTS

All processes cause changes in nutritional value of foods, even storage causes fresh foods to loose nutrients. It is well demonstrated that irradiation up to 10 kGy does not cause any significant change in the nutritional value of macronutrients, i.e., lipids, proteins and carbohydrates.

Vitamins are the most essential micronutrients present in foods. Certain vitamins like A, E, C, K and B_1 are radiation sensitive. They can be reduced by irradiation but they are similarly reduced when treated by other food processing methods. Irradiation may convert Vitamin C (ascorbic acid) to dehydro ascorbic acid, which is another equally usable form of Vitamin C. Fat soluble vitamins like Vitamin D are radiation resistant and survive irradiation of food products.

Minerals are virtually unchanged. Iron is oxidized but the nutrient value of oxidized iron is same as that of unoxidized iron. Other processes like freezing, thawing, storage have similar effects on iron.

So, the bottom line is that irradiation does not have any adverse impact on the nutritional content of a person's diet.

The FAO / IAEA / WHO Joint Expert Committee has concluded that any food commodity irradiated up to an overall dose of 10 kGy is safe and wholesome for human consumption.

8.4 RADIATION SENSITIVITY OF MICROORGANISMS

In case of living organisms, exposure to radiation causes structural and functional changes in macromolecules thereby leading to cell death / injury. DNA or RNA is the most important target for radiation inactivation of living cells. Please note that a low dose that may cause little chemical changes in food can cause sufficient changes in DNA to cause cell death. As you must be aware that DNA carries genetic information and its intactness is important for it's functioning. So, any damage to DNA will result into severe cell injury / death.

Now, radiation acts on DNA in two ways, i.e., i) direct and ii) indirect. In direct action, DNA absorbs radiation and is damaged. The damage to DNA is of various types – single strand breaks, double strand breaks (dsb), alteration of purine or pyrimidine bases or interchain bond formation. In the indirect action, other molecules like water and the free radicals thus produced react with DNA absorb radiation. This primary and secondary effect (direct & indirect effect) we have studied earlier under section 8.2.2.

Both prokaryotic as well as eukaryotic cells possess various DNA repair mechanism, such as direct rejoining of broken ends, excision repair, past replication repair, etc. The double strand breaks are important because most of the microorganisms cannot repair these damages and cells cannot replicate.

When a population of microorganisms is irradiated with a low dose, only a few of the cells are damaged or killed. With increasing dose, the number of survivors decreases exponentially. Different species and different strains of same species require different doses to reach the same degree of inactivation. In order to characterize organisms by their radiation sensitivity, the decimal reduction dose (D_{10}) is used. D_{10} is the dose required to kill 90 per cent of a population.

i) Bacteria

Bacteria are prokaryotic organisms. The cytoplasm is highly hydrated (70-80% water) and is surrounded by cytoplasmic membrane and a cell wall. Chromosomal DNA is not surrounded by a nuclear membrane. Because of high water content and large amount of DNA, bacteria are very sensitive to radiation.

In general, gram –ve bacteria are more sensitive while some gram +ve cocci are extremely resistant due to their highly efficient DNA repair system. Spores are 10-20 times more resistant than vegetative cells because they have little or no free water and are surrounded by thick impermeable wall. Each bacterium is characterized by a particular D_{10} value reflecting its inherent sensitivity to radiation. Certain extrinsic factors like temperature, O_2 content, water activity, nature of medium and presence or absence of sensitizers or protectors also determine the D_{10} value of a particular microorganism.

ii) Virus

Viruses are simplest biological entities. They are metabolically dormant and do not contain cytoplasm or metabolic enzymes needed for growth. They are the obligate intracellular parasites. The simplest virus particle consists, basically, of a nucleic acid genome (DNA or RNA) and a protein coat. The genome size is 100 to 1000 times smaller than that of bacteria. Therefore, viruses are considerably more resistant to radiation than bacteria or fungi. Further, estimation of dose requirements, to ensure safety from viral infections solely through irradiation, ranged from 20 to 100 kGy, which makes irradiation an unlikely choice for virus treatment in foods.

iii) Yeasts and Moulds

Yeats and moulds are eukaryotic cells, i.e., they have a true nucleus. Generally, they are as sensitive to radiation as vegetative cells of bacteria. However, filamentous fungi contain more than one nucleus (may be 100 nucleus per cell) and are highly resistant to radiation.

iv) Prion

The prion particles associated with BSE (Bovine spongiform encephalopathy), commonly known as mad cow disease, do not have nuclei at all. They are not inactivated by irradiation except at extremely high doses. This means irradiation will work very well to eliminate parasites and bacteria from food but will not work to eliminate viruses and prions.

8.5 EFFECT OF IRRADIATION ON INSECTS (QUARANTINE TREATMENT)

Of all the contaminating organisms to which food irradiation is directed, insects are the most complex. The number of insect species probably exceeds a million and around 500 are considered pests of major importance. Pests and their life stages vary in their sensitivity to radiation. The insects that are not immediately killed by radiation are rendered sterile and unable to reproduce. So, irradiation is most accurately called a Pest Control measure. Lethality is not always quarantine application; requirement can be met by using doses that effectively stop reproduction in insects.

Irradiation has marked advantages over chemical fumigants as:

- Irradiation does not leave harmful toxic residues unlike chemical fumigants/pesticides.
- Even at very low dose levels, radiation affects pests at all life stages. Even eggs can be eliminated by radiation unlike chemical fumigants.
- To control pests in stored grains, insecticides / pesticides may need to be applied repeatedly and thus, leading to higher levels of toxic residues. On the contrary, irradiation is one-time effective process.
- As quarantine treatment, irradiation brings two kinds of useful effects:
- Prevention of transfer of insects from one locality to another, as might occur in the shipment of infested foods. Such a transfer could lead to the establishment of the insects in a new area.
- Prevention of insect damage to foods.

Check Your Progress Exercise 2

4. Write True (T) or False (F) for the following statements:

   i) Gram +ve cocci are more radiation resistant in comparison to gram –ve bacteria.

   ii) Single strand breaks of DNA are more important in radiation exposure.

   iii) Protein get adversely affected when foods are irradiated at a dose of 10 kGy.

   iv) Irradiation can even eliminate eggs of pests present in food.

   v) Viruses and prions are easily killed by irradiation.

8.6 PRACTICAL APPLICATIONS OF FOOD IRRADIATION

The recommended doses of ionizing radiation for different purposes in food preservation are different as explained below

a) Low dose, up to 1 kGy

- Sprout inhibition in bulbs and tubers (0.03 – 0.15 kGy).
- Delay in fruit ripening (0.25 – 0.75 kGy).
- Insect dis-infestation and elimination of food-borne parasites (0.25 – 1 kGy).

b) Medium dose, 1 – 10 kGy

- Reduction of spoilage microbes to improve shelf-life of meat, poultry and sea foods under refrigeration (1.5 – 3 kGy).
- Elimination of pathogenic microbes in fresh and frozen meat, poultry & sea foods (3 – 7 kGy).
- Reduction of microbes in spices to improve hygiene (10 kGy).

c) High dose, 25 – 70 kGy

- Elimination of viruses.
- Sterilization of packaged meat, poultry and their products which are shelf stable without refrigeration (25 – 70 kGy).
- Sterilization of hospital diets for immuno compromised patients.
- Food for astronauts in space.

8.7 BENEFICIAL ASPECTS OF FOOD IRRADIATION

8.7.1 Decontamination of Spices

Spices, herbs and vegetable seasonings are valued for their distinctive flavours, colours and aromas. Unfortunately, they are often contaminated with high levels of bacteria, moulds and yeasts. If untreated, the spices will result in rapid spoilage of foods they are supposed to enhance. Since spices are often contaminated with pathogenic bacteria, they can result in serious food-borne illnesses.

Spices are generally decontaminated by irradiation or fumigation with ethylene oxide gas (ETO). To understand the advantages of irradiation over ETO, the various points are given below:

i) Effectiveness

Irradiation is considered the most effective way to sanitize spices and the most countries have allowed it worldwide. Irradiation at a dose between 7.5 – 15 kGy (average dose 10 kGy) has been established to effectively control the microbiological contamination. Storage further enhances the sanitation effect because injured cells are unable to repair and die out over the time.

In comparison, ETO is far less effective. Although, it is a known fact that ETO is highly toxic to microbial contaminants but, it cannot be used alone. To stabilize ETO, it is mixed with 80% CO_2 and steam is used to deliver the gases, which in turn, reduces its microbiological efficacy. Infact, steam increases the moisture level of treated spices and may result in increased mould growth. Moreover, ETO has low penetration than radiation and hence, bulk ground spices cannot be treated effectively using ETO.

Further, to meet the requirements of international standards, spices are generally treated twice or more with ETO and thus, can easily result into unacceptable high levels of toxic chemical residues in treated spices. On the contrary, irradiation is an effective one time process.

ii) Toxic residues

ETO reacts with organic spice components to leave harmful residues, like ethylene chlorohydrin and ethylene bromohydrin, in spices. Ethylene chlorohydrin is a known carcinogen that persists in the spices for many months, even after food processing. For this reason, ETO is banned in many countries. On the contrary, irradiation does not leave any harmful toxic residue and is completely safe.

iii) Loss of sensory attributes

The use of steam with ETO is a strong argument against its use as a spice treatment. Steam results in the loss of volatile oils and hence, loss of aroma and flavour. Treatment with ETO can also result in unacceptable colour change. It results into darkening of onion and garlic powder. Chilies, paprika and turmeric may loose their bright colour. It may cause development of off-flavours in mustard and mustard flour.

On the other hand, radiation treatment preserves all sensory attributes in spices. Chili, paprika and turmeric colours are stable to radiation treatment.

iv) Environment safety issues

Since ETO is a known carcinogen, worker safety issues are the biggest concern in ETO operations. Irradiation has been established as an environment friendly food processing technique.

v) Packaging problems

Most spice packaging materials are compatible with irradiation. Spices packed in bulk packages, retail packages, heat-sealed bags, and gas impervious packs, can be easily and effectively irradiated. Irradiation allows the spice package to remain closed and sealed at all times. On the other hand, in ETO treatment gas impervious packs cannot be used. Further, after treating with ETO, spice packages need to be stored open (for a week or so) gas escape. This causes increased warehousing cost as well as recontamination of spices. In irradiation, there is no waiting period after processing and the material can be shipped directly and thus, no additional storage costs are incurred.

So on the basis of above-mentioned facts, it is concluded that irradiation is the most effective method to sanitize spices, particularly because

- it results in cleaner, better quality spices,
- it does not significantly change the sensory or functional properties of spices,
- it results in much lower levels of microbial contamination and thus, it is an effective treatment to meet international standards of food safety.

A prototype commercial demonstration irradiator with a throughput of 20 tonnes per day for treatment of spices is operational in Vashi, Navi Mumbai. This is under the management of Board of Radiation and Isotope Technology (BRIT), a constituent unit of Deptt. of Atomic Energy (DAE), BARC, Mumbai. A commercial irradiator, Shriram Applied Radiation Centre (SARC), a constituent unit of Shriram Institute for Industrial Research, Delhi is also licensed by AERB to irradiate spices for sanitization.

8.7.2 Delayed Ripening in Fruits

Irradiation at low dose levels (0.25 to 0.75 kGy) can delay ripening and over-ripening in mature but unripe tropical fruits like banana, mango and papaya. Climacteric fruits exhibit delay in ripening only if irradiated in the preclimacteric stage. Once the ripening has been initiated, irradiation does not change or alter the course of ripening.

The self-life of irradiated fruits can further be extended by combing other post harvest procedures like waxing, packaging in perforated bags, refrigeration and modified atmosphere.

8.7.3 Sprout Inhibition in Tubers and Bulbs

Traditionally, onions are bulk stored under ambient conditions in chawls, medas or sheds, the size and design of which varies from region to region. During prolonged storage, losses occur due to sprouting, desiccation and microbial rottage. The estimated losses are 30–50 per cent. Low ambient temperature and high humidity during rainy season promote sprouting. The losses through microbial spoilage can be reduced but sprouting can’t be checked by improving ventilation. Sprouting alone causes 25–30 per cent of total losses. Sprouted onions shrivel faster due to increased water loss by transpiration. The reserve food substances present in the fleshy scales are also used up for the sprout growth, which ultimately renders the onion bulb unfit for consumption.

Some chemical sprout inhibitors such as maleic hydrazide and isopropyl carbamate are used in temperate countries but these are not very effective in sub-tropical and tropical climates. Cold storage at 0-1°C with low relative humidity (65-70%) is also practiced in many temperate countries but strict temperature and humidity control is must. Moreover, cold storage is energy intensive and expensive technique.

On the other hand, irradiation at very low dose levels (0.06-0.09kGy) inhibits sprouting when properly cured bulbs are irradiated within 2-3 weeks of harvesting.

Potatoes cannot be stored more than 4-6 weeks at ambient temperature. They are stored in cold storage at 2-4°C having relative humidity 85-95 per cent. Since the refrigeration facilities in India are not meeting the requirements of increased crop production, so it is feared that 25-30 per cent of the commodity is lost within 2-3 months of harvesting due to dehydration and microbial spoilage.

Irradiation of potatoes combined with refrigeration at 15°C can extend the storage period up to six months with minimum losses. Irradiation has extra benefit over prevailing refrigeration technique.

In general, irradiation at the dose levels required for sprout inhibition of bulbs and tubers does not change their texture, and external appearance, sensory qualities and processing potential.

The first prototype commercial demonstration irradiator for potatoes and onions (POTON) with a throughput of 10 tonnes/hour is being set up in Lasalgaon, Nashik, Maharashtra. This unit is under the management of Board of Radiation & Isotope Technology (BRIT), a constituent unit of Department of Atomic Energy (DAE), BARC, Mumbai. Besides, two pilot plant irradiation facilities, namely the Food Package Irradiator in Food Technology Division, BARC, Mumbai and another at the Defense Laboratory, Jodhpur have been licensed for irradiating food items that have been cleared for domestic trade and consumption.

8.8 LET US SUM UP

- Three types of ionizing radiations are approved for food irradiation.
- Any food commodity irradiated up to 10 kGy is wholesome and safe for human consumption.
- Bacteria, viruses and fungi differ in their sensitivities towards radiation.
- Foods are irradiated at different dose (low, medium and high) levels for different applications.
- Irradiation has benefits over chemical fumigants and other food preservation techniques.
- Irradiation is one time, safe, environment friendly and efficient technique.
- Irradiation can effectively address many issues like food safety, food losses and quarantine treatments. This is a very promising technique in the field of food preservation.
- All irradiated products are labelled with an international logo called 'Radura'. It is also marked with statement "Processed by ionizing radiation" and purpose of Irradiation.

8.9 KEY WORDS

Irradiation : It is the process of preserving the food by ionizing gamma-rays, X-rays and electrons. It destroys the microorganisms and inhibits the biochemical changes.

Gamma-rays : Radioisotopes Co-60 or Ce-137 produce gamma (γ) rays. These rays are photons and have a deep penetration ability.

X-rays : These rays are photons, generated by X-rays machines, operate at an energy level of 5 MeV. They have less penetrative effect them r-rays.

Electron beams : They are fast moving electrons, produced in electron accelerators, operate at a maximum energy level of 10 MeV. They have selective application due to their poor penetration ability.

Mechanism of irradiation : The ionizing radiation preserve the food material by acting in two ways. The primary effect is through ejection of electrically charged or neutral radicals which destroy microorganisms. The secondary effect is ionization of water present in food by radiation. It helps in destruction of microorganism and inhibition of biochemical changes.

8.10 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answer should include the following points:

1. a) √ b) X c) √ d) X e) √

2. The three kinds of ionizing radiations are:

   Gamma rays, X-rays, and Electron beams.

   i) *Gamma rays* – These rays are produced from radio isotopes Co.60 or Ce-137. The gamma rays are photons and have a deep penetration ability. The energies emitted by Co-60 and Ce-137 are 1.33 and 0.67 million electron volts (MeV), respectively.

   ii) *X-rays* – These rays are generated from machine source and operate at an energy level of 5 MeV. These rays are photons and can penetrate through even whole cartons of food.

   iii) *Electron beams* – These are streams of very fast moving electrons produced in electron accelerators and operate at a maximum energy level of 10 MeV. Electron beams have a selective application in food irradiation due to their poor penetration, i.e., only one to one and a half inch deep into the food.

3. The preservative effect of ionizing radiation is due to primary and secondary effects resulting from interaction of radiations with molecules and microorganisms present in food.

The primary effect is due to the ejection of electrons with atoms and molecules present in food. The ejected electrons cause excitation of molecules present in food. The secondary effect of ionization radiation is to excite and ionize water and other molecules, present in food, which in term give rise to excitation, ionization and free radicals.

Check Your Progress Exercise 2

Your answer should include the following points:

1. Since viruses and prions do not contain cytoplasm and metabolic enzymes needed for growth, they are more resistant to irradiation in comparison to bacteria.

2. When living organisms are exposed to radiation structural and functional changes in macromolecules take place which result in cell injury or even death.

3. i) Vitamins A and E.
   ii) Vitamins C and D.
   iii) D_{10} is the irradiation dose required to kill the 90 per cent population of microorganisms present in food.

4. i) T ii) F iii) F iv) T v) F

Check Your Progress Exercise 3

Your answer should include the following points:

1. The two important beneficial applications of irradiation are:

   i) it delays ripening in fruits
   ii) it inhibits sprouting in tubers and bulbs

2. i) F ii) T iii) F

3. The advantages of irradiation are:
   i) It is more effective.
   ii) It does not leave any toxic residues.
   iii) Sensory quality is not affected.
   iv) It is more safe as compared to ETO.
   v) Irradiated food is easy to pack.

UNIT 9 TYPES OF BY-PRODUCTS

Structure

9.0 OBJECTIVES

After reading this unit, you should be able to:

- list fruit and vegetable handling and marketing wastes;
- characterise the wastes;
- describe by-products from fruit processing waste;
- explain the types of by-products from vegetable processing waste; and
- define the uses of these by-products.

9.1 INTRODUCTION

Fruits and vegetables are integral part of a balance diet as they contain vital nutrients like vitamins, fibre and minerals. Due to the diverse agro-climatic conditions of the country, all kinds of fruits and vegetables are grown. The production of fruits (46 MT) and vegetables (96 MT) has increased at a faster rate in the last decade making the country second largest producer of fruits and vegetables in the world after Brazil and China, respectively. Despite the fact that production of fresh fruits and vegetables is very high, the level of their processing remains at a low ebb, i.e., 2 per cent. In the developed and developing nations like USA, Brazil, Malaysia, Philippines and Israel the level of processing of fruits and vegetables is more than 50 per cent of the total product. So, there is a vast scope of increasing the level of processing in the country. At present there are more than 6000 processing units in the country where installed capacity is around 23 lakh tones. The main fruit and vegetable processed products are juice, concentrate, sauce, slices, jam dehydrated, canned etc. During processing, a huge amount of solid waste is generated, which is some times more than 50 per cent of the produce processed. Apart, waste is also generated at the place of production, handling and marketing and places of consumptions like hotels, restaurants, colleges, essential homes, etc. The effective disposal of waste is waste / by product generated vary from place to place depending upon fruits and vegetables and the way they are utilized. The waste products are in various forms. For instance we have the peel, rag and seeds in case of citrus fruits, peel and stones in mangoes; rings and seeds in jack fruit, core and peel in guavas; seeds, skin and trimmings in tomatoes, etc. Many fruit and vegetable processing plants produce a large amount of by-products. Peel, core, pits, veins, stem, leaves, etc., are the materials discarded by fruit and vegetable processing industries. Their appropriate utilization would not only yield other valuables end-products and lower the cost of production but also minimize pollution problem caused by unhygienic disposal methods.

9.2 HANDLING AND MARKETING WASTES OF FRUITS AND VEGETABLES

The harvested fruits and vegetables are cleaned/ washed/ graded according to size and appearance. These are then packed / bagged or loaded in containers for transportation to markets or retail outlets or to the processing unit. A large number and huge quantity of wastes and by products are generated during handling and marketing of fruits and vegetables. The type and quantity of waste depends upon the crop, the packaging material and the duration / time period of handling the produce. Fruits and vegetables are highly perishable in nature and their quality starts deteriorating the moment they are detached from the plant. Environmental conditions such as ambient temperature, relative humidity, produce storage conditions and, above all, infestation of microbes in the produce, are the main factors responsible for quality degradation during handling and marketing. After identifying the type of available waste it is very important to have a knowledge of general characteristics, such as physical, chemical and microbiological, for deciding their appropriate disposal/ utilization.

Various types of by-products available during fruit and vegetable handling and marketing are:

9.2.1 Fruit Wastes

a) Peel, core, and trimmings
b) Seed/ kernel, stem and pomace
c) Cull fruit
d) Over-ripe and blemished
e) Bruised and diseased

9.2.2 Vegetable Wastes

a) Seed, skin and trimmings
b) Vine and pods
c) Peel and pomace
d) Husk and cobs
e) Over mature and cull
f) Bruised and diseased

9.2.3 Packaging Wastes

Various types and sizes of packaging materials are used for different fruits and vegetables. Waste generated during handling and marketing due to various packagings are as follows:

a) Gunny bags
b) Bamboo crates/"tokras"
c) Wooden boxes

d) Plastic sacks or bags
e) Paddy straw/pine waste/leaves or any other coushing material
f) Foam or thermocole
g) Paper bags or corrugated fibre board boxes

9.3 BY-PRODUCTS FROM FRUIT PROCESSING

The fruit and vegetable processing industry in India is highly decentralized. A large number of units are in the cottage/home scale and small scale sector, having small capacities up to 250 tonnes/annum. But big Indian and multinational companies in the sector have large capacities in the range of 3.0 tonnes per hour or so. In the food processing industries, up to 30 per cent of incoming raw material becomes waste rather than a value-added product. Generally fruit processing wastes are either used as animal feed or as compost.

Specific wastes and by-products from different fruit and vegetable processing industries and their appropriate use are discussed below:

Apple

Apple (*Malus pumila Mill.*) is the most important deciduous fruit. These are mainly grown in the North-Western Indian States of Jammu and Kashmir (J&K), Himachal Pradesh (H.P.) and Uttaranchal hills. The North-Eastern Hills region, comprising of the States of Arunachal Pradesh, Nagaland, Meghalaya, Manipur and Sikkim, also grows some of the deciduous fruits on a limited scale. Major wastes and by-products of apple processing are:

- pomace - obtained after juice extraction
- peel - obtained during canning and murabba preparation
- core and cull fruits

Apple wastes contain pectin varying from 2.5 to 3.4 per cent on fresh weight basis. These wastes can be used for preparation of pectin, cider, vinegar, chutney, etc. Pomace can be dried and utilized for preparation of pectin. Apple pomace being rich source of pectin and a fairly good source of sugars, can be utilized on a small scale for blending with fruits poor in pectin for the preparation of jam, jellies, etc., which require addition of pectin. Apple chutney can be prepared from pomace.

Amla

(Indian goose berry): The amla/aonla (*Emblica officinalis* syn. *Phyllanthus emblica*) is an important minor fruit. Although, it is found growing in different states throughout tropical India, it is more popular in Uttar Pradesh. It is highly nutritive and is one of the richest source of vitamin C. The fruits are made into preserves (*murabba*)**,** pickles, dried chips, candy, toffees, powder, juice, sauce etc. Amla seed is obtained from amla processing industry. The seed can be dried and used in ayurvedic preparations.

Apricot

Apricot (*Prunus armeniaca L.*) is grown in the drier pockets of north-western Himalayas and Leh-Ladakh areas of J&K State. Apricot is a small, soft fruit with white/orange skin. Its kernels are sweet and can be added to jam after removing the seed coat. Generally there are two types of apricot, namely, sweet kernel type and bitter kernel type. Oil can be extracted from kernels and after refining it is just like almond oil and can be used in pharmaceutical and cosmetic preparations. The oil cake is rich in protein and can be used as cattle feed. The kernels are sometimes used for making macaroon paste which is usually made from almonds.

Banana

Banana (*Musa paradisiaca*) is the cheapest, plentiful and most nourshing of all fruits. It is basically a plant of humid tropics and is grown in south, west and east India. All parts of this plant are useful. Various products like banana chip, banana fig, soft drink, flour and powder, jam, etc., can be made. Banana peel and pseudostem are the main waste products from banana processing. The pulpy portion scraped from thick peel of banana can be used for preparation of banana cheese. Pseudostem of banana can be utilized to prepare paper pulp as well as a starch resource for food and feed purposes.

Cashew

Cashew (*Anacardium occidentale*) is an important tropical tree crop. It is mostly grown in malabar coast of India, particularly concentrated in Kerala, Karnataka, Maharashtra, Tamil Nadu and Andhra Pradesh. Every part of cashew is useful to man. The kernels are of high nutritive value, rich in protein, carbohydrate, unsaturated fats, minerals and vitamins. The main by-products are: cashew apple, cashew testa and cashewnut shell liquid. Because of its astringent taste and fibrous texture, only a small quantity of the annual production of cashew apple is consumed locally and a major portion is wasted. About 65 per cent of the juice can be obtained from the apple by extraction. The juice, after removal of astringent and acrid principles, has been found to be suitable for a variety of beverages like clarified juice, cloudy juice and juice blended with other fruit juices. Cashew apples can also be used for the preparation of cashew apple candy, syrup, canned cashew apple, fruit chutney, curried vegetable, pickle, etc. The brown thin skin covering the cashew kernel is called the cashew testa. It is a by-product of the cashew processing industry. Cashew testa is a good source of tannin. At present, this is mostly wasted or occasionally used as a manure in small quantities. However, the disposal of this product is a big problem. Quite often, storage of this husk is found as a ready place for *dryboleum* and so is hazardous in the cashew factories.

The reddish brown viscous liquid inside the two layers of the cashew shell is a versatile industrial raw material known as cashew shell liquid. Its major application is in the manufacture of cashew liquor, cashew cement, laminating resins, rubber compound resins, brake linings, intermediate for chemical industry, epoxy resins, foundry chemicals, composite wood, insulating varnishes, electrical windings, electrical conductors, coating compositions, water and weather proofings, bituminous solutions, specialised protection coatings and compositions based on cardanol.

Citrus

The most important commercial citrus in India is mandarin orange followed by the sweet orange and acid limes. Besides being used as fresh fruits, the citrus fruits are processed into marmalade, juice, concentrate, powder and canned product. The flowers, leaf and rind of citrus contain oils of good fragrance and have good commercial value. Other commercial products are citric acid and pectin, made primarily from cull and unmarketable fruits**.** In case of citrus fruits major waste materials are peel, rags, seeds, and sludge from lime and oranges. The peel can be utilized for getting peel oil, which has a number of uses. The rags can be used for preparation of citrus patty, marmalade and orange toffee. The dried rag can also be used as cattle fed. Orange residues can be fermented into fruit vinegar. Lime juice sludge is used to extract lime oil. Seeds from oranges and lime can be used for extraction of seed oil, which has enormous industrial applications. Juice residues of orange and gulgal can be used to get pectin. Waste from cull, lime, gulgal and khatta can be used to prepare citric acid.

Coconut

Coconut (*Cocos nucifera*) is most beautiful and useful tree of tropics. This crop is of considerable economic importance in the state of Kerala, Tamilnadu, Karnataka and Andhra Pradesh. These have more than 90 per cent of the total production of the crop in the country. There are number of industries which are directly or indirectly dependent on coconut farm. The major wastes and by-products of coconut are stem, leaves, buttons, coconut husk, pit, shell and water. The quire industry utilizes coconut husk and is earning considerable foreign exchange for the country. Quire husk is a waste left over after extraction of fibre from the coconut husk. This light fluffy refuge is a mixture of corcipith, fibre short and apricot. High moisture and saline content are the main problems restricting its utilization. It has been limited agricultural use. It can be used as an accident soil mulchi material. It has certain industrial uses. It can be used for preparation of boards from quire wastes, preparation of installation slabs, air conditioner and refrigeration, manufacturing of moulded articles, expansion joint filler, furfural production, electric plate edited in battery industry and as a tacifying agent in rubber industry. Coconut shell is the endocarp of the coconut fruit. It is available in large quantities near copra making centre or desiccated copra making centre. It can be used as a fuel and manufacturing of fancy articles. Since coconut shells are available in different sizes and shapes, it can be polished and carboned and decorated with lacquer in load with ivory, silver or other metals. A number of fancy articles prepared from coconut shells are lamps, flower, bulb covers, ash tray, paper, tea sets, musical instruments, bangles, etc. Coconut shell flour can be used as a compound film for synthetic season blues, as a fuel for pneumatic moved powder, etc. Furfural can also be extracted from ground coconut shell. Large volumes of coconut water from ripe nuts are run off as waste product by copra manufacturer. The biochemical analysis of coconut water shows negligible amount of sugar. It can be used as a growth media, a rubber coagulant and soft drink. In view of the relatively high potassium content coconut water can be mixed with compost or can be applied directly to coconut palms after mixing with slag lime. Coconut pith can be used for preparing the insulation and as a structural material.

Grape

Major grape (*Vitis vinifera L.*) growing states in India are Maharashtra, Karnatka, Andhra Pradesh and Tamil Nadu. The cultivation of grapes has also started under North Indian conditions. The grapes are used into five different ways, such as, table purpose, canned, juice, wine and raisins. Stem, pomace and seed are main by-products of grape industry. Stem, separated from grapes, normally constitute about 5 per cent of original weight of grapes. The stems can yield cream of tartar (potassium tartrate). The pomace consists of pressed skin and seeds. From the pomace, seeds can be separated and pressed to extract oil, which is edible in refined state. Oil cake can be used to extract tartaric acid. Hulls of decorticated grape seeds can be used to obtain toxin extracts. The pomace can be used for preparation of grape jelly and chutney. It can also be used for preparation of animal feed. Pomace must be dried to less than 10 per cent moisture in order to prevent spoilage by moulding and spontaneous heating. Grape marc can be used for preparation of pectin. Argols (potassium hydrogen tartrate) can be obtained from grape juice settlings.

Guava

Guava (*Psidium guajava L.*) is grown all over the country in tropics and sub tropics. It is a rich source of vitamin C and pectin. It is used for table purpose and for processing to prepare jelly, nectar, juice, cheese, powder and canned guava. Guava peel, seeds, pulp and core are main by-products of guava fruit. These can be utilized to prepare cheese, separately as well as collectively or animal feed. Cheese prepared from peelings only is brown in colour and has satisfactory flavour and good set, whereas cheese from seed is dark brown in colour, sticky and has soft texture and good flavour.

Jack fruit

The Jack fruit (*Artocarpus heterophyllus*) is very popular in eastern and southern parts of the country. The fruit has high nutritive value and is rich source of pectin. It is preserved into pickles, dehydrated, leather, thin *papad* and canned product. Nectar can also be prepared from pulp. The skin and leaves are excellent cattle feed. Seed, thick rind and broken bulbs are the main by-products of jack fruit. Broken bulbs are used to prepare 'leather'. Thick rind with inner perigones can be used for preparation of jelly and pectin. Seeds can be roasted to be used as snack food. Seeds can also be grinded into flour which can be blended with other cereal flours for preparation of products.

Mango

The mango (*Mangifera indica L.*), because of its luscious taste, captivating flavour and great utility, is called the "King of fruits" or "Shahi fruit". It is a major fruit crop grown throughout India. Unripe fruits, because of their acidic taste, are utilized for culinary purpose as well as for preparing pickles, chutney, panna and amchoor. Ripe fruits are utilized in preparing pulp, squash, juice nectar, jam, cereal flakes, dehydrated slices, powder, mango leather (am papar) and toffee. Some mangoes are also sliced and canned for catering to the needs of consumers during off season. The wastes constitute about 50 per cent of the weight of fresh mangoes. Peel and kernel are the wastes from green mangoes as well as ripe mangoes. Pulping machine generates processing wastes. Mango kernel contains about 8.5 per cent crude fibre and 75 per cent N-free extract. Starch obtained from seed kernel can be used to partly replace wheat atta for making chapatees. Oil which forms about 12 per cent of the weight of the kernel is another by-product. Pectin and fibre can be extracted from peel and processing wastes vinegar, citric acid, etc., can be obtained by fermentation of processing waste. The mango waste can also be utilized as animal feed or compost.

Papaya

Papaya (*Carica papaya*) is an important fruit of tropics and subtropics. In India, though it is successfully grown all over the country, the important papaya growing states are Kerala, Tamil Nadu, Assam, Gujarat and Maharashtra. Papaya is a wholesome fruit and ranks second only to mango as a source of precursor of vitamin A. Unripe fruits are commonly used as vegetable for cooking much tenderizer and preparation of tutti-frutti. The ripe fruits are used for table purpose and processed for preparation of jam, soft drink, ice-cream flavouring, crystallized fruits and syrup. Papaya waste a usually peel and trimmings can be used to get proteolytic enzyme papain which has a number of applications in textile, cosmetic and pharmaceutical industries. Pectin can also be recovered from papaya waste.

Passion fruit

Passion fruit (*Passiflora edulis*) is adapted to tropics and subtropic areas with high rainfall. It is a fruit with unique flavour and aroma. Fruit is cut in halves and the pulp scooped out and eaten fresh or added to fruit salad, ice creams or fruit juices. It is processed into fruit nectar, juice, jam, jelly, squash and concentrate. The main wastes of passion fruit are hard rind and seeds. Thick hard rind of this fruit can be used for recovery of pectin, whereas seeds are utilized for extracting oil and pectin.

Peach

Peach (*Prunus persica L. Bats. Ch*) are now being grown commercially in certain areas of the north Indian plains and North-Western States of Jammu and Kashmir, Himachal Pradesh and Uttranchal**.** Peach kernel is the main waste material, which can be used for extraction of kernel oil for industrial uses.

Pear

Pear (*Pyrus communis Berm.f.*) is mainly grown in the North-Western Indian States of Jammu and Kashmir, Himachal Pradesh, Uttranchal and certain areas of the north Indian plains. Peel and core are the main waste by-product obtained from pear and both are used to prepare alcoholic beverage as well as fruit vinegar.

Pineapple

Pineapple (*Ananas comosus)* is most wanted tropical fruit. In India, it is grown mostly in West Bengal, Manipur, Meghalaya, Assam and Tamil Nadu. Pineapple is a good source of vitamins A, B and C and calcium and phosphorus. The processed products from pineapple are slices in cans tit bits, juice, squash, jam and candy. Pineapple wastes constitute 40 to 50 per cent of the fruit weight. Shells, trimmings, peel and pomace are the main waste and by-product of this fruit. Shells and trimmings are utilized to recover pineapple juice mixed with cane sugar syrup for further use in canning of pineapple slices. This juice has also been found useful for preparation of alcohol. The core of pineapple can be used to prepare candies as well as extraction of juice. The press cake from the juice can be used as animal feed. The pomace obtained after extraction of juice from peeled fruit, trimmings and cores can also be used as animal feed. Other products which can be prepared from this waste are alcohol, citric acid, mannosidase, oxalic acid, pineapple gum, flavour and vinegar. Leaves are used for making fine fabric called pina cloth.

9.4 WASTES AND BY-PRODUCTS FROM VEGETABLES

Tomato

Tomato (*Lycopersicon esculantum*) is an important vegetable crop available round the year. It outranks all other vegetables, except potato crop in popularity and value. It is grown universally in farmer's fields, home gardens and green houses. Peel, seeds and pomace are the wastes obtained during processing of tomato into juice, concentrate, ketchup and sauce. When tomato is canned in lime and sugar solution, some peel and seeds are obtained as wastes. The pomace is either thrown away or used in preparation of compost. Seeds are washed, dried and used for propagation. Edible grade seed oil can also be extracted from seeds. Tomato peel can be utilized for preparation of varnishing and arranging seed oil which compare well with Vit. E and can be used as salad oil and in the manufacture of margarine. The seed meal can be used in fields as fertilizers and also for the preparation of surfactants such as veterinary agents and detergents, etc. The marc constitutes about 12-13 per cent of tomato.

Onion

Onion (*Allium cepa L.*) is one of the most important commercial vegetable crops grown in north as well as in south India. The most important onion growing states are Maharashtra, Tamil Nadu, Andhra Pradesh, Bihar and Punjab. Onions are used as salad and cooked in various ways in all curries, fried, boiled, baked, soup, pickles, etc. The roots are trimmed and the outside skin peeled off leaving the stem clean for further storage/ marketing. Trimmings are obtained as onion wastes. These trimmings are either thrown away or used as compost. The flour component can be extracted from this waste. During handling and grading operations and dehydration loose outer scales are rubbed off. These can also be used as compost.

Potato

Potato (*Solanum tuberosum* L.) is the maximum produced vegetable crop in India. About 80 per cent of the dry matter of potato is starch, which occurs in the form of granules of larger size than those of cereals. Raw potato is generally boiled, cooked, baked or processed into various products such as chips, fingers, cubes, extruded and flour. Potato peel and starch are the waste and by-products obtained during potato processing. Potato peel can be used for preparation of alcoholic beverages as well as compost. Starch is utilized as flour or in cosmetic industry.

Cauliflower

Cauliflower (*Brassica oleracea* L. var. *botrytis*) is an important cole crop. India's production of cauliflower in the world is highest. It is an important winter-session vegetable. It is grown for its white tender head or curd. It is used as vegetable in curries, soups, stuffing in parathas and for pickles. It contains good amount of vitamins and fair amount of protein. Plants are cut below the head and leaves trimmed off. Stalks and trimmings are the main wastes obtained from cauliflower, both in the field as well as in processing industries. These stalks and trimmings can be used as cattle field.

Okra/ Ladyfinger

Ladyfinger (*Abelmoschus esculentus* L.) is a warm season vegetable crop. It is cultivated throughout India for its immature fruits which are generally cooked as vegetable**.** Okra soup and stew are popular dishes**.** Black or brown seeds of ripened okra are roasted and used as a substitute for coffee. The wastes available in the field such as stem of the plant is used for extraction of fibre in paper industry. Stalks are the main by-product in leading processing industry, which can be used as animal feed.

Peas

Pea (*Pisum sativum* L.) is a vegetable crop important from agricultural economy as well as nutrition point of view. Peas are highly nutritive and contain a high percentage of digestible protein along with carbohydrates and vitamins. It is an excellent food taken either as a vegetable or in soup, canned, frozen or dehydrated form. The winnings and rolls are the main waste material from green peas. These wastes can be directly fed to animals or can be dried to make ingredient in animal feed. These wastes are also used as compost.

9.5 LET US SUM UP

Fruits and vegetables are valuable parts of a balance diet. The diverse agro-climatic zones of the country make it possible to grow almost all types of fruits and vegetables. Major Indian fruits consist of mango, banana, citrus group, apple, guava, papaya, pineapple and grapes. In case of vegetables, potato, tomato, onion, cabbage and cauliflower account for around 60 per cent of the total vegetable production in the country. Wastes/by-products generated vary from place to place depending upon fruit and vegetable production, marketing sites, processing industries, and major consuming places such as hotels, restaurant, hospitals, schools, colleges and community langars. The fruits and vegetables are processed into various products such as juice, concentrate, canned, dehydrated, jams, jellies, etc. Many fruit and vegetable processing plants produce a large amount of by-products. Peels, cores, pits, veins, stem, leaves, etc., are the materials discarded in processing industries. The waste products are in various forms. For instance peel, rag and seeds in citrus fruits, peel and stones in mangoes; rings and seeds in jack fruit, core and peel in guavas; seeds, skin and trimmings in tomatoes, etc., are obtained. Their appropriate utilization would not only yield other valuables end-products and lower the cost of production but also minimize the pollution problem caused by unhygienic disposal methods. Wastes and by products from important fruits and vegetables such as mango, banana, citrus fruits, apple, guava, papaya, pineapple, grapes, potato, tomato, onion, pea, okra and cauliflower have been discussed. The nutritional quality/characteristic of these by-products varies. Previously, these residues were considered as wastes material to be transported to landfills, burnt, added to soil or fed to cattles. However, these residues are viewed as input materials that can become value-added products with further processing. These wastes are economically utilized for the production of pectin, oil, alcohol, flavours, etc.

9.6 KEY WORDS

By products : Any material or product contingent upon or incidental to a manufacturing process.

Processing waste : Any material generated as waste, in a food processing operation.

Packaging waste : Any material generated as waste from a fruit/ vegetable packaging.

Peel : Outer covering of any fruit or vegetable.

Skin : Outer layer or covering of a fruit or vegetable.

Core : The innermost or centremost part of fruit containing the seeds.

Seed : It is a part of plant capable of developing into another such plant.

Pomace : Waste material obtained during processing of fruits like apple, citrus, etc.

Stem : Stalk of fruit/vegetable or plant.

9.7 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answers should include the following points:

1. There are more than 6000 fruits and vegetables processing industries where installed capacity is around 23 lakh tonnes.

2. Various types of by-products generated during fruits and vegetables handling & marketing are:

   a) *Fruit wastes:* Peel, core, trimmings, seed/ kernel, stem and pomace, cull fruit, over-ripe and blemished fruits and bruised and diseased

   b) *Vegetable wastes:* Seeds, skin, trimmings, vines, pods, peels, pomace, husk, cobs over mature and cull and bruised and diseased

   c) *Packaging wastes:* Different types and sizes of packaging materials are used for different fruits and vegetables in different areas. Major wastes generated during fruit and vegetable handling and marketing due to various packagings are as follows: Gunny bags, bamboo crates/ "tokras", wooden boxes, plastic sacks or bags, paddy straw/pine waste leaves or any other coushing material, foam, or thermocole and corrugated packing or paper bags.

Check Your Progress Exercise 2

Your answers should include the following points:

1. Peel, core, rags, sludge, pits, pomace, veins, seeds, kernel, shell, rind, stem, leaves, etc., are the materials discarded in fruit processing industries. The waste products are in various forms depending upon the type of fruit being processed. For instance we have the peel, rag and seeds in case of citrus fruits.

2. The major wastes and by-products of coconut are stem, leaves, buttons, coconut husk, pit, shell and water.

3. The main by-products of cashew processing industry are cashew apple, cashew testa and cashewnut shell liquid.

4. The wastes and by-products from mangoes constitute about 50 per cent of the weight of fresh fruits. Peel and kernels are the wastes from green mangoes as well as ripe mangoes. Pulping machine generates mixture of peel and pulp.

Check Your Progress Exercise 3

Your answers should include the following points:

1. Trimmings, peel, core, rags, sludge, veins, seeds, stem, leaves, etc., are the materials discarded in vegetable processing industries.

2. Peel, seeds and pomace are the wastes obtained during processing of tomato.

9.8 SOME USEFUL BOOKS

1. Bose, T.K. and Mitra, S.K. (1996) Fruits: tropical and subtropical. Ist Edition, Naya Prokash, Calcutta.

2. Choudhury, Bishwajit (1967) Vegetables Ist Edition, National Book Trust, India.

3. Cruess, W.V. (2000) Commercial Fruit and Vegetable Products, Agrobios, India.

4. Pandey, P.H. (1997) Post Harvest Technology of Fruits and Vegetables (Principles and Practices) Ist Edition, Saroj Prakashan, Allahabad, India.

5. Lal, Girdhari, Siddappaal, G.S. and Tandon, G.L. (1986) Preservation of Fruits and Vegetables, Publications and Information Division, Indian Council of Agricultural Research, New Delhi.

6. Luh, B.S. and Woodroof, (1975) Commercial Vegetable Processing. The AVI Publishing Company, Inc., Westport, Connecticut, USA.

UNIT 10 UTILIZATION OF FRUITS AND VEGETABLES PROCESSING WASTES FOR FOOD, FEED, FUEL AND INDUSTRIAL PRODUCTS

Structure

10.0 OBJECTIVES

After reading this unit, you should be able to:

- list various types of fruit and vegetable by-products and processing wastes;
- evaluate quantity of important wastes and their qualitative composition;
- describe the major value added products obtainable from processing wastes;
- transform the fruit and vegetable wastes into value added products for food, feed , fuel and industry;
- develop value added products from fruit and vegetable wastes by fermentation process; and
- define the fruit and vegetable waste water processing techniques and the products developed from waste water.

10.1 INTRODUCTION

You already know that India is one of the largest producer of fruits and vegetables. Fruits are consumed mostly raw and fresh, while the vegetables are usually consumed after cooking. We also know that fruits and vegetables are more prone to spoilage. This spoilage occurs at the time of harvesting, handling, transportation, storage, marketing and processing.

Fruits and vegetables are rich source of vitamins, carbohydrates and minerals and even the inedible portion is rich in nutrients. In most of the countries up to 80 per cent of the total production of fruits and vegetables are processed. However, in India, only around 2 per cent of the total production is processed and that too mostly at cottage and small scale. At present there are more than 4000 processing units with a turn over of more than 8.0 lakh tones of fruit and vegetable products. The processing waste generated by these factories is either gifted away or it is allowed to add to the environmental pollution.

The processing waste can be categorized into solid or liquid wastes. Solid wastes comprise of peels, skins, fragments, pits, spillage, trimmings, cores, fibre and seeds. Liquid wastes include mainly the wash water coming out of factory after processing operations like raw material washing, container washing, blanching, sterilization, cooling and plant and machinery clean up.

We do not have organized method of waste collection and its handling and utilization. Most of the solid waste is dumped or used as landfills. A part of the solid waste is also utilized for cattle feed and manure. Some of the processing units discharge the liquid waste in municipal sewage system. If we do not attend to these wastes, they become a source of pollution and contamination. If we attend to these wastes in scientific manner these can become a rich source of vital constituents like carbohydrates, proteins, fats, minerals, natural colours, pectin, oils, biogas fuel, etc. Efficient disposal and recycling of these by products and wastes will also provide pollution free environment and vital constituents to our foods, feeds and industries. Besides, utilization of waste for by products development will economise the cost of processed products.

In this unit you will learn about various types of fruit and vegetable wastes, their sources of availability and their utilization for food, feed, fuel and industrial raw material.

10.2 FRUITS AND VEGETABLES WASTES

When we process the fruits and vegetables for juices, squashes, jams, jellies, canning and other products, we get large quantities of left over materials. These are called solid wastes. During processing fruits and vegetables produce different kinds of waste material which are described below:

i) Fruit wastes

a) peel, rag, pulp and seeds in citrus
b) peel, stones, and pulper waste in mango
c) rind and seeds in jack fruit
d) peel, core, seeds in guava
e) seeds, and skins in grape
f) pomace of apple
g) apricot kernel, shell and skin
h) peel, core, trimmings, shreds and leaves of pineapple
i) peel, pseudo stem, leaves of banana
j) over ripe and blemished fruits
k) cull fruits and unmarketable surplus

ii) Vegetable wastes

a) tomato seeds, skins and trimmings
b) asparagus wastes from canning
c) vines and pods from pea canning
d) wastes from dryers
e) peel and cores solids of potato

10.3 BY-PRODUCTS FROM FRUIT AND VEGETABLE WASTES

The solid waste obtained from processing of fruits and vegetables is not really a waste but sometimes is an asset. A number of by-products may be obtained from the waste. Some by-products are extracted chemically while others are prepared by using the waste as such (Table 10.1). Here, we will discuss some of the important products prepared / obtained from solid waste.

i) Fat

Mango processing ends up in considerable proportion of peel and stones. On an average stone content in mango is about 15 per cent. India produces around 21 lakh tonnes mango stones or 16 lakh tonnes kernels. The kernel is obtained by decorticating the seed. The estimated fat content in mango kernel is more than 10 per cent. If we can collect and process half of the stones, India can produce about 80,000 tonnes mango fat.

ii) Magaz

Magaz is a seed kernel. You can obtain magaz by decorticating the seeds of cucumber, pumpkin, water melon, musk melon, etc. These have a big market in confectionary, bakery, ice creams and beverages. Apricot kernel is sweet in taste. It looks like almond. It is used in confectionery along with almond. It is also used to improve the appearance of apricot jam. Magaz production can be a good house hold industry.

iii) Starch

Mango kernel obtained after decorticating the seed and banana pseudo stem are good sources of starch. Banana plants provide about 5 per cent edible starch. You will be happy to know that presently more than 1,40,000 tonnes of starch is available from mango seed kernel and 4-5 tonnes starch per thousand banana plants is available.

iv) Tutti-Frutti

The papain extracted papaya and water melon rind after removal of green portion are most suited for the production of tutti-frutti. For this the raw material is needed to cut into small cubes and dipped in sugar syrup. You can give any colour to the syrup of your choice. The tutti-frutti is used in cakes, ice cream, bakery products, etc.

v) Amchur / pickle

Large quantities of dropped green mangoes are available in orchards after dust and thunder-storms. These dropped mangoes may be used for the preparation of pickles, amchur and raw mango slices.

vi) Food grade flavours

Citrus is a good source of flavour. It is a by-product from shaved citrus peel. You can obtain the shaved peel by shaving the spongy albedo layer of the peel and then the flavour is extracted. The flavour life is enhanced by encapsulation so it is adopted to keep the citrus oil-based flavours safe.

vii) Chutney

You can utilize fresh apple pomace, grape pomace, mango and tomato wastes to prepare chutney of various tastes and colours.

viii) Edible oil

You can obtain edible oil from apricot kernel, grape seed and citrus seed. Apricot oil and kernel paste are used like almond oil and paste in cosmetics and pharmaceutical preparations. Grape oil is used to produce grape resins of lustrous appearance. Tomato seed oil is golden in colour. It is used as salad oil.

ix) Cheese and halwa

Guava core, seeds and peel are utilized for the preparation of cheese and halwa. There are certain varieties of banana which have thick peel. The pulpy portion from the thick peel is scraped and used to make cheese.

x) Flour and fortified atta

You can prepare flour of jack fruit seeds, mango kernel and residues left after extracting juice or the unmarketable surplus of fruits like anola and jamun, and vegetables like carrot, radish, spinach, tomato, bitter gourd, etc., by drying and powdering. The flour may be blended with cereal flour. This powder can be mixed with the wheat flour in 1.5 to 3.0 proportions. This flour contains 5.56-11.5 per cent protein, 16.1 per cent fat, 0.35 per cent minerals and 69.2 per cent carbohydrate. You can market it as a health protective flour.

xi) Jam and jelly

You can use apple pomace to make jelly. The thick rind and inner perigones of jack fruit is also used for preparation of high class jelly. White apricot kernel is added to apricot jam to make it more attractive.

xii) Marmalade

You know that marmalade is prepared from citrus peel. The process involves washing of fruit peel, slicing or comminuting the peel, boiling to tenderize and remove bitterness, cooking with sugar or fruit syrup, and adding pectin.

xiii) Candied peel

You can prepare candied peel from orange or grape fruit peel. The primary use is in baking, where candied peel is a condiment used for flavour, appearance, and texture in products like fruitcakes. The peels are cooked to tenderize, remove bitterness and undesirable flavours, drain and dice. The diced peel is equilibrated and cooked in sugar syrup and food dyes are added. The final product is drained, air dried and packaged in polyethylene containers after coating with fine dust of corn starch.

xiv) Citrus purées and bases

You can utilize citrus pulp and unconsumed fruits to manufacture purees and bases. Preparation generally involves grinding, pasteurizing, addition of pectinase to reduce viscosity, comminuting to make a paste of smooth puree, followed by sieving to remove broken seed hulls and non-disintegrated particles. Different preparations are used for different product base purees.

Table 10.1: Possible by-products from solid wastes in fruit processing units

Fruit / vegetable	Waste (%)	Nature of waste	By-products
Apple	20-30	*Pomace*	Juice, wine, vinegar, pectin cattle feed
Citrus Orange	50	Peel, seeds, pulp	Essential oil, pectin, cattle feed, peel candy, pulp wash etc
Lime	60	Peel, seeds, pulp	Essential oil, pectin, cattle feed, peel candy, etc
Mango	40-60	Peel, Stones, Pulper waste	Pectin, cattle feed, alcohol, fat, starch, tannins, vinegar
Mango peels	12-15	Peel and pulp	Pectin, alcohol, cattle feed
Mango pulper waste	5-10	Fibre	Wine, vinegar, juice
Mango Kernels	15-20	Hull & Kernel	fat, tannins, starch
Pine-apple	30-60	Peel, leaves, core, trimmings, shreads	Brome line, cattle feed, biogas, fiber
Tomato	20-30	Core, peels and seeds	Cattle feed, seed oil and meal
Potato	10-11	Peel and coarse solid	Cattle feed, single cell protein
Banana	20-30	Peel	Poultry and cattle feed
Banana	20-25	Pseudo stem	5% starch
Banana dry leave	20-25 /plant	Dry leave	Cups and Trays
Banana	20-25/plant	Green leave	To serve meals

10.4 INDUSTRIAL PRODUCTS FROM FRUIT AND VEGETABLE WASTES

Apart from utilizing the solid waste for preparation of some products as discussed above, it could also be used for the preparation of some industrial products. Some of these products are described below:

i) Industrial oil

Cashew shell contains about 20 per cent oil and resin. You can use this oil for insulation of electric wiring, break lining and preparing foundry moulds and cores. In many countries cashew shell is finding better place than the cashew nuts. Other sources of sweet and bitter oil are the waste of wild apricots (*chulli*), peach kernels, citrus seed and tomato seed. These oils are used in cosmetics and pharmaceutical, and after refining in food items.

ii) Pectin

Pectin is a by-product of mango and citrus peel, apple pomace, raw papaya, cashew apple, etc. Pectin is used for making jam, pharmaceutical preparations and industrial uses.

iii) Essential oil

Do you know that citrus wastes are a rich source of essential oil? You can extract peel oil in small- scale unit. For such unit you can get fresh peel from fresh-juice vending stands. There are two systems of oil extraction. One, cold pressing and second steam distillation. You can choose any one of these. The current production potential of essential oil is more than 15,000 tonnes per annum.

iv) Natural colour

You know that coaltar dyes have carcinogenic effects. Therefore, it is better to replace them as rapidly as possible the herbal or natural colours. Industries are now extracting colours from blue grape skins, kokum (*Garcinia indica*), phalsa (*Grewia subinaequalis*), jamun, safflower, etc. Methods are also available to produce colour concentrates and powders.

v) Cups and plates

A banana plant contains 20-25 green leaves. Farmers harvest banana along with the plant. The green and dried leaves are used to prepare disposable cups and plates to serve meals.

vi) Other industrial uses

Beside the products described above, there are numerous other items which can be prepared from the fruit and vegetable wastes. The few important ones are:

- Citric acid from lemon peel
- Varnish and resin from tomato peel
- Surfactantants, wetting agents and detergents from tomato seed meal
- Citrus seed and mango kernel oils for soaps and detergents
- Glucosides and bioflavins anti-oxidants from citrus peel
- Papaya latex for proteolytic enzyme papain
- Paper pulp from banana stem
- Fibre from pineapple leaves, mango peel and apple pomace

10.5 ANIMAL FEED FROM WASTES

We know that wastes and by-products obtainable from fruits and vegetables are a good source of cattle and poultry feed. Let us know how to utilize the major wastes for feed.

i) Citrus wet peel

Citrus peel contains 6% protein, 5% fat, 12% crude fibre, 7% ash and about 60% nitrogen-free extract. Wet peel contains 70-90% moisture. Wet peel or fresh peel is consumed by the animals directly. This practice is feasible only in the close vicinity of peel availability. Life of wet peel is very short due to rapid decay and sap leakage through transport trailer. It is transportable to only short distances. You can overcome this problem by pressing the wet peel where about 10% moisture is removed. This is called press liquor. Before pressing, you must treat the peel by lime. Storability and transportability of lime treated pressed peel is more as compared to wet peel.

ii) Citrus dried peel

Dried citrus peel is the most common form of animal feed. Before drying, peel is shreded and treated with 0.2 per cent lime. The lime aids in breaking down the pectin and in turn releasing the pectin-bond moisture. The peel is then pressed to remove the moisture. The peel is dried mechanically or in the sun. Process the dry peel into pellets or powder bran. You can use citric molasses as a binding agent. Pellets are easy to feed, easy to store and easy to handle and transport.

iii) Skin, core, trimmings, shreds and leaves

Skin, core, trimmings, seeds, shreds, leaves and pomace make a good cattle feed. One can feed them directly to the animals or dry for future use in various forms. You can also ensile them with rice/wheat straw or with stovers of millets and maize in 1:10 proportion with 1 per cent molasses and 0.2 per cent urea.

iv) Wet pineapple bran

The pineapple skin and ends are the major source of pineapple bran. The process involves maceration of the material and pressing. The pressed material is called wet pineapple bran. In this state it is easier to handle and store for short duration.

v) Dry pineapple bran

It is dried form of wet bran. The dried stuff is easy to handle, store and transport. The citrus peel, pomace of different fruits, residues of vegetables and pineapple bran can be dried in sun, polyhouse or rotary drier. The pineapple press liquor has about the same composition as pineapple juice. It can be concentrated and mixed with bran. You can sell such bran in market as concentrate feed for animal.

vi) Poultry feed

You can prepare quality poultry feed from banana peel, mango seed kernel, dried mango peel and citrus and tomato seeds. The dried peel is milled and used as poultry feed. Citrus seed meal contains 32.5 per cent protein, 7.5 per cent fat and 8.0% crude fibre. Tomato seed meal contains 37 per cent protein. It is energy food for poultry feed. Similarly, apricot kernel oil cake is also rich in protein.

vii) Tomato waste

Tomato waste is available in the form of peel, seed and pomace. After extracting varnish from peel and oil from seed, you get marc or solids. This amounts to 12.4% of fresh tomatoes. The marc contains 8-10 per cent protein and 10-12 per cent fat. Therefore, it is a good source of cattle feed.

viii) Molasses

The extract of mango and citrus waste such as peel, peel juice, pomace and trimmings is raw material to produce feed grade molasses. You can either feed it to the animals in liquid form or convert it into molasses. The waste is collected and lime is added to raise the pH. A reaction time of about 18 minutes is given in the mixing tank. The mixture is pressed and the press liquor is collected in a tank. The residue left after extraction of press liquor is dried. The press liquor is concentrated into molasses by evaporating the liquor to a brix value of 72.

10.6 PULP WASH, RECOVERY AND UTILIZATION

i) Pulp washing process

During the process of juice extraction you get pulp and pulpy juice as by-products. Scientifically they are called Water Extracted Soluble Fruit Solids (WESFS) or Washed Pulp Solids. For efficient extraction, you can use four-staged countercurrent pulp washing system. Each stage has screw type mixing device. The pulp put into the process at stage-1 exits at stage –4 as spent pulp. Pure water enters at stage-4 and exits at stage-1 as the pulp wash or strong liquor. The average Brix value of orange pulp wash are in the range of 4-7°Brix. The spent pulp goes for feed. The pulp wash is either concentrated or combined with juice which goes for concentration.

Towards the end of fruit season, soluble pectin in the pulp wash increases. This happens especially in grape fruits. The soluble pectin increases viscosity of the strong liquor which retards the concentration process of strong liquor. You can use pectinolytic enzymes to overcome this problem. This enzyme facilitates in viscosity reduction. Manufacturers of juice, beverages and drink products use pulp wash concentrate. This adds fruit solids and natural cloudiness to juice and beverages. This is also cheaper than juice concentrate.

ii) Juice pulp recovery

During juice recovery, the juice contains part of ruptured juice vesicles or floating pulp. This pulp is recovered as a by-product. The juice first goes to a paddle finisher to remove seeds and rag. Then the pulpy juice passes to a conical cyclone separator, called hydrocylone, to remove the embryonic seeds and other defects. The pulpy juice comes out at the top of the hydrocyclone and goes to pasteurizer and again to finisher (screen) for separation of pulp and juice.

This pulp is used for blending in juice concentrates. It adds texture, body and pulpy character to the reconstituted juices or drinks.

iii) Whole juice sacks or edible tissue

The dried juice sack is a by-product of juice from grape fruits and lemons. It has application in number of food products. It is a functional food ingredient. It imparts textural properties. It increases the water binding and retention property of products. The dried juice sacs hydrate readily. It can mute flavour in some food products. The potential uses are: to provide pulp for dry beverages mixes, to provide thickening or gelling in jams, sauces, fibre breads, cake, cookies and cereals.

To separate out the sacks, you need to peel and sectionize the fruit. Now carry out vigorous agitating and rinsing. The sacks start floating in the mixture which recovered by passing the mixture over a vibrating screen. Now dry the sacks carefully in the poly house or mechanical drier.

iv) Peel fiber

Considerable interest has been generated recently in using the fibre in human diet. It is a by-product left after pectin recovery from peel of many fruits like citrus, apple, mango, etc. The pectin free dried peel contains about 60 per cent dietary fibre. This fibre ranks with cereal bran in importance. The manufacturing process involves chopping the residue into small pieces, reacting with calcium hydroxide, pressing to remove soluble sugars and water, blending with sesame flour, dehydration to 8 per cent moisture, and milling to an acceptable small particle size.

10.7 FERMENTATIVE UTILIZATION OF FRUIT AND VEGETABLE WASTE

It is already clear to us that wastes from fruits and vegetables processing industries are valuable natural resources for many products. They have enormous economic potential. We can make a number of value-added products from these wastes. Principally the waste include water and organic substances. The organic substances are simple and complex polysaccharides (sugars, starch, pectin, etc.), vitamins and minerals. Utilization of the wastewater has been discussed under Unit 10.8. Here we will deal with the conversion of organic substances into value-added products through microbial fermentation technology.

The value added products obtainable from fruit and vegetable wastes are:

i) Fermented edible products
ii) Single cell protein
iii) Animal feed
iv) Ethanol
v) Enzyme
vi) Food additives
vii) Organic compounds
viii) Biogas

i) Fermentable edible products

You can prepare a number of beverages such as cider, beer, wine and brandy, and vinegar by fermentation of fruit wastes.

Cider: Dried, culled, undersized, substandard and unmarketable surplus of apples, grapes, oranges, pineapple and their by-products such as pomace are suitable for cider making. Cider is obtained by combining the distillates from fermented pomace with fermented juice. It contains 1 to 8 per cent alcohol, 4 per cent acetic acid, 5 ppm Cu, 10 ppm Fe, and 1 ppm Pb.

Vinegar: You can use mango peel and stones to prepare mango vinegar. We know that fermentable sugars adhere to the fruit processing waste. It is an ideal substrate for fermentation. The alcoholic level in this fermentation remains between 2.5 to 3.5 per cent. This quantity is not sufficient for alcoholic fermentation. Therefore, you need to raise this level by conducting secondary fermentation or by adding cane sugar. The batch type process takes 3-12 days for completion. You can produce mango vinegar by recycling of *Saccharomyces cerevisiae* and immobilized *Acetobacter aceti.* The good quality vinegar will have 5.3 per cent acetic acid, light yellow colour and pleasant flavour. Similarly, we can prepare vinegar from the substandard and unmarketable fruits of plum, pineapple, banana, etc.

ii) Single cell proteins (SCP)

SCP is a non-conventional source of protein. Microbial growth and microbial biomass are the basis for SCP. A number of organisms like yeast, fungi, algae and bacteria are employed for the production of SCP on different kind of substrates (Table 10.2). You can use SCP as protein supplement for food and feed.

Table 10.2: Different substrates and microorganisms to produce SCP

Name of substrate	Microorganism used	Effect on protein content or BOD
Pectin extracted apple pomace	*Trichoderma viride,* *Aspergillus niger* *Candida utilis*	35% content protein
Grape waste and pressed apple pulp	*Aspergillus niger*	35% content protein
Pineapple waste and citrus peel	*Fusarium*	35% content protein
Cassava waste	*Aspergillus niger* *Endomycopsis fibuliger* *Candida utilis* *Aspergillus tomari*	20-22.5% content protein
Molasses	*Saccharomyces cerevisiae* *Torulopsis utilis*	40-47% content protein
Potato peels and wastes from grape and orange	*Pliorotus astreatus* *S. fibuliger* *C. utilis*	31.6% content protein
Sweet potato waste	*fungi imperfecti*	31.6% content protein

The different wastes support the growth of different microorganisms. The microorganisms use these substances as starting materials for fermentation and SCP production by assimilation.

iii) Animal feed

The wastes obtained from processing of fruits and vegetables are rich in fibre but poor in protein content. Owing to their low protein content and low digestibility, these are poor sources of animal feed. You can increase the feed value of these waste materials through substrate fermentation technique. The various substrates and microorganisms employed for preparation of animal feed are given in the Table 10.2.

iv) Ethanol

You can produce ethanol from wastes of fruit and vegetable processing industries. These wastes are rich in cellulose, hemi cellulose and lignins. Solid-state fermentation (SSF) technique is useful to produce ethanol. The ethanol has several uses such as liquid fuel or liquid fuel supplement or solvent for many industries. Apple pomace, cherry wastes, citrus wastes, etc., can produce ethanol by employing *Saccharomyces cerevisiae, Candia utilis* and *Torula* for apple pomace, *S. cerevisiae* for citrus waste, and *E. coli* and *Klebsiella oxyloca* for lignocellulosic wastes.

v) Enzyme

Submerged fermentation (SF) and solid-state fermentation (SSF) techniques are useful for enzyme production. Food production industries have wider application of various enzymes. Different enzymes can be produced by fermenting different wastes of fruits and vegetables. For this you need different types of microorganisms. To produce cellulase and xylanase enzymes from apple pomace you need *T. viridae and Aspergillus spp* as microorganisms. Similarly to produce cellulase, xylanase and ligninase from grape wine waste you need *Cerrena unicolor*.

vi) Food additives

Brewery wastes, apple pomace, pineapple residues, molasses, sweet potato residue, mandarine orange wastes, grape pomace, etc., are potential sources for citric acid production. Industries utilize solid-state fermentation (SSF) technique to produce citric acid on commercial scale. They use microorganisms *Aspergillus niger* for SSF.

You can also produce pectin by growing microorganisms on wastes. *Trichosporon penicilliatum* is the most common microorganism grown over citrus peel for production of pectin. This pectin has high level of neutral sugar and molecular weight.

The use of colours to the food is an ancient practice. Earlier people used natural colours. But now, people turned to the coal tar dyes. These synthetic colours adversely effect our health. On the other hand, the microbial colours have anti- neoplastic activity. Therefore, encouragement is being given to produce microbial colours from the wastes of fruits and vegetables. Microorganisms like *Rhodotorula*, *Cruptococcus*, *Phoffia rhodozyma*, *Monoascus purpureus* and *Bacillus spp* are known to produce pigments through fermentation techniques.

Wastes available from fruits and vegetables are the cheapest renewable sources to produce flavours and gums. Microorganisms can produce specific flavours and aromas like fruity, spicy, *pyrazines*, *terpenes*, *lactones* and esters. Microbial enzymes like *lipase* are used to generate flavours. Similarly, microorganisms can also produce microbial gums like xanthan. *Xanthamonas compestris* are employed to produce xanthan from cabbage and citrus wastes.

vii) Organic compounds

The organic compounds like butamol, acetone, citric acid, lactic acid and acetic acid are produced through microbial fermentation of wastes molasses. 2, 3-butylenes glycol can be produced by fermenting citrus peel juice and citrus waste after adding molasses.

viii) Biogas

Biogas is an important by-product prepared from numerous agricultural wastes. Fruit and vegetable processing waste is rich in biodegradable substances and can be used for the production of biogas. It is produced by anaerobic digestion of the waste. Methanotropic bacteria like *Methanobacterium* and *Methanococus* spp have the ability to utilize CO_2 from these wastes to produce methane – a biogas. Sometimes, pretreatment of the wastes is useful for higher methane production.

10.8 FRUIT AND VEGETABLES PROCESSING WASTEWATER TREATMENT AND UTILIZATION

You know that the fruit and vegetable processing industries generate a lot of waste water containing organic material. This waste has high Biological

Oxygen Demand (BOD). BOD is the measured amount of oxygen required by acclimated micro-organism to biologically degrade the organic matter in the waste water to CO_2 and H_2O in a closed system. Oxygen consumed or BOD is proportional to the organic matter converted. If you discharge this waste in the natural water stream without treatment, it will deplete the dissolved oxygen. As a result of this the fish and other biological life in water will parish. The stream water will also become unfit for any domestic use.

The major characteristics of wastewater are pH, total suspended solids (TSS), BOD, oil and grease and nutrients (nitrogen and phosphorous) available for bacterial growth. The quantitative characteristics of some selected fruit and vegetable processing industries are given in the Tables 10.3 and 10.4 below.

Table 10.3: Wastewater characteristics from some selected fruit and vegetable processing industries

Fruit/Vegetable processed	Wastewater (kg / tonne of raw product)	BOD (kg / tonne of raw product)	TSS (kg / tonne of raw product)
Apple	10	09.0	02.2
Apricots	23	20.0	04.9
Dry beans	37	30.0	21.0
Beets	11	26.5	11.0
Carrot	14	15.0	03.5
Cauliflower	71	8.0	03.0
Mushrooms	33	7.0	03.6
Olives	34	13.5	13.0
Peaches	13	17.5	04.3
Pears	15	25.0	-
Plums	10	05.0	01.0
Pickles	15	21.0	04.1
Potatoes/Sweet potato	09	46.5	28.1
Pumpkin	01.2	16.0	38.1

Table 10.4: Wastewater characteristics of some fruit juices

Type of juice production	pH range	BOD range (g/L)	COD range (g/L)
Apple	3.2-3.4	61.5-94.5	85.0-155.0
Orange	3.6-3.8	60.9-5.0	83.4-134.6
Pear	3.2-3.6	88.0-109.2	72.8-175.3
Apricot	3.5	105	194.0
Peach	3.2	100	174.2
Mixed	3.2	65	95.5
Banana	4.1	110	184.1
Grape, white	3.2	80.0-89.0	116.8
Grape, red	2.9	78.0-99.0	115.6

Vegetable	3.8	20.0	050.0

The wastewater from fruit and vegetable industry is not really a waste. It is a useful by-product or a resource material. You can recover the following useful materials from the wastewater as by-product.

- pectin from apple waste
- essences from citrus peels
- alcohol by solid state fermentation
- feed from pomace
- soup and chutney from mushroom wastes
- single cell protein from potato wastes

I. By-product recovery and treatments

The waste water contains oil and grease, suspended solids and organic load. The following steps are involved in recovery of the by-products from waste water.

a) *Screening or removal of solids*

You can remove the floating and suspended matter by passing the wastewater through 20-40 mesh stationery screen or vibrating gyro screens.

b) *Oil and grease removal*

Remove the oil and grease present in wastewater using the principle of density variation in water and oil. You can construct skimming tanks with baffle walls of 24 to 30 min retention capacity for this purpose.

c) *Primary clarification*

Primary clarification is also termed as primary settling. It separates the solids from liquid. The solid particles settle on bottom of tank under gravity. The clarifier is also equipped with oil and grease removal mechanism. It has peripheral drive mechanism for scrapping of sludge. About 50-60 per cent all the settleable solids can be removed by primary clarification. BOD is also reduced to the extent of 25 - 30 per cent.

d) *Aerobic biological treatment*

In this system dissolved starches, sugars and other carbohydrates are utilized by the micro organisms as food. In the process, more bacteria get generated and later get converted to waste bacterial solids. Proper conditions are maintained for bacterial growth through the supply of oxygen and nutrients.

e) *Activated sludge process*

The wastewater is first collected in primary settling tank where 50-60 percent of all settleable solids are separated. The clarified wastewater then flows into the aeration tank where more and more bacteria get generated. Thereafter, the wastewater flows into the secondary settling tank. A part of the activated sludge is returned to the outlet of primary settling tank. This hastens the multiplication of bacteria in the secondary tank. It is aerated in the aeration tank to keep on the bacteria multiplying. BOD removal efficiency of this process ranges between 80 to 85 percent.

f) *Trickling filter*

Trickling filter is a circular tank of about 1.8 m depth. Its width is designed on the basis of the quantity of wastewater. The tank is filled with 100-125 mm aggregates of stones or plastic balls. Wastewater is sprayed on the aggregates with a rotating arm. Microorganisms develop around the aggregates. A microbial film is formed on the surface of the aggregates. This film oxidizes the organic matter present in the wastewater. In this process you can get BOD reduction of 70 - 85 per cent.

g) *Aerated lagoons*

Aerated lagoons are simple wastewater holding basins of 2-4 m depth. The organic wastewater is degraded by aerobic microorganisms. Floating mechanical aerators are fitted for the supply of oxygen. A BOD reduction of 80-95 per cent can be achieved in this method in a retention period of 4-5 days.

h) *Waste stabilization ponds*

This is a natural process of wastewater treatment. The ponds are usually used where land is cheap and temperature is moderate. The pond depth is 0.9 to 1.5 m and area depends on the volume of the wastewater. The wastewater is treated and stabilized by a combination of aerobic, anaerobic and facultative bacteria. In a retention period of 10-40 days it can remove BOD from 80-95 per cent.

i) *Oxidation ditch*

It is an oval shaped closed channel of 1-1.5 m depth. Cage rotors are used for intensive aeration of the waste water. In retention period of 10- 40 days it can remove BOD from 80-95 per cent.

j) *Rotating biological contactors*

The system consists of concrete or steel tank through which the wastewater passes. The rotating biological contactors consist of polymeric material discs. These discs are closely spaced and mounted on a shaft. A drive motor rotates the shaft at a very slow speed of 2 - 3 rpm. The discs are submerged in wastewater tank. When the discs rotate, the wastewater passes through them continuously. The discs expose to wastewater and atmospheric oxygen alternatively. Like this a bio film develops on the disc's surface. In this process BOD reduction is achievable to the extent of 90 per cent.

k) *Activated biofilter process*

The activated bio filter is a biologically active column. It is made biologically active by the return sludge. High level concentrated suspended growth of microorganisms can be obtained in the filter. Achievable BOD removal is quite high in this filter.

l) *Combined activated bio filter and activated sludge process*

It is a combination of activated bio filter and aeration tank You can achieve best performance and economics by combining aerobic treatment process with activated bio filter. It is becoming popular due to higher organic loading rate, better BOD reduction and lower cost of construction.

II. Bio-energy production

You can utilize the wastewater obtainable from fruit and vegetable processing industries to produce bio-energy through anaerobic biological treatment.

Anaerobic biological treatment process proceeds in two steps. The first step is, degradation of organic matter or waste into volatile acids. In the second step, the volatile acids convert into methane gas. It is an improvement over the conventional anaerobic biological system which takes 30-60 days to complete the treatment process. The two-stage anaerobic reactor enhances energy production and reduces hydraulic retention time to 1-4 days. Layout of the system is shown in Figure 10.1.

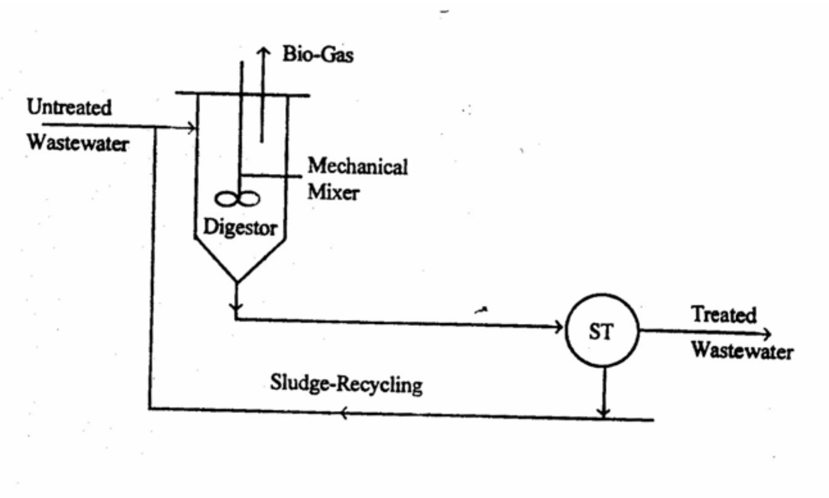

Figure 10.1: Anaerobic biological treatment

III. Utilization of organic solids for soil improvement

a) *Solid waste from wastewater treatment plant*

The secondary sludge obtained in these systems need drying. You can use sludge drying beds or the ground drying method. This can be used as a good quality compost for agricultural crops. You can palletize this organic waste for direct drilling along with the seeds for better production. Pelletization also helps in storage and economic transportation to distant places.

b) *Land application*

The wastewater after primary and secondary treatment becomes suitable for land application. You can use this water for irrigation.

c) *Wet land application by macrophyte treatment*

To utilize the treated wastewater artificial wet lands such as marshes and swamps are created. Floating plants, like water hyacinth, serve as mechanical filters. The wet land becomes useful to grow crops and aquatic species. Fish ponds can also be constructed for economic recovery.

10.9 LET US SUM UP

The left over materials after processing of fruit and vegetables into various products are termed as waste. The waste is of two types, viz. solid and liquid. Solid wastes are peel, stone, seeds, trimmings, core, etc. Liquid waste is the wastewater coming out of the processing plant after washing, peeling, sterilizing, etc., of the food stuffs and the machinery.

The solid wastes could either be utilized as such, e.g., animal feed, or a number of by-products could be prepared. Through chemical extractions dietary fibre, pectin, pigments, etc. could be obtained. The microbial fermentation of waste could produce biogas, citric acid, vinegar, ethanol, enzymes, etc.

The wastewater from fruits and vegetable processing industries is a resource for many useful materials such as pectin, essences, alcohol, soup, feed, fuel, manure, etc. Treatment and utilization of wastewater is important both for environmental protection and economic returns. This wastewater has higher and immediate BOD because of the availability of soluble sugars which have a rapid rate of oxidation. The wastewater treatment strategy includes by-product recovery, screening for separation of solids, neutralization, oil and grease removal, equalization, and aerobic, anaerobic and combination of aerobic and anaerobic processes. The solid wastes can be palletized and used as manure.

10.10 KEY WORDS

Aerobic	:	Reaction or biological degradation in presence of air/oxygen.
Anaerobic	:	Reaction or biological degradation in absence of air/oxygen.
Activated sludge	:	Sludge with microbial activity.

Biogas	**:**	Microbial production of methane by *methanotropic* bacteria.
Biodegradable substances	**:**	The biomass convertible by microorganisms.
By-products	**:**	The products manufactured from the leftover materials obtained during processing of fruits and vegetables.
BOD	**:**	Biological oxygen demand measures amount of O_2 required by acclimated microorganism to degrade organic matter biologically.
Cloud	**:**	Unprecipitable suspension of the insoluble essential oils, pectins, lipids and proteins in juice.
Cider	**:**	A product obtained after fermentation of pomace.
COD	**:**	Chamical oxygen demand.
Dietary fibre	**:**	Insoluble hemi cellulose and cellulose, obtained from wastes.
Molasses	**:**	Concentrated form of pre treated juice.
Microbial pigment	**:**	The colour obtained by microbial fermentation of fruit and vegetable wastes is termed as microbial pigment.
Pulp wash	:	Residue obtained by washing the pulp.
Peel seasoning	**:**	Carefully cleaning and drying of peel at low temperature for maintaining the volatile oils.
Pulp wash concentrate	**:**	Evaporated juice or strong liquor up to 50-65°Brix.
Residue	**:**	Leftover materials during consumption and processing.
Single cell protein	**:**	It is microbial biomass used as food supplement.
Strong liquor	:	Liqour obtained during multi-stage extraction of pulp wash having TSS between 4-7°Brix.
Spent pulp	**:**	Residue of pulp wash after extracting strong liquor.
Wastes	**:**	The culled, undersized, disfigured, substandard, spoiled, injured, unmarketable surplus of fruits and vegetables and the leftover materials during by-products utilization including washing are termed as waste.
Whole juice cells	**:**	Juice containing vesicles or sacs.

10.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answer should include the following points:

1. • Wastes are of two types – solids and liquid.
   • Solid wastes are peel, pomace, seed trimmings, core, etc.
   • Liquid waste is the wastewater coming out of the factory after washing fruits, vegetables, machinery, etc.

2. Important food products are fat, starch, magaz, tutti-frutti, jam, jelly, marmalade, chutney, pickle, amchur, flavour, cheese, halwa, health flour, etc.

3. Important industrial products are oils, essential oils, pectin, colours, varnish, surfactants, fibre, glucosides, citric acid, paper pulp, etc.

4. Fat ---*Mango kernel* ; Starch---*Mango kernel;* .Magaz---*Musk melon;* Natural colour---*Blue grape skin;* Essential oil---*Citrus waste;* Amchur---Dropped m*ango;* Cheese---Guava waste; Health Flour---Jack fruit seeds.

Check Your Progress Exercise 2

Your answer should include the following points:

1. Important wastes are peel, pomace, seed, leaves, trimmings, core, etc.

2. Wastes such as banana peel, mango peel, mango seed kernel, citrus and tomato seeds are used as poultry feed.

3. Skin and ends of the pineapple constitute the bran. There are two types of pineapple bran, i.e., wet and dry.

   • The wet bran is prepared by macerating ends and skins and then pressing.
   • Mechanical and natural drying of bran constituents resulted in dry bran.

4. • Molasses is the concentrated form of pressed liquor obtained by treating waste with lime.
   • Raw materials used are peel, pomace, trimmings etc., obtained after processing of mango and citrus fruits.

Check Your Progress Exercise 3

Your answer should include the following points:

1. • The water washings of the pulp remained after juice extraction is known as pulp wash.
   • The solids extracted in the water wash are termed as pulp wash solids.

2. • Juice pulp is the ruptured juice vesicles or floating pulp obtained during juice recovery.
   • It is used for blending in juice concentrates.

3. • The juice sacks are the by-product obtained from the juice of grape fruit and lemon.
   • The juice sacks are dried and used in dry beverages mixes, jams, sauces, cookies, etc.

Check Your Progress Exercise 4

Your answer should include the following points:

1. The important products obtainable from organic waste substances from fruits and vegetable processing industries are single cell protein, animal feed, ethanol, enzyme, pigment, pectin, flavour, etc.

2. The vinegar can be produced from mango peel and stones by double fermentation. The TSS of these wastes is increased by adding came sugar and fermentation is done with *Saccharomyces cerevibial* and immobilized *Acetobacter acet*.

3. The protein supplement obtained from microbial growth and microbial biomass are called SCP. The protein content can be enhance and upto 35 per cent. The microorganisms used for SCP production are *Trichodemia uiride, A.niger, Candia utilis, Fusarium* sp, *A. tomari, S. cerevisiae, S. fibuliqer.*

4. The pigments that are produced through microbial fermentation on fruit and vegetable wastes are called microbial pigments. The microorganism like *Rhodotorula, Cruptococcus*, etc. are known to produce pigments.

Check Your Progress Exercise 5

Your answer should include the following points:

1. • The wastewater discharged from processing industries contain organic matter which have high BOD values.
   • If the waste is discharged without treatment it will deplete the dissolved oxygen.

2. • Screening or Removal of Solids
   • Oil and Grease Removal
   • *Primary Clarification*

3. • The process of bio-gas generation
   • Labelled sketch of the system and its working (10.1)

4. • The separated solid waste could be used as compost.
   • Palletization helps in storage and transportation.

UNIT 11 FOOD FORTIFICATION

Structure

11.0 OBJECTIVES

After reading this unit, you should be able to:

- list the advantages, limitations and risks in fortifying foods;
- describe the methods of food fortification;
- define the importance of fruits and vegetables in human diet;
- decide the points to be considered for fortification of fruit and vegetable products; and
- prepare fortified fruit and vegetable products.

11.1 INTRODUCTION

All living beings require nutrients to perform various functions of life. While plants can prepare them from simple chemicals present in the soil and the environment, higher organisms can not perform this synthesis and have to depend on plants and other animals for their nutritional requirements. Body performs several functions related to growth and development and it has to cope up with the normal wear and tear process. Several nutrients are required for promoting these activities which should be available in sufficient quantity. But no single food contains all the nutrients; their nature and quantity vary with the source. Improper diet may result in deficiency of one or more of these nutrients. Nutritional deficiencies reduce mental and physical efficiency of people and increase their susceptibility to diseases. It is for this reason the Indian Constitution enshrines in its Article 47 that “the state shall regard the raising of the level of nutrition --- as among its primary duties”. In this chapter we will see how fortification of fruits and vegetables could improve the nutritional status of people.

11.2 NECESSITY OF FOOD FORTIFICATION

11.2.1 Nutritional Requirements of Man

Human body requires at least 45 nutrients; 5 macronutrients (protein, fat, carbohydrate, water and oxygen) and 40 micronutrients, which include 13 vitamins (A, C, D, E, K and eight members of vitamin B group) and 17 minerals (Ca, Cl, Fe, K, Mg, Na, P, and S whose requirements are 1 µg to 1 g per day, and Cr, Co, Cu, F, I, Mn, Mo, Se, and Zn which are required in traces). Water and oxygen are not regarded as nutrients because they are present in foods and readily available for body use.

Nutrient requirements vary from person to person and are influenced by factors like age, sex, height, physiological state, physical activity and environmental conditions. No single food contains all 45 nutrients. Food items included in daily diet should be carefully selected so that the nutritional requirements are fulfilled.

11.2.2 Pattern of Food Consumption in India

In order to survive, man's main effort in ancient times was to collect enough food for his requirements and store them for difficult periods. But he soon realized that foods from different sources differ in nutritive value. Through experience over ages, he selected his foods carefully to meet his nutritional requirements and to ensure a good health. It led to the development of dietary habits. Food habits were also influenced by the foods available in the locality and practices prevalent among them.

Indian Council of Medical Research has divided the foods consumed in India into five groups: (1) cereals, grains and their products, (2) pulses and legumes, (3) fruits and vegetables, (4) milk, meat, egg and their products, and (5) fats and sugars. Cereals constitute major part of the Indian diet. Being rich in carbohydrates, they contribute up to 80 per cent of daily energy intake and about 50 per cent of daily protein intake of an average Indian. They are also dietary source of minerals like calcium, iron and vitamin B.

Pulses and legumes are the major source of proteins in the Indian diet. They are also rich in vitamin B.

Fats and oils and sugar/jaggery serve essentially as source of energy. They improve palatability of foods. Further, fats and oils provide essential fatty acids and act as carrier of fat soluble vitamins. For a good health, maximum of 20 per cent calorie requirements should be derived from fats and oils.

Milk holds a high place in the Indian diet. Milk proteins are of very good quality. It is rich in calcium and riboflavin and is a good source of many other nutrients. But it is deficient in iron and vitamin C.

Fruits and vegetables are rich in vitamin C, beta-carotene, crude fibre and minerals. In general, they are not regarded as a good source of calories and proteins; dried fruits, tree nuts, olives, avocado, beans and peas are some of the exceptions to this. Roots and tubers like potato, tapioca, yams, sweet potato, etc., contain substantial amount of starch and thus contribute substantially to the dietary calories.

Eggs and meat are good source of proteins and vitamins of group B. Their proteins are of very good quality. They are rich in calcium and riboflavin and are good source of many other nutrients.

11.2.3 Strategies to fulfil Nutritional Requirements

Inadequate and insufficient diet may result in deficiency of one or more of these nutrients. Often deficiency of one nutrient results in incomplete utilization of other nutrient(s) present in food. Nutritional deficiencies observed in India are: (i) protein-calorie malnutrition, (ii) vitamin A deficiency, (iii) iron deficiency, (iv) iodine deficiency, and (v) deficiency of vitamins of group B.

The challenge of nutritional deficiency can be overcome by increasing availability of nutrients through higher and diversified production of food and careful planning of diet. Diet planning becomes complicated because (i) foods differ in their nutrient composition, (ii) method of processing/preparation may cause losses, (iii) foods may suffer from certain deficiencies specific to a region such as iodine deficiency in Sub-Himalayan region, (iv) certain group of people may have special requirements of some of the nutrients, and (v) economic status of a group of people or population may limit the choice of food items. Further, all the nutrients present in a food may not be biologically available due to (i) the presence of anti-nutritional factors like trypsin inhibitor, (ii) their poor solubility, (iii) destruction of nutrients in the gastrointestinal tract, (iv) poor digestibility of a food source, or (v) varying degree of losses during preparation/processing.

Other methods of controlling malnutrition are (i) nutrition education, (ii) dietary diversification, (iii) dietary supplementation, and (iv) food fortification. Nutrition education and dietary diversification take long time to show results. Dietary supplementation is a very effective method but it is used in the cases of acute deficiencies in high-risk groups and is expensive. Food fortification is a simple and inexpensive method of fighting the problem of a nutritional deficiency prevalent in a known region or segment of population.

11.3 FOOD FORTIFICATION

The term food fortification is defined as a process of adding one or more dietary essentials to a food. Various terms are used to describe the process of addition of nutrients to foods which are discussed below.

i) **Enrichment:** This term is used for a process in which the level of one or more nutrients, already present in a food, is moderately increased by addition to make its level higher so that it becomes a richer source of that nutrient.

ii) **Fortification:** According to WHO fortification is the addition of nutrient(s) to a food or an article of diet to improve the quality of the diet of a group, community or a population. Level of nutrients added may be more than those found in original or comparable food. Objective of fortification is to help correct nutritional deficiencies in a specific population. Fortification may also include addition of small quantities of nutrient to improve intake of that nutrient by a population.

iii) **Nutrification:** It is a general term used to indicate the practice of adding vitamins and minerals to compounded and processed foods used as entire meals or meal-replacers, viz., infant formulas, instant breakfast foods etc.

iv) **Restoration:** Loss of some of the nutrients takes place during handling, transport, processing and storage of foods which can not be prevented. Restoration refers to the replacement of the nutrients lost during the above processes.

v) **Standardization:** There may be natural or seasonal variations in the nutrient composition of foods. The term standardization refers to the process of adding nutrients to compensate for the above variations and bring them to a predetermined level. It is helpful in meeting the requirements of nutritional labelling.

vi) **Supplementation:** This term refers to the process in which nutrients not present normally or contained only in very small quantities in a food, are added to it.

The above terms are often used interchangeably. Fortification is now a general term used to indicate addition of nutrients to improve nutritional quality of foods.

11.3.1 History of Food Fortification

Probably the earliest recorded attempt of fortification is of 4000 B.C. when the Persian physician Melamus prescribed a diet including sweet wine laced with iron filings for the sailors. In 1833 a French chemist Boussingault advocated addition of iodine to table salt to prevent goiter in South America and thus may have introduced the concept of "food fortification". Another important observation was made in 1897 when Dutch army doctor Eijkman while working in Indonesia, noted that beriberi was more common in people whose staple diet was polished rice. Vedder and Williams used a crude extract from rice bran, to cure advanced cases of beriberi despite the fact that they were unaware of its active constituent. In 1911, Funk established that the anti-beriberi compound of unpolished rice was an amine. He named this compound as vitamine, i.e., vital amine. Williams continued his work in Philippines and synthesized it. Since this amine contained sulphur, he named it as thiamine, i.e., sulphur amine. A Swiss company, Hoffman-Roche developed a process for adding thiamine, niacin and iron to rice.

Introduction of margarine, a butter substitute, in Denmark led to vitamin A deficiency. Therefore, fortification of margarine with vitamin A was started in 1918. Fortification of flour with thiamine, riboflavin, and niacin and sometimes iron and calcium was started in the United Stated of America during World War II. Addition of vitamin D to infant formulations and milk and dairy products to prevent rickets among children are other examples of early efforts of food fortification.

In India, fortification of salt with lysine, iron and vitamin A was tried in 1970. At present, several food products available in Indian market are fortified, viz., common salt is being fortified with iodine salts, vanaspati with vitamins A and D and bread with lysine. For fortification of salt with iodine, potassium and sodium salts of iodide and iodates are used. They are added at the rate of 30-200 mg per kilogram of salt, depending on the amount of salt consumed per day by a population. In India, salt consumption is 15 gm per day per person. Therefore, potassium iodate is added at the rate of 15 mg per kilogram of salt.

11.3.2 Advantages of Fortification

Food fortification does not require people to change their dietary habits and it does not alter organoleptic qualities of foods. Therefore, it is socially acceptable. The other benefits of fortification are (i) minimum risk of excess intake of the nutrient, ii) safe, quick and cheap method of ensuring availability of a nutrient, (iii) introduction through existing marketing and distribution system without any extra effort, (iv) every segment of affected population gets necessary amount of the nutrient, and (v) synthetic nutrients used in food fortification become available just after their absorption in the intestinal tract.

11.3.3 Limitations of Food Fortification

Food fortification requires knowledge of dietary habits and nutrient intakes in the target group(s). Consumers have to be educated about fortification, particularly if it is causing any change in the sensory qualities of the food or it necessitates any modification in the method of preparation of food at home. Food fortification is a temporary method of improving nutritional status of the people and should ultimately be substituted by balanced diet based on better food supply and food usage.

11.3.4 Safety of Food Fortification

Excessive intake of nutrients may sometimes lead to undesirable interactions with other nutrients. For example, excessive intake of an inorganic element can depress the absorption or utilization of another. Similarly, excessive intake of a strongly reducing nutrient, like vitamin C, can reduce absorption of selenium or carbon and strongly enhance bio-availability of iron. Higher intake of fat-soluble vitamins A and D exert toxic effect, while other vitamins are non-toxic even if ingested at high levels (up to 100 times of recommended level). The safety range is smaller for vitamin A (10 times of RDA) and iron (5 times of RDA). Level of food fortification generally ranges between 15 to 25% per serving, which is much below the critical levels.

In fortified food products, the level of fortification must be documented. Level of nutrients which amount to excessive intake should be established scientifically and the consumers should be made aware of such levels and their adverse effects. Response of consumers on quality of fortified foods, nutritional benefits or other relevant information must be collected and used to improve the product.

11.3.5 Methods of Fortification

Methods used for food fortification with nutrients are as follows:

i) *Dry mixing:* It is used for foods like salt, beverage powders, cereal products, milk powder, etc.

ii) *Dissolution in water:* The nutrients are dissolved in water or the product and mixed, e.g., fruit juices, beverages, drinks, etc.

iii) *Spraying:* Processed foods that require cooking or extrusion like potato chips, fruit bars, etc.

iv) *Dissolution in oil:* Oily products such as vanaspati are enriched by nutrients dissolved in oil.

v) *Adhesion:* It is used for sugar fortification. Vitamin A in powder form is adhered onto the surface of the sugar crystals when used with a vegetable oil.

vi) *Coating:* The vitamins sprayed over the grain must be coated to avoid losses when they are washed before cooking. It is generally used in case of rice.

vii) *Pelleting:* It is also used for rice. The vitamins are incorporated into pellets reconstituted from broken kernels.

11.4 FORTIFICATION OF FRUIT AND VEGETABLE PRODUCTS

Fruits and vegetables posses rich colour and have varied aroma. They add variety to the food, and improve aesthetic appeal of the diet. Fruits and vegetables are generally consumed for their aesthetic appeal but their nutritional significance is not fully realized by the consumers. They are rich sources of vitamins, minerals and dietary fibre. Dietary fibre (hemicelluloses, celluloses, lignins, oligosaccharides, pectin, gums and waxes) though resistant to digestion play an important role in human health. They do not provide nutrients directly, but low dietary fibre have been associated with diseases like cardiovascular diseases, obesity, diabetes, constipation, bowel cancer, etc. Daily intake of 30 g dietary fibre by a normal healthy adult has been suggested. Fruits and vegetables, in general, contain 1.0 to 2.2 % fibre and contribute up to 50% of dietary fibre. Fruits and vegetables, contribute about 90% of total dietary ascorbic acid, 50% of vitamin A, 35% of riboflavin, 25% of magnesium, 20% each of thiamine and niacin, 20% of fat, 7% protein and 10% of food energy.

Nutritional composition of fruits and vegetables depends on species, variety, location, season and agro-climatic conditions. Moreover, nutrient loss also occurs during storage, preparation and processing. Consumer may not be aware of these changes. Fortification helps in standardizing fruit and vegetable products to a pre-decided level of nutrients. It also enables processors to fortify the products to meet the nutrient requirements of specific group of people such as sport persons and athletes.

11.4.1 Principles of Fortification of Fruit and Vegetable Products

Following points are to be considered before fortifying a product:

1. *Principle of need:* There should be a deficiency/ malnutrition in a population which makes food fortification necessary.

2. *Principle of food distribution:* A proper carrier should be identified for fortification programme. Any such carrier that is consumed by a large population should be centrally processed and centrally distributed. Fortified food should be made available to the people who need them at their place.

3. *The principle of stability:* Nutrients should be stable during processing, storage and distribution. To compensate for these losses an overdose of nutrient is added. But for determining overdose, the maximum amount of

particular food likely to be consumed by an individual per day should be known, and it must be ensured that there is no excessive consumption of nutrient.

4. *Principle of compatibility:* Nutrient being used for fortification should be physiologically and chemically compatible to natural or other food ingredients. It is very important that the added nutrient does not react and remains biologically available.

5. *The principle of camouflage:* Fortification should not cause noticeable changes in sensory characteristics of food products. This is an important point to be considered during fortification.

6. *Principle of economy:* Cost of a fortified product is influenced by the cost of nutrient added, form of the nutrient, shelf life of the product and overages needed to achieve a specified shelf-life. Fortification should not make much difference in the cost of the food product.

7. *Principle of accessibility:* Standards and specifications for fortified food and methods of enforcing them should exist.

8. *Principle of disclosure:* The form and amount of nutrient used for fortification should be declared on the label so that the consumers could know it.

9. *Availability of technology and equipment:* Fortification on commercial scale requires special equipment, proven technology and skilled manpower. They should be available.

11.4.2 Fortified Fruit and Vegetable Products

Fruit and vegetable products generally selected for fortification are those which are consumed more regularly and therefore, can serve as a better carrier of nutrients. Beverages, juice concentrates, juice powders, fruit bars, jellies and jams are a few examples of such products. Fortification should ensure that the normal amount of that food product consumed in a day supplies the whole requirement of the consumer for that nutrient.

Retention of nutrients in fruit and vegetable products are affected by the conditions prevailing during processing and storage. Therefore, sufficient overdose should be added to these products.

Information about the nutrient content is given on the label of container on the basis of a serving. The term ‘serving’ denotes that quantity of a food in a meal which is suitable for consumption by an adult male doing light physical activity. Unit of ‘serving’ should be understandable to common consumer, such as cupfuls, teaspoonfuls, etc.

11.4.3 Fortification of Beverages

The term beverage includes fruit juices, squashes, nectars, ready-to-serve beverages, carbonated beverages or aerated waters, synthetic juices, fruit juice concentrates and dry instant drinks. Beverages are the most commonly fortified fruit and vegetable products. They are fortified with vitamin C and to some extent with vitamins A and B. For vitamin A, the substance used is beta carotene, which is a precursor of this vitamin and also gives colour to the juice.

Synthetic sources of vitamins are used, though blending with aonla juice as a source of vitamin C and carrot juice as a source of beta carotene can also be carried out. Losses of vitamins may take place during processing. Therefore, contact of fruit juice with iron and copper should be minimized by using stainless steel or glass lined equipments and vessels and juice should be de-aerated before pasteurization.

Vitamins, particularly thiamin, folic acid and vitamin C, are sensitive to heat. Beverages fortified with these vitamins must not be over heated; their temperature should be kept at 90^0C or less for a maximum period of 15 seconds. Fortification of beverages with vitamin A, folic acid and calcium pentothenate present problems because these nutrients are very unstable at pH around 3.0, which is normal pH of most fruit juices. Further, solubility of folic acid in water is very low.

Vitamin premix is dispersed in juice/ beverage, before homogenization step. Subsequent step of homogenization insures thorough mixing of vitamins in beverage.

Amount of vitamin C added should be such that each serving of 110-170 ml provides about 40 mg, which is the minimum daily requirement of an adult. Since some of the vitamin C may be lost during processing and storage, its 35-70% extra amount is added. In other words, total amount of vitamin C should be 54 to 68 mg per serving.

i) Fortified apple juice

Apple juice contains only 0.2-0.6 mg vitamin C per 100 ml as compared to 9.7-70.0 mg per 100 ml in orange juice. Further, colour of apple juice is light after extraction. But colour of juice becomes dark within 1 hour due to action of enzyme polyphenol oxidase on tannins of juice in the presence of air. Apple juice is fortified with vitamin C to raise its vitamin C content and to utilize oxygen present in the head space. Removal of oxygen from headspace checks oxidation of tannins and thus prevents discoloration of juice. But fortified apple juice, when exposed to oxygen, starts loosing vitamin C at the rate of 1 to 4 mg per 100 ml per day and its colour may again become dark. Therefore, it should be protected from air.

Vitamin C is added at the rate of about 70 mg per 100 ml at the time of extraction when apple juice comes out of press. Excess amount of added vitamin C may get degraded during processing and storage but it ensures that 40 mg of this vitamin per 100 ml remains in the juice.

ii) Fortified orange juice

Vitamin C content of orange juice varies from 27 to 67 mg/ 100 ml depending upon location of orchard, variety, etc. Therefore, orange juice is fortified so that it provides the minimum recommended amount of 40 mg vitamin C per serving.

iii) Fortified fruit juice concentrates and powders

Fruit juice concentrates and powders serve as base for various fruit beverages. They are easy to store and transport and reduce packaging requirements as compared to juices and other beverages. But during preparation, fruit juices are heated for long period which results in greater loss of vitamins. Therefore, they are fortified. High TSS of concentrates protect vitamins and reduce loses during storage. Synthetic orange juice concentrates are prepared using orange pulp and rind. Other ingredients added are gum *arabic*, cellulose gum, natural and synthetic flovours, artificial colour, potassium citrate and calcium phosphate. It is fortified with vitamin A, B and C.

Fortified fruit juice powders are prepared from fruits like apple, peaches, cherry, etc., by foam-mat drying process. In this process solubilized soy protein and methyl cellulose is added to fruit pulp.

Instant dry mixes of beverages and juice powder are fortified with vitamins by dry mixing. Water dispersible forms of vitamins are used. Mixing must be complete but over mixing should not be done because it results is segregation.

iv) Fortified carbonated beverages

Many carbonated beverages are fortified with vitamin C. During carbonation process, CO_2 expels the air. Removal of air and oxygen increases stability of this vitamin. Fortification of carbonated beverages with vitamin C improves nutritional value of the beverage, and some of it react with and remove residual oxygen from the head space of bottle which extends shelf-life of the beverage. Theoretically, 3.3 ml of vitamin C reacts with 1 ml of air. An overdose of vitamin C should be added to carbonated beverages to compensate for the losses.

v) Fortified banana powder

Banana powder fortified with soy protein can be used as a weaning ford for babies. To prepare it, whole soybeans are blanched in boiling water for 30 min, ground into fine paste with 10 times its weight of water and mixed with ripe banana pulp. Ratio of banana solids and soy solids in paste is kept equal. To the blend 100 ppm sodium meta bi-sulphite is added which prevents darkening. The paste is dried to 3% moisture level over a drum drier.

vi) Fortified jellies

To fortify jellies, a concentrated vitamin premix is prepared and some sucrose is added. Fat soluble vitamins are used in water dispensable forms. Vitamin premix is added to the jelly near the end point but before addition of citric acid. Vitamin C reduces the pH of jelly which may prevent their setting. Therefore, pectin jellies are not fortified with vitamin C.

vii) Fortified fruit cloth and fruit bar

Fruit cloth and fruit bars are products prepared from fruit pulp and concentrates by sun drying or drum drying. Fruit clothes from apples, apricots, dates, mango, papaya, etc., are prepared. 'Amavat' or 'Ampapar' is traditionally prepared in India by sun drying ripe mango pulp in the sheets, the thickness of sheet is gradually increased. The fruit bars can be moulded into different forms. They may be pre-treated with SO_2, viz., 0.5% sodium bisulphite. Sulphur dioxide improves colour and protects vitamin C and beta-carotene. Level of total soluble solids in pulp is raised to about 30% by adding sugar, also reduces drying time. Depending upon requirement, citric acid is added to improve the taste and acceptability of fruit bars. It can be fortified with protein powders (skim milk powder, whey protein isolate, ground nut or soy protein isolate, yeast protein), vitamins and other nutrients. Fortification is done by adding nutrients to the pulp concentrate and then drying it or spread the nutrient premix over the surface of dried fruit material.

11.5 LET US SUM UP

Nutritional requirements of men are varied and no single food can provide all the dietary essentials. It has resulted in various types of nutritional deficiencies. In such cases fortification offers an inexpensive and quick method for combating problem of nutritional deficiencies. People should be educated about needs and benefits of food fortification. Commonly fortified fruit and vegetable products are beverages, fruit bars and jellies which are consumed by a large section of people. Essentially fortification should be done only when it is necessary as proved by scientific studies, should be safe and effective. It should not be used as a marketing strategy.

11.6 KEY WORDS

Beverages	:	This term includes fruit juices, squashes, nectars, ready-to-serve beverages, carbonated beverages, synthetic juices, fruit juice concentrates and dry instant drinks.
Dietary fibre	:	It is that part of plant food which is resistant to digestion in the human beings.
Fortification	:	It is defined as a process of adding one or more dietary essentials to food.
Fruit bars/clothes	:	They are products prepared by drying fruit pulp and concentrates in the form of sheets.
Overage	:	Extra amount of nutrients added during fortification process to compensate for the losses during processing, storage and distribution.

11.7 ANSWERS TO CHECK YOUR PROGRESS EXCERCISES

Check Your Progress Exercise 1

Your answer should include following points:

1. • Five food groups have been identified by ICMR.
   • i) cereal, grains and their products, ii) pulses and legumes, iii) fruits and vegetables, iv) milk, meat egg and their products and v) fats and sugars.

2. • It is a process of adding dietary essentials.
   • Type of nutrient(s) added, their quantity and objective of adding them.

3. • Necessity of fortification
   • Basic principles of fortification

4. • Enhancement of aesthetic appeal of the diet.
   • High amounts of vitamins, minerals and fibre.

5. • Capability of vitamin C in removing oxygen
   • Nutritional improvement

6. • Vitamin C is added at the time of juice extraction to check.
   • Oxidative discolouration in apple juice.
   • Dry mixing of vitamins to reduce adverse effects of heat on vitamins in pre-mix in instant juice powders.
   • Vitamin premix is added in jelly near the end point but before addition of citric acid.

7. • Effect of heat, pH and oxygen on vitamin C.
   • Effect of pH and oxygen on beta-carotene.

11.8 SOME USEFUL BOOKS

1. Verma, L.R. and Joshi, V.K. (2000) Post-harvest technology of fruits and vegetables, Vol. II, Indus Publishing Co., New Delhi.

UNIT 12 PACKAGING – NEED AND IMPORTANCE

Structure

12.0 OBJECTIVES

After reading this unit, you should be able to:

- state the definition of food packaging;
- define the functions of packaging and its importance;
- explain the types of packaging;
- classify various packaging materials;
- describe the properties of packaging technology and its applications in processed food products; and
- design and develop the packages.

12.1 INTRODUCTION

The term food is defined as any substance containing nutrients such as carbohydrates, proteins, and fats that can be ingested by a living organism and metabolised into energy. Food is necessary for survival, growth of physical and mental ability and good health. The need and importance of food was known even to primitive men.

The nutritional status of a nation is complicated in nature as it depends on many inter-related set of factors such as food adequacy and its distribution, levels of poverty, level of literacy, status of women, rate of population growth and the extent of economic growth. In our country, the trend of nutritional level improvement for the last fifteen years has been gradual and modest despite steep rise in population.

The Indian economy is predominant agrarian. Agriculture constitutes 33% of our GDP, supports 64% of work force and earn 19% of our exports. The country produces 46 million tonnes of fruits and 96 million tonnes of vegetables and is the second largest producer next to Brazil and China, respectively. In spite of having such a good production, it incurs a loss of 25-30% every year. The spoilage of food products are due to improper infrastructure facilities for storage, handling, transportation and unscientific and inadequate packaging. India wastes more fruits and vegetables than are consumed in a country like U.K. This indicates that there is an urgent need to give more emphasis on packaging of food.

The level of food processing in our country is very low which has to be considerably increased if losses are to be minimised and also to ensure marketing of good product in packaged form. The selling of loose and exposed product is unhygienic and affects the health of the common masses. There could be considerable amount of savings in this context if all surplus quantity of produce are processed and sold in the market in a packaged form. But, consumer awareness and education are extremely important if this has to be achieved.

Indian consumer prefers to buy fresh produce and cook at home. Generally, processed and packaged forms are less preferred and purchased by Indian consumer as compared to the market trend elsewhere in the world. The primary reason is a myth and an inertia. There is still a perception that processing reduces the nutritive value and add to the cost. This myth needs to be broken on an urgent basis. The fact is that packaging reduces waste, adds value and assures a product to the consumer.

In our country, any fresh produce fruits, vegetables or processed products have never been associated with packaging. It is only in the recent times that the importance of packaging has been accepted. This is mainly due to growing consumer awareness and their willingness to pay for quality and hygienic products. In addition, increase in growth of exports has also made it obligatory to pack the product in attractive and consumer friendly packages. Considerable amount of improvement and development in packaging has taken place, especially for food products, in the last one decade. However, these efforts need to be augmented and implemented effectively to minimise the problems and make the food available more easily and economically. It may be pointed out that there is a tremendous scope for further improvement and development of packaging. In fact, the per capita consumption of packaging materials in India is much lower as compared to other developed and developing countries. Many more food products are still available in Indian market in unpacked condition, particularly the fresh produce like fruits, vegetables, meat, fish, poultry, etc. In order to maintain the hygienic condition of these food products and also to ensure their assured quality, it would be desirable to sell these products in packaged conditions. This will also increase the consumption of packaging materials enormously.

The subject “Food Packaging” has been introduced to modern technology recently. But this technology was existent on earth without having any proper attention. Most of the fruits like coconut, orange, banana, etc., having a skin or peel are available to us in packaged form in hygienic conditions this type of packaging is considered to be natural packaging. Further, the use of dry leaves for wrapping meat, animal skin based bags for storage, etc., wherein vogue since long. But recently, the importance of packaging has been understood in the food supply chain.

Food packaging is defined as a mean or system by which a fresh produce or processed product will reach from the production centre to the ultimate consumer in safe and sound condition at an affordable price. In other words, packaging is a combination of science, art and technology. Packaging is an integral part of production, storage, handling, distribution, retailing and end-use. Packaging is also considered as the last output of production but the first input of marketing. In other words, packaging acts as a tool or instrument for marketing.

The functions of packaging is performed by 3 P's, i.e., Preservation, Protection and Presentation. The above three P's are applicable to consumer products. However, this has minor role to play in industrial products.

Packaging serves two basic objectives, i.e., marketing and logistics. In its marketing function

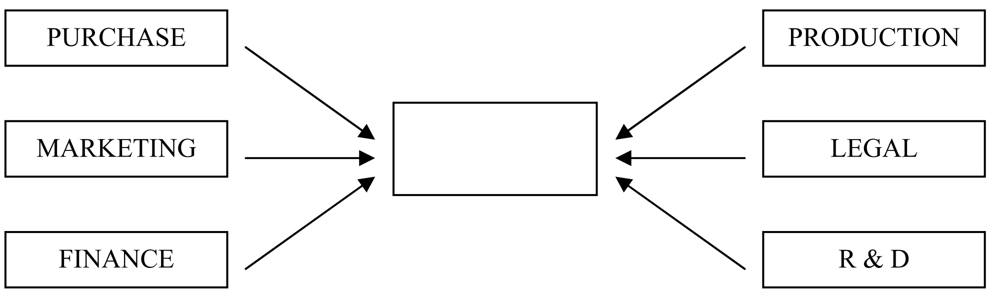
- it provides information about the product to customers,
- it promotes the product with attractive graphics and printing,
- it acts a medium of communication,
- it acts as a silent salesman and it is the final interface between the company and the consumers.

From the logistic perspective, the role of packaging is to ensure the safe delivery of a product to the ultimate customer at minimum cost.

In the logistic perspective, it performs six functions:

- Containment
- Protection
- Apportionment
- Unitisation
- Convenience
- Communication

The packaging function is closely associated with many other functions in an organisation. Effective communication is, therefore, important. In an organisational set up the packaging function is interrelated and this is illustrated below:



Due to this fact, packaging department is considered to be the nucleus in any FMCG (Fast moving consumer goods) company. The launch of any consumer product in a new package needs constant interaction among the inter departments of the company.

The package should be designed to provide efficient storage. However, its design is influenced by:

- Standardization
- Price or cost.
- Package or product adaptability.
- Protective level.
- Handling ability.
- Product packability
- Reusability or recyclability

12.2 TYPES OF PACKAGINGS

The container or the package serves mainly as a protectional device to avoid deterioration in the quality of contents against external agencies. However, in many instances, the packages are also designed taking into account the marketing considerations such as sales appeal, easy acceptability, handling convenience and distribution factors. Hence, it is desirable that you should know about the components of packaging or types of packaging available in the market.

12.2.1 Package Components

A broad classification of package components is given below:

i) Unit pack
ii) Intermediate pack
iii) Outer or shipping container
iv) Inner packaging components
v) External reinforcements

i) Unit pack

It is considered to be a package containing single unit, e.g. a toffee or chocolate is wrapped, 200 ml beer is packed in metal container. Unit package should be able to protect the product against the deterioration of quality. Naturally, the material selected for unit pack should have adequate functional properties to serve such function. This package serves as a retail pack and thus the package should have good eye appeal, easy openability and easy to carry or handle. In short, the package should be customer friendly.

ii) Intermediate pack

The unit packs further unitised to satisfy the marketing requirement, are called intermediate packs. For example, 10 unit pack of 100 g of butter packed in paper board carton are unitised to facilitate handling and enhance display value.

iii) Outer or shipping container

The intermediate packs are further packed into corrugated fibre board boxes or wooden boxes or Jute bags or HDPE woven sacks to transport the products. These packages are also termed as transport packages. These packages provide protection to the contents from journey hazards such as shock, vibration, drops and climatic hazards like rain, dust, sea water, etc., during handling, storage and transportation from one place to another.

iv) Inner packaging components

These components are normally given to the transport package by way of providing the resistance of movement of contents during journey due to vibration. The materials like separators are used in package where glass bottles are packed. Cushioning materials like thermocole, expanded polystyrene (EPS), expanded polyethylene (EPE), paper cuttings, wood wool are used either to protect the product against the shock hazards or space fillers to prevent the movement of contents during journey.

v) External reinforcement

The shipping containers are further reinforced by means of either plastic straps or metal straps applied along the girth as well as the length in order to strengthen the shipping container. Reinforcement also helps to improve the stacking strength, avoid bursting in case of failure and increase weight carrying capacity.

12.2.2 Packaging Materials

Packaging materials are broadly classified into two major types.

i) Primary packaging materials
ii) Ancillary packaging materials

I) Primary packaging materials

a) Flexible packaging materials

i) Cellulose based materials
ii) Regenerated cellulose or cellophane

iii) Jute or hession materials
iv) Aluminium foil
v) Plastic films and laminates
vi) Plastic woven sack

(i) Cellulose based materials

These materials are available in two forms, i.e., Paper and paper board. More than 180 gsm paper is generally termed as paper board.

- Paper: Different types of paper used in packaging are:

  - Tissue paper
  - Coated (varnish or wax coated)
  - Butter paper
  - Glassine paper
  - Art paper
  - Kraft paper
  - VPI paper
  - High gloss paper
  - Vegetable parchment paper

- Paper Board : Different types of paper boards used are:

  - Coated board
  - Duplex board
  - Triplex board
  - Asphalted board
  - Grey board
  - Mill board
  - Clay coated board
  - Kraft board
  - Chip board
  - Straw board

(ii) Regenerated cellulose or cellophane

The most common types of cellophane used for packaging are:

- Moisture proof sealable transparent cellophane(MST)
- Moisture proof sealable transparent coloured cellophane (MSCT).
- Moisture proof sealable transparent anchored cellophane (MSAT)
- Moisture proof saran coated cellophane (MXXT)

(iii) Aluminium foil

Different thicknesses of aluminium foils are available for the packaging application.

(iv) Jute or hession materials

Jute fabrics of different types, like single warp and double, are used for making the jute bags. Sometimes, the jute fabrics are also made water proof either by lamination or coating with bitumen or plastic for packaging.

(v) Plastic films and laminates

There are various types of polymeric materials which are converted into plastic films and have got wide application in packaging.

Some of the important polymeric materials are as follows:

- *Polyethylene*
  - Low density polyethylene (LDPE)
  - High density polyethylene (HDPE)
  - High molecular high density polyethylene (HMHDPE)
  - Linear low density polyethylene (LLDPE)
  - Very linear low density polyethylene (VLLDPE)
  - Copolymers like surlyn or primacor (EAA)
- *Polypropylene*
  - Bioxially oriented poly propylene (BOPP)
  - Cast poly propylene (CPP)
  - Tubular quenched poly propylene (TQPP)
- *Polyvinyl chloride (PVC)*
- *Polyethylene terephthalate (PET)*
- *Polystyrene (PS)*
- *Poly carbonate (PC)*
- *Poly amide or nylon (PA)*

Depending on the requirement, the plastic films are converted into composite structure either in co-extruded form or in laminated form. The packaging materials are available either as 3 layered or 5 layered coextruded film.

- LDPE/ HDPE/ LLDPE. (3 layered co-extruded)
- LDPE/ TIE/ NYLON/ TIE/ LDPE.(5 layers co-extruded)

These types of films have got extensive application for the packaging of fresh milk and edible oil.

But for the consumer products like bakery items, snack foods, pan masala, confectionary, etc., the plastic based laminate in three or four layer are commonly used in order to meet the requirement of barrier properties against moisture, oxygen and light.

Some of the important structure of plastic laminates are given below:

Spices	:	BOPP film/ Adhesive/ LDPE. Metallised PET/ Adhesive/ LDPE. BOPP/ Adhesive/ PAPER/ LDPE.
Snack foods	:	Oriented PET/ Adhesive/ Met PET/ Adhesive/ LDPE. Oriented PET/ Adhesive/ Met PET/ Adhesive Aluminum foil/ LDPE.
Mouth refresher	:	Oriented PET/ adhesive/ Opaque BOPP/ adhesive/ Met. PET/ adhesive/ LDPE.

(vi) Plastic woven sack

Available in laminated or non-laminated forms.

b) Rigid packaging materials

The packaging materials are available in following types:

(i) Metal container – Drum, barrels, tin containers aluminium containers TFS Containers (Tin free steel)

(ii) Glass container – Glass bottle, glass jar carboys, ampules

(iii) Plastic containers – Plastic bottles, drum, barrels, jerican

(iv) Plastic crate

(v) Wooden containers – Box, crate

(vi) Corrugated fibre board boxes

(vii) Fibre drum

(viii) Ply wood container

c) Semi rigid packaging materials

The important types of packaging materials are as follows:

i) Aluminium collapsible tube
ii) Plastic collapsible tube
iii) Composite container
iv) Paper based carton

II) Ancillary packaging materials

The important types of materials which have got application in packaging are as follows:

(i)	Printing ink	–	Flexo ink, gravure ink, offset ink
(ii)	Adhesives	–	Lamination adhesive, pasting adhesive, corrugation adhesive
(iii)	Labels	–	Self adhesive pressure sensitive

(iv) Cushioning materials – Resilience, non-resilience and space fillers
(v) Strapes – Plastic metal,
(vi) Tapes – Paper tapes, plastic tapes
(vii) Nails, hooks, clips, etc.

3. Fill up the following blanks:

a) Full form of PET is ________________________________
b) CPP means ________________________________
c) MAP means ________________________________
d) '3P' stands for ________________________________
e) Cushioning materials are ________________________________

4. Tick (✓) the correct answer:

a) Cellophane is

i) Paper ii) Plastics
iii) Regenerated cellulose

b) Corrugated fibre board boxes are considered to be

i) Primary packaging materials
ii) Ancillary packaging materials

12.3 PROPERTIES OF PACKAGING

Packaging is an integral part of product processing and preservation. It has a direct influence on the system in respect to physical and chemical changes. The barrier properties and packaging materials play a significant role in preservation and thus, extension of shelf life of processed food product.

With the advancement of preservation technologies for food products coupled with the introduction of newer packaging materials and systems, it has been possible to introduce new generation products into the market.

Almost all types of packaging materials are used by food industry. Metal cans made of tin plate have been used by the canneries over the years. However, the thin wall tin containers, welded or cemented joint cans with lead free solders and 2 piece tin plate cans are recently introduced in the market for the packaging of fresh produce. The food products are processed at high temperature and pressure to make containers hermetically sealed. These type of containers provide about one year shelf life to the processed food.

Despite of having the difficulties of breakage and more tare weight, the glass bottles are used extensively for packaging of the processed food products. This material is non-toxic, non-reactive and high temperature resistant. The processed food like tomato ketchup is normally hot filled in glass bottles.

The use of paper board cartons as bag in box for packaging of liquid products like edible oil is widely accepted. Paper board carton with appropriate liner is used for packaging tea.

Plastic containers, because of light weight, easy availability, economical, diversified sizes and shapes and recyclablility property are widely used for food packaging.

Dual ovenable containers made of C-PET (Crystalline PET) have a high heat resistance up to 230°C. These trays can be frozen and then directly heated in the oven and, therefore, are used for packaging of ready to eat products.

High gas barrier plastic bottles are produced by co-extrusion blow moulding process or co-injection blow moulding process have got wide application in food packaging. The polyolefin materials like PE/PP bottles are commonly used.

However, the new development of co-extruded bottle made of PE or PP/ tie/ EvoH/ tie/ PE or PP are used for the packaging of edible oil, tomato ketchup, mayonnaise and salad dressings. PVDC coated PET bottles with improved gas barrier properties are used for beer and wine.

The flexible packaging materials having number of advantages are suitable for the packaging of processed food items. A wide variety of combination of packaging materials are developed to improve the barrier properties of moisture, oxygen, CO_2, and light and thus help to enhance the shelf life of food product. Recently, the application of flexible packaging materials have gone up tremendously due to their light weight, high barrier properties and cost effectiveness. These materials are used as monolayers like PE, BOPP, CPP or as composite structure like 3 layered/4 layered laminated form or 3 layered/5 layered coextruded film for the application of packaging of liquid milk, edible oil, spices, snack food, tea, coffee, etc.

In addition, there are certain innovative technologies like retort packaging, aseptic packaging which play a great role in enhancement of shelf life of processed food product. A retort pouch, made of polyester film/ aluminium foil/ cast polypropylene combination has got the property of with standing high temperature and pressure, while sterilized in the retort. This technology is very common in developed countries but in India this has recently been introduction for ready to eat products.

The introduction of aseptic technology to the Indian market has revolutionised the packaging of liquid food products like milk, fruit juices, etc.

Moreover, vacuum packaging and gas flushing techniques are very common in food packaging. Food products rich in fat tend to get rancid due to oxidation and get spoiled. However, evacuation of air from the package and introduction of inert gas like nitrogen inside the package not only retains the shape of the content but also protects from oxidation. This type of packaging is mostly used for snack food items like chips, namkeen, bhujia, etc. However, the products like tea, coffee, spices, etc., could be packed by using only vacuum packaging as the products are powder in nature to extend the shelf life at ambient conditions.

This clearly stated that different types of packaging materials and systems have got unique properties and these are to be chosen depending upon the requirement and application in packaging of various types of processed food products.

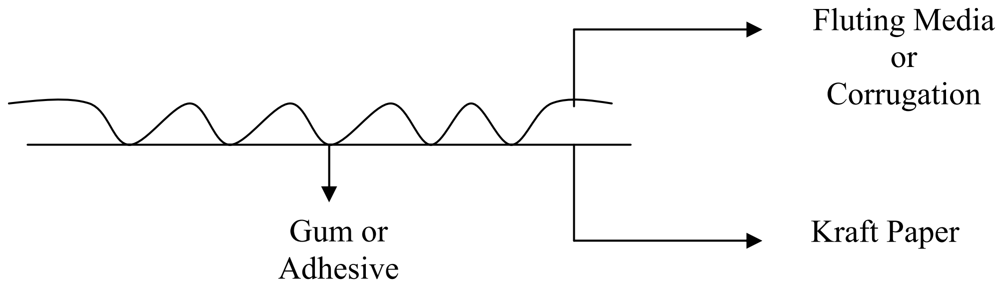
12.4 IMPORTANCE OF SUCCESSFUL PACKAGE

It is strongly desirable to keep the food products as fresh as possible for a longer duration so that these products can be distributed to a longer distance. At the same time, it is also necessary that the package has adequate strength so that the products can be transported without any breakage.

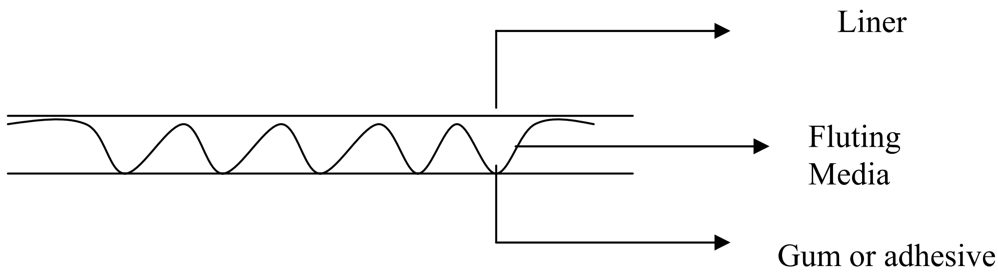
Fresh fruits and vegetables remain biologically alive even after harvest. The physiological function like respiration continues even after the supply of nutrition is cut off. The stored nutrition then begins to be consumed and gets depleted. The metabolic activity of ripening and aging also continues. Due to these facts, it is necessary to make proper ventilation in the package so that the respiration process continues, otherwise the produce will rot or spoil within a short period of time. The use of traditional packages like jute bag and bamboo basket for packaging of fresh fruits and vegetables is now being discontinued as these packages are unable to provide adequate protection to the produce during handling, storage and transportation.

The traditional packages are being slowly replaced by the use of corrugated fibre board boxes. These boxes are made from die-cut corrugated fibre board where the craft papers are passed through corrugating machine to get the fluting media or corrugation and finally stuck into a plain layer of craft paper by means of adhesives or gum to form 2 layer or 2 ply corrugation roll.

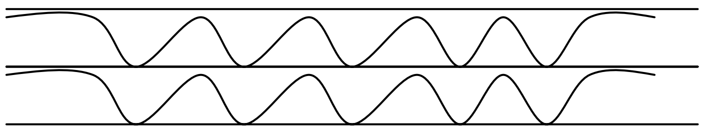
In the same manner, 3 or 5 ply corrugated fibre board boxes can be made by pasting the adequate number of craft liner or facing material. This could be illustrated by the following diagram (Figure 12.1).



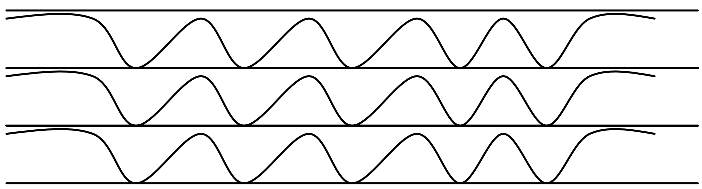
2 ply corrugating roll



3 ply or single wall corrugated fibre board



5 ply or double wall corrugated fibre board



7 ply or triple wall corrugated fibre board

Figure 12.1: Diagram illustrating different plys in a corrugated fibre board

The use of jute or gunny bag for packaging of apples is completely replaced by corrugated fibre board boxes. Similarly, the use of the bamboo busket for packaging of grapes has been discontinued and the fresh grapes are packed only in corrugated fibre board boxes. The new developed boxes are made from die-cut corrugated board with proper ventilation. The boxes are not only having adequate compression strength to prevent the crushing of fruits in stacked condition during storage and transportation but also enhance eye appeal to the consumer through attractive graphics and printing on the outer surface of the packages. The changing trend has substantially reduced the loss of fruits due to damage in transit. These examples clearly indicate that there is an urgent need to have proper package for all types of fresh produce to distribute at distant places by retaining the freshness of the produce. These are easily available, accepted internationally and can be recycled and thus considered to be environment friendly. Sometimes, the outer surface of the boxes are given adequate coating to provide moisture proofness so that packages will not be damaged even after exposing to the high humid condition.

The use of modified atmosphere technology has led to the introduction of newer plastic films, such as OPP (Oriented polypropylene) film, coated by interfacial active agent (such as charcoal) for absorbing water vapour. The other films are:

- PE (Polyethylene) film blended with microporous materials absorbing ethylene gas.
- LLDPE (Linear low density polyethylene) film blended with anti-microbial materials, preventing the growth of bacteria and mould.
- PVC (Polyvinyl chloride) film blended with silver ions for anti-microbial properties.
- Antigas barrier film having micropores which allows oxygen to enter inside the package for respiration and for prolonged shelf life.

There is a wide variety of fresh commodities and each has a different respiration rate and requirements for storage. A judicious selection of the packaging medium is thus very significant to make a successful package for fresh produce.

Similarly, there is a wide variety of processed food products which are produced by using number of ingredients and different processing technologies. This has resulted into wider variation in requirement of packaging for longer shelf life.

You know that shelf life is the time between the production and packaging of a product and the point at which it becomes unacceptable under defined environmental conditions. It is a function of the product, package and the environment through which the product is transported, stored and sold.

The bakery products like bread and biscuit, both made from maida, require different packagings to satisfy the consumer.

Bread has got moisture content of 38 to 40% due to which the crumb of bread is soft in nature and preferred by the consumer. Whenever bread is kept outside, it starts losing moisture and becomes dry and unacceptable to consumers. Hence, bread is to be packed where the packaging materials should have low water vapour permeation or high barriers to moisture content. On the other hand, biscuits are crispy in nature due to low moisture content of about 2 per cent. When the biscuits are kept outside, the product intends to pick up moisture from the environment and becomes soggy and should unacceptable to the consumers. So, the packages for biscuits also have high moisture barriers property where moisture should not move from outside to inside. The properties of foods like ghee, butter or snacks are likely to get changed during storage. The products are fried in oil and when exposed to environment, react with atmospheric oxygen and undergo oxidation. The product becomes rancid resulting into the changes in taste. Moreover, UV light also plays a role to accelerate the oxidative reaction. Hence, the packaging requirement for these items are high barriers to light and oxygen.

Aroma loss in freshly ground spice or stimulating product like tea, coffee is very common. The packaging materials for these items should have high aroma resistance property.

The requirement of packaging for different processed food is required to be understood by you prior to decide the selection of packaging materials. This is possible only by understanding the critical characteristics of the products that means how the product gets spoiled or changes its characteristics or original properties during storage.

Hence, the selection of proper packaging materials with required quality depends upon the requirement of individual variety of processed food product. Considering this, the materials are to be selected so that products can be packed to maintain the quality of food during storage. A successful package can only meet the requirement of desired shelf life of a product.

12.5 LET US SUM UP

Food is considered to be one of the basic need of human being for survival, growth of physical and mental ability and good health. This has always played an important role in the rise or fall of economy of the nation because of its effect on the health of population.

It has been reported that there has been an average loss of 25 to 30 per cent of fresh produce in our country which is mainly due to improper handling and inadequate packaging. This has forced us to understand about the importance of packaging and its needs to prevent the material loss.

Food packaging is a system by which the fresh produce or processed one will reach from the production centre to the ultimate consumer in safe and sound condition at an affordable cost. It serves two basic objectives, i.e., marketing and logistics.

The different types of packaging materials have been discussed in detail in this chapter. For processed food, the important packaging materials like metal cans, paper board carton, plastic container and plastic bottle, and flexible packaging materials with different combinations are used. Similarly, the traditional packaging materials like gunny bags or bamboo baskets are being replaced by the introduction of corrugated fibre board boxes with proper ventilation and strength for packaging, handling and transportation of the fresh produce.

In addition, the innovative packaging technologies like aseptic packaging, retort packaging, gas flushing and vacuum packaging for processed food and modified atmosphere packaging for fresh produce have also been discussed. Shelf life is the time between the production and packaging of a product and the point at which the produce first become unacceptable under defined environmental conditions.

The requirement of packaging for different processed food products varies depending on the critical factors of different products. The product requires packaging materials of having moisture barriers, gas barriers, aroma barriers or digest barrier which ultimately play a key role in determining its the shelf life.

12.6 KEY WORDS

LLDPE : Linear low density polythylene – a polymeric material.

MAP	:	Modified atmosphere packaging – a packaging system for extending shelf life of fresh produce.
C-PET	:	Crystalline polyster – a polymeric material.
PVDC	:	Poly vinylidine chloride – a coating is given to a polymeric materials to improve the barrier properties.
TFS	:	Tin Free Steel – the base plate is coated with chromium than tin.
Resilience	:	A cushioning material like sponge; it means after pressing it will come back to its original position.
Non-resilience	:	A cushioning material like expanded polystyrene or thermocole, which does not come back after releasing the pressure.
Space filler	:	Cushioning materials like paper cutting, shreded wood wool, used to fill up the space in the package.
Duplex board	:	Two layer of pulp is used to make the paper board
Triplex board	:	Three layers of pulp is used to make the paper board.
Composite container	:	A container where the body is made from paper and the ends are made from either metal or plastics.
Chip board	:	A board made on continuous machine mainly from low grade waste papers. It has got extensive use for making sweet box.
Grey board	:	A board made from mixed waste pulp with or without screenings and having the thickness less than 1 mm, used for packaging of shoes.
Clay coated board	:	High grade bending board, the top of which has been coated with fine clay to produce a surface for printing, mainly used for gift items.
Mill board	:	A homogeneous board made usually of mixed waste papers with or without screenings and mechanical pulp on an intermittent board machine and having thickness not less than 0.5mm.
Straw board	:	A board made from partially cooked straw, bagasse or grass or a mixture of these.
Glassine paper	:	Grease proof and translucent paper.
Waxed paper	:	Dry or wet waxing is done on paper to obtain the resistance to moisture and oil.

VPI paper	:	This is called vapour phase inhibitor paper. The base paper is kraft paper coated on one side with corrosion inhibiting chemical and is used for protection from rusting.
High gloss paper	:	High gloss papers are sometimes coated with metallic powder to obtain a decorative finish.
Vegetable parchment	:	Low grammage chemically bleached paper.
Butter paper	:	Grease proof paper used for packaging of butter, etc.
Retort pouch	:	A plastic based laminated pouch which can withstand high pressure and temperature.

12.7 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answer should include the following points:

1. • System to deliver the food products from production centre to the consumer in safe and sound condition at an affordable cost.
   • A coordinated system which include production, storage, transportation, retailing and end use.

2. • Marketing and logistics functions.
   • To provide the information about the product to the customer and to promote the product to the customer and to promote the product with attractive graphics and printing.
   • To act as a medium of communication and a silent salesman.
   • Logistics functions like containment, protection, apportionment, unitisation, convenience, and communication.

3. 1) Standardisation — 2) Price or Cost
   3) Package or Product adoptability — 4) Protective level
   5) Handling ability — 6) Product packability
   7) Reusability or recyclability

Check Your Progress Exercise 2

Your answers should include the following points:

1. • Unit pack, Intermediate packs, Outer or Shipping containers
   • Inner packaging components
   • External reinforcement

2. • Flexible packaging materials
   • Rigid packaging materials
   • Semi rigid packaging materials

3. a) Polyethylene terephthalate
   b) Cost poly propylene
   c) Modified atmosphere packaging
   d) Protection, preservation and presentation
   e) Resilience, non-resilience and space fillers

4. a) Regenerated cellulose
   b) Primary packaging materials

Check Your Progress Exercise 3

Your answer should include the following points:

1. • Metal cans made of tin plate mainly either 3 piece or 2 piece can.
   • Glass bottles as they are non-toxic, non-reactive, and high temperature resistant.
   • Paper board carton like bag in box and lined cartons.
   • Plastic containers as they are light in weight, easily available, economical, and recyclable.
   • Flexible packaging materials like laminated film or coextruded film.

2. • Retort packaging for ready to eat products.
   • Aseptic packaging of liquid food products which have got about one year shelf life.
   • Vacuum and gas packaging for fatty foods in order to prevent oxidation process and thus extends shelf life.
   • Modified atmosphere packaging for extending shelf life of fresh fruits and vegetables.

3. • Dic-cut corrugated fibre board boxes made of either 3ply, 5 ply or 7ply.
   • Boxes should have proper ventilation to facilitate respiration process of fresh produce.
   • Adequate compression strength to resist crushing during handling, storage and transportation.

4. • Processed food products are made of different ingredients.
   • Products have got different initial moisture content (IMC) and critical moisture content (CMC).
   • Critical characters of the products are different like moisture sensitive resulting into the spoilage of products during storage.
   • The packaging materials are chosen depending on the requirement of products to prevent the spoilage and thus to enhance the shelf life.

12.8 SOME USEFUL BOOKS

2. Modern Food Packaging, Indian Institute of Packaging, E-2, MIDC Area, Chakala, Andheri (East), Mumbai, 1998.

3. Packaging of Food Products, Indian Institute of Packaging, E-2, MIDC Area, Chakala, Andheri (East), Mumbair, 1986.

4. Packaging Technology Educational Volumes (Part–2), Indian Institute of Packaging, E-2, MIDC Area, Chakala, Andheri (East), Mumbai, 2001.

5. Sacharow Stanley and Griffin, Jr. Roger C. (1970) Principles of Food Packaging. AVI Publishing Company, Westport, Connecticut.

UNIT 13 PACKAGING MATERIALS

Structure

13.0 OBJECTIVES

After reading this unit, you should be able to:

- describe the manufacturing processes of different packaging materials used for processed food products;
- explain the properties of packaging materials;
- discuss the advantages and disadvantages of packaging materials;
- state the application of packaging materials for different processed food products; and
- define the quality control measures of packaging materials.

13.1 INTRODUCTION

In our country, the packaging technology was not given due importance for long time but recently, the approach has been slightly changed. However, the concept of value addition to the product by means of new types of packaging materials and forms are yet to be recognised by the major quarters of population. Even today, many quarters of community consider that packaging materials always add cost to the product and thus these has been given a low priority. But with the increase standard in living and per capita income, the Indian consumers have moved to new sophistication era resulting in their demand of packaged commodities. The demand of packaging materials also have, therefore, shown a steep rise, particularly in the last three decades.

In fact, the packaging in the country appeared in the 1950's, became noticeable in the 1960's, grew in dimensions in the 1970's and with the advent of the 1980's the industry showed a tremendous progress which is continuing and likely to grow many fold in future. The poor rate of growth in the past had been attributed to lack of awareness, lack of education and skill as well as inadequate support. The other reasons could be the lack of serious attempts on standardisation of packaging materials and systems.

In the wake of industrial growth a number of industries manufacturing and marketing different range of product groups have been setup. Different kind of packages introduced over a period of time have replaced the conventional packs successfully. At the same time, industry strived its best to keep packs with the growing demand and also to cater the export requirement. Moreover, in the WTO era, it has become imperative for the Indian industry to upgrade these technologies to innovate alternate packaging materials at affordable cost to become globally competitive.

Wood, probably the oldest form of packaging medium, still dominates its use in the specific area of packaging like heavy engineering and electronics products and defence articles. But the introduction of fibre board materials like corrugated fibre board box and solid board box have completely replaced wood for the packaging of most of light engineering, automobile, textiles, etc. Today, these materials are considered to be most economical and eco-friendly.

Jute is another type of natural packaging material available in the country and has got extensive application in food grain packaging. This old age system continuing to expand with the new technologies in the combined form and has got newer applications.

Glass is a traditional packaging material. Despite its inherent characteristics like fragility, it is still in use in packaging of processed products due to its reusability.

The indigenous production of tin plates have reduced the import of these materials substantially. But the growth of these materials have been slow due to their expensiveness as compared to other packaging materials like plastics.

Plastics have entered in the packaging scene only from the mid fifty's and early 1960's. These particularly referred to low-density polyethylene and PVC. Subsequently, high-density polyethylene, polypropylene and polyester were introduced. Although, the thermosets were used earlier for caps and closures, but these are being replaced by thermoplastics. In our country, a great revolution has occurred due to the introduction of plastic carry bags in the late 70's and early 80's. Further to this, plastics by virtue of versatility have captured the market in a big way. Meanwhile, the concept of consumerisation has also played a great role in the usage of more plastics for packaging of rice, atta, maida, salt, etc. In addition, plastics packaging materials have entered in the applications of newer systems like blister and skin packaging for processed food, pharmaceuticals, shrink packaging for unitisation, strip packaging for medicine and thermoformed containers for ready to serve food products. With the same pace of development, plastics multilayered collapsible tube has also been introduced in the Indian market for the packaging of toiletries, cosmetics and processed food also.

Aluminium is used as sheets, slugs for collapsible and rigid tubes for packaging pharmaceutical ointments and for foil for making flexible laminates to pack processed food products.

The constant increase in consumer demand has forced to introduce newer packaging system for extending shelf life of food products like fruit juices. One of the most important system, like aseptic packaging system, had been introduced in our country during the early 1970's. Though, there had been certain initial inertia of consumer to purchase these packages due to prohibitive cost but slowly, its advantages were realized. Now, this system has been well accepted and more and more liquid and paste food products are being packed.

In short, packaging is a need based technology. The need of consumer forced to develop newer packaging materials as an alternate media and thus, a wide variety of packaging materials have been invented. But there is always a thrust to develop newer packaging materials at lower price so that more variety of products could be made available in packaged form. The consumption of packaging materials will increase substantially in the years to come.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Write down in chronological order of appearance of packaging materials in the country.

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

2. Please tick mark (✓) the correct answer.

a) Which of the packaging material is considered to be the oldest one?

i) Plastics
ii) Wooden container
ii) Paper

b) Which of the packaging material have really gone ahead as compared to others?

i) Aluminium container
ii) Plastics
iii) Glass

c) The most important natural packaging material available in the country is

i) Tin container
ii) Glass
iii) Jute

13.2 GLASS CONTAINERS

Glass, the oldest packaging material, is used as container for over 3000 years. The first glass container was made in Egypt in 1500 B.C. During the first golden age, the Romans produced some exquisite glass ware including containers. This very ancient packaging material has withstood the challenges and competition with many types of packaging materials and the same is being continued till date. With the fast development of science and technology all over the world, newer types of packaging materials like metal, plastic, etc., have been developed resulting into stiff competition with the application of glass containers in packaging. Hence, the use of glass containers have been reduced to a great extent. Despite of having certain inherent characteristics like fragility, tare weight, the glass containers have made an established application in packaging to certain specific areas like carbonated and alcoholic beverages, perfumes, etc. This is mainly due to its certain unique properties which have made it to take a lead over other packaging materials.

I. Properties

a) Chemically inert

It has no inherent property of action which enables the packaging of products without any danger of reaction or spoilage.

b) Non-permeable

Glass does not allow gases, odours, vapours and liquids to pass through its walls.

c) Transparent

You can see the packaged product.

d) Mouldable

Glass containers can be moulded easily in any shape or size ranging from a tiny vial to a 18 gallon carbouy.

e) Strength

The ultimate strength of glass is equal to that of the strongest sheet.

g) Light weight

Glass is as light as aluminium roughly 1/3rd the weight of steel or of a density 2 1/2 times that of water. Progressively, the weight of a given capacity glass container is being reduced by suitable change in design and uniform distribution of glass for increasing the strength of the container.

h) Unlimited supply

Glass container can enter to an unlimited market because of its basic raw materials – sand, lime stone and soda ash which are available in plenty. Arsenic, selenium and cobaloxides are used to make clear glass. Carbon and sulphides are added to make brown (amber) coloured glass. Boron addition provides strength to glass.

II. Advantages

a) This packaging material is used for all types of products like liquid, powder, paste, granules, etc.

b) Glass has got high and low temperature resistance. The processed food products like tomato ketchup is filled hot and can be refrigerated too.

c) Glass containers do not contaminate the contents with crystals or fibres as found in packages made of metals or alloys.

d) Climatic variations do not affect the glass container or the product packed in it.

e) Due to see through property of glass containers, the colour, appearance and consistency of the product can be easily detected.

f) Containers can be made in any size, shape and capacity depending on the requirement.

g) The glass container does not taint, pollute or affect the quality of product packed in it.

h) The closures made of metal, plastic, cork or rubber, depending up on the requirement, can be chosen.

i) Glass containers are impermeable to moisture and gases.

j) Glass containers may be coloured (like brown, green, blue) to protect the product from sum light.

III. Applications

Glass containers have wide applications in the packaging of pharmaceuticals, dairy, liquor, breweries, food, soft drinks, cosmetics, chemicals, inks and other industries. More specially, glass containers are used to pack jams, jellies, squashes, pickles and other preserves. In addition, containers are also used for processed meat and fish products, tea, coffee, spices, baby food, cheese, ghee and vegetable products.

13.3 METAL CANS

Metal cans could be made either from aluminium, tin plate or tin free steel. But the tin plate containers and aluminium containers have got extensive application in packaging. The most popular form of metal containers is tin plate container which has been used in food packaging for the last five decades. Most probably, this packaging material could be considered to be oldest one, next to glass containers, for food packaging industries.

There are two types of tin plate containers namely:

a) Open top container
b) General line container

a) Open top container

This range of containers is a standard variety from which a customer selects the size suitable for its requirement. These are also called as open top sanitary (OTS) cans and are essentially round in shape. A standard open top can is supplied by can making company with bottom seamed to the body and the top ends are supplied as loose. The processed food manufacturer fill the content into the tin can and then seam with the top lid by using a machine called seamer and then the filled tin cans are subjected to heat process. This can is also called as 3-piece can. Open top sanitary cans are widely used for processed food and beverages. One of the recent developments in open top market is the advent of easy open end. This is specially designed and accurately made to components of the can, which is made either of tin plate or aluminium. It is fitted with a "ring pull tab" whenever the customers pull the ring, it gets tear and open the top lid without much efforts. This development has definitely helped the consumer to get away from the traditional method of opening the can with the help of a 'can opener', which requires more time in opening the periphery of the top. Recently DWI can or "Drawn and Wall Iron" can has been developed. These cans are called two piece cans as the cylindrical body and bottom become single piece and lids are separate. These cans score more over conventional 3-piece cans in terms of savings of considerable amount of materials without sacrificing the speed of the machine. But these cans are confined to the applications of pressurised beer and beverages.

b) General line container

General line containers range from tiny containers like pharmaceutical ointment to 15lts capacity containers for vanaspati or biscuits and 20 litre drum for paints and varnishes. A large number of tailor made sizes of containers are added into this category. These containers are round as well as un-round (known as irregular) and are filled with various kinds of fitments made from tinplate, aluminium and plastics. These containers do not have much application for processed foods, rather bakery products, hydrogenated oils and confectionery items are packed in them.

Application

Tin plate containers have got extensive application in packaging of different products like:

i) Beer and beverages
ii) Processed food
iii) Lubricants
iv) Tooth powder/ Talcom powder/ Creams
v) Confectionery
vi) Edible oils
vii) Coffee, baby food and chocolate
viii) Aerosols
ix) Paints
x) Insecticides and pesticides
xi) Thermos flask
xii) Battery cells

13.4 ALUMINIUM FOIL

Over the years, aluminium foil has been established as the best flexible packaging material in terms of barrier properties against moisture, gases, light, aroma, etc., as compared to any other material. No other flexible material can match the characteristics of aluminium because foil retains all metallic properties of aluminium.

Aluminium foil is a continuous web/sheet of aluminium metal rolled to thickness/gauges ranging from 0.005 to 0.2 mm. It is produced from commercial purity aluminium having aluminium content of not less than 98 per cent. Foil in hard or soft temper (i.e., annealed), is available with bright or with one side dull/ matt surface. It is available in plain, coloured, coated, lubricated and embossed forms.

I. Properties

The important properties are as follows:

i) Impermeability: Foil of 0.025 mm thickness is impermeable to moisture vapour and gas transmission.

ii) Non toxic: Due to inertness in nature, the foils are completely non-toxic.

iii) Stable: It does not get brittle at low temperature.

iv) Light and heat barriers: It acts as a barrier against light and heat.

v) ***Tasteless and odourless:*** It neither absorbs any odour from food nor releases any off odour to the food.

vi) *Tagger:* It is pilfer proof diaphragm for tin containers.

vii) *Retort pouch:* Foil is used as middle layer in the three layered flexible laminate helps to withstand temperature and pressure in the retort for extending shelf life of ready to eat products.

Advantages

i) Tearing properties facilitates to use the Web as sealing surface in the blister pack.

ii) Impermeable in nature – extensively used for lamination.

II. Applications

i) *Decorative label:* Foil of 0.009 mm thickness can be laminated to paper for flexible label.

ii) *Confectionery:* 0.009 mm thick foil wax backed by paper like glassine, greaseproof or poster is used to pack chocolates, toffee, etc.

iii) *Biscuit wrappers:* Base laminate of 0.009 mm thick foil and 30 gsm poster paper printed in multicolour and wax coated are used as biscuit wrappers.

iv) *Milk products:* Cheese wrappers are composed of 0.012 mm foil coated by heat sealable, anti corrosive coatings.

v) *Multilayer laminates:* Packaging of instant coffee, Pan masala, snack foods, and also for aseptic pouch.

vi) *Stand up pouches:* These are used for packing ready to serve (RTS) beverages.

vii) *Tea chest lining:* Bulk packaging of tea is done.

viii) *Milk strip:* It is used for capping milk bottles.

13.5 PLASTIC MATERIALS

A plastic material is one which is a solid at ordinary temperatures and allows appreciable and permanent change of form without losing its coherence on the application of pressure and heat.

This quality in synthetic or natural materials containing an organic or inorganic compound of high molecular weight is an essential ingredient. The materials are usually solid in finished form but at some stage during manufacture or processing finished articles can be moulded or shaped by flow. The substances of high molecular weight are synthesized from simple chemical components either by condensation or polymerization reactions, yielding products called synthetic resins. The term ‘plastic’ covers a broader group of materials than the term ‘resin’. Usually, heat and pressure together are used to mould or shape the plastic.

Plastic materials are perhaps the most versatile group of materials used in packaging. The use of plastic is fast growing in India due to easy availability of resins. Plastics are light in weight, very strong, hygienic and non-conductive. They do not rust, rot or react with most chemicals.

The development of plastics has resulted into its application in many ways despite its appearance in the market much later as compared to other packaging materials.

The plastic resins are generally categorised as thermoset or thermoplastic resin. Thermoset resins are those materials which can be heated and set to a definite shape but unable to change into another shape by application of heat. The products like electrical switch and other liner materials made of bekelites are covered under this category. Whereas the thermoplastic materials are flexible in nature. These materials can be changed into different types of plastic films with the help of heat application and further, these could be melted and convert into resin form. For example, different types of plastic films used in packaging may be converted into recycled plastic resin materials with the application of heat.

In the current scenario, about one third of all thermoplastic materials manufactured are used in packaging. The plastic materials used for packaging include the polyolefins, principally polyethylene, and polypropylene, poly vinyl chloride (PVC), polystyrene(PS) and polyethylene terephthalate (PET). Out of these about two thirds are used for packaging of food and beverages. Plastics offer distinct advantage over other packaging materials due to its important characteristics like light weight, good mechanical strength, flexibility and recyclability. These materials have excellent barrier properties towards moisture and gases and thus have got wide application in the packaging of food products.

Some of the important thermoplastic materials which have got extensive application in packaging are normally classified into different group based on the polymerisation process and molecular structure like

a) Polyolefins – Polyethylene and Polypropylene (PP)

b) Polyvinyl group – Polyvinyl Chloride (PVC)

c) Condensation polymer – Polyester (PET), Nylon-6 or Polyamide (PA)

d) Styrene polymers – Polystyrene (PS) and Expanded polystyrene (EPS)

e) Carbonate group – Polycarbonate (PC)

a) Polyolefins groups

Depending upon the molecular weight and density, the polyolefins group materials are available in different forms. The important properties of these materials are given below:

i) Low density polyethylene (LDPE) film

- Density ranges from 0.910 – 0.925 gms/cc
- Average molecular weight is 3×10^5
- Resistance to heat (82 – 100°C)
- Translucent type of clarity
- Water absorption is 0.015%
- Permeability to gas is 1.0 cc/m^2/ 24hrs at 27°C and 1 atmospheric pressure
- Good tensile strength properties and high percentage of elongation.
- Good dart impact resistance

- Resistant to weak acids and alkalies
- Good barrier to moisture vapour

ii) Linear low density polyethylene (LLDPE)

- High film tensile strength properties as compared to LDPE
- High percentage of elongation as compared LDPE
- High tear strength properties
- Better stress crack resistance and low temperature brittleness
- Improved stiffness properties
- Excellent puncture resistance
- Excellent heat seal properties

iii) Medium density polyetheylene (MDPE) film

- Density varies from 0.926 – 0.940 gm/cc
- Average molecular weight is 2×10^5
- Resistance to heat (105 – 121°C)
- Translucent type of clarity
- Percentage of water absorption is 0.01
- Permeability to gas is 1.33 cc/m^2/24 hrs at 27^0 and 1 atmospherics pressure
- Very resistant to weak acids, alkalies, etc.
- Effect of sunlight is yellow.

iv) High density polyethylene (HDPE) film

- Density varies from 0.941 – 0.965 gm/cc
- Average molecular weight is 1.25 x 10^5
- Resistance to heat is 121^0C
- Opaque in nature
- High barrier to moisture vapour
- Permeability to gas is less as compared to other polyethylene films
- Effect of sunlight is yellow

v) High molecular high density polyethylene film (HMHDPE)

- High mechanical strength is both directions
- Pleasant white translucence in clarity
- High tear resistance properties.
- Does not impart any taste or odour
- Suitable for food contact application.
- Less elongation as compared to other polyethylene film.
- Excellent moisture barrier properties

vi) Polypropylene (PP) film

- High tensile strength
- High chemical resistance and high temperature performance than HDPE
- Very low permeability to moisture vapour and gas compared to polyethylene
- High transparency
- Chemical inertness
- High softing point

b) Polyvinyl chloride (PVC)

- It is hard, brittle and transparent material

- Low GTR
- Moderate WVTR and good resistance to fat and oil
- Glass like clarity
- Good mechanical strength
- Retention of flavour
- Excellent printability
- Lower weight/ volume ratio
- Resistant to chemicals

c) Condensation polymer

i) Polyester film (PET) film

- It has got excellent gloss
- Very low moisture and gas permeability.
- High mechanical strength
- Resistant to tear, puncture, burst and flex crack
- Dimensionally stable over a wide range of temp. from
- 70C° to + 130°C
- Excellent machinability
- Excellent printability
- Light in weight
- Free from all kinds of additives
- Good surface properties for metallization

ii) Polyamide or Nylon-6 film

- High mechanical strength
- High elongation capability
- Excellent resistance to cutting, perforation, abrasion and bursting
- High chemical resistance to oils and fats
- Outstanding impermeability to gases and vapours
- Easy printability
- Easy metallising
- Economical
- Could be biaxially oriented

d) Styrene polymers

i) Polystyrene (PS)

Polystyrene is not flexible in nature unlike LDPE and PP and is mostly used as rigid containers in the field of packaging. The important features or properties of this polymer are as follows:

- Crystal clarity of containers
- Availability in attractive light or dark colours
- Lustrous finish
- Rigidity and dimensional stability
- Resistant to chemicals
- Easy processing
- Good barrier to moisture.
- Ability to take post moulding decorations like hot stamp foiling, screen printing, inlay foil moulding, etc.

ii) Expanded polystyrene (EPS)

Expanded polystyrene (EPS) is neither flexible nor rigid in nature rather the material is cushing in nature. Normally, the material is called 'thermocole' which has extensive application in the packaging of electronic and light engineering products. In addition, it is also used for the packaging of sea foods. These materials are manufactured in the following forms, i.e., rigid sheets, flexible sheets, granules, cushion moulded and general purpose moulding.

………………………………………………………………………………

6. Indicate True or False for the following:

   i) Polypropylene films are more transparent than polyethylene films.

   ii) Polyester films have got more gloss as compared to other plastic films.

   iii) The moisture barrier properties of polyethylene is better than nylon film.

   iv) Polyester film has got better oxygen barrier properties than polyethylene.

   v) Expanded polystyrene has got good cushioning property as compared to polystyrene.

13.6 PLASTIC CONTAINERS

Plastic containers are manufactured with the help of different processes and are available in different forms like bottle, drums, carboys, jars, etc. These have wide application in packaging of processed food products.

The plastic containers are manufactured by means of different processes like:

a) Blow moulding process
b) Extrusion blow moulding process
c) Stretch blow moulding process
d) Injection blow moulding process
e) Coextrusion blow moulding process

13.7 COLLAPSIBLE CONTAINERS

The collapsible containers are mainly available in the form of tube for packaging application. The collapsible tubes are either made from multilayer plastics or aluminium. The aluminium collapsible tubes have been used for long time for the packaging of pharmaceutical products. Now a days, number of products like tooth paste, ayurvedic medicines, cosmetics, stationery, gum, etc., are being packed in collapsible plastic tubes. Due to this innovation, consumers have got alternative packaging materials for the packaging of same products. But it would be necessary for you to understand in detail about both the packaging materials and also applications.

I. Alluminium collapsible tube

The collapsible tube is manufactured by means of extrusion process. However, after extrusion of aluminium slug stampings, tubes remain hard and do not collapse. Tubes are then subjected to annealing process after trimming and threading operation. The annealing is done to impart softness and turning away of greases and other minor extraneous impurities at high temperature. The dimensional accuracy beginning with the slugs punched out from extruded/rolled strips right through the manufacturing process should have a high accuracy with near 'nil' tolerance. Extrusion at a very high pressure, 40 tonnes horizontal or vertical, 'blows' the slug into tube.

After the annealing is over, the tubes are given an enamel coating which is dried for about six minutes in a zig zag conveyor type oven. Then the tubes are printed. Once the tube is ready, it is subjected to capping operation.

Advantages

i) ***Temper proof:*** Cannot be refilled or reused.

ii) ***Protective***: Contents remain well protected and free from contamination.

iii) ***Elegant:*** Attractive, posses a bright surface and lend themselves to trouble free printing.

iv) ***Non-toxic and hygienic:*** Non toxic, non-absorbant and hygienic. Impart no taste, flavour, odour or colour to contents.

v) ***Light weight:*** Reduces transport and handling cost.

vi) ***Complete collapsibility:*** Highly ductile and ensures complete collapsibility.

vii) ***Easy availability:*** Increased production of aluminium has resulted in easy availability of raw material.

*viii)****Economical:*** Unbreakable and easy to use and carry.

Applications

a) *Industrial products:* Adhesives, artist's colour, paints, duplicating inks, lubricants and rubber solutions are packed.

b) *Cosmetics and toiletries:* Cosmetic creams, shampoos, deodorant depilatories, hair cream, hair dyes, shaving cream and tooth paste, are packed.

c) *Food products:* Chutney, condensed milk, honey, mustard cream, tomato ketchup, etc., are packed.

d) *House hold items:* Cream detergents, insecticides and rodenticides, shoe polish, mosquito repellent creams, etc., are packed.

e) *Pharmaceuticals:* Antiseptic cream, pharmaceutical creams, ointments, vaginal jellies, veterinary creams, etc., are packed.

II. Multilayer collapsible plastic tube (Lamitube)

The multilayer collapsible plastic tube, commonly known as 'Lamitube', has been introduced in the Indian market recently and now it has taken a lead in many areas by overtaking the aluminium collapsible tube.

The tubes are produced by extruding a continuous tube by a single or more extruders and then cutting into its required length. The tube shoulder is compression moulded and then welded to the tube in line operation. The tubes are then printed separately in multicoulor graphic. As the tube is seamless and printed individually, the printing is continuous all around the tube. A lacquer coat is given further to protect the surface and provide necessary surface finish.

Applications

- Mainly used for different types of cosmetic products like lotions, cream, spray or liquids.
- In toiletry products like tooth paste, shaving cream, etc.
- Available for industrial products like greases, varnishes and creams used for automobile industry.

13.8 COMPOSITE CONTAINERS

A composite container is a canister or a container made from more than constituent material, generally consisting of paper, boards and kraft papers with metal or plastic ends. It is also called as Combican. A laminated composite container is a container made from kraft papers and boards, laminated with polyethylene or aluminium and heat sealed with the membrane to make it completely leakproof. Because of this unique heat sealing property, the aroma retention capacity of the container increases and permeability of moisture vapour decreases

Applications

i) Food products like custard powder, masala powder, etc.
ii) Detergents and detergent powders.
iii) Pharmaceutical products like tablets.
iv) Pesticides.

I. New Developments

Leak proof composite containers are the new addition where the inner layers are made in such a manner that double seaming of the cans become possible to pack liquid product.

The new developed composite can becomes suitable for the packaging of fruit juice, fruit pulp, preservatives, lube oil, motor oil, tooth powder, talcom powder, etc.

Advantages

i) Acts as an alternate packaging material to tin plate container.

ii) This is disposable packaging and can be used for filling of goods with shelf life of 1-2 years.

iii) Composite container is environment friendly.

iv) The stability of the can for a volume upto one litre is as good as tin or glass containers.

v) Seaming or sealing can be effected on the same line as tin plate containers.

13.9 LET US SUM UP

Packaging is considered to be a need based technology. Depending on the requirement of consumer, the development of packaging is also being occurred. On the one hand, continuous development of food technologies resulted into production of new types of products requiring innovate variety of packaging materials and packages to provide effective barrier properties and adequate strength for longer shelf life. On the other hand, the consumers are demanding for lighter, cheaper, durable and attractive packaging materials or packages. This has compelled to develop variety of packaging materials which could be either rigid, semi rigid or flexible in nature. The packaging materials converted directly into package form to pack the processed food products are termed as primary packaging materials. In addition, certain packaging materials like adhesive, printing ink, etc., are called as ancillary packaging materials.

The packaging materials like glass containers, metal containers, plastic containers, composite containers and collapsible containers used prominently for the packaging of processed food products have been discussed in this chapter. The manufacturing process, types of containers, their properties, application in packaging and important quality measures with respect to each materials have also been described in detail.

There has been tremendous use of flexible plastic packaging materials for the packaging of processed food products in the form of consumer packages. These materials are being preferred by the consumer mainly due to thinner, cheaper and lighter in weight.

Though, there has been lot of criticism by the environmental scientist about the application of flexible plastic materials, but there is a constant growth of consumption of these materials. Due to this fact, the properties of these materials have been covered in this chapter.

You have also learnt about another important packaging material the aluminium foil. Its being flexible in nature and has high barrier properties against moisture, gases, light, aroma, etc., this particular material is extensively used as substrate in the flexible laminate to meet the customers requirement. In short, all the important packaging materials, manufacturing processes, properties and applications have been discussed in this chapter.

13.10 KEY WORDS

WTO : World Trade Organisation

Annealing : Regulated way of cooling of an article to eliminate internal stress and thus breakage.

Throat	:	The channel of the furnace through which the molten glasses are passed away.
Ring pull top	:	A newly designed lid of the can where the lid gets opened up through tearing by puling the ring.
Dead fold characteristic	:	It is the characteristic of soft annealed aluminium foil. While the foil is folded, it remains in folded condition and does not come back.
Grease proof	:	It is the resistance of aluminium foil by which there will not be any seepage of oil or grease on the other side.
GTR	:	Gas Transmission Rate. It is an important property of plastic film.
WVTR	:	Water Vapour Transmission Rate. It is another important property of plastic film.
EVAL	:	Ethylene Vinyl Alcohol. It is another polymer.
LCC	:	Leak proof Composite Container. Enables to make double seaming so that liquid products can be packed.
UV curing	:	The drying of printed surface under ultra violet light which improves scuffproofness property.
Tensile strength	:	The strength or force by which the polymeric material breaks while under tension.
Parasite	:	The thermoplastic material when extruded in the form of pipe under blow moulding process is called as parasites.
Billets	:	Billets are the rectangular blocks of caste metal, used for the manufacturing of aluminium foil.

13.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answers should include the following points:

1. i) Wood is the oldest packaging material appeared in the beginning of 1950 for the packaging of heavy engineering and electronic products.

   ii) Jute fibre is considered to be the second appearance as natural packaging material. The material has got tremendous application in packaging of food grains.

iii) Glass containers have appeared in the market as packaging material especially for the packaging of pharmaceuticals, alcoholic beverages, etc.

- Plastics materials have entered in bigway during the period of mid fifties and early 1960's. Initially, polyethylene and PVC have shown the application in packaging.
- In the late 1970's and early 1980's, plastic carry bags have been introduced in the Indian market. Subsequently, these materials have taken a lead over other materials for the packaging application.

2. a) Wooden containers
   b) Plastics
   c) Jute

Check Your Progress Exercise 2

Your answers should include the following points:

1. - The main constituents are sand, lime stone and soda ash.
   - Other ingredients like arsenic, sclenium and cobaloxides are added to make clear glasses.
   - Boron is added to make it stronger.
   - Carbon and sulphides are added to make amber (brown) coloured glass.

2. - Inertness, non permeable, transparent, mouldable
   - Impact strength, light weight and unlimited supply

3. - Used for all types of product packaging
   - High temperature resistance
   - Can be made in any size, shape and capacity
   - Impermeable to moisture and gases
   - Can be made in different colour depending upon the requirement

Check Your Progress Exercise 3

Your answers should include the following points:

1. - General line can
   - OTS can

2. - Open top sanitary (OTS) cans are three piece cans where as Drawn and Wall Iron (DWI) cans are tow piece cans.
   - Open top sanitary cans are mainly used for processed food but the other one is confined to the application of pressurised beer and beverages.

3. - Processed food
   - Edible oil
   - Coffee, baby food and chocolate
   - Paints, insecticides and pesticides

4. • Hydrogenated fat or vanaspati
   • Bakery products
   • Confectionery items

5. • Can be fabricated readily
   • Imperable to light, gases and moisture
   • Non-toxic
   • Amenable to heat sterlization
   • Amenable to printing

Check Your Progress Exercise 4

Your answers should include the following points:

1. A continuous sheet of aluminium metal rolled to thickness ranging from 0.005 to 0.2 mm.

2. Impermable, non toxic, light and heat barriers, tearability, moisture and gas barrier.

3. • Lidding foil, biscuit wrapper.
   • Decorative label, tagger and an important substrate of flexible laminate

4. • A plastic material is a solid at ordinary temperature and allows appreciable and permanent change of form without losing its coleurence on the application of pressure and heat.

5. • Polyolefin group
   • Polyvinyl group
   • Condusation polymer
   • Styrene polymers
   • Carbonate group

6. i) True ii) True iii) True
   iv)True v) True

Check Your Progress Exercise 5

Your answers should include the following points:

1. • Injection blow moulding
   • Co-extrusion blow moulding
   • Extrusion blow moulding
   • Stretch blow moulding

2. • Can be made in any size, shape and capacity
   • Good impact resistance
   • Low permeability to gases and moisture vapour
   • Customer friendly due to innovative opening device
   • Smooth finish surface enhance eye appeal

3. • Aluminium collapsible tube
   • Lami tube

4. • Tamperproof

- Non-toxic and hygienic
- Elegant
- Economical
- Light weight

5. - Cosmetic products
   - Toiletries products
   - Industrial products like greases

6. A can made of dissimilar material where the body is made from paper and the ends are made either from plastic or metal.

7. - Convolute
   - Spiral winding
   - Lap seal method

8. Leak proof composite can which could be used for packaging of liquid products like fruit juice, tube oil etc.

9. - Detergent powder
   - Pesticides
   - Pharmaceuticals products

13.12 SOME USEFUL BOOKS

UNIT 14 PACKAGING PROCESS AND MACHINERY

Structure

14.0 OBJECTIVES

After reading this unit, you should be able to:

- describe about the packaging systems for the transportation of fresh or chilled fruits and vegetables;
- explain the mechanism of various packaging systems for processed food products;
- discuss about the manufacturing processes of different packaging materials; and
- define the machinery, techniques and processes used for packaging processed food products.

14.1 INTRODUCTION

In India, the processed food industry requires primarily the technology in three areas. These are food preparation, packaging and techniques that allow the extension of shelf life of food products. Moreover, the constant research work in the field of food technology has made it possible to develop newer products which require different packagings. At the same time, there has been continuous effort by the industries as well as Government to promote the exports of processed food products. Exportable products require different packagings in terms of durability, higher strength properties, attractiveness and also shelf life.

In order to meet the requirement of export market, there has been enormous development of packaging technology in terms of newer materials, systems and machinery. These developments have not only made it possible to compete with the International brand but also made a position on the shelf of super markets.

Moreover, the newer system of packagings have made the products available throughout the year by enhancing the shelf life. At the same time, there has been enormous development in the packaging machinery also. The newer types of packaging machinery accelerated the productivity with high accuracy and low wastage.

On the other hand, the conversion technology of packaging materials resulted in the availability of various options for processing technology. This technology enabled to manufacture newer types of packaging materials having high barrier properties in order to improve the shelf life of processed foods and higher impact strength to withstand shock and vibrations during handling, storage and transportation. This conversion processes also enhance the productivity with low energy inputs and reduce the cost of packaging materials.

However, there is a constant need to upgrade the existing processing machinery by way of incorporating newer techniques and systems so that the Indian food products and packages could become globally competitive.

14.2 PACKAGING OF FRESH/CHILLED FRUITS AND VEGETABLES

Fresh or chilled (at 4^0C temperature) fruits and vegetables are basically living tissues, high in water content and diverse in terms of morphology, composition and physiology. The package design depends on the requirement of the produce within the frame work of handling and marketing system. The main causes of deterioration in fresh produce are metabolic changes, mechanical injury and attack by pests and diseases. Though, there are variety of packages but there is no rigid rule that a particular material or style is to be followed for a particular type of fruits and vegetables.

I. Product characteristics of fresh produce

i) Highly perishable in nature and are very easily affected by the climatic conditions, distribution hazards and microbial decay.

ii) Respiration process of fresh produce releases oxygen and carbon dioxide. Rapid respiration results in fast ripening or aging of the produce.

iii) Loss in moisture of fresh fruits and vegetables during storage and transportation resulting into drying causing wilting, shrivelling and loss of rigidity. In addition, there will also be loss in weight.

iv) Appearance of microorganisms like bacteria and mould.

v) Very low temperature causes chilling injury which damages the delicate tissues of fresh produce and thus restrict the shelf life.

vi) Changes in colour, texture, odour and flavours.

II. Requirement of package design

a) Pre-cooling

Pre-cooling of fresh fruits and vegetables after harvesting is required to slow down the enzymatic and respiratory activity, minimize susceptibility to micro organisms and to reduce water loss and ethylene production. Pre-cooling helps in removing the field heat prior to storage. The different methods of pre cooling are forced air cooling, vacuum cooling and hydro cooling.

b) Ventilation

The package should be provided with proper ventilation holes during transportation. Cold air is constantly circulated through the container to remove the heat transmitted during the cooling process.

c) Mechanical damage

The package should have adequate impact strength to withstand the shock and vibration which occur during handling, storage and transportation resulting into mechanical injury of fruits and vegetables. In addition, the fresh or chilled produce will have bruising affect during transit due to vibration.

III. Packaging materials

The packages for fresh fruits and vegetables can be classified as:

A) Consumer/ Retail packs

B) Transport/ Bulk packs

A) Consumer or retail package

Consumer packages are small in size designed to hold half dozen or one dozen fruit or ½ kg to 1 kg vegetables. There are many types of consumer packs used for the packaging of fresh fruits and vegetables. The selection for the type of consumer pack depends on marketing characteristics of the product. The most commonly used packages are listed below:

i) Flexible plastic film: Plastic pouches made of LDPE, PVC or PP are used for the packaging of horticultural produce.

ii) Trays with overwrap: The trays used are usually made of moulded pulp tray or thermoformed plastic materials like EPS, PVC and PP. The produce is placed in individual cavities so that abrasion and brushing is avoided. Transparent LLDPE based cling films are used to wrap the trays. The films are semi permeable and allow exchange of gases for respiration of the product.

iii) Plastic punnets: Punnets made from either PET or PVC are food grade, odourless and light in weight. These are also amenable to stacking during storage.

iv) Plastic net bag: The plastic net bags have feature to stretch and accommodate all sizes and shapes of produces. These nets are generally made of HDPE or PA (Polyamide).

v) Foam sleeve: This is a tubular film made of polyethylene foam available in different colours, diameters and lengths. It is hygienic, non-toxic and odourless. This could be easily slipped over the individual fruit in a snug fit form.

vi) Shrink wrap: This is one of the latest trend to shrink wrap the individual produce. This pack restricts the moisture loss. In addition, it provides see through property. The films most commonly used are LDPE or LLDPE.

B) Transport packs

The normal size of transport package is between 15 to 20 kg which is suitable to carry by hand. Transport packages can be broadly classified as follows:

(a) Rigid containers:

i) *Bamboo basket:* Bamboo baskets are widely used even today as transport pack for domestic market. These are available in various shapes, sizes and designs but they do not have the rigidity and stackability during long distance transport.

ii) *Wooden box or container:* The conventional baskets are replaced by wooden box. However, the use of wooden boxes are discouraged now a days as they directly promote deforestation.

iii) *Plastic crates:* Crates made of HDPE or PP have got high impact strength. In addition, these are reusable, amendable to withstand journey by different mode of transportation and also provide good stackability during storage and transportation.

iv) *Solid fibre board:* These materials have got very limited application.

v) *Corrugated fibre board boxes:* The boxes are widely used as shipping containers for fresh produce because of numerous advantages over wooden boxes.

vi) *Plastic corrugated box:* These are usually made of HDPE or PP. HDPF have got light impact strength and low degradation by Ultra Violet radiation while polypropylene has a better scratch resistance.

(b) Flexible containers:

Sacks made of either plastic, jute or paper could be used for the packaging of horticultural produce. This facilitates breathing of fresh produce and have also got high stackability during storage and transportation.

IV. New trend

Modified atmosphere packaging (MAP) is a system involving the removal of air from the packages and replacing with a single or mixture of gases. The gas mixture used depends on the type of the produce.

The MAP system is a dynamic one where respiration and permeation occur simultaneously. Factors affecting both of these must be considered when designing a package. The selection of a film or combination of more than one film (laminates) depends on the expected transpiration and respiration rate of the produce.

14.3 PACKAGING OF FROZEN FOODS

Freezing is considered to be one of the most important technique for the preservation of food products. This technique is mostly employed for the preservation of fresh fruits and vegetables. At low temperature, both microbial growth rate and metabolic activity of foods are reduced by a factor of 1/2 to 1/3 for each 10°C drop in temperature.

Frozen fruits and vegetables should be stored nearly at –16°C to maintain the superior quality. Storing frozen foods at temperatures higher than –16°C increases the rate of deterioration and reduces their shelf life. Fruits and vegetables of high quality and good nutritional value can be achieved under frozen conditions. However, these are primarily based on the following aspects.

a) Physical and chemical changes which take place during freezing process

b) The effect of freezing on fruit and vegetable tissues

c) Food spoilage microbiology

I. Critical factors of frozen food

During freezing operation fruits and vegetables undergo certain physical and chemical changes which affect their quality. Under physical changes, the following critical aspects are to be considered.

i) Moisture is lost as ice crystals evaporate from the surface of the product, producing freeze burn – a grainy, brownish spot where the tissues become dry and tough.

ii) This freeze-dried surface area is prone to development of off flavour.

iii) Freezing of fruits and vegetables consequences into freezing of water resulting into rupturing of cell walls. The texture of the produce, when thawed, becomes much softer as compared to raw produce. This kind of physical change is generally found in vegetables like tomato, which become mushy and watery. However, this type of change is less noticeable in high starch vegetables such as peas, corn and beans.

Similarly, some chemical changes also occur in fresh fruits and vegetables during freezing. The important critical factors to be considered are:

i) Development of brown colour and loss of vitamin C due to enzymatic reactions. In order to prevent this reaction, there is a need to inactivate the enzymes by blanching. This process also helps in destroying the microorganisms present on the surface of fruits and vegetables.

ii) The development of rancid oxidative flavours is another chemical change that takes place through contact of the frozen product with air.

Most of frozen fruits maintain high quality for 8 to 12 months. Unsweetened fruits lose quality faster than those packed in sugar syrup as sugar itself acts as a preservative. Similarly, most of frozen vegetables maintain a high quality for 12 to 18 months at –16°C or lower. Longer storage of frozen fruits and vegetables may not be unfit for consumption but the quality of produce is reduced drastically.

II. Requirement of packaging

Considering the critical factors responsible for the physical and chemical changes of produce that occur due to freezing, the packaging materials should have the following properties to meet the requirement.

i) The packaging materials should have high moisture barrier property so that the material could be used as wrapper to prevent “freeze burn”.

ii) Frozen foods also require the packaging material with high oxygen barrier property so that the products could be wrapped to prevent the development of oxidative rancid flavour.

iii) The packaging materials should have light barrier property so that the effect of UV light in the oxidative reaction could be minimised.

iv) The material should have good printability and heat seal property.

v) The packaging materials should also have low temperature resistance so that wrapped product could be freezed at low temperature without having any crackness on the materials.

III. Types of packaging materials and packages

Frozen fruits and vegetables are normally subjected to blanching or sealing process to destroy the enzymes. Subsequently, they are packed prior to freezing operation. In general, there are two types of packages namely dry pack and tray pack.

a) *Dry pack*

This is the method used to pack the blanched and drained vegetables into containers or freezer bags. The vegetables like broccoli, pack tightly in the freezer bag by arranging the heads and stems in alternate manner so that there should not be any air inside the bag. This kind of bag is normally made from either low density polyethylene (LDPE) or PVDC coated plastic film, 3 layered laminate structures with PET/Al-foil/Polyethylene or five layered coextruded multilayered plastic film (PE/Tie/ Nylon/ Tie/ PE). These type of packaging materials have high impact strength, low temperature resistance and moisture barrier. These packages can be subjected to freezing at a temperature of –16°C or below.

b) *Tray pack*

This type of packages, where the trays are made of collapsible corrugated fibre board, are made from either 3 ply or 5 ply. However, top layer of the board is coated with plastic film to provide water proof property. This kind of board is converted into tuck-n-type tray by means of die-cut machine. However, one single layer LDPE film is spread on the tray so that the produce may not have direct contact on the inner surface of the board. The blanched and drained vegetables are then placed on the tray. As an alternative, the plastic bag filled with blanched and drained vegetables can further be packed into collapsible tray.

IV. Properties of packs

i) Tray pack can be more attractive by way printing on the surface as compared to dry pack.

ii) While freezing, tray pack may not be deformed as the package will have adequate strength. But there is a possibility of deformation or appearance of wrinkles on the products during freezing.

iii) Dry packs are cheep as they are made from either single or multilayered flexible packaging materials.

iv) Dry pack made of plastic bag should have good heat seal property whereas the tray pack should have high compression strength.

v) In both the cases, the selection of flexible packaging material is very important as the materials should have low temperature resistance.

V. New developments

i) *Aluminium tray*

Tray can be made from aluminium sheet instead of paper board. This type of package can be stored at even –40°C without any damage to the tray. Moreover, the oxygen barrier property is excellent and prevention of freezer burn is good.

ii) *Plastic tray*

Plastic tray made of HDPE is extremely used as transport package for the storage of fruits during freezing. However, the individual fruit is washed properly, packed in plastic bag with sugar syrup, heat sealed and then stored in plastic tray for freezing.

VI. Application

The following fruits and vegetables are normally available in frozen form.

A) Fruits **:** Apples, apricots, peaches, straw berries, pine apples, citrus fruits, etc.

B) Vegetables **:** Beans, carrots, cauliflower, peas, potatoes, pumpkin, spinach and other green vegetables.

14.4 PACKAGING OF DEHYDRATED FRUITS AND VEGETABLES

Dehydration of fruits and vegetables or removal of water from fruits and vegetables is the simplest techniques of food preservation. There are number of products which are available in the dehydrated form, for example raisin, mushrooms, apples etc.

The drying process has to be controlled so as to avoid common problems such as tissue shrinkage, browing and heat damage, case harding, loss of rehydrability or solubility and loss of flavour volatiles. Many a times, the dehydrated product is subjected to agglomeration or instantanization for better solubility and quality.

I. Product characteristics

i) Highly moisture sensitive and tends to absorb moisture resulting into stickiness.

ii) Changes in colour, texture and odour during storage.

iii) Susceptible to microbial spoilage due to the appearance of fungal growth on the surface.

iv) Certain products are oxygen sensitive resulting into rancidity which affects the taste of products.

II. Packaging requirement

i) Air tight package

The package could be made of high moisture barrier plastic films like coextruded plastic film, polyester/ polyethylene laminate, etc. The package should be air tight in the form of either pillow pouch, made in FFS machine, or 3 sides sealed pouch.

ii) Plastic containers

The plastic containers made of either PET blow moulded HDPE could be used.

iii) Vacuum package

The dehydrated fruits and vegetables could be packed in plastic pillow pouch and then subjected to vacuumisation. The vacuum pack will help to avoid oxidation rancidity and also protect the product from moisture absorption. Thus, the shelf life of product will be enhanced. The plastic pouch could be made either from laminate made of aluminium foil/polyethylene or polyester/ polyethylene.

iv) Gas package

To enhance the shelf life a product can be packed by creating a vacuum and flushing with inert gas in a container. As an alternative, laminated plastic pouch could be vaccumised, gas flushed and sealed in automatic FFS machine.

v) Pouch in box

The vacuum pouch of dehydrated products could further be packed into composite can and sealed at top to make it air tight. In some cases, the vacuum pouch could to be packed in either carton made from duplex board or 3 ply microflutted (E flute) corrugated fibre board box.

14.5 MANUFACTURING OF PACKAGING MATERIALS

14.5.1 Glass Containers

I. Composition

The main constituent of glass are sand, lime stone and soda ash. The sand used is known as silica or glass sand. Silica sand is melted at the first stage of making glass where soda ash helps it to melt with greater ease. Glass made with the glass sand and soda only is partly soluble in water. When crushed lime stone is added, the resistance of glass to water increases greatly. There are few other chemicals that are added to these three main ingredients to make the glass container stronger and cleaner or coloured as may be required.

In some cases, arsenic, selenium and cobalt oxides in proper proportion are added to make clear glass. The green or brownish shade in glass comes from the impurities in natural sand, mainly iron.

Boron from borax is added to glass to make the container stronger and to increase its resistance to acids. This chemical also reduces the thermal expansion of the glass.

Colours are added to glass by adding small quantities of chromium, cobalt, iron and other colourants depending on the colour required.

For amber (brown) glass, carbon and sulphide are added. Depending upon the qualities and the colour, raw materials are mixed in requisite proportions.

II. Manufacturing process

Depending upon the requirement of type and colour of glass containers to be manufactured, the raw materials are weighed, mixed thoroughly and fed into a glass melting furnace by maintaining a temperature of about 2700°F (1560°C). The melted glass is then passed into the refining chamber of the furnace. Impurities are retained in the melting chamber and the purified glasses are passed through a channel in the furnace called “Throat”. The molten glass passing through the ‘throat’, enters into the refining zone of the furnace where some bubbles, normally escaped through the throat, are allowed to be fined or eliminated and then it enters to the gob feeder. At the precise position, just above the forming machine, the glass is allowed to leave the furnace through a cylindrical hole in the bottom of the feeder and the stream of glass is cut off to a predetermined diameter and length of shears to form a gob. The gob falls into a blank mould, usually made of cast iron, to be shaped into a parison or semifinished container. It is then transferred into a second mould, called finished mould, whose internal cavity is accurately machined to correspond to the desired external shape of the container. The glass container as it emerges from the finished mould has a temperature about 800°C but it cools and hardens quickly. It is then immediately transferred to a tunnel like annealing with planned heating zones to cool slowly. This gradual and regulated cooling of the container eliminates the internal stresses and as it emerges from the other end of the lehr. Then the glass containers are inspected for any faults or defects before packed into corrugated fibre board boxes for the despatch to the user industries.

14.5.2 Metal Cans/Open Top Cans

The tin plate is purchased in the form of sheets either locally or imported. Depending up on the requirement the thickness of tinplate used varies from 0.006” to 0.012”. The following steps are used for the decoration and the manufacturing of tin plate (Figure 14.1).

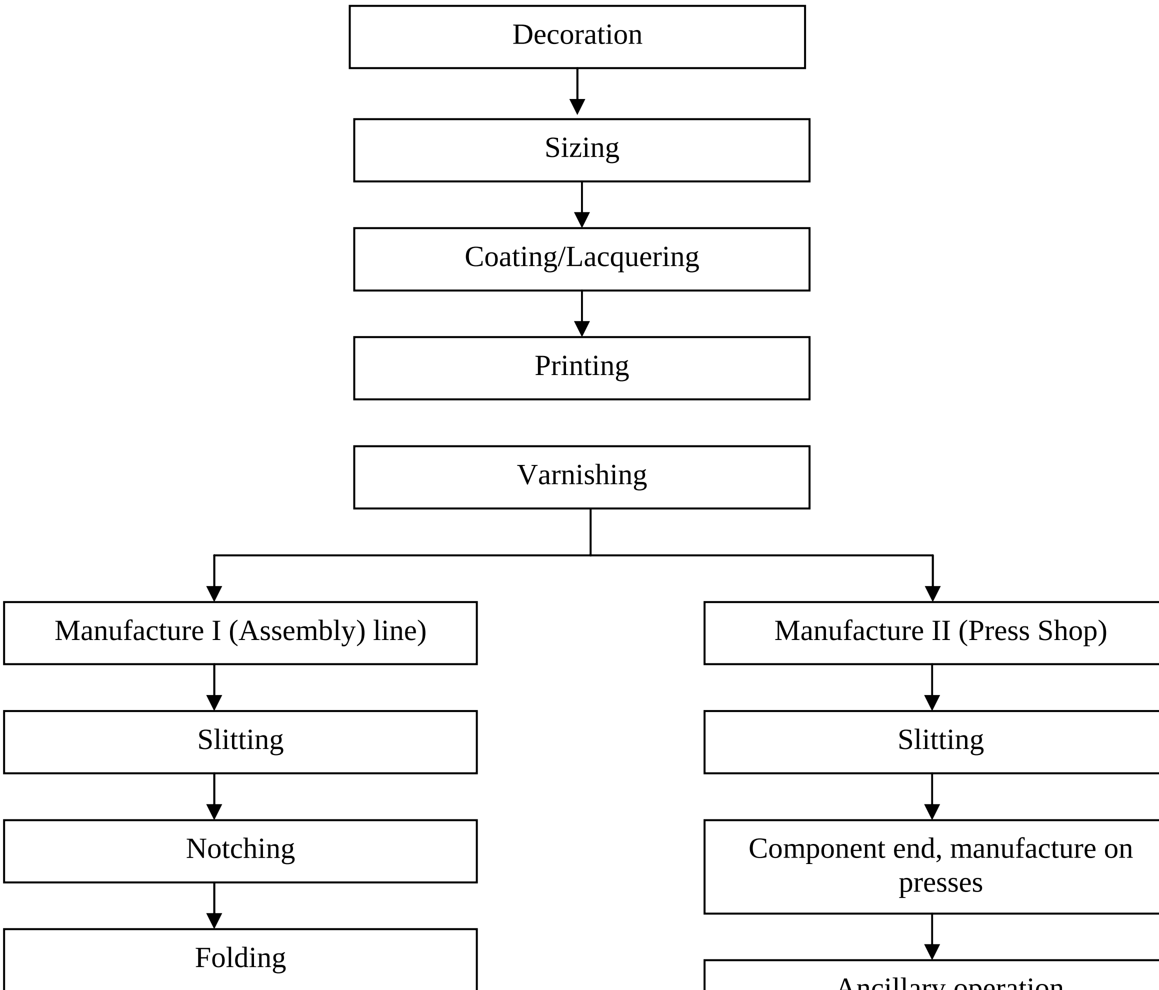

Figure 14.1: Flow diagram of decorated tin plate manufacturing

Though, the plastic containers are constantly replacing tin plate containers in many areas, even though, tin plate containers are continued to be an ideal packaging material for processed food due to the following advantages:

i) They are strong enough to protect the contents during handling and transportation.

ii) The materials are light enough for commercial handling.

iii) They can be readily fabricated into desired sizes.

iv) They are impervious to air and water.

v) They are capable of being heated for sterilization. These containers can with stand the internal pressures during processing of the food.

vi) The materials are not harmful or toxic to their contents.

vii) They can be easily printed for good market appeal.

viii) They can be manufactured at very high speed.

ix) The processed food has got maximum shelf life of 12 months in tin plate containers as compared to any other packaging material.

14.5.3 Plastic Materials

A) Plastic rigid container

Different manufacturing processes are involved in the production of plastic containers by using thermoplastic materials.

a) Blow moulding process

In this process, the thermoplastic materials are extruded in the form of pipe (it is called as parasite) through an annular die (directed downwards) and then blowing it inside the cavity of a closed mould with the help of compressed air to assume the shape of the cavity. Depending on the die, the plastic containers of different capacities, sizes and shapes are manufactured. This method has got most of the major advantages over extrusion and injection techniques and is used to produce thermoplastic hollow ware like bottles.

b) Extrusion blow moulding

Basic parts of this machine are the extruder, die head, mould, clamping unit, blow pin and new blowing unit and control system.

At the first stage, extrusion of the parison is accomplished with a heated, hollow barrel in which a rotating screw conveys solid feed material, compresses and melts it and finally pumps the melt through a tubing die to form the parison. The actual shape and design of the screw is dependent on the theological properties of the plastic materials. Hence, for different types of polymers, different screws are used.

After the plastic has been melted at a low temperature to maintain high melt strength the vertically extruded tube supports itself and then the plastic melt is fed into an extrusion head. For polyethylene, die head with programmable mandrels can be used.

c) ***Stretch blow moulding process***

This method differs from the conventional blow moulding. In that the parison is "Biaxially Oriented" to impart much superior mechanical properties to the blow moulding containers. This process has the following sequence:

- Formation of a parison by injection moulding or by extrusion
- Longitudinal stretching of the parison
- Radial orientation while blowing the parison into the mould
- Ejection

This process can be continuous or in two stages. In the 2-stage process, perform is moulded first and then subsequently reheated, stretched and blown in a secondary operation. Mineral water bottles made of PET are manufactured by using this technique.

d) ***Injection blow moulding***

It is almost same as stretch blow moulding. A parison is injection moulded over a core pin and the threaded neck is formed. The core pin can be shaped so that the plastic can be thin and thick at different points to produce an acceptable bottle. The injection-moulded perform is then transferred to a blow station where the core pin opens and allows air to blow a bottle into the shape of the blow mould. This method is quite popular in advanced countries for moulding small bottles up to 250 ml capacity. In India, injection blow moulding method is yet to be used.

e) ***Co-extrusion blow moulding***

This method can only be accomplished through the multilayer combination of resins to produce co-extruded bottles. This system includes additional extruders and head system where the plastic is brought in at different points and layered to form a parison and follow the same process of blow moulding technique.

The polymeric materials like polystyrene (PS), high density polyethylene (HDPE), polypropylene (PP), polycarbonate (PC), etc., are normally used to manufacture the rigid containers by using the injection blow moulding process.

f) ***Compression moulding***

The science of compression moulding, particularly thermosetting plastics and rubber, is well established. The use of this technique is very rare for processing thermoplastics because of longer moulding cycles involved. In principle, this technique involves the following steps

i) Filling the heated female mould cavity with the moulding powder.
ii) Pressing the powder with the male mould into shape after a breathing stroke.

iii) Maintaining the desired temperature and pressure over a length of time.
iv) Cooling the mould to a minimum possible temperature.
v) Ejection of the article.

B) Plastic films

The thermoplastic polymeric materials are also used to make the flexible plastic films having thickness from 8 to 250 microns. Plastic films are manufactured mainly by two methods, i.e. blown film co extrusion process and cast film co extrusion process.

In case of blown film coextrusion process, the extrusion machine used with either 3 or 5 extruders. However, single extruder machine can also be used to make plastic film by using blown techniques. In this process, polymeric material of single or multiple type is blended and fed into separate hopper, subjected to melt with separate melt channels and then passed through one die that is bonded to form single web of multilayer co extruded plastic film. Now a days, blown film coextrusion process has become very popular as this technique provides plastic films higher impact strength, barrier properties and high seal strength.

In cast film co-extrusion process, the individual layers are combined in multilayer adapters and distributed across the width of a cast film die. Now a days, multilayer co-extruded plastic sheets are being produced by using this technique. This kind of cast plastic sheet has got wide application in manufacturing of thermoformed containers, used extensively for the packaging of processed food products.

14.6 ASEPTIC PACKAGING

Aseptic packaging can be defined as a procedure consisting of sterilization of the packaging materials or container, filling of a commercially sterile product in a sterile environment and producing containers which are hermetically sealed so that recontamination or reinfection is prevented. This results in a product which is shelf stable under ambient conditions. The term 'aseptic' is derived from the Greek word 'Septices' and implies the absence or exclusion of any unwanted organisms from the product, package or other specific areas. The term 'hermetic' is used to indicate suitable mechanical properties to prevent the passage of microorganisms and gas or vapour into or from the container.

I. Steps followed in aseptic system

Aseptic processing comprises the following:

a) Sterilization of the product before filling

b) Sterilization of the packaging material or container before filling operation

c) Filling the product into the sterile package by maintaining the aseptic condition

a) Sterilization of product

The product sterilization is carried out by in-process or on-line sterilization which is popularly known as the ultra high temperature (UHT) or high temperature short time (HTST) depending upon the product treatment. The essential difference between the sterilization through autoclave, i.e., conventional canning method, and on-line UHT treatment is that in canning, the sterilization is done after the product is packed, whereas in UHT method, the sterilization is done prior to packaging. Normally, the sterilization temperature is maintained at 133–135°C for 3 to 5 seconds under HTST/UHT method to make the product sterile. However, there may be slight variation in temperature and duration depending on the type of product.

b) Sterilzation of packaging materials and equipment

Different kind of sterilizing agents like heat, chemicals and radiation are used alone or in combination for sterilization of aseptic equipment and packaging materials.

i) Heat

Initially, product supply lines and fillers are commonly sterilized by moist heat in the form of hot water or saturated stream under pressure. 'Dry heat' in the form of superheated steam or hot air may also be used to sterilize equipment. However, due to the relatively high dry heat resistance of bacterial endospores, the time-temperature requirements for dry heat sterilization is high. Systems enjoying moist heat are frequently sterilized at temperatures ranging from 121–129°C, while 176–232°C is used for sterilization by dry heat.

ii) Hydrogen peroxide

Hydrogen peroxide (H_2O_2) is not an efficient sporicide when used at room temperature. Therefore, most aseptic packaging systems use H_2O_2 (at concentrations of 30 to 50%) as a sterilant for packaging materials followed by hot air (60–125°C) to dissipate residual hydrogen peroxide.

Other chemicals which have been used as sterilents for acid foods include various acids, ethanol, ethylene oxide and peracetic acid.

iii) Radiation

A dose of approximately 1.5 megaradians (MGRAD) Gamma radiation is commonly used to decontaminate containers for acid and acidified foods. Doses required to sterilize containers for use with low acid foods are considerably higher than those required for acid and acidified foods.

Ultraviolet (UV-C) light has been used to decontaminate food contact surfaces. The low penetration and problems associated with shadowing limit the use of UV-C for aseptic systems packaging of low acid foods.

c) Filling of the product under aseptic condition

Once the product has been brought to the sterilization temperature, it flows into holding tube. The tube provides the required residence time at the sterilization temperature. No external heating of holding tube should take place.

A deaerator is used to remove air from the product processed and packed aseptically. The deaerator generally consists of a vessel in which the product is exposed to a vacuum on a continuous flow.

The sterilized product is accumulated in an aseptic surge tank prior to packaging. The product is pumped into the surge tank and is removed by maintaining a positive pressure in the tank with sterile air or other sterile gas.

Aseptic packaging system has been introduced in India by Tetrapack Company and marketing the different process food in tetra packs. The most commonly system is followed by Tetra pack, called as Tetra classic aseptic (TCA) system. The packages produced have a tetra hedronal shape. The ratio of packaging material to packaged product is a very favourable one, i.e., the amount of packaging material needed to package the volume of food is small.

Similarly, the TBA/3 (Tetrabrik Aseptic) system was introduced into the Indian market in the beginning of 1970. The containers produced are ‘brick shaped’ and easier and more efficient to handle during storage and distribution.

The tetrabrik packages are brik like shape and made of six layers of packaging materials. Composition of Tetrapack Aseptic carton is given below (Figure 14.2). The 6 layers in the brick provide total protection to the packaged product.

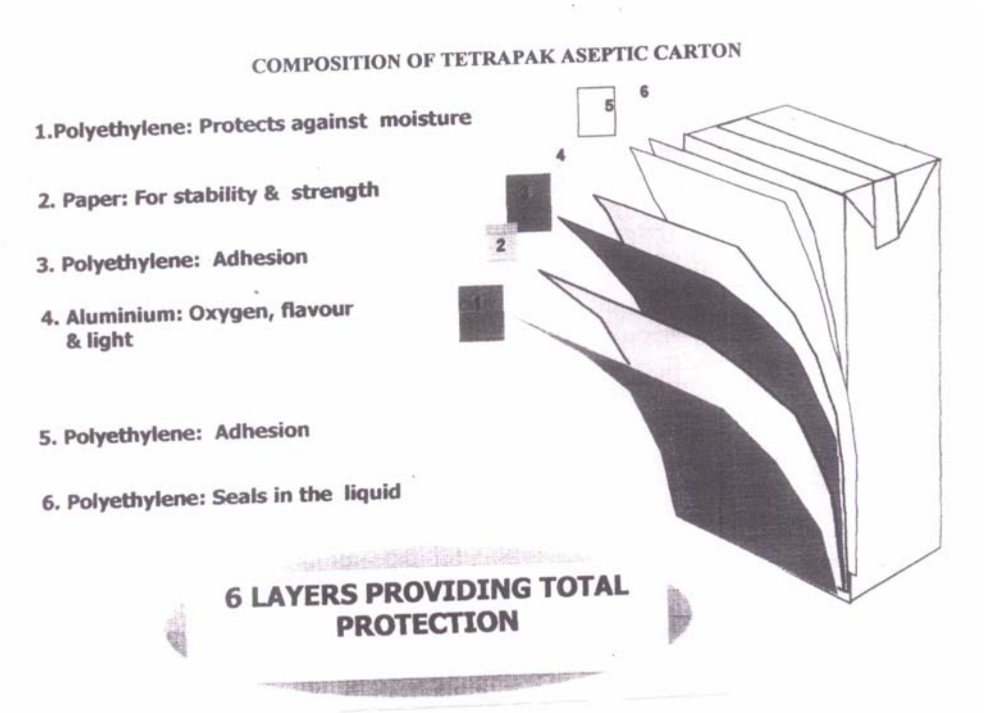

Figure 14.2: Composition of tetrapack aseptic carton

A number of processed food products which are liquid or semi solid in nature, are available in the aseptic packages. The common products aspeticall packed are fresh milk and flavoured milk, fruit juices, yougurt, vegetable oil, chocolate milk, Milk curd, cream.

II. Types of aseptic packages

A variety of consumer packages may be filled aseptically as listed below:

i) Carton box

ii) Bags and pouches

iii) Cups and Trays – Polypropylene based multilayered materials with EVOH barrier materials are used.

iv) Glass bottles and Jars

14.7 VACUUM AND INERT GAS PACKAGING

Vacuum packaging is the simplest and common method of modifying the internal gaseous atmosphere in a pack. The food product is placed in a pack made of a plastic film or laminate of low oxygen permeability. Air is then evacuated and the package is sealed. An evacuated package collapse around the product so that pressure inside is much less than atmosphere.

Similarly, the gas and vacuum package is dealt with the removal of air from the pack and the vacuum space is replaced by a single gas or mixture of gases. The gas mixture used is dependent on the type of product.

I. Vacuum packaging

In this process a vacuum is applied to remove the air from a preformed flexible pouche, containing the processed food product and then sealing it. The plastic film used should have low oxygen permeability under good vacuum condition, the oxygen level is reduced to less than 1%.

The main significance behind this technique is to extend the shelf life of processed food product. The processed foods having high content of fat like deep fried potato or banana chips, namkeen, bhujia, roasted peanut, roasted ground nut, etc., become rancid due to reaction with oxygen present in container. Due to this fatty foods become bitter in taste and unacceptable to the consumers.

In order to preserve these products, there is a need to evacuate the air from inside the package. However, this technique is most suitable for the products which are powder in from like tea, skimmed milk powder, etc. But this technique is not suitable for granular or flaked or bakery products as the products get crushed due to evacuation of air from the package.

II. Gas packaging

Gas packaging can be achieved by two fundamental methods. One is the replacement of air with a gas or a mixture of gases mechanically. The other is by generating the atmosphere within the package either passively, as in the case of fruits and vegetables, or actively by using suitable atmosphere modifiers such as oxygen absorbents, carbondioxide absorbents or emitters. In general, gas flushing process is usually performed on a form-fill-seal machine. Gas is injected into the package to replace the air. This dilutes the air in the head space surrounding the food product. When most of the air has been replaced, the package is sealed. There is a limit to the efficiency of the system since replacement of air in the package is accomplished by dilution. Typical residual oxygen levels in gas flushed packs are 2-5% oxygen. Inert gas like nitrogen is also used to flush the packages.

In case of fresh fruits and vegetables, the atmosphere inside the package is modified passively. Fruits and vegetables continue to respire even after harvest. That means, the produce consumes oxygen and produce carbon dioxide and water vapour. If the respiration characteristics of the commodity can be accurately matched to the permeability of the film used for packaging, then a favourable modified atmosphere can be created passively within the package and an equilibrium concentration of oxygen and carbondioxide is established. Equilibrium modified atmosphere (EMA) containing 2.5 per cent oxygen and 3.8 per cent carbon dioxide could delay the maturation process and softening of the vegetables, reduces chlorophyll degradation, microbial spoilage and enzymatic browning.

Under active packaging, the package containing food products where certain additives are incorporated either in the packaging film or within packaging container to modify the head space atmosphere. Different additives are added to the package to act as oxygen absorbant, carbon dioxide absorbant or scavenger, ethylene absorbant and ethanol vapour generator, etc. This is relatively a new technology and presently quite expensive.

14.8 FORM-FILL AND SEAL EQUIPMENT

Over the years, the form-fill-seal machine has gained popularity and acceptance for packaging of commodities. This particular equipment is suitable for flexible packaging materials and as well as semi rigid packaging materials. The machine operates with either one or two ebs of films which are transported vertically and horizontally. This machine helps to form a package from packaging material and allows to fill the package with the product. Then there is a provision to seal the package and make it ready for transport. Due to this fact, this particular packaging machine is also considered as system packaging.

There are two types of form-fill-seal machines which have got extensive application for the packaging of processed food products.

i) Vertical form-fill-seal machine.
ii) Horizontal form-fill-seal machine.

i) Vertical form-fill-seal machines

This particular machine performs different operations like film formation, back seal production and making top and bottom cross seal simultaneously. The film is fed from a roll and the operations are as follows:

a) Form-fill-tube

Film formation starts at the forming shoulder. In this process, the flat film passes over the shoulder to form a round tube shape with sides overlapping each other. In some cases, machine uses a metal tube to maintain the shape. The back seal could be formed either as LAP, FOLD OVER or FIN to make the basic shape of the pouch or package.

b) Heat seal along back

Once the tubular shape has been formed, the overlapping edges of the flexible packaging materials are sealed. This is normally done with the help of a pair of heated jaws which come together and press the overlap edges of film to make the back or centre seal. In most of the cases, the impulse seal is used for certain film types while other methods such as hot air or high frequency are also used. This machine creates the longitudinal seal that is generally centered on the back of the bag formed at the front of the forming tube.

c) Cross seal formation

Once the tube has been formed with back or centre seal, cross sealing and filling takes place. The bottom of the pouch is then sealed with the help of heating elements in the horizontal jaws and then the seal is cut at the middle and allow to drop the filled package freely. In this case, the horizontal seal where one part act as top seal of the bottom pouch and the other part will be the bottom seal of the subsequent pouch and the operation thus continuous.

Vertical form-fill-seal machines are particularly suited for material that drop freely on its own weight. These are fed by fillers that are normally positioned at the top of the machine. Fillers are (i) gravimetric where a cup is filled, levelled and discharged to the pouch or (ii) auger filler where product volume is measured by the number of revolution of a screw within the tube or (iii) weight fillers based on a scale system where precise quantities by weight are accumulated and released to the bag machine. Edible oil, milk, sugar, cereals, pan masala, spices, tea powder, etc., are packed by this machine.

ii) Horizontal form-fill-seal machine

This type of machine is extensively used for the packaging of processed food products. In this machine, the flexible film is moved horizontally through the machine which form or folds it into a simple 'V' shape. Once 'V' shape is formed, proportional heat control dies make the side seals and the pouches or bags are separated. Horizontal film advancement is intermittent or continuous. This machine has a control device based on electromechanical, electronic or micro processor. Products like chocolates and other confectionery items, sauces, salt, sugar, tomato ketchup, pickles, etc., could be packed by using the machine.

Types of pouches / package formed

By using the form-fill-seal (FFS) machine either vertical or horizontal, the flexible pouches could be made in the form of pillow pouch, 3-side seal pouch or 4 side seal pouch. A single web is used to form pillow pouch or 3 sides seal pouch either by vertical or horizontal FFS machine. In case of pillow pouch, there will be one centre seal at back and two seals, i.e., one at top and the other at bottom. But two numbers of independent web can also be used to make 4 sides seal pouch in this machine. Figure 14.3 illustrates a form-fill-seal machine.

Figure 14.3: A form-fill-seal machine

5. Fill up the following gaps:

   i) In Vertical FFS machine, the fillers are ____________ , ____________ and ____________.

   ii) In vacuum packaging, the oxygen level is reduced to___________.

   iii) EMA contains ____________ oxygen and ____________ carbon dioxide.

   iv) In active packaging, normally ____________ and ____________ are used to absorb oxygen and ethylene.

   v) In gas flushing technique, inert gas ____________ and ____________ are normally used.

14.9 LET US SUM UP

Food products either in fresh or processed form available in the market are consumed by the human beings. There has been constant growth in production of fresh fruits and vegetables but unfortunately, it is not distributed in proper manner across the country. This is mainly due to improper handling and storage mechanisms and also inadequate packaging. In addition, there could also be other reasons like improper infrastructure facilities and transportation. As the fresh produce is highly perishable in nature and continue to respire there is special requirement of its packaging. Similarly, chilled and frozen foods have different packaging requirements.

Aseptic packaging has got extensive application in the packaging of fruit juices for longer shelf life. The foods which have got high fat content, require modern packaging systems like vacuum and gas packaging to enhance the shelf life of these products in consumer pack. Dehydrated fruits and vegetables have got special requirement of packaging which has also been covered in this unit.

For any packaging system, packaging machinery plays an important role. In fact, good and effective machinery has made possible to pack processed food products without much loss in their quality. Form-fill-seal machine is considered to be one of the important machine for system packaging of variety of food products like powders, granules and pastes.

You have also understood the manufacturing processes for the production of important packaging materials like glass bottles, tin plate containers, plastic films and plastic containers which are normally considered as primary packaging materials. These materials have got wide application in the packaging of processed food products.

In short, you have learnt the important packaging materials, their manufacturing process, packaging systems and machinery in this unit.

14.10 KEY WORDS

Annealing	:	Regulated way of cooling an article to eliminate internal stress and thus breakage.
Throat	:	The channel of the furnace through which the molten glass is passed away.
Parasite	:	The thermoplastic material when extruded in the form of pipe under blow moulding process, is called parasite.
HTST	:	High temperature short time. This is the latest technique of sterilization of food products where the microbes are completely killed within short period of time.
Freeze burn	:	During freezing moisture is lost from the surface of the product, the product tissue becomes dry and tough brownish and a grainy spot occurs on the surface.
Parison	:	A semi finished container or a blank mould made of cast iron, used normally prior to sent the gob into finished mould.
Gob	:	A stream of glass cut off to a predetermined diameter and length of sheats to form a gob.
TBA	:	Tetrabrick aseptic system which was introduced in Indian market by Tetrapak Company in the year of 1970.
TCA	:	Tetra classic aseptic system. This system produces the package of hedronal shape.
EMA	:	Equilibrium modified atmosphere containing 2.5% oxygen and 3.8% carbon dioxide, it can delay the maturation process and the softening of vegetables, microbial spoilage and enzymatic browning.

14.11 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answers should include the following points:

1.
   - Highly perishable in nature.
   - Changes in colour, texture, odour and flavours.
   - Apearance of micro-organisms like moulds.
   - Damages of delicate tissues due to chilling injury.
   - Loss in moisture causing loss in weight.
2
   - Consumer package:

     Flexible plastic film, plastic punnets, plastic net bag, foam sleeve, plastic crate, shrink wrap, etc.

   - Transport Package:

     - Bamboo basket, wooden box, corrugated fibre board box.
     - Plastic crate, solid fibre board, plastic corrugated box.
     - Jute sacks, plastic woven sacks, multi wall paper sacks.

3. Modified atmosphere packaging where the atmospheric gas mixture is modified inside the package by considering the requirement of fresh fruits and vegetables. The shelf life of fresh fruits and vegetables increases to a great extent in this packaging.

Check Your Progress Exercise 2

Your answers should include the following points:

1.
   - Physical and chemical changes.
   - The effect on tissue of fruits and vegetables.
   - Food spoilage microbiology.

2. i) Physical changes that occur are

   - Freezer burn – a grainy, brownish spot on the surface, tissue becomes dry and tough.
   - Development of off flavour.
   - Changes in texture as the cell wall ruptures due to the formation of ice crystal during freezing.

   ii) Chemical changes that occur are

   - Development of brown colour due to enzymatic browning.
   - Loss of vitamin C.
   - Development of oxidative rancid flavour on the frozen foods.

3.
   - High moisture barrier property
   - Barrier property to avoid oxidative rancidity.

- Light barrier property to control the oxidative rancidity.
- Low temperature resistance.

4. - Dry packs – LDPE, PVDC coated plastic film, Five layered coextruded plastic film (PE/Tie/Nylon/Tie/PE)
   - Tray packs – made of aluminium sheets, plastic corrugated board, 3 ply or 5 ply corrugated fibre board sheet.

Check Your Progress Exercise 3

Your answers should include the following points:

1. - The main constituents are sand, lime stone and soda ash.
   - Other ingredients like arsenic, selenium and cobalt oxides are added to make clear glass.
   - Boron is added to make the glass strong.
   - Carbon and sulphides are added to make amber (brown) coloured glass.

2. - Raw materials are mixed and fed into melting furnace at (1482°C).
   - Melted glass is passed into refining chamber of furnace and then to form a gob.
   - Gob passes through a parison and then to a finished mould at a temperature of 800^0C to form the glass container.
   - Finally, the glass container cools and hardens quickly.

3. - **Decoration Sizing** – Coating/ Lacquering → printing → varnishing.
   - **Assembly Section** – Slitting → Notching → Folding → Soldering/ Cementing.
   - **Press Shop** – Slitting → Component end → Ancillary operation.

4. - Thermoplastic material extruded in the form of pipe is called parasite.
   - Formation of a parison by injection moulding or extrusion process and then stretching the parison.
   - Radial orientation while blowing the parison into mould.
   - Ejection.

Check Your Progress Exercise 4

Your answers should include the following points:

1. Aseptic packaging is a system by which the commercially sterile products are packed in sterilized containers and the filling operations are also held in sterilized environment.

2. - Sterilization of the product before filling.
   - Sterilization of packaging materials or containers before filling operation.
   - Filling of the product into the sterile package by maintaining the aseptic condition.

3. Products are sterilized by means of UHT method where a temperature of –135°C for 3 to 5 seconds are maintained. However, there may be slight variation in temperature and duration depending upon the type of product.

4. • Moist heat at 121–129°C and dry heat at 176–232°C.
   • Hydrogen peroxide at 30 to 50% concentration.
   • Radiation

5. • Carton box
   • Bags and pouches
   • Cups and trays.
   • Bottles and jars.
6. • Fresh milk and flavoured milk
   • Fruit juices
   • Vegetables oil
   • Cream
   • Chocholate milk

Check Your Progress Exercise 5

Your answers should include the following points:

1. Vacuum packaging is a technique by which all the air inside the package is evacuated resulting into collapsing of package around the product so that pressure inside the package is much less than the atmosphere.

2. Replacement of air from inside the package → inert gas or mixture of gases are injected mechanically → package is sealed.

3. • Vertical Form – Fill-Seal machine
   • Horizontal Form – Fill- Seal machine

4. • Vertical FFS Machine.
   • Edible oil, sugar, spices, ghee, pan masala, milk, fruit juices, hydrogenated fat etc.
   • Horizontal FFS Machine.
   • Confectionery, Sauces, Pickles, Tomato ketchup etc.

5. • Gravimetric, augar and weight fillers
   • 1%
   • 2.5% and 3.8%
   • oxygen seavanger and ethylene absorbant
   • Nitrogen and carbondioxide

EXPERIMENT 1 ADEQUACY OF BLANCHING OF FRUITS/ VEGETABLES

Structure

1.1 INTRODUCTION

Inadequate blanching has a negative effect on quality of finished product. As various types of fruits and vegetables differ in size, shape, heat conductivity, and natural levels of their enzymes, blanching treatments have to be established on experimental basis.

The larger the food item, the longer it takes for heat to reach the center. Thus, small fruit or vegetable may be adequately blanched in boiling water in a minute or two; larger ones may require several minutes.

Objectives

After going through this experiment, you should be able to:

- blanch any given fruit or vegetable; and
- determine the blanching time of any given fruit/vegetable.

1.2 EXPERIMENT

1.2.1 Principle

Adequacy of blanching is determined in terms of inactivation of two most important and heat resistant enzymes catalase and peroxidase in vegetables and some fruits. If these are destroyed, then the other significant enzymes would also be inactivated.

1.2.2 Requirements (Equipment/Machinery/ Instrument and Chemicals/Material)

- Heating vessels (SS Patiala)
- Stainless steel sieve
- Weighing balance
- Measuring cylinders-Plastic
- Heating equipment a) cooking gas cylinder; b) gas burner
- Carrots, Beans, Cabbage, Potatoes
- Potable water
- Labels

- 1% Guaicol in alcohol solution –1 g guaicol is dissolved in about 50 ml of 50% ethyl alcohol and then the volume is made up to 100 ml with the same solvent.
- Peroxide solution 0.3%-5ml perhydrol is brought to 150 ml with distilled water.

1.2.3 Procedure

i) Peel and cut the vegetables into small pieces. Weigh 100g of the prepared vegetable.

ii) Take 400ml water in a beaker and boil. The ratio of water:vegetables is 4:1.

iii) Dip the prepared 100g vegetables in to boiling water and start the timer.

iv) After every 30seconds remove 1g(approx) of vegetables from the beaker and immediately put in cold water.

v) Take this 1g of sample, homogenized in a motar-pestle.

vi) Filter through a muslin cloth and do the tests for the presence of catalase and peroxidase enzyme.

Catalase presence test

Take 1ml of extract and add 1ml of H_2O_2 solution. In the presence of Catalase, a strong oxygen generation (effervescence) is observed for 2-3 minutes.

$$2H_2O_2 \longrightarrow 2\,H_2O + O_2 \uparrow$$

Peroxidase presence test

i) To the same tube to which H_2O_2 is added, add 0.5ml guaicol solution. Keep the tube aside for sometime for colour development.

ii) Appearance of red colour confirms the presence of Peroxidase.

iii) Continue step (4) to (6) till red colour with guaicol ceases to appear.

iv) The time taken from zero minute to the time when red colour is no more observed is called Blanching time for the vegetable under study.

1.2.4 Observation

i) Catalase inactivation time and temperature.

ii) Peroxidase inactivation time and temperature.

Note: For cabbage, Catalase inactivation by blanching is sufficient; blanching further to Peroxidase inactivation would have negative effects on product quality and even complete browning.

For all other vegetables and for potatoes, both tests MUST be negative, for Catalase and for Peroxidase.

Observation Table

Vegetable/Fruit	Time(seconds)	Catalase	Peroxidase

1.2.5 Results

Based on the results of the above exercise, the given vegetable is adequately blanched as no colour development took place.

Absence of colour development indicates adequate blanching.

1.3 PRECAUTIONS

- Select only microbiologically safe vegetables.
- Remove all spoiled, rotten vegetables/fruits.
- Maintain clean, hygienic working atmosphere.

EXPERIMENT 2 CANNING OF FRUITS AND VEGETABLES

Structure

2.1 INTRODUCTION

Canning is a preservation technique used to preserve fruits and vegetables in order to increase their shelf life. It also enables the processor, to store excess amount of fruits and vegetables available in season to be used in off-season.

Objectives

After going through this experiment, you should be able to:

- utilize fruits/vegetables for canning;
- increase the shelf life of the fruit/vegetable; and
- process seasonal fruits/vegetables to be used in off-season.

2.2 EXPERIMENT

2.2.1 Principle

The principle of canning is to sterilize the food inside by a heat process, after sealing the can, to increase its shelf life.

2.2.2 Requirements (Equipment/Machinery/ Instrument and Chemicals/Material)

- Heating vessels (SS Patiala)
- Stainless steel sieve
- Weighing balance
- Measuring cylinders-Plastic
- Heating equipment a) cooking gas cylinder; b) gas burner
- Double seamers.

2.2.3 Procedure

Testing of cans

The empty cans are tested for leaks with a vacuum or air pressure tester. Can is subjected to the gradual air pressure inside it. It is kept in water and the leakage is determined by bubbling. Thus, the maximum pressure the can is able to withstand is determined.

Specifications for a can is that it should be able to withstand pressure not less than 15 pounds.

Canning of fruits and vegetables

Canning of fruits/vegetables involves the following steps:

A) Preparation of fruit and vegetable for canning

i) Sorting and grading

ii) Washing

iii) Peeling, coring and pitting

The washed fruits and vegetables are prepared for canning by peeling, coring, etc.

a) Peeling

- By hand or with knife
- By machine
- By heat treatment
- By lye solution

b) Cores and pits: In fruits they are removed by hand or by machine. e.g., Pineapple. Coring removes fibres and proteolytic enzymes.

iv) Blanching

B) Filling in the cans

C) Syruping or Brining

D) Liding

E) Exhausting

F) Sealing

2.2.4 Observations

- Size of the can used
- Amount of fruit or vegetable/Number of cans used
- Time of exhausting
- If there is any leakage
- If there is any swelling of can
- If can remains flat (seems to be normal and properly processed without any defect)
- Tapping sound a) metallic; b) dull.

2.2.5 Results

The given fruit/vegetable is adequately canned. The procedure followed for canning of fruits and vegetables is correct. The can remains flat and without any defect.

2.3 PRECAUTIONS

- The cans used should be checked for corrosion.
- Fruits and vegetables should be absolutely fresh. It should be free from all-unsightly blemishes, insects damage and malformation
- Ripe, firm and evenly matured fruits should be selected. Over ripe fruit is generally infected with microorganisms and would yield a pack of poor quality. Under-ripe fruit will generally shrivel and toughen on canning.
- Worker should wear apron and cover the head with a cap.

EXPERIMENT 3 CUT-OUT ANALYSIS OF CANNED PRODUCT

Structure

3.1 INTRODUCTION

Cut-out analysis refers to the analysis of packed / finished product for various quality parameters. It is done to check the overall acceptability of the canned product.

Objectives

After going through this experiment, you should be able to:

- if the given canned product is as per specifications;
- the adequacy of heat treatment (over-processing or under-processing)
- the condition of the can and the canned product;
- the adequacy of blanching that has been given before processing;
- corrosion of interior of can; and
- other types of microbial spoilage like hard swell or soft swell of can.

3.2 EXPERIMENT

For measuring Salt and acidity you should consult practical of Course-III (BPVI-003) and Course-VII (BPVI-007)

3.2.1 Principle

The testing of overall acceptability of the canned product is done by observing the physical condition of the can and chemical, microbial and organoleptic quality of the products.

3.2.2 Requirements (Equipment/Machinery/ Instrument and Chemicals/Material)

- Canned products
- Can opener
- Weighing balance
- Refractometer
- Vacuum and pressure gauges
- Seam testing or headspace gauge
- Hot plate
- Burette-50ml capacity

- Pipette-5ml capacity
- Silver nitrate(0.1N)
- Fehling's Solution A and B
- Methylene blue
- Potassium chromate
- Distilled water

3.2.3 Procedure

i) Note the external conditions of can such as body dents or scratches, leakage around seams, condition of ends, etc. In describing the conditions of the can, categorize as per the following:

- Flat cans
- Flipper
- Springer
- Swell

ii) Gross weight: Weigh the can as such and note the gross weight.

iii) Vacuum or Pressure-Use a gauge, which indicates both, vacuum and pressure. Open the can with a good can opener.

iv) Inspection of content: As soon as the can is opened, note the appearance on the surface. Underfilling and overfilling can be seen. Cloudiness in the syrup or brine, or unsatisfactory appearance of the fruit or vegetable must be noted.

v) Gross headspace: This is the distance from the top of the double seam to the surface of the contents of the can. Measure it with a seam-testing gauge or headspace gauge.

vi) Drained weight: Weigh the empty dried sieve. Then, empty the contents of the can in such a manner so as to distribute the product evenly upon a circular sieve which should be so inclined as to facilitate drainage of syrup or brine. Allow the product to drain for 5 minutes.

vii) The drained weight = (weight of the sieve along with the contents- weight of the dry sieve).

viii) Net weight: The net weight is the weight of the contents along with the syrup. Wash the empty can with water and record the empty weight of the can. Subtract the empty weight from gross weight to get the net weight of the contents.

ix) Internal condition of the can: When cans have been emptied and washed, examine the internal surface for evidence of corrosion, blistering or defects in lacquer, pitting, scratching, discolouration, leaks, evidence of scortching along seams, etc. State whether internal surface is lacquered or not.

x) Syrup or brine: Note the colour, clarity and the flavour of syrup or brine. Determine the soluble solids in canned fruits using a refractrometer.

xi) Salt content in brine/total sugars in syrup: For the can containing fruits, determine the total reducing sugars by Lane-Eynon method, whereas for a vegetable, determine the salt content by Mohr's titration.

xii) Inspection of can contents

- *Colour*: It is an essential feature to be considered. Pale or dull appearance makes the product unattractive and unappetizing. Blemished and diseased fruit must be noted very carefully. Discoloration, if any, should be noted.

- *Firmness*: Soft, pulpy or disintegrated fruit pieces must be noted.

- *Flavour:* The flavour is an important factor. Subject the product to a panel of judges and report the flavour in terms of good, acceptable, normal, slight off –flavour or unpalatable.

xiii) Bacteriological examination: The principle of canning is to sterilize the food inside by a heat process after sealing the can. In the canned fruit products, the low pH generally inhibits the growth of bacteria, and only yeasts, moulds and enzymes have to be destroyed. They are comparatively less heat-resistant and are killed by heating for a short period in boiling water. Vegetables of a pH higher than 4.5 are capable of supporting the growth of heat resistant spore forming organisms and hence their processing is based on destruction of spores of toxin producing *Clostridium botulinum.* Sometimes leaker spoilage may occur, which is a post-processing spoilage caused by the percolation of the cooling water through the unsettled seam immediately after processing.

To detect the presence of living bacteria in the canned product, incubate the cans at 37°C and 55°C for 7 days. The organisms growing at 37°C usually cause spoilage accompanied by the production of gas (CO_2) which causes the cans to become springers and then a hard swell. If left too long in the incubator, the cans may blow up. A can, which swells at 37°C indicates the presence of living mesophilic organism, usually caused by leakage.

Subject the swollen cans for bacteriological examinations-TPC, yeast and moulds etc.

3.2.4 Observations

Record the observations in a cut out proforma as mentioned below:

Cut-out Performa

A) Product Details

i) Name of the product
ii) Date of manufacture
iii) Date of inspection
iv) Description of the product

B) Inspection of the can conditions

i) Size of the can
ii) External appearance
iii) Condition of ends of can
iv) Vacuum
v) Gross weight
vi) Headspace
vii) Drain weight
viii) Weight of empty can

ix) Net weight
x) Weight of syrup
xi) No. of pieces
xii) Internal can corrosion

C) Inspection of cans content-organoleptic evaluation

i) Slices Appearance
Colour
Texture
Taste
Foreign matter

ii) Syrup Appearance
Color
°Brix

D) Microbiological examination

3.2.5 Results

FPO specifies standards for canned products. Compare the results obtained with the following FPO standards for canned products, tabulate as per the table given below and conclude whether the given canned product complies the FPO standards.

S. No.	Parameter	FPO standard	Results for given canned product	Comments
	CANNED FRUITS			
1.	**Drained weight**	Not less than 50%, Exception Berry fruits-40%		
2.	**Drained solids**			
2a)	Appearance	Free from blemished,stalks,leaves etc		
2b)	Texture	Free from disintegration, damage from bruises and uniformly prepared		
2c)	Organoleptic quality	Characteristic taste		
3.	**On whole product**			
3a)	Preservatives	Not permitted		
3b)	Added colour	Permitted only in cherry & strawberry		
	CANNED VEGETABLES			
1.	**Drained weight**	Not less than 55%, Exception canned tomatoes-50%		

2.	**On Solids**			
2a)	Appearance	Free from pods, stalks, detached skins, woody fibres, roots and blemishes.		
2b)	Texture	Free from disintegration, damage from bruises		
3.	**On Brine**			
3a)	Added colour	Not permitted except for processed peas		
3b)	Preservatives	Not permitted		

3.3 PRECAUTIONS

- Maintain clean and hygienic working atmosphere.
- Titration should be done as rapidly as possible.
- Normality of silver nitrate should be checked.

EXPERIMENT 4 TESTING OF FLEXIBLE PACKAGING MATERIAL

Structure

4.1 INTRODUCTION

All foods undergo varying degrees of physical, chemical and biological deterioration during storage. This may lead to losses in organoleptic quality, nutritional value, safety and aesthetic appeal of the food product.

The highly sensitive organic and inorganic compounds which make up food that contribute to texture and consistency of unprocessed and manufactured products are affected by nearly every variable in the environment. Heat, cold, light and other radiation, oxygen, moisture, dryness, natural food enzymes, microorganisms, industrial contaminants, time, etc., can adversely affect foods.

Therefore, packaging food in suitable materials is of paramount importance in increasing the shelf life of the products. Packaging is the physical entity that functions as the wall between the contents and the exterior.

Seal strength/Tensile strength is a fundamental property indicative of the serviceability of the packaging material. In the packaging of food products, tensile strength of a flexible packaging **material determines the resistance to rupture when subjected to a pulling force**. Packaging materials of high tensile strength are required when packages are made in semi-automatic pouch forming and filling machines, and to hold heavy packaged items. It is measured using a Instron tensile strength measuring machine

Another property, Elongation at break is also an important parameter of a flexible packaging material, especially for food products which are likely to experience drops during distribution. Such materials need to have a higher elongation property. It is measured on the same machine as that of tensile strength, and **is a measure of the extent to which materials will stretch before breaking.**

Objectives

After going through this experiment, you should be able to:

- test the quality standard of packaging materials;
- predict the quality and shelf-life of the processed product;
- determine the tensile strength/seal strength of the pack; and
- elongation at break.

4.2 EXPERIMENT

Testing methods can be divided into:

i) Chemical parameters: Identification of the plastics, resistance to grease, etc.

ii) Mechanical parameters: Barrier properties, strength, heat-seal ability and clarity

In our practical course, we would be doing the following three main tests

i) Water Vapour Transmission rate (WVTR)
ii) Leak test
iii) Seal strength

The procedure and details for each of the above mentioned methods are described below in Experiment Nos. 4a, 4b and 4c, respectively.

EXPERIMENT 4A TO DETERMINE THE WATER VAPOUR TRANSMISSION RATE (WVTR) FOR THE GIVEN PACKAGING MATERIAL/ PRODUCT PACK

Structure

4A.2 EXPERIMENT

4A.2.1 Principle

The water vapour permeability of the package is defined as the rate at which water is transmitted into the package from the test atmosphere (Normally 90± 2% RH at 37.8° C ± 1°C) surrounding it while a desiccant is sealed within.

4A.2.2 Requirements (Equipment/Machinery/ Instrument and Chemicals/ Material)

- Anhydrous calcium chloride
- Humidity Cabinet – It should have a provision for circulation of air
- Analytical balance-Readability of 0.0001g
- Oven

4A.2.3 Procedure

i) Dry anhydrous calcium chloride in an oven at 200°C for 1 hour.

ii) Place known weight of the desiccant within the pack to be tested. The weight should be more than the half capacity of the pack. Prepare three such experimental samples.

iii) Label each pack as 1, 2, and 3. Seal the packs and record the weight for each pack.

iv) Pre-warm the sealed packets at 37.8°C. Place the warm samples in the test chamber/humidity cabinet maintained at 90±2% R H and 37.8±1°C.

v) Remove one pack from the chamber after 24 hours, weigh and immediately place it back. Repeat the same for all packs.

vi) Repeat the above, till no change in the weight gain is observed.

4A.2.4 Observations

i) Plot the weight gained against time.

ii) The end point is indicated by at least three successive points on a straight line.

iii) The slope of this portion of the curve is measure water vapour permeability.

4A.2.5 Results

- Calculate the average Water Vapour Transmission Rate for the sample by taking the average of the slopes obtained for the three packs.

- Report the water vapour permeability as grams of water per 15 days (till whatever time the weight gain becomes constant) for the package as a unit.

4A.3 PRECAUTIONS

- For accurate weighing, check the bubble of the analytical balance and adjust it to the centre.

- While weighing the packs, care must be taken to take out only one pack at a time and immediately place it back after recording the weight.

- Carry out the experiment in triplicates in order to get most representative results.

EXPERIMENT 4B TO PERFORM THE LEAK TEST ON THE GIVEN FOOD PRODUCT PACK

Structure

4B.2 EXPERIMENT

4B.2.1 Principle

Leak test is done to check: 1) if the seal integrity of the pouch/pack is proper or not 2) if the seal integrity is good enough to undergo handling during transportation.

It is usually used as an online check to see if all the settings of temperature and pressure of the sealing machine are correct.

4B.2.2 Requirements (Equipment/Machinery/ Instrument and Chemicals/ Material)

- Water bath.

4B.2.3 Procedure

i) Fill the water bath with water up to the indicated level.

ii) Hold the pack to be tested from the upper most corners and immerse the same in water while holding it tightly with both the hands.

iii) Observe for the bubbles rising from the seal areas of the pack.

4B.2.4 Observations

- Report if there is any air bubble.

4B.2.5 Results

Air bubbles rising in the water bath indicate a leak in the pack. Hence, the product will not be stable till the indicated period as mentioned on the pack.

If no bubbles are observed, it may be concluded that the product seal is intact and pack is free from any leak.

EXPERIMENT 4C TO DETERMINE THE SEAL STRENGTH OF THE GIVEN PACK

Structure

4C.2 EXPERIMENT

4C.2.1 Principle

The strength of the seal in a flexible packaging is determined by the temperature, pressure and time of sealing. The tensile strength and elongation of the flexible material are important parameter to check the seal strength.

4C.2.2 Requirements (Equipment/Machinery/ Instrument and Chemicals/ Material)

- Instron Tensile Strength Testing Machine

4C.2.3 Procedure

i) Select the packs to be tested for the seal strength.

ii) Cut the back seal of the pack (or top seal/bottom seal whichever is to be tested) yielding a strip about 15mm wide and maximum 50mm in length. Care should be taken not to cut off any of the back heat seal region (or top seal/bottom seal whichever is to be tested).

iii) Place the seal specimen in the Intron tensile test clamps.

iv) Set the machine at a pull rate of 15mm/min using a 5 Kg load cell is used.

v) Begin the test pull. Record the peak value (g/15mm) obtained.

4C.2.4 Observations

i) Calculate the maximum force(peak value) from the chart recorder and record as g/inch.

ii) Following parameters may also be calculated or noted directly from the machine:

   a) Breaking Factor, Kg/cm=Maximum Load/original thickness of specimen.

   b) Tensile strength at break, Kg/cm2= Maximum load at break/Original minimum cross-sectional area of specimen.

   c) Elongation at break %= Elongation at the moment of rupture of specimen/Initial length of specimen*100.

4C.2.5 Results

- The results are expressed as maximum force required in grams/inch.

  A larger value for elongation is an index of toughness, since it indicates that the material will absorb large amounts of energy before breaking.

4C.3 PRECAUTIONS

- Care should be taken while cutting the test specimen. A precision cutter with sharp edges should be used so that there is no damage to the seal area to be tested.
- The material placed between the jaws should not be touched while the test is running.
- Calibrate the equipment, as mentioned in the manual provided along with the instrument, before conducting the test.

EXPERIMENT 5 PREPARATION OF FRUIT-BASED CARBONATED DRINKS

Structure

5.1 INTRODUCTION

People of all age groups consume beverages to quench their thirst. These beverages are non-alcoholic and include fruit based drinks, synthetic drinks, sweetened aerated water or carbonated drinks. The cold drinks are in demand for greater part of the year in the country. India produces more than four thousand million bottles of aerated water annually. This aerated water contains synthetic colouring and flavouring additives, which may potentially be allergenic. It is a huge business in comparison to fruit juices and beverages. These aerated waters if fortified / substituted with fruit juices will provide more nutrition than aerated water and would prove a boon to the consumer as well as grower.

Thus, the fruit based carbonated beverages can provide a new product having natural colour and flavour along with nutrition.

Objectives

After going through this experiment, you should be able to:

- utilize fruit juices for new type of beverages;
- produce fruit based carbonated drinks;
- avoid use of synthetic colouring and flavouring agents; and
- utilize indigenous fruits.

5.2 EXPERIMENT

5.2.1 Principle

The fruit based carbonated drinks can be produced and preserved by hurdle technology, i.e., chemical preservative, carbon dioxide and heat treatment without addition of synthetic colouring and flavouring additives.

5.2.2 Requirements (Equipment/Machinery/ Instrument and Chemicals/ Material)

a) Preparation and preservation of fruit juice

- Fruit mill
- Hydraulic press
- Stainless steel (S.S.) Tanks
- Heating vessels (S.S. Patiala)
- Stainless steel sieve
- Glass bottles
- Crown corking machine
- Crown corks
- Heating equipment a) Cooking gas cylinder; b) Gas burner
- Thermometer
- Weighing balance

b) Preparation of carbonated fruit drinks

- Carbonating machine including CO_2 gas cylinder
- Water chiller
- Water filtering unit

c) Chemicals / materials

- Fruit juice, (Fruits-Jamun, Amla, Lime and coloured grapes)
- Sugar
- Citric acid
- Sodium benzoate
- Labels
- Carbon dioxide gas
- Potable water
- Filtration cloth

5.2.3 Procedure

a) Preparation and preservation of fruit juices

Fully ripe fruits are selected; injured and spoiled fruits are sorted out. Cull fruits can also be used. Fruits are cleaned and washed thoroughly with clean water. Fruits are crushed in a fruit mill and the crushed mass is pressed into a hydraulic press to get juice. The juice is filtered and preserved either by chemical preservative or by heat application (i.e., pasteurization or sterilization). The processed fruit juice could be stored at refrigerated temperature for better quality during storage.

b) Preparation of carbonated fruit drinks

Preparation of fruit syrup: Carbonated drinks are made by post-mixed method. Fresh or preserved fruit juice is used to prepare syrup base. Syrup base is prepared by mixing fruit juice, sugar, citric acid and water and preserved by sodium benzoate. These ingredients are mixed in such a way so that the syrup base has 50% (or °Brix) total soluble solids and 1.0% acidity.

The general formulations based upon our past experience of commercial productions are given in the box below:

Recipes	Aonla	Grape	Jamun	Lime
Juice (kg)	1.0	1.0	1.0	1.0
Sugar (kg)	1.17	1.066	1.16	3.254
Citric acid (g)	11.43	12.00	11.11	-
Water (kg)	0.322	0.443	0.341	2.254
Sodium benzoate (g)	1.25	1.25	1.25	3.25
Total (Kg)	2.50	2.50	2.50	6.50

The amount of above ingredients may be altered as per requirement.

The sugar and citric acid are dissolved in water by heating to a boil, filter through a four-fold muslin cloth and then cooled. After cooling it is mixed with the juice thoroughly. The sodium benzoate is mixed with a small quantity of clean water and then mixed thoroughly with the syrup base and filled into the clean and presterilized glass bottles leaving a head space of 4 cm and sealed by crown corking, labelled and stored at low temperature (5-6°C).

Carbonation: The properly filtered clean water is chilled to a temperature of 4°C. The chilled water is taken into the carbonator and the desired pressure of carbon dioxide gas is maintained, so desired gas volume is achieved in the finished drink when measured.

The desired amount (50g) of a fruit juice syrup is dosed into the previously sterilized and clean glass bottles (200 ml capacity) and then filled with the carbonated chilled water and sealed by crown corking.

The fruit based carbonated drinks can be stored for a week if prepared without preservative. But if preserved with sodium benzoate and heat processing then it can be stored for a period of 3 months at ambient temperature (30°C) under dark conditions and 6 months if stored at low temperature (6-7°C).

Heat processing: Bottles are placed in the water heated to a temperature of 70°C in a stainless steel or aluminium vessel so as to maintain a temperature of 66°C for 30 minutes in the contents of the bottle. After heat processing, the bottles are removed and cooled under fan. After cooling, bottles are washed, shaken a little bit and stored, labelled and marketed as and when required.

5.2.4 Observations

In fruit juice and syrup base

i) Total soluble solids (TSS)
ii) Acidity
iii) pH

In final carbonated fruit drinks

i) TSS
ii) Acidity

iii) PH
iv) CO_2 gas volume
v) Sensory quality on the basis of colour, flavour and taste (0-9 score of Hedonic scale)

For measuring TSS, acidity and pH you should consult the practical manual III Food Chemistry and Physiology and VII Food quality Testing and Evaluation.

Calculations

CO_2 gas volume: For measuring gas volume in a carbonated beverage, a gas volume tester is required. It is screwed on the top of the neck of the bottle. By pressing the handle crown cork is punctured and gas pressure is observed in the pressure gauge which is released by unscrewing the side valve until the first bubble rise in the liquid. Then shut the valve and shake the bottle until gauge reaches maximum pressure. Note the pressure on the gauge. Remove the crown cork and note the temperature of the drink. With these values, gas volume is seen through a Table 5.1. Gas volume denotes how many gas volumes are dissolved in one volume of liquid.

5.2.5 Results

Analysis of finished beverage

- Gas volume (gas volume about 2.5 to 3.5 are acceptable for fruit based drinks)
- TSS
- pH
- Acidity
- Sensory quality

The product which has received a score of 5.5 and above is acceptable.

Any abnormal change in TSS, acidity or pH will indicate that the product is not fit for consumption.

5.3 PRECAUTIONS

- Select only microbiologically safe fruits.
- Remove all spoiled, rotten fruits.
- Thick glass bottles should be used, which can sustain CO_2 gas pressure.
- Maintain clean, hygienic working atmosphere.
- Workers should wear apron and head gear.
- Proper CO_2 gas pressure should be maintained in the cylinder containing chilled water.

Table 5.1: Gas volume test chart (Volumes of carbon dioxide dissolved by 1 volume of water)

Temp., (°F) in bottle — **Gauge pressure of bottle (lbs. per sq. in)**

A figure in this column represent the volume of carbon dioxide gas (reduced to 0º and 760 mm.) dissolved by I volume of water at the temperatures indicated, if the partial pressure of the carbon dioxide gas is 760 mm. Hg, solubility data correspond to Bohr and Bock published in Landolt-Bornstein, Physikalische-Chemische Tabellen. Figures in body of the table were calculated for various temperatures and pressures based on the Boyle-Mariotte law for isothermal compression.

UNIT 1 DEFINITION AND IMPORTANCE OF QUALITY

Structure

1.0 OBJECTIVES

After reading this unit, you should be able to:

- define food quality;
- state the quality specifications for consumers;
- classify and explain food quality attributes; and
- explain food borne hazards and infections.

1.1 INTRODUCTION

Food quality and safety are the two of the most important aspects of food processing. Therefore an understanding of what constitute food quality is very essential. Equal or more important is ensuring food safety. Food poisoning through microbial and viral means is a major concern.

An efficient quality control department in a food processing unit plays vital role in ensuring both quality and safety. These aspects are dealt with in this unit.

1.2 DEFINITION OF FOOD QUALITY

Quality of foods may be defined as the composite of those characteristics that differentiate individual units of product; these characteristics should have significance in determining the degree of acceptability of that unit by the buyer.

Some important characteristics of the food / food products are:

- Colour and gloss, viscosity and consistency, size and shape, texture and flavour.
- Nutritive values (vitamins, minerals) – hidden attributes.

Quality is commonly thought of as degree of excellence. It may be considered as a set of specifications, which are to be met within given tolerances or limits. Quality Control may be defined as the maintenance of quality at levels and tolerances acceptable to the buyer while minimizing cost for the vendor.

1.3 FOOD QUALITY ATTRIBUTES

The quality attributes referred to as sensory may readily be classified in accordance with the human senses by which they are perceived. The sensory attributes namely, the senses of sight, touch, taste and smell are given in Table 1.1.

Table 1.1: Classification of quality attributes

Sight	—	• Appearance • Colour • Gloss • Viscosity • Size and shape • Defects
Touch	—	• Kinesthetic (texture) • Hand or finger feel • Mouth feel
Smell and taste	—	• Flavour • Odour • Taste
Hidden	—	• Nutritive value • Adulterants • Toxicity

Some of the important sensory quality attributes are described below:

Colour and gloss

Colour is an appearance property due to spectral distribution of light. Glossiness, transparency, haziness, and turbidity are properties of materials due to the differences in reflectance and transmittance of light.

Physically, colour is a characteristic of light, measurable in terms of intensity and wavelength. It arises from the presence of light in greater intensities at some wavelengths than of others.

Light may be reflected, transmitted, absorbed, or refracted by the object being illuminated. Spectrophotometers are used to measure colour of the products.

Viscosity

Viscosity or consistency is an appearance property of great importance to food products such as ketchup, creams, juices, pulp, jams, jellies, syrups, etc. The measurement may be used to indicate the consistency of the products. It may also be used as an index to the amount of ingredient in the product.

Liquids flow as if they were composed of individual layers. The friction resulting from the resistance to flow between the liquid layers is called apparent viscosity. Brooke field or Ostwald viscometer is used to determine the viscosity of the product.

Size and shape

Grading into various size and shape categories is usually one of the first steps in food processing operations. This may be accomplished by hand or by means of mechanical sorters, using screens, reels, slots, etc. Grading helps in maintaining uniformity.

- *Defects*

  Defects have been defined as "imperfections, due to the absence of something necessary for perfection, or the presence of something that distracts from perfection".

  In grading foods for defects, tolerances may be established in terms of maximum numbers of defective units allowable.

  Defects may be classified into:

  1. Genetic – physiological,
  2. Entomological,
  3. Pathological,
  4. Mechanical, and
  5. Extraneous or foreign matter.

Kinesthetics of texture

Kinesthetic characteristics deal with the sense of feel. They can be classified as follows:

Finger feel:

- Firmness as encountered by the customer selecting a firm apple, measured physically by compression.
- Softness or yield quality as in selecting a peach, or plum measured physically by compression.
- Juiciness as in immature sweet corns where the thumbnail is used to test the ease and amount of juice squeezed out of a kernel.

Mouth feel:

- Chewiness, as sensed by the resistance of the product to compression and shearing action of the teeth.
- Fibrousness as sensed by the presence of an inedible residue remaining in the mouth after mastication, as well as resistance to cutting forces of the teeth.
- Grittiness, as sensed by the presence of small grit particles, such as sand, or stone cells.
- Mealiness, as sensed by the coating of starch or other material with adhesive properties, over mouth tissues.

- Stickiness, as sensed by the mouth while chewing foods with adhesive properties.
- Oiliness, as sensed in the mouth, caused by oily or soapy products.

The characteristics may be determined by tenderometers, texture meters, puncture meters, succulo meters, fibro meters and pressure testers.

Flavour

Flavour includes taste and odour/ aroma. Taste is a four-dimensional phenomenon, consisting of sweet, sour, salt and bitter. Sweetness can be measured by use of refractometers, sourness by pH meters, and saltiness by flame photometer or by argentometric titration. Bitterness is not estimated but compared to that of quinine sulfate. Odour/ aroma is determined by gas chromatography.

Hidden characteristics

The hidden characteristics of quality are those, which the consumer cannot evaluate with his senses, and yet are of real importance to his health and economic welfare. Nutritive value is one of the hidden characteristics, which is now considered by the consumer as an important attribute. Adulterants and toxins are the other hidden characteristics. Toxins can be microbial toxins, pesticide residues or heavy metals.

1.4 QUALITY SPECIFICATIONS FOR THE CONSUMER

The Quality Control System – should be properly geared to meet the consumer's specifications, the quality control cycle usually begins and ends with the customer's specifications.

1st Step : Determine what are the customer's specifications for the product.

2nd Step : Set up procedures to measure these specifications, objectives; scientific methods should be used as far as possible.

3rd Step : Workout the sampling schedule and set up control points in the plant.

4th Step : Final inspection of the finished product.

1.5 FOOD BORNE HAZARDS / FOOD POISONING

In recent years, a number of bacteria, viruses and parasites have emerged as food-borne pathogens resulting in numerous food-borne disease outbreaks. Genetic changes in microorganisms resulting in increased virulence, changes in social attitudes and eating habits, changes in food production and distribution systems and demographic shifts are some of the factors responsible for this.

1.5.1 Microbial Infections

Bacillus cereus

Bacillus cereus is a Gram-positive, motile, spore -forming, facultative anaerobic rod. It is ubiquitous in nature, commonly found in soil (especially rice, paddy, soil) and vegetation. It has been isolated from many foods, including cereal and cereal derivatives, spices, milk and dairy products, vanilla sauce, recipe dishes, chicken soup, mashed potatoes, vegetables, rice dishes and dried foods.

Bacillus cereus can cause two distinctive forms of food poisoning caused by enterotoxins. Emetic food poisoning is caused by the ingestion of emetic toxin that has been pre-formed in food. It causes general malaise, nausea and vomiting and occasionally diarrhoea. This type of food poisoning has been linked with starchy foods such as cooked rice, pasta and noodles. Diarrhoeal food poisoning is caused from the formation and release of enterotoxin in the small intestine. However, the enterotoxin can also be pre-formed in food.

Clostridium botulinum

Clostridium botulinum is a Gram- positive rod. It is a spore-former and an obligate anaerobe. It is ubiquitous, so is widely distributed in soil and marine sediments throughout the world. It is also found in the intestinal tract of animals, including fish.

Non-proteolytic strains of Clostridium botulinum are psychrotrophic. It is because of their non-proteolytic characteristics, that their growth in foods cannot be detected by off-odours and off-flavours. The risk of toxin production prior to the food becoming unacceptable to the consumer is considerably higher than in those foods contaminated with proteolytic strains. In the spore form, it is resistant to heat treatments such as pasteurization. A heat process called a "Botulinum Cook" at high temperatures is commonly recommended for low acid canned products.

Clostridium botulinum produces preformed toxins. The toxin itself can be destroyed by heat treatment (80°C or above) for only a few seconds. Botulism is extremely serious and unless recognized and treated promptly, carries a high risk of mortality. It is the most severe form of food poisoning.

Most of the outbreaks of botulism have been associated with products of fish or marine animals, meat and fruit and vegetables - including mushrooms. Insufficiently heated, canned and bottled foods are at high risk as these provide the anaerobic environment required by the organism to grow. Other inadequately processed products such as farm-cured pork products or those produced where process control is insufficient e.g. traditional fermented products have also been implicated in outbreaks.

Salmonella

Salmonella is a Gram-negative motile rod. It is non-spore forming and facultatively anaerobic in nature. Pasteurization and equivalent heat treatments will generally destroy the organism.

The main source of *Salmonella* for man is food from infected food animals. These animals become infected via the environment, contaminated feed or water, or from other infected animals, birds or rodents. Therefore, meat, poultry, raw milk and eggs should be considered as potentially contaminated with *Salmonella.*

Types of foods involved in food borne salmonellosis have been wide -ranging, but involve mainly poultry and meat products, egg and egg products, cereal and grain products, desiccated coconut, chocolate and dairy products.

The clinical disease of *Salmonella* infection is gastroenteritis. It is one of the main causes of food borne illness the world over. Although death from salmonellosis is rare, it can occur in "at risk" groups, e.g. infants, the elderly and the immuno -compromised (such as hospital patients).

Listeria monocytogenes

Listeria monocytogenes is a Gram -positive, non-sporing rod. It is aerobic and facultatively anaerobic in nature. *Listeria monocytogenes* is psychrotrophic in nature Of all the non-sporing, vegetative food pathogens, Listeria is the most heat resistant. It is, however, generally agreed that milk pasteurization will destroy normal levels of *L. monocytogenes* in milk.

Listeria is ubiquitous in the environment and so can be transferred to foods from a wide variety of sources. Infection from Listeria can also originate from direct or indirect contact with animals (sheep and cows can both excrete *L. monocytogenes* in faeces and sometimes in milk).

Listeriosis is a comparatively rare disease; however, because of the potential severity of the disease, measures for its control in foods are very important. It is generally agreed that the majority of cases of listeriosis are food borne and may be preventable. Symptoms are typically meningitis or septicaemia and in pregnant women it can cause a flu-like illness, which can result in miscarriage, stillbirth or birth of a severely ill infant.

Staphylococcus aureus

Staphylococcus aureus is a Gram-positive coccus. It is a non-motile, non-sporing, facultative anaerobe. Staphylococcus aureus can grow within the temperature range 7°C – 48°C, with an optimum of 35°C – 37°C.

Although *Staphylococcus aureus* is a ubiquitous organism, the largest reservoir of enterotoxin producing staphylococci is man. Therefore, the presence of *staphylococci* in cooked or processed foods can serve to indicate poor hygiene amongst food handlers. Animals may also act as a source of *Staphylococcus aureus*. Typically raw milk and raw meat (particularly pork) may be contaminated with the organism. Some strains of *Staphylococcus aureus* are capable of producing heat-stable toxins (enterotoxins) in food. It is the toxin that causes the typical symptoms associated with *Staphylococcus aureus* food poisoning. Typical symptoms are nausea and vomiting with occasional abdominal cramping and diarrhoea. Foods involved in *Staphylococcus aureus* food poisoning are typically those that have been handled and then temperature abused prior to consumption. Foods implicated in Staphylococcus aureus food poisoning have been cooked meats (notably salted meat such as ham), poultry products, custard or cream -filled pastries, egg foods, cheese, prawns and salads containing potato.

Shigella spp

The genus Shigella consists of four species: *S. dysenteriae* (subgroup A), *S. flexneri* (subgroup B), *S. boydii* (subgroup C), and *S. sonnei* (subgroup D). -sporulating, non -motile rods in the family *Enterobacteriaceae.*

Shigellosis, although commonly regarded as waterborne, is also a food borne disease restricted primarily to higher primates, including humans. Food handlers with poor personal hygiene usually spread it among humans. Foods most often incriminated in the transmission have been potato salad, shellfish, raw vegetables, and Mexican dishes.

Vibrio cholerae

The genus *Vibrio* includes Gram-negative, oxidase-positive (except two species), rod- or curved rod-shaped facultative anaerobes. Many *Vibrio* spp. are pathogenic to humans and have been implicated in food borne disease. Pathogenic *V. cholerae* produces a heat-sensitive enterotoxin that causes the characteristic cholera symptoms, including "rice water stool."

1.5.2 Water and Food Associated Viruses

Several viruses like *Hepatitis* A, *Norwalk* and *Norwalk* like viruses; *Poliovirus* and *Echovirus* may cause food borne disease. Some of the other viruses that have also been associated with food are: *Astrovirus, Calcivius, Enteric Adenovirus, Parvovirus* and *Rotavirus*. These enteric viruses replicate in the intestine of infected individuals and are transmitted by faecal-oral route. The most common types of food-borne viral diseases are *Hepatitis A* (infectious hepatitis) and acute viral gastroenteritis.

The *Hepatitis* A virus (HAV) is one of more than 70 members of enterovirus group of *Picronaviridae* family. Food borne viral gastroenteritis is usually a mild disease with various degrees of nausea, diarrhoea, malaise, abdominal pain, muscle pain, anorexia, headache, and low-grade fever. Illness develops 20 to 50 hours after the consumption of contaminated food and lasts for 1 to 8 days.

Ice, water, ice cream, milk, pastries, salads, sandwiches, shellfish, and other foods consumed raw or subjected to additional handling after cooking are major food vehicles for virus transmission.

1.5.3 Preventive Measures

Prevention and control of food borne disease depends on careful food production, handling of raw products and preparation of finished products. Hazards can be introduced at any point from field to table. The 20th century witnessed revolution in food sanitation and hygiene including refrigeration, chlorination of drinking water, pasteurization of milk, potassium permanganate washing of root vegetables like carrots, lettuce etc. which was a consequence of applied technologies.

Chlorination of drinking water sources for food animals, sanitary slaughter and processing of meat, poultry and seafood, irradiation and other microbial reduction measures for raw agricultural commodities are significant as approaches for food safety. Hazard Analysis Critical Control Point (HACCP) process occurs when monitoring and control technologies are systematically applied to food production to prevent food borne illnesses.

Food cooks are the last but one point of critical control before meal is consumed, the last being those responsible for meal service on the table or in the dishes. Therefore, interventions to promote safe food practices are needed.

1.6 FUNCTIONS OF QUALITY CONTROL

A well functioning quality control organization will contribute to the reduction of rejects, maintenance of uniform quality, increased customer satisfaction and employee morale.

Some of the specific responsibilities of Quality Control Department are listed below:

- Inspection of supplies and materials.
- Scheduling of operations.
- Measurement of production efficiency.
- Inspection of the finished products.
- Shipping and storage controls.
- Preparation of specifications and procedures.
- Sanitation inspections.
- Conformance to food regulations.
- Waste disposal control.

The quality control department to be effective should have good liaison with the other departments like Sales and Purchase, Production, Research and

Development etc. and also should have complete support from the management.

1.7 LET US SUM UP

Quality is the composite of those characteristics of which determine the degree of its acceptability by the consumer. The characteristics of food include measurable characteristics like colour and appearance, texture, flavour and also hidden characteristics like nutritive value, presence or absence of adulterants or toxicants.

There is a number of food borne infections. A large number of microorganisms are implicated in food poisoning. Besides, some water borne viruses are also of great concern.

An efficient quality control system in a food processing unit has a major role to play in maintaining consistent quality of finished products and ensure food safety.

1.8 KEY WORDS

Food quality : The composite of those characteristics of food determining the degree of acceptability by the consumer.

Colour : Colour is an appearance property due to spectral distribution of light.

Viscosity : The resistance to flow of a liquid is termed viscosity.

Kinesthetic of texture : Texture perception by feel.

Flavour : Combined sensory perceptions of taste and aroma.

Hidden characteristics	:	Nutrients content and presence or absence of adulterants and toxicants.
Botulism	:	Food poisoning caused by *Clostridium botulinum*.

1.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following:
   - Characteristics differentiating individual units.
   - Degree of acceptability
2. Your answer should include the following:
   - Colour, texture, appearance.
   - Nutrients, toxicants
3. Your answer should include the following
   - Nutrients, toxicants.

Check Your Progress Exercise 2

1. Your answer should include the following:
   - Clostridium botulimum, Salmonella, Staphylococcus aureus.
   - Insufficient heat processing of canned foods.
   - Poor hygienic handling of foods.
2. Your answer should include the following:
   - Hepatitis A, Norwalk, Astrovirus, Rotavirus.
   - Unhygenic handling of food after cooking.
3. Your answer should include the following:
   - Hygienic handling, chlorination, pasteurisation.

Check Your Progress Exercise 3

1. Your answer should include the following:
   - Inspection of raw materials.
   - Inspection of finished products.
   - Preparation of specifications and procedures.
   - Conformances to food regulations.
   - Waste disposal control.

1.10 SOME USEFUL BOOKS

2. Multon, J.S. (1995) Quality control for Foods and Agricultural Products, VCH Publishers, New York.

UNIT 2 QUALITY STANDARDIZATION

Structure

2.0 OBJECTIVES

After reading this unit, you should be able to:

- state the importance of food control;
- describe various national food legislations; and
- international food regulations.

2.1 INTRODUCTION

Effective national food control systems are essential to protect health and safety of the domestic consumers. They are also critical in enabling countries to assure the safety and quality of their foods entering international trade.

Especially to facilitate international trade in food and food products, international agencies have laid down regulations. The national food regulations of most countries are being harmonized with these international regulations.

2.2 NATIONAL FOOD CONTROL SYSTEMS

Some of the **objectives** of the National Food Control Systems are:

- Protecting public health by reducing the risk of food borne illness.
- Protecting consumers from unsanitary, unwholesome, mislabelled or adulterated food.

- Contributing to economic development by maintaining consumer confidence in the food system.
- Providing sound regulatory foundation for domestic and international trade in food.

The **scope** of Food Control Systems should cover all food produced, processed and marketed within the country, including imported food. Such systems should have a statutory basis and be mandatory in nature.

2.3 NATIONAL FOOD LEGISLATIONS

The laws regulating the safety and quality of food in India date back to 1899. Before 1954, states or provinces in India had their own food laws. The variations in food standards created conflicts in inter-state trade.

2.3.1 PFA Act, 1954

In 1943, Central Advisory Board was appointed which recommended for Central Legislation. Consequently in 1954, Central Legislation called "Prevention of Food Adulteration Act (PFA Act)" was enacted in the parliament, which came into effect from 1st June 1955.

Ministry of Health and Family Welfare is responsible for ensuring safe food to the consumers. The objective of the Act is to ensure supply of pure and wholesome food to the consumers and also to prevent fraud or deception. Major amendments in 1964, 1976 and 1986 have been effective in making the punishments more severe and also empowering consumers and voluntary organizations to play effective role in food safety.

Some of the salient features of the legislation include:

a) Definition of term – adulteration.

b) Powers to consumer organizations to draw legal samples and initiate legal proceedings.

c) Regulation on quality of imported foodstuff.

d) Provision of a warranty by a manufacturer, distributor or dealer to vendor.

e) Provisions for seizure and disposal of perishable foods, unfit for human consumption by local authority.

f) Appointment of an Advisory Committee called Central Committee for Food Standards (CCFS) and its sub-committees.

Adulteration

Under the PFA the food is said to be adulterated:

a) If it does not meet the specifications prescribed in Appendix - B of PFA,

b) If it contains injurious substances,

c) If any inferior or cheaper substance has been added,

d) If any constituent is abstracted from the food,

e) If article had been prepared, packed or kept under unsanitary conditions whereby it became contaminated,

f) If an article of food consists wholly or in part of any filthy, putrid, rotten, decomposed or diseased substance or otherwise is unfit for human consumption.

The PFA Rules, 1955, are divided into XVII parts. Some of the parts, which are of direct consequence to the food preservation and processing industry, are discussed.

Part VI - deals the colouring matters. It lays down the list of permitted, natural and artificial colours, as well as the maximum limit of synthetic dyes which can be used and the list of food products where the colours can be used (Rule 23 to 31).

Part VII – deals with the packing and labelling of food. It lays down the labelling provisions, the details of the label, procedure for claiming nutritional status of the product and certain restrictions on the misleading statements. It also lays down the form of labels which is to be declared on different food products. The important rule under this part is Rule 37 A which deals with the proprietary food which is the major commodity available in the market now-a-days. The important provisions under this part have been incorporated recently for declaring "Best Before Date", Non-Vegetarian & Vegetarian, Irradiation and also prohibiting misleading claims. (Rule 32 to 43).

Part VIII – provides for prohibition and regulations of sales. It prohibits the sale of certain admixtures and various products regarding their labelling and other things. It also lays down the certification of various food colours as well as food additives under ISI Certification Mark Scheme of Bureau of Indian Standards (Rule 44 to 48 C).

Part IX – deals with the condition for sale and licence. Under this Part, condition for sale and condition of licence, duration- of licence and procedure for issue of licence have been provided. Manufacturing premises, manufacturing products, Requirements for Fruit & Vegetable Products, Meat and Meat Products, Vanaspati, Solvent Extracted Edible Oils (Rule 49 to 51).

Part X – deals with the preservatives. It classifies the preservatives, lays down the quantity of various preservatives which can be used and certain restrictions on the use of some of the preservatives (Rule 52 to 55B).

Part XI – deals with the crop contaminants and naturally occurring toxic substances such as Aflatoxin, Agaric Acid, Hydrocynic Acid, and Saffrole (Rule 57A and 57B).

Part XII – deals with the use of anti-oxidants, emulsifying/ stabilizing and anti-caking agents. Under this chapter, the definition of anti-oxidants, emulsifying and stabilizing agents along with maximum limit of these additives, which can be used in food products, have been prescribed. (Rule 58 to 62B).

Part XIII – deals with the flavouring agents and related substances.

Part XIV – deals with the use of insecticides and pesticides in food products. Direct use of pesticides on food is prohibited. This part also lays down the tolerance limit of various pesticides in different food products. (Rule 65).

Part XV – Solvent extracted oil and edible flour: deals with the products which are manufactured by Solvent Extraction Process. Only n-Hexane (food grade) shall be used as solvent. The limits of n-Hexane in food has been prescribed.

Part XVI – Sequestering and Buffering Agents: deals with sequestering and buffering agents and lays down the definitions of these agents. Under this part, a list of these agents has been given with the maximum level, which can be used in different food products (Rule 70 to 72).

Part XVII – deals with the Irradiation of food. Under this part, around 13 category of food products have been permitted for irradiation.

Appendix 'A': Different forms used by Food Inspectors, Public Analysts, Central Food Laboratories, have been informed. (Form I to VIII).

Appendix 'B': Under PFA Rules, specifications of various food products have been laid down which are in Appendix 'B' to the Rules. The food products which have been standardized are Carbonated Water (A.01), Baking Powder (A.02), Starchy foods (A.03), Spices & Condiments (A.05) Bean (A.06), Sweetening Agents (A.07), Coffee (A.08), Edible Fat (A.10), Milk & Milk products (A.11), Margarine (A.12), Tea (A.14), salt (A.15), Fruits and Vegetable products (A.16), Edible Oils (A.17), Cereals & Cereal products (A.18), Vanaspati (A.19), Vinegar (A.20), Catechu (A.21), Gelatin (A.22), Sweets and Confectionary (A.25), Food colours (A.26), Silver leaf (A.27), Groundnut Kernel (A.28), Alcoholic Beverages (A.29), Pan Masala (A.30), fat Spread (A.31), Mineral Water (A.32), Packaged Drinking Water (A.33) and Packed Meat and Meat products (A.34).

Under Appendix 'B' most of the foods, which are in market generally, are covered, but still there are large number of foods, which are not standardized. Such products are treated as proprietary food under Rule 37A.

From the foregoing, it is proved that the Food Laws in India are comprehensive covering all aspects.

2.3.2 Fruit Product Order, 1955

The Fruit Product Control Order was issued in 1946. Subsequently, this Order was brought under Essential Commodities Act, 1955 and thereafter this Order is known as Fruit Products Order, 1955.

The Ministry of Food Processing Industries, Govt. of India, administrates this Order. The Order provides for compulsory licensing for manufacturing fruit and vegetable products.

To ensure hygienic conditions of the manufacturing unit and its workers, the Order lays down the hygienic and sanitary requirements for setting up factories for the manufacture of fruit and vegetable products. It is also essential to have a laboratory in the manufacturing unit to test the quality and specification of the products.

Under this Order, specifications of various fruit and vegetable products have been laid down. These specifications are at least equal to the specifications laid down under PFA Act if not higher.

2.3.3 Vegetable Oil Products (Regulation) Order, 1998

The Vegetable Oil Products (Regulation) Order has been issued in 1998 in super session of Vegetable Oil Product Control Order, 1947 which was issued under Section 3 of Essential Supplies Act, 1946, in super session of Vegetable Oil Products Control Order, 1946 which was in existence at that time. Later on, after passing the Essential Commodities Act, 1955, the Vegetable Oil Product Order was adopted under Essential Commodities Act. This Order is implemented by Directorate of Vanaspati, Vegetable Oils & Fats, Ministry of Food & Civil Supplies. Govt. of India. Products covered under this Order are Vegetable Oils, Vanaspati, Margarine and Bakery & Shortening. The Order provides for compulsory licensing for manufacturing units. The specifications of the products, namely, Vanaspati, Margarine and Bakery & Shortening have been laid down under this Order.

2.3.4 Solvent Extracted Oil, De-Oiled Meal and Edible Flour (Control) Order, 1967

This Order issued under Section 3 of Essential Commodities Act, 1955, for controlling the production and distribution of Oils, De-oiled Meal and Edible Flour, which are obtained by the methods of solvent extraction. This Order provides for compulsory licensing of manufacturing units. The licence to such units under Rule 50 of the PFA Rules is exempted. The specifications of the edible oils produced by solvent extraction method have been laid down under the said Order. The packing & labelling conditions of such oils are also laid down but these oils shall conform to the specifications laid down under item A.17 of Appendix ‘A' of the PFA Rules.

2.3.5 Meat Product Control Order, 1973 (Ministry of Rural Areas and Employment)

This order has been issued under the essential commodity act, 1955. Licensing under PFA Rules, 1955 are exempted for those industries which manufacture meat and meat products. Quality and safety parameters have been prescribed for meat and meat products under this order. The quality and safety parameters have now been provided under PFA Rule, 1955 for these products also. However, under this order, requirement of Heavy metals and Pesticide Residues have been prescribed. Additionally, the list of preservatives, sequestering and buffering agents for use in these products have also been provided. This order emphasizes for the hygienic conditions of the plant machinery and personnel. Agricultural Marketing Advisor to Government of India is implementing this order.

2.3.6 Edible Oil Packaging (Development and Regulation) Order, 1998

Ministry of Consumer Affairs has issued this order in 1998 during the period of dropsy in India. In 1998, some mustard oils were found to be adulterated with argemone oil. To control the quality of edible vegetable oils the above order was issued. The main provision of this order are as follows:

- All edible vegetable oils shall be sold only in packed conditions.
- All the edible vegetable oils shall be packed only after testing by the manufacturers.

- All the edible oils shall meet the requirement prescribed under PFA Rules, 1955 for such oils.
- The methods of analysis to be used are the same, which have been prescribed in the manual prescribed by Directorate General of Health Services.
- All the manufacturers will have to register themselves with the local civil supply departments and shall file the returns as prescribed under that order.

2.3.7 Milk and Milk Product Order, 1992, Ministry of Agriculture

This order was issued under the essential commodities act, 1955. The Ministry of Agriculture, Department of Animal Husbandry and Dairying, Government of India are implementing this order. Under this order, conditions for registration and its renewal have been prescribed. The concerned inspector assesses the hygienic conditions of the premises and the quantity of such product being processed. Quality and safety parameters for milk and milk products have not been prescribed under this order meaning thereby that all the milk and milk products shall meet the Standards prescribed under PFA Rule, 1955. The main aim of this order is to control the collection of milk and production of milk products in addition to hygienic requirement of the plant, machinery and personnel.

2.3.8 Standard of Weights and Measures Act, 1976

The Standard of Weights and Measures Act, 1976 was enacted to establish standards of weights and measures, to regulate inter-state trade or commerce in weights, measures and other goods which are sold or distributed by weight, measure or number, and to provide for matters connected therewith or incidental thereto. The Act extends to the whole of India.

When commodities are sold or distributed in packaged form in the course of inter-State trade or commerce, it is essential that every package must have:

- Plain and conspicuous declaration thereon showing the identity of the commodity in the package,
- The net quantity in terms of the standard units of weights and measures and if in nos., the accurate number therein,
- The unit sale price of the commodity and the sale price of that particular package of that commodity.
- The names of the manufacturer, and also of the packer or distributor, should also be mentioned on the package.

In this regard the Packaged Commodities Rules were framed in 1977. These Rules extend to the whole of India and apply to commodities in the packaged form which are, or are intended or likely to be sold, distributed or delivered or offered or displayed for sale, distribution or delivery or which are stored for sale, or for distribution or delivery in the course of inter-state trade and commerce.

2.3.9 Export (Quality Control and Inspection) Act, 1963

The Export Inspection Council (EIC) was set up by the Government of India Export (Quality Control and Inspection) Act, 1963 (22 of 1963), in order to ensure sound development of export trade of India through Quality Control and Inspection and for matters connected thereof. The Council, constituted by the Central Government, is the apex body and has powers to constitute specialist committees to assist it in discharge of its functions. Accordingly, the Council has constituted Administrative Committee to advise it on administrative matters and a Technical Committee to advise it on technical matters.

Besides its advisory role, the Export Inspection Council, also exercises technical and administrative control over the five Export Inspection Agencies (EIAs) at Chennai, Delhi, Kochi, Kolkata and Mumbai. EIA's were established by the Ministry of Commerce, Government of India, under for the purpose of implementing the various measures and policies formulated by the Export Inspection Council of India.

Further, under the Export (Quality Control and Inspection) Act, 1963 following units have been set-up by the Ministry of Commerce for ensuring promotion and quality control of export of food item:

- Export inspection Council. (E.I.C.);
- Agricultural and Processed Food Export Development Authority (APEDA);
- Spices Board;
- Coffee Board;
- Tea Board;
- Marine Products Export Development Authority (MPEDA).

Pre-shipment inspection and analysis is carried out in order to ensure that exported items conform to the quality prescribed by the importing countries and do not pose any health hazard.

In case of some of the food article like spices and condiments, fruit products, and meat products, the system of compulsory certification has been introduced.

Check Your Progress Exercise 2

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

In addition to the above legislations, there are a few voluntary based product certification agencies in the country viz. BIS, and Agmark.

2.3.10 Bureau of Indian Standards Act, 1986

Bureau of Indian Standards has been constituted under an act of Parliament i.e. BIS Act, 1986, which deals with standardization of various consumer goods including food products.

The organization also runs a voluntary certification scheme known as "ISI Mark for certification of processed food items". The authorities after inspection and ensuring that the manufacturers have got the necessary technical know-how, hygienic conditions and other facilities available, grant them a certificate to use ISI mark on their products. Under the provisions of PFA Act, it has been made compulsory that commonly used food additives permitted for use in specified items of food, condensed milk, different categories of Milk Powder, Infant milk substitute, Infant food, packaged drinking water and mineral water and some food additives will be sold only under ISI Certification Mark.

2.3.11 Agmark Grading and Marking Act and Rules, 1937

Under the Grading and Marking Act the Directorate of Marketing and Inspection was constituted in the Ministry of Rural areas and Employment, which operates a voluntary scheme of certification of agricultural products (raw and processed) for safeguarding the health of consumers under 'Agmark'. An approved chemist tests each batch of consignment before certification is granted. The PFA Rules, 1955 provide compulsory Agmark certification of Blended Oils, *Carbia callosa* and Honey dew; Kangra tea; Ghee moving from one state to another; Til Oil produced in Tripura, Assam and West Bengal. Further, certain food items meant for export have been brought under compulsory Agmark certification viz. walnuts, black pepper, cardamom, chillies, ginger and turmeric etc.

The Directorate of Marketing and Inspection has 21 laboratories and 50 sub offices spread all over the country. The Central Agmark Laboratory at Nagpur carries out research and development work in this field.

2.4 FOOD REGULATIONS FOR INTERNATIONAL ORGANIZATIONS

Since ancient times authorities all over the world made attempts to codify the tools to protect the consumers from dishonest practices in sale of foods. With development in food science, food chemistry and consumer awareness, national governments and international organizations stepped into food and health area, to protect consumers from fraud and to provide clean, wholesome, nutritious and safe food to all.

2.4.1 Codex Alimentarius Commission (CAC)

An UN resolution passed in 1963 to establish Joint FAO / WHO programme paved way for CAC's Food Standard Programme.

During the past 4 decades, all aspects of foods – processing, labelling, packaging, nutrition, consumer health and fair practices in trade have come under the commission's scrutiny.

So far Codex has:

- Formulated standards for 237 food commodities.
- Formulated 41 codes of hygienic practices.

- Evaluated 185 pesticides.
- Prescribed limits for contaminants.
- Developed guidelines for 25 contaminants.
- Evaluated 1005 food additives.
- Evaluated 54 veterinary drugs.

Codex India is the National Codex Contact Point (NCCP) for India, it is located at the Directorate General of Health Services, Ministry of Health and Family Welfare, New Delhi. It coordinates and promotes Codex activities in India.

2.4.2 International Organization for Standardization (ISO)

The objective of ISO is to promote the development of standards in the world with a view to facilitate international exchange of goods and services, and to develop mutual co-operation in the sphere of intellectual, scientific, technological and economic activity. Other functions of ISO are:

- Helps in Harmonization of food standards throughout the world.
- Facilitates exchange of scientific knowledge between countries.
- Promotes economic development.
- Promotes exchange of goods.
- Promotes free and fair global trading with strategic partnership with WTO.
- Standards help to revise levels of quality, safety, reliability, efficient, compatibility and inter-exchangeability.
- Safeguards consumers and users.
- Global exchange of goods and services incorporating rationality, practical applicability, environmental protection, safeguards safety and health, and provides equal opportunities in world trade.

2.5 LET US SUM UP

Food quality and safety are of paramount importance. Each country has evolved its own food legislations to safeguard the health and well being of its citizens and also promotes its international trade in raw and processed foods. India has enacted the food legislation called the Prevention of Food Adulteration Act (PFA). Besides PFA, few other Acts and Orders of the Government of India deal with specific food commodities. Certification of quality by BIS and Agmark also ensures food product and fresh produce quality.

International food standards like CODEX play very important role in international trade of fresh and processed foods. National food standards are being harmonized with the international standards to further strengthen world trade in food and food products.

2.6 KEY WORDS

PFA	:	Prevention of Food Adulteration Act, 1954.
FPO	:	Fruit Product Order, 1955.
ISI	:	Indian Standards Institution.
BIS	:	Bureau of Indian Standards.
ISO	:	International Organization for Standardization.

2.7 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:
   - Food borne illnesses
   - Adulterated food
   - Domestic and international trade
2. Your answer should include the following points:
   - Microbial
   - Pesticide residues
   - Misuse of food additives
   - Metals, toxins
3. Your answer should include the following points:
   - Definition of adulteration
   - Public analysts and food inspectors
   - Consumer organizations, legal proceedings
   - Imported foodstuffs
   - Warranty
   - Trial and punishment

4. Your answer should include the following points:

   - Not meeting specifications
   - Containing injurious substances
   - Addition of cheaper, inferior substances
   - Food prepared under insanitary conditions
   - Unfit for human consumption

Check Your Progress Exercise 2

1. Your answer should include the following points:

   - Ministry of Food Processing Industries
   - Hygienic and sanitary conditions in factories
   - Specifications of fruits and vegetable products
   - Compulsory licensing

2. Your answer should include the following points:

   - Compulsory licensing solvent extraction units
   - Specifications of oils
   - Packaging and labelling
   - Quality and safety of meat products
   - Heavy metal and pesticide residues
   - Preservatives, sequestering and buffering agents

Check Your Progress Exercise 3

1. Your answer should include the following points:

   - FAO/ WHO
   - International food standards
   - Standards for food commodities
   - Codes of hygienic practices
   - Limits for food contaminants
   - Food additives

2. Your answer should include the following points:

   - ISI mark is covered under Bureau of Indian Standards Act, 1986
   - Certification Mark of quality
   - Standardization of goods including food products
   - To ensure production of food products under hygienic conditions
   - Under PFA Act food additives, specific food and drinking water and mineral water will be sold under ISI certification Mark
   - Agmark a voluntary scheme of certification of agricultural produce
   - It is operated under Agmark Grading and Marketing Act and Rules, 1937
   - Agmark ensure for safeguarding the health of consumers
   - Blended oils, Ghee, Til oil, etc. are sold under Agmark certification

Check Your Progress Exercise 4

1. Your answer should include the following points:

   - Codex Alimentarius Commission (CAC) operates under Joint FAO/WHO Programme
   - It scrutinized Food Standard Programme
   - Formulate standards for food commodities, hygienic practices, pesticides residues, food additives etc.

2.8 SOME USEFUL BOOKS

1. Prevention of Food Adulteration Act (1954) 24th Edition, 2003, Easterb Book Company, Lucknow (www.nohfw.nic.in/pfa).

2. Fruit Products Order (1955) All India Food Preserver's Association, New Delhi. (www.mofpi.nic.in).

UNIT 3 FOOD SAFETY MANAGEMENT

Structure

3.0 OBJECTIVES

After reading this unit, you should be able to:

- explain the importance of food safety and understand different food safety programmes like:
  - good manufacturing practices;
  - hazards analysis and critical control points;
  - international organization for standardisation; and
  - total quality management.

3.1 INTRODUCTION

The demand for fresh and processed foods throughout the world is increasing steadily along with the increasing population. This has necessitated bulk handling, processing, storage and distribution of foods. There is every possibility that some times these operations are carried out defectively introducing food hazards. The developments in food science have opened up the possibility of using numerous food additives capable of preserving and modifying foods to the requirements of the consumer. However, inadvertent use of these additives can also result in food hazards.

The conventional quality control methods in which the quality of the fresh or processed foods is tested just before distribution, though has been very useful in ensuring food safety, is a post-mortem exercise. This means that if the food at the distribution stage is found to be defective, there is no way to salvage it. In order to overcome this drawback, new Food Safety Management Systems have evolved. These systems, besides ensuring food safety, also enable production of food products with no or minimum defects. You will be learning the basic aspects of some of these systems in this unit.

3.2 FOOD SAFETY

Food is comprised of an array of chemicals, namely; proteins, fat, carbohydrates, vitamins, minerals and fibre which are required to sustain life. These constituents of food have nutritional value. We all expect food to be nutritious, wholesome, and safe. **Absolute safe food** is the one, which will not cause any damage or harm. However, our food is subject to contamination and therefore, **relative food-safety** can be defined as the practical certainty that injury or damage will not result from a food used in a **reasonable** and customary manner and **quantity**.

Food safety can be understood in a better way if we use two basic concepts – Toxicity and Hazard. Toxicity is the capacity of a substance to produce harm or injury. Hazard is the relative probability that harm or injury will result when the substance is used in a proposed manner and quantity.

3.2.1 Food Hazards

You have already learned some aspects of food hazards in an earlier unit. A hazard is a biological, chemical or physical agent in a food, which has the potential to cause harm or injury to the health.

Biological hazards include pathogenic bacteria, fungus, virus and parasites and toxins elaborated by these organisms. They may cause infections and produce toxins.

Chemical hazards include naturally occurring toxicants such as trypsin inhibitor, solanins, haemagglutinins, phytates, cyanogenic glycosides and alkaloids; heavy metals such as lead, cadmium, arsenic and mercury; pesticide residues like DDT, malathion, parathion, endosulfan, etc. Chemical hazards can also be mycotoxins like aflatoxins developed on nuts and corns, veterinary drug residues and also unapproved food additives or additives added in excess.

Physical hazards include extraneous matter such as stones, glass fragments, dirt, metal bits, etc.

3.2.2 Importance of Safe Foods

A safe food ensures prevention of food borne diseases, and provides nutrition and good quality to the consumer. It also promotes international trade and stimulates economic development.

Maintaining food safety and quality is essential in the entire chain of food production ranging from raw agricultural commodity at farm level; primary food processing at the farm, dairy, abattoir (slaughter house) and grain mills; secondary food processing level such as canning, freezing, drying and brewing and packing; food distribution both at national and international level; food retailing and food catering and domestic food preparation.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Differentiate between absolute and relative food safety.

…………………………………………………………………………………
…………………………………………………………………………………
…………………………………………………………………………………
…………………………………………………………………………………
…………………………………………………………………………………
…………………………………………………………………………………
…………………………………………………………………………………

2. Explain different types of food hazards.

…………………………………………………………………………………
…………………………………………………………………………………
…………………………………………………………………………………
…………………………………………………………………………………
…………………………………………………………………………………
…………………………………………………………………………………
…………………………………………………………………………………

3.3 FOOD SAFETY PROGRAMMES

Consumer confidence in the safety and quality of the food supply is an important requirement. A successful safety programme involves a shared responsibility among Food Industries, Government and Consumer. Food Safety Management has progressed rapidly in recent years. The international agencies like Food and Agriculture Organization (FAO) and World Health Organization (WHO), Codex Alimentarius Commission (CAC) – a joint FAO / WHO programme, and International Organization for Standardization (ISO) are playing vital role in the safety management of foods.

3.3.1 Good Manufacturing Practices (GMP)

Good Manufacturing Practices can achieve food safety. Good Manufacturing Practices in manufacturing and packing are pre-requisites for acceptable food safety. GMPs are essential for the manufacture and distribution of foods that are safe from microbiological, chemical, and physical hazards. It is essential that the food industry manage a comprehensive programme that evaluates, identifies, and controls potential hazards at every step in the production, development and manufacturing environment.

Requirements for GMP for Food Industry

Good Manufacturing Practices are prescribed to ensure that:

- Factory is at proper location.
- Factory has right layout and building design.
- Raw materials used in the products are of right specifications.
- Manufacturing processes are properly prescribed and implemented to ensure right quality finished products.
- Adequate quality standards are in place.
- All critical control points are specified by hazard analysis.
- Finished products are released for market only after prescribed quality analysis.
- These are stored and transported in hygienic manner.
- All market returns are properly stored, analyzed, reworked or disposed off with proper procedure.
- Traceability procedure is in place.

To achieve the above objectives each manufacturer ensures that each step is properly followed with detail procedures in place.

3.3.2 Hazard Analysis and Critical Control Point (HACCP) System

Hazard Analysis Critical Control Point (HACCP) system is a prevention system. Here the focus for control is on the manufacturing process. Various monitoring and control methods are applied to reduce or eliminate the possibility of contamination. HACCP is a worldwide – recognized systematic and preventive approach that addresses biological, chemical and physical hazards through anticipation and prevention during manufacturing process.

Important Definitions

Hazard: the potential to cause permanent or temporary injury to a consumer

Severity: The magnitude of consequences resulting from a hazard.

Risk: An estimate of the probability of a hazard occurring.

Control: Actions taken or conditions applied either to reduce to acceptable levels or to eliminate a hazard.

Critical Control Point: A point in the food manufacturing, distribution and use chain where control is exercised.

Benefits of HACCP Certification

- It will reduce the risk of customers being food poisoned.
- It will increase quality of the product.
- It will ensure compliance with the law.
- It will reduce reliance on end-product inspection and testing.

Principles of HACCP

Food Safety Management System by HACCP has seven principles:

1. Identify the hazards:

   Look at each step (e.g., purchasing, delivery, storage, preparation, cooking, serving and display, etc.) in your operation and identify what can go wrong.

2. Determine the Critical Control Points (CCPs):

   Identify the points in your operation that ensures control of hazards, e.g., adequate cooking will kill E.coli and other pathogens.

3. Establish Critical Limits:

   Set limits to enable you to identify when a CCP is out of control, e.g., the critical limit for hot holding of cooked foods is +63°C.

4. Establish a system to monitor control of CCP you should decide

   - Who should check that the critical limit has not been exceeded,
   - How often the check should be done, and
   - What exactly the check involves.

5. Establish the corrective action to be taken when monitoring indicates that a particular CCP is not under control.

   When monitoring indicates that a CCP is not under control, corrective action must be taken, e.g.

   - Discard the food when it is past the use before a particular date

6. Establish procedures for verification to confirm the HACCP system is working effectively. Review and correct the system periodically and whenever you make changes to your operations, e.g.,

   - Change of recipe, installation of new equipment, etc.

7. Establish documentation concerning all procedures and records appropriate to these principles and their application.

   For the successful implementation of the system, appropriate documentations and records must be kept and be readily available, e.g., - Temperature record sheets.

A safety food management system based on these principles will enable hazards to be identified and controlled before they threaten the safety of the food served to customers and damage the reputation.

3.3.3 International Organization for Standardization (ISO)

The global market place provides opportunities for food processors and also creates concerns for consumers. International standards provide tools to reduce consumer concerns and provide tools for the promotion of food trade.

The International Organization for Standardization (ISO) is a non-governmental organization located in Geneva, Switzerland. It was formed in 1947 to develop a common set of manufacturing and trade and standards to facilitate international trade. ISO is made up of 138 nations.

ISO: 9000 – 1994 is an international standard directed at the quality management process of an organization; it included the group of standards ISO-9001, ISO-9003 and ISO-9004.

ISO-9001 standard is a management tool that focuses on meeting the customer's needs and expectations; every step in achieving the quality is documented. The documented system defines policies, objectives, and expected performance.

"Quality Management" refers to "all activities of the overall management function that determines the quality policy, objectives and responsibilities of the quality system".

Quality System is "organizational structure, procedures, processes and resources needed to implement the quality management. The ISO-9001: 1994 standard focuses on the existence, implementation, and effectiveness of the quality system as a whole. ISO-9001: 2000 is the latest Quality Management system.

ISO Certification is provided to the organization that has a quality management system that meets the scope of the stated standard.

Certification is the procedure by which third party gives assurance that a product, process, or service conform to specific requirements. [First party is the manufacturer and second party is the consumer. Here third party is ISO certifying agency.

Benefits of ISO Certification

Improved efficiency through both documentation and communication

- Improved consistency of manufactured items.
- Reduction in amount of re-work and non-conforming product.
- Improved customer satisfaction.
- Improved motivation and employee involvement through all levels of process.
- Reduced customer complaints.

3.3.4 Total Quality Management (TQM)

Japanese designed and built goods such as motorcars; cameras, radio and TV sets have quality and reliability. It is because Japanese industry has the ability to cope up with change and accordingly improved their management skill by adopting Total Quality Management System (TQM).

Definition: TQM is the application of quantitative methods and human resources to improve:

i) The material and services supplied,
ii) All the processes within the organization, and
iii) Degree to which the needs of the customers are met.

The TQM is a process and a journey and continuous; it is not a destination. It is a philosophy, culture and a way of doing business.

Basic Tenets of TQM

- Focus on customer satisfaction,
  - Internal customers
  - External customers
- Continuous improvements,
- Employee investment and empowerment,
- Measurement and documenting the work,
- Doing it right the first time,
- Effective communication, education and training,
- Leadership from top,
- Providing everyone with the opportunity to do their job properly.

Benefits of TQM

- Improvements in leadership qualities and more visible leadership from executives and senior managers.
- Involving personnel in decision making process.
- Increased confidence of personnel in their ability to carry out their work and to achieve targets.
- Reduction of mistakes, increased pride in work, sense of achievement for workers.
- Opportunity for self-development and self-improvement of personnel through a pro-active involvement in work.
- Opportunity to engage in creative thinking to improve product quality and work environment.
- Increased co-operation quality and work environment.
- Increased co-operation, improved teamwork and reduced conflict.

3.4 LET US SUM UP

Ensuring the safety of fresh and processed foods is the primary responsibility of all those involved in food handling and food processors. In order to achieve that the industry has been relying on quality control methods since long time. Although quality control has been successful in ensuring food safety and quality, it has certain drawbacks. Since it is carried out mostly at the end of the manufacturing process, retrieval of defective products is rather impossible. Rejection of defective products above a certain level adversely affects the economics of the industry. Besides, certain hazards entering the food processing operations are difficult to detect by routine analysis. Therefore, certain food safety programmes have evolved, which are capable of ensuring virtually zero levels of defects and hazards. The maim advantage of such programmes is the possibility of tracing the cause of defects easily based on the documentation, so that such recurrences can be averted.

3.5 KEY WORDS

Biological hazards : Pathogenic bacteria, fungus, virus and parasites and toxins elaborated by these organisms.

Chemical hazards : Naturally occurring toxins in foods, pesticide residues etc.

Physical hazards : Extraneous matter.

GMP : Good Manufacturing Practices.

HACCP : Hazard Analysis and Critical Control Points.

ISO : International Organization for Standardization.

TQM : Total Quality Management.

3.6 ANSWERS TO CHEECK YOUR PROGRAESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:
   - Will not cause any harm
   - Practical certainty of no harm
2. Your answer should include the following points:
   - Biological
   - Chemical
   - Physical

Check Your Progress Exercise 2

1. Your answer should include the following points:
   - Proper factory location
   - Proper layout
   - Good raw materials
   - Quality standards
   - Quality analysis
   - Traceability
2. Your answer should include the following points:
   - Permanent or temporary injury
   - Point where control is exercised
3. Your answer should include the following points:
   - Reduce risk of food poisoning
   - Increase quality

- Compliance with law
- Reduce reliance of end product analysis

4. Your answer should include the following points:

   - Identify hazards
   - Determine CCPs
   - Critical limits
   - Corrective action
   - Verification
   - documentation

Check Your Progress 3

1. Your answer should include the following points:

   - Improved efficiency
   - Consistency
   - Deduced non conformity
   - Customer satisfaction
   - Less customer complaints

2. Your answer should include the following points:

   - Application of quantitative methods and human resources to improve
   - Materials and services supplied
   - Processes within the organization
   - Needs of customers

3. Your answer should include the following points:

   - Leadership
   - Decision making
   - Confidence
   - Sense of achievement
   - Self- development
   - Product quality
   - Team work

3.7 SOME USEFUL BOOKS

2. Ralph, Early (1955) Guide to Quality Management Systems for Food Industry, 1st Edition, Blackie Academic Professional, London

UNIT 4 TESTING AND EVALUATION: PHYSICAL METHODS

Structure

4.0 OBJECTIVES

After reading this unit, you should be able to:

- understand colour in quantitative basis;
- describe methods for measurement of colour;
- understand viscosity, consistency and texture of foods; and
- describe methods for their measurement.

4.1 INTRODUCTION

Physical methods are used for both analysis and quality control. Analytical methods based on physical properties of food constituents are covered in detail under "Instrumental methods of analysis" in Block 7.3. In this unit, some of the important quality control parameters such as colour and Texture are described.

4.2 COLOUR

We associate colour and appearance of food with its quality. Quite often, colour plays the dominant role in assessing the overall quality of a food material. Examples are colour of fruits, vegetables, sweet meats, bakery products, ice creams and so on. Colour changes in foods during processing and storage are common. Change of the green chlorophyll colour of vegetables, browning reactions etc. is examples. In order to make foods more attractive to the consumer, natural and artificial colorants are some times added.

What is colour? Why an object is red, yellow or green? Colour is an appearance property attributable to the spectral distribution of light. Light as we commonly refer to is that part of the electromagnetic radiation to which the human eye is sensitive. The radiations of different wavelengths are called the spectrum of the radiation. The visible region of the spectrum is only a very minute part of the electromagnetic spectrum in the range of 380 to 780 nm. You will be learning more about the properties of electromagnetic radiation in the unit on 'Instrumental methods of analysis'.

As you may know, visible light can be split into its spectrum by passing it through a prism. The spectrum consists of the colours red, orange, yellow, green, blue, indigo and violet. If the light radiation striking the retina of the eye does not contain all the wavelengths of the visible spectrum, or if their intensities differ considerably, the sensation of colour results. This happens because when light radiation strikes an object, it may interact with the object in different ways depending on the nature of the object, one being absorption of the radiation. The absorption of all the wavelengths of the radiation may not take place uniformly. As a result, some wavelengths are reduced in intensity and the resultant radiation having certain dominant wavelength of the radiation is either reflected (opaque medium) or transmitted (transparent medium). The reflected or transmitted light is perceived as the colour of an object by the eye. Measurement of the transmitted radiation is the basis of spectrophotometry, which you will be learning in the next block. The measurement of the reflected light radiation is the basis of objective measurement of colour of objects like food products.

4.2.1 Factors Affecting the Colour of Objects

The perceived colour of an object in terms of its shade, brightness etc. is dependent on three major factors:

i) the chemical and physical nature of the object;
ii) the spectral power distribution in the light from the light source;
iii) the sensitivity perception system.

The colour of an object is primarily dependent on the colour producing chemical substances present in it. However, the shade, brightness and appearance of the colour can be greatly affected by its physical form. For example the colour of a whole apple is different from the crushed apple, or the colour of roasted coffee beans is different from ground coffee. In case of liquid foods, the colour varies with the depth of the solution (light path).

The perceived colour of an object is also dependent on the light illuminating it. A colour may appear dull in dim light but bright in bright light. The colour also depends on the spectral distribution of the light. The colour of an object viewed under a coloured light is different from the colour under white light.

The object properties and illumination interact to provide the stimulus for the receptor mechanism i.e. the eye and the brain system to perceive the colour. Perception of colour is unique to the individual. They change with colour vision abilities. Approximately 8% of the population perceive colour in a different way from the remainder. The other 92% of the population do not perceive colour in exactly the same way.

The above factors make it necessary to evolve an agreed terminology for colour description and measurement. Colour measurement implies expressing the above concepts in numerical dimensions.

4.2.2 Approaches to Colour Measurement

Two approaches are possible for colour measurement. The simplest method is to use a numerical index, which defines a colour adequately for specific purposes and enables comparison. This could be termed '**colour comparison'.** Obviously, this method does not specify all the attributes of a colour, which is required for several purposes. The second approach is to quantitatively specify the colour by determining the recognizable attributes of the colour.

4.2.3 Colour Matching

The eye has tremendous capacity to discriminate colours. However the capacity of the brain for remembering them is poor. For example, the brain cannot exactly remember the colour of a fruit of a previous year. During storage studies of food products, its colour changes and the original sample with out the colour change may not be available for comparison. Therefore, matching the colour with a colour order system is followed. Colour dictionaries (atlases), disc colorimeters and tintometers are usually used for the purpose.

Colour dictionaries: Colour dictionaries usually consist of sets of colour charts grouped into different hues. In order to get reliable data, matching of colours should be done by individuals with normal colour vision using standard viewing and lighting conditions. One of the most popular colour atlases used for horticultural crops is the **Royal Horticultural Society (RHS) Charts.**

Another colour atlas, which used to be widely quoted in food industry, is the **Munsell System.** In the Munsell System, colour dimensions are Hue (H), Value (V) and Chroma (C). The Figure 4.1 below is a sketch of the Munsell colour solid.

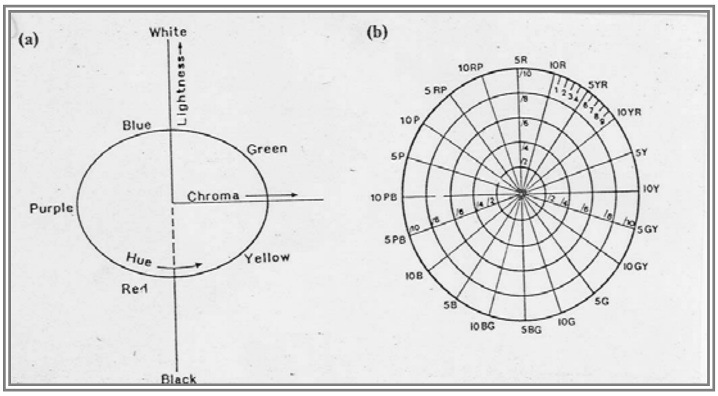

Figure 4.1: The Munsell colour system: a) dimensions of the Munsell colour system solid; b) organization of Hue and Chroma in the Munsell System solid.

The hue circle consists of ten major hues, each divided into ten equally spaced steps. The central achromatic Value (lightness) axis consists of ten equal steps, extending from ideal black = 0 to ideal white=10. The distance from this axis indicates an increase in Chroma that is an increase in hue content, and departure from grey. The Chroma is zero at the achromatic axis, and increases in visually equal steps to /10, /12, /14 or greater for particularly saturated colours. The Munsell atlas consists of pages of coloured chips. The chips are arranged so that the vertical axis of the pages represents an increase in V, the horizontal axis an increase in C. The Munsell description of a yellow-red colour of hue 3YR, Value 5/, and Chroma 6/ is denoted as 3YR 5/6.

Munsell system is some times used in conjunction with Disc colorimeters like the Macbeth- Munsell Disc colorimeter. In the Disc colorimeter, rapid spinning mixes two or more colours in the form of interleaved discs. The resultant hue is the average hue of the sample, which is useful in certain situations like colour of vegetables or homogenised samples, but not for comparing non-uniform colour surfaces like the colour of fruits like apple.

Tintometers: The Lovibond Tintometer used to be widely used in the food industry for a long time before more refined instruments became available. It is still in use for specific applications. The instrument is provided with sets of red, yellow and blue glass slides as permanent standards. The slides form an evenly graded series from very light tints (0) to deep colours (20), numbered according to their depth of colour. The three series are so related that when three slides of equal value are combined and viewed against white, they appear grey or neutral in colour. With the help if an optical system in the instrument, the illuminated sample is made to occupy half the field of view while the other half receives reflected light from a standard white surface, which passes through the selected coloured glass. When the colour is matched, it is specified by the values of red, yellow and blue slides required as for example 14.0 R + 6.0 Y + 1.0 B.

4.2.4 Quantitative Measurement of Colour

A complete specification of colour requires measurement of three attributes of colour.

i) **Hue**: the kind of colour, red, blue or green.

ii) **Saturation**: the depth or strength of the hue or the extent to which the pure hue is mixed with white.

iii) **Lightness**: the extent to which the hue is diluted with black. It is associated with brightness of the hue.

The International Commission on Illumination (CIE: *Commission Internationale de l'Eclairage*, 1931) adopted a set of standards, which has made it possible to define the colour in absolute terms. The system is rather elborate and hence only some salient points are explained here.

4.2.5 The CIE System

The CIE system is based on the principle that any colour can be matched exactly by a suitable mixture of only three colours selected from the red or amber (R), green (G) and blue (B) parts of the light spectrum. The three colours are called "**primaries**" and their relative amounts required to match a colour are called "**tristimulus**" values of the colour. This postulate has been confirmed by colour matching using additive mixing of monochromatic lights of wavelength 650 nm (R), 530 nm (G), and 460 nm (B) to obtain colour matches by observers with normal colour vision called the standard observer. The amount C of each colour (C) is matched using amounts of R, G, and B of each particular stimulus (R), (G), and (B). i.e.

$$C\ (C) = R\ (R) + G\ (G) + B\ (B)$$

When C is unity:

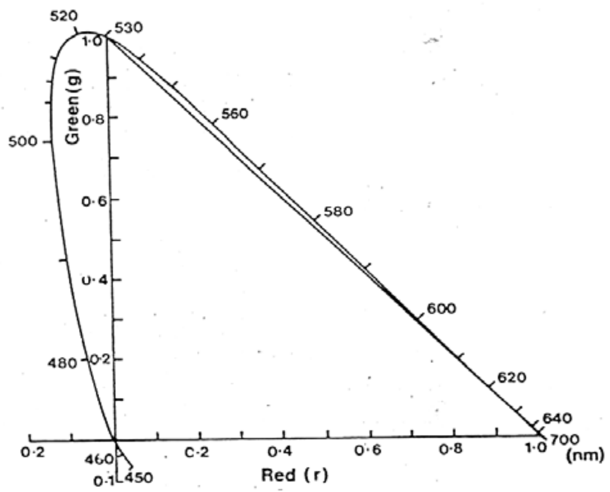
$$1.0\ \ (C) = r\ (R) + g\ (G) + b\ (B)$$

where:

$$r = \frac{R}{R+G+B}, \quad g = \frac{G}{R+G+B}, \quad b = \frac{B}{R+G+B}$$

Where: r, g and b are chromaticity coordinates of the colour i.e., r+g+b = 1

Therefore, if any two of r, g and b are specified, the third can be calculated. Hence, the results can be shown in the form of the two-dimensional **chromaticity diagram** in which r and g are usually plotted as x and y axis (Figure below).



The data from Fig. 7.3 plotted as a chromaticity chart. The matching stimuli used were 650, 530 and 460 nm (Wright 1969, with permission).

Figure 4.2

The spectral colours, for which the wavelengths are noted on the diagram, are shown as spectrum locus. The blue of wavelength approximately 460 nm, near one end of the locus is at the origin where r and g are zero and b = 1. The locus progresses to a wavelength of 530nm, where r is zero and g = 1 (and b is therefore zero).

It can be seen from the above figure that r, g and b have negative values. This is because the spectrum locus is convex and hence no real primaries exist which will always yield positive values. Therefore, CIE decided to use three unreal primaries (X), (Y) and (Z) so that the chromaticity coordinates x, y and z will always be positive. The modified chromaticity diagram is called the **CIE Chromaticity Chart,** which is shown below. Any given colour to be described in CIE terms can now be located in the spectrum locus by the relative distances along the x and y coordinates, representing respectively the values of X and Y.

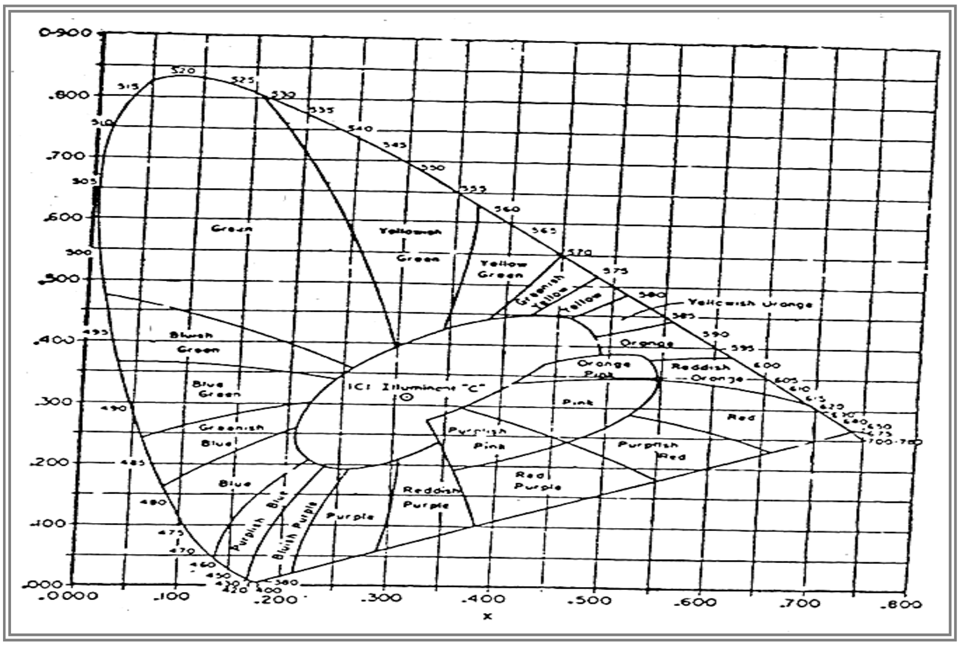


Figure 4.3: Chromaticity diagram

Having located a given colour in the Chromaticity chart from its chromaticity coordinates, it is necessary to find out its light intensity or brightness factor. This is done by assuming that all of the light energy represented by a colour is regarded as coming from Y stimulus. Therefore, the amount of Y is a direct measure of the brightness or lightness of the colour. If Y values are plotted perpendicularly to the chromaticity plane, the irregular colour solid is created within which any colour can be defined as a unique point with the CIE coordinates x, y and Y.

To determine the other visual dimensions of a colour, the colour (C) and the illuminant (S) used are marked on the chromaticity diagram as shown below.

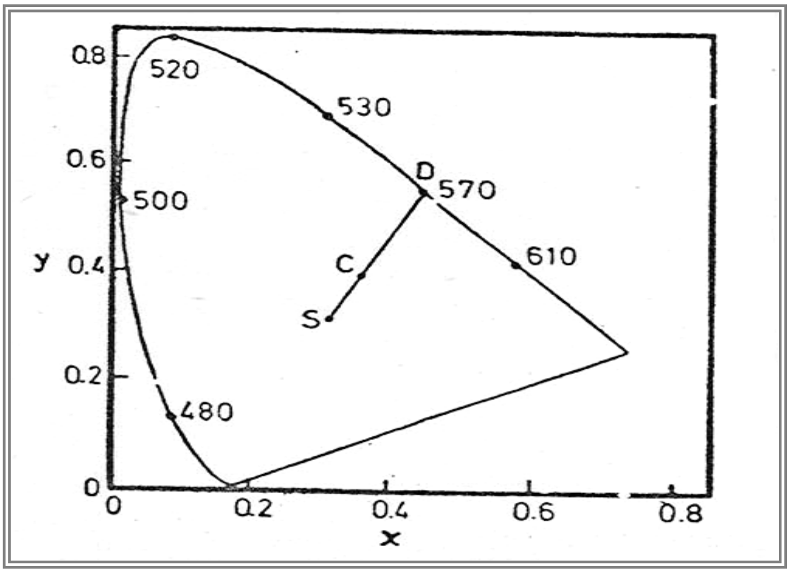

Figure 4.4: Determination of dominant wavelength and purity of colour

A line is drawn joining the two points and extrapolated to the spectrum locus (D), which is the **dominant wavelength** of the colour. Now the specification of the colour can be represented with reference of the above figure as:

Hue of the colour C is given in terms of the **dominant wavelength**

Saturation or chroma of the colour C is measured in terms of purity, which is the ratio of the distance SC to the distance SD. The ratio is usually expressed as percent.

Lightness of the colour C is given by its Y coordinate perpendicular to the chromaticity plane and is represented as Y%.

As mentioned earlier, the colour of an object is also dependent on the illuminant. Therefore, CIE system has defined three standard illuminants and their trichromatic coefficients. The illuminants are:

Illuminant A: Corresponds to the light from a gas filled tungsten lamp operated at a colour temperature of 2,856^{o}K.

Illuminant B: Corresponds to the more yellow type of average daylight, and consists of the standard illuminant in conjunction with a colour filter.

Illuminant C: Corresponds to light from the sky rather than sunlight. It consists of the illuminant A in conjunction with a different filter.

A spectrophotometric curve giving the intensities of light at different wavelengths of the visible region gives a complete specification of the colour. This can be calculated from the spectral data, which is quite tedious and hence not given here. This is made easy in the present day spectrophotometers, which automatically records the spectral curve and compute the CIE values Hue, Chroma and Lightness values.

4.2.6 Hunter Colour System and Colour Difference Meter

In the Hunter colour meter, tristimulus amber, green and blue filters together with suitable detection and measuring devices provide close approximation of the X, Y and Z functions of the CIE System. The Hunter colour space is slightly different to the CIE colour space (Figure below).

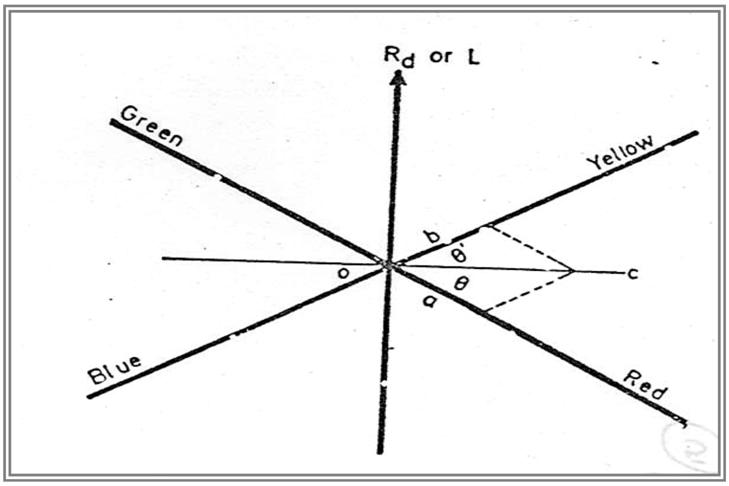

Figure 4.5: Hunter colour dimensions

The chromaticity plane is defined by dimensions *a* and *b*. The white point is at the origin. The Hunter positive *a* values indicate redness and negative *a* values greenness. The Hunter positive *b* values indicate yellowness and negative *b* values blueness. The *a* values are functions of x and y and *b* values those of Z and Y. For a particular colour C, hue or dominant wavelength is given by the ratio *a/b*. The saturation is given by the distance from the colour point C to the white point, which is $(a^2 + b^2)^{1/2}$. The Hunter R_d (diffuse reflectance) or visual lightness (L) is directly comparable to the Y of the CIE system.

Hunter values permit calculation of the colour difference (ΔE) between two colours like sample and standard colours. ΔE is given by:

$$\Delta E = [(\Delta L)^2 + (\Delta a)^2 + (\Delta b)^2]^{½}$$

The modern Hunter colour difference meters are capable of providing outputs of the various colour parameters.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. What is colour of an object?

4.3 VICOSITY AND CONSISTANCY

The kinaesthetic attributes of food products, viz. viscosity, consistency and texture are perceived by human senses of sight, touch and mouth feel. We are able to judge whether a fluid food is thin or thick by watching how it flows, feeling it with fingers or by mouth feel. We decide the texture of fruits, vegetables etc. by finger feel. We also assess texture by biting or chewing. Obviously these assessments are subjective and tend to differ from individual to individual. Therefore, objective measurement of these quality attributes is important in quality control and product development.

Food products exist in various physical forms like thin liquids, viscous liquids, semi-solids and solids. You have observed that most of the thin liquids like beverages, milk etc. just flow out from containers. Products like tomato ketchup or sauces require some initial push (like hitting the bottom of the bottle) before they start to flow. Solids like fruits require much more pressure to compress and finally break (deformation). The study of flow and deformation of materials is called **rheology**.

Viscosity and consistency are flow properties of fluids while texture is the deformation property of solids. Obviously, the force required to initiate solid deformation is much higher than that required to initiate liquid flow. If the force required is 1.0 gravity or less, the term used is viscosity or consistency and when the force required is more than 1.0 gravity, the term used is texture.

4.3.1 Flow Behaviour of Fluids

Fluids (liquids) are classified as Newtonian or non-Newtonian depending on their flow behaviour. This can be explained easily with the help of a simple diagram.

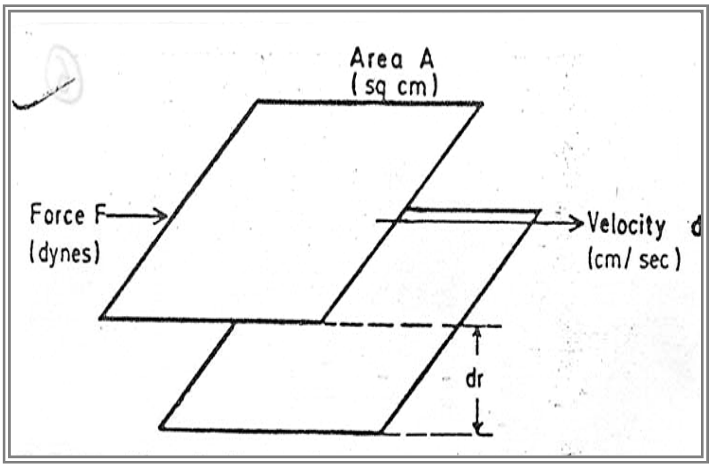

Figure 4.6: Schematic diagram illustrating the response of fluids to an imposed shearing force

Let us assume two layers of a fluid; each having an area of A cm^2 are separated by a distance dr cm. If the top layer moves parallel to the bottom layer at a velocity of du cm/sec relative to the bottom layer, a force of F dynes is required for maintaining the velocity. The velocity gradient represents the deformation, and is commonly referred to as the **shear rate**, which has the unit of per second. The shearing force per unit area (F/A) is the **shear stress** and is denoted by the symbol τ. The relationship between the shear stress and shear rate is used to define the flow properties of fluid foods.

Newton's law states that for flowing fluids, the shear stress required to maintain the flow is proportional to the shear rate.

i.e. $$F/A = \mu \frac{du}{dx}$$

Where du/dx = velocity gradient (shear rate) and μ is called the viscosity (poise) of the fluid. This is equal to:

$$\mu = \frac{F}{A} \times \frac{dx}{du}$$

$$= T \cdot \frac{|}{\gamma}$$

$$\mu = \tau / \gamma$$

where T = Shear stress
γ = Shear rate

where γ is the shear rate.

The unit of viscosity (poise) is dynes.sec/cm^2. In SI units it is equal to 0.1 N s/m^2 where N is Newton. As this unit is large, usually centipoise (cp), which is 1/100 poise, is used.

Fluids having this type of flow behaviour are called Newtonian fluids. Several fluid foods like fruit pulps, fruit juice concentrates, ketchup and sauces do not obey this law. Therefore, such fluids are called non-Newtonian fluids. For such fluids, if measurements are made at different shear rates, the ratio of shear stress to shear rate will not be constant. This ratio is called the apparent viscosity (μ_a or μ_{app}) or consistency. The consistency of non-Newtonian fluids can be expressed by the power law equation:

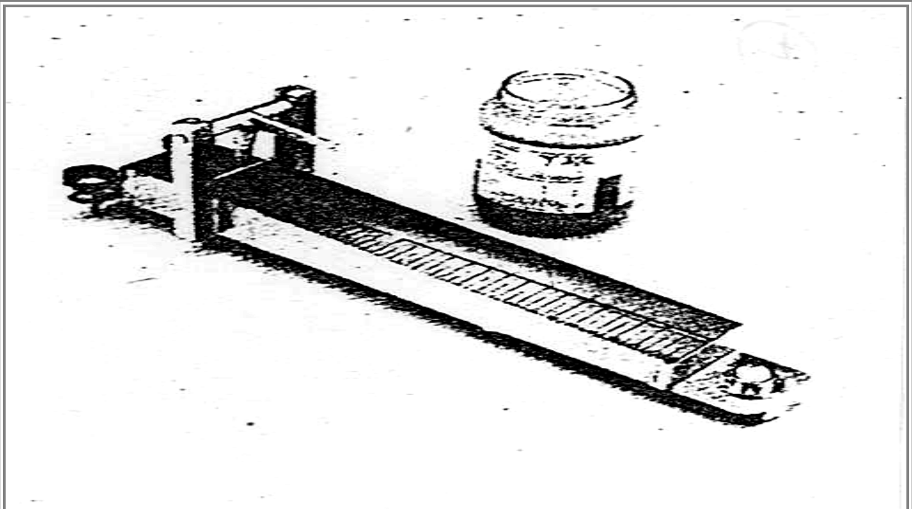
$$\tau = K (\gamma)^n + C$$

where, K = fluid consistency coefficient (dynes^n sec cm^2)
n = flow behaviour index (non dimensional)
C = yield stress (dynes / cm^2)

It can be seen from the equation that in the case of Newtonian liquids, n is equal to one and K becomes the viscosity. The constant, n for non-Newtonian liquids is a measure of the extent of departure from Newtonian behaviour, and hence is called the **flow behaviour index**. The constant K is more a measure of viscosity or consistency and is termed the fluid consistency coefficient. The viscometric parameters of non-Newtonian fluids can be determined with either capillary tube or rotational viscometers. Since determination of the parameters is very elaborate and not required for routine quality control of products, the same is not discussed here. Instead, a few viscometers and consistometers commonly used are described here.

4.3.2 Bostwick Consistometer

The Bostwick consistometer is a simple devise widely used in the industry for measuring the consistency of tomato ketchup and sauce. The instrument is based on the principle that the length of flow of the sample is proportional to its consistency.



Bostwick consistometer

Figure 4.7: Bostwick consistometer

The Bostwick consistometer (Figure above) consists of a channel with sides. It has a triggered gate on one side and a centimetre scale is itched on the floor of the channel. Before taking measurements, the consistometer is levelled by adjusting the levelling screws provided at the bottom of the instrument. Then the gate is closed by engaging the trigger release mechanism and the sample is filled in the sample holding compartment fully. The gate is released by the trigger and simultaneously a stopwatch is started. The consistency is measured after 30 sec by recording the extent of flow of the sample on calibrated scale, taking an average of the values at the centre and sides of the scale. The Bostwick consistometer readings are expressed as cm per a fixed time.

4.3.3 Brookfield Synchrolectric Viscometer

The Brookfield synchrolectric viscometer is a versatile instrument that can be used for measuring viscosity of Newtonian liquids as well as the consistency of non-Newtonian liquids. The instrument is based on measurement of resistance to rotation of a spindle immersed in the test material. The resistance is recorded in terms of torque by a calibrated spring. The dial of the instrument is graduated and the viscosity in centipoises can be read directly from the factor finder for different sizes of spindles supplied along with the instrument. As the instrument is supplied with different sizes of spindles, a wide range of viscosity measurements can be made.

The instrument is provided with a high torque motor, which is geared for different speed. Therefore, measurements can be made at different shear rates, which is required for non-Newtonian liquids. Brookfield viscometer is widely used to measure the consistency of products like tomato products, custards, dairy products, cream style corn etc.

4.4 TEXTURE

Texture is the property of food, which is associated with the sense of feel or touch experienced by fingers or the mouth. Texture of foods perceived by the mouth is a very complex phenomenon. It is perceived in three stages of ingestion of food viz. initial, masticatory and residual each consisting of different textural parameters. Therefore, objective quantitative description of the texture perceptions is quite difficult.

The physical or the mechanical textural characteristics of foods are related to the reaction of the food to stress and can be divided into parameters of hardness, brittleness, chewiness, gumminess, cohesiveness, viscosity, elasticity and adhesiveness.

In objective measurement of texture, food is subjected to compression, tension, shear and flow and the resultant deformation is measured. Measurements are made in terms of integral powers of force (m), length (l) and time (t).

All texture measuring instruments/ devices have a few essential parts. They are: I) driving mechanism to apply force, ii) probe element in contact with the sample, iii) mechanism to suitably direct the applied force, iv) sensing element, and v) read out system.

The instrumental methods of measuring the texture are based on applying force under controlled conditions. Standardisation of test cells for different types of products is crucial for getting useful data, which can be interpreted to give meaningful results. Each product in each test cell produces a characteristic force-deformation curve. Under controlled conditions of the test, the magnitude of the curve is influenced by the textural behaviour of the material tested. A typical force- deformation curve is shown in the following Figure.

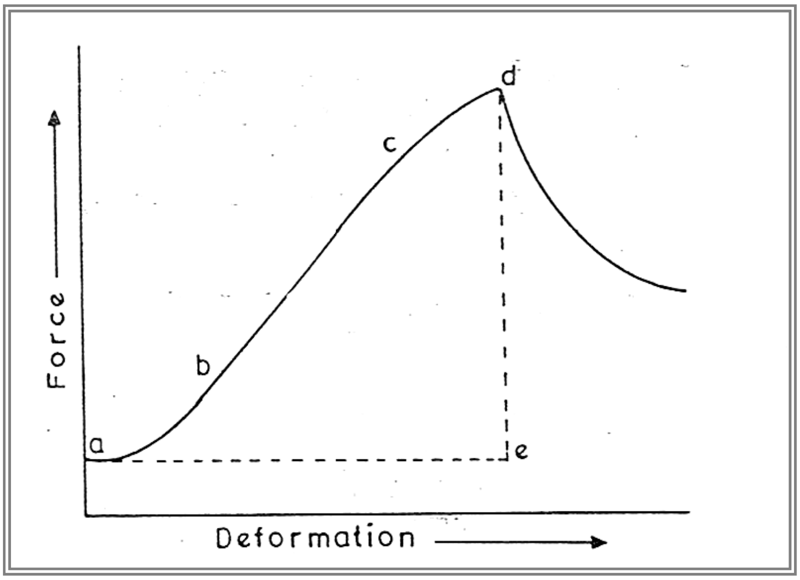


Figure 4.8

In general, the curve exhibits the following characteristics.

i) An initial non-linear portion representing packing of the cellular components of the sample under the applied stress.

ii) An approximately linear portion as the material is compressed. This slope of this portion of the curve represents the force required to attain a given deformation and hence a measure of the firmness.

iii) An abrupt change in the slope is seen when the sample begins to rupture.

iv) After the rupture point d, the force reduces.

There are different types of texture measuring instruments. Some instruments are very simple, measuring only a single mechanical textural characteristic of the product. Quite often, this is sufficient for quality control purposes. Fruit pressure tester like the Magness-Taylor pressure tester is an example of such an instrument. However, for research and development, one would like to get more extensive information on the various textural parameters of the product. This is called **texture profile analysis**.

4.4.1 Magness-Taylor Pressure Tester

This hand held instrument is widely used to determine the softening of fruits during maturation. The pressure tester uses a spring to measure applied force and a spring scale indicates the maximum test force. The tester consists of a metallic barrel inside which a spring is placed. A shaft to which a removable punch (plunger) is attached supports the spring (Figure 4.9). A small chuck at the end of the shaft ensures the fixed length of penetration. The instruments are available with springs of different force ranges to suit objects of different firmness. Each instrument is provided with punches of different diameters. The smaller diameter punches are used on firmer material and the larger on softer material.

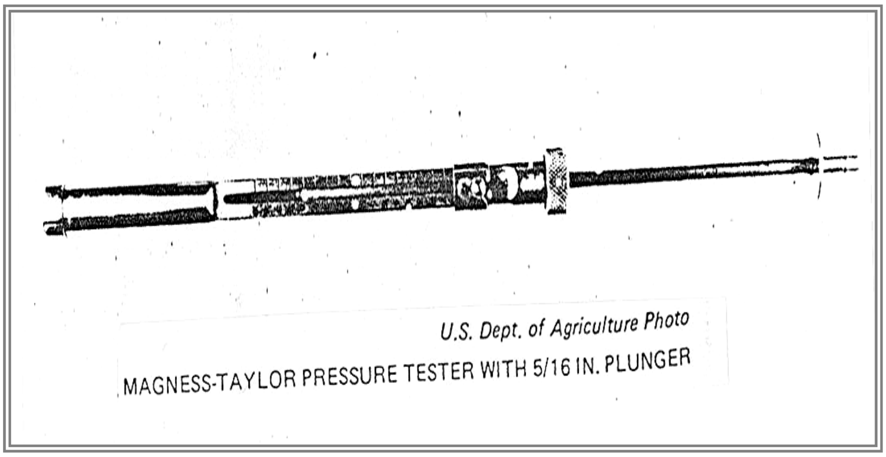

Figure 4.9

For measuring the pressure of a fruit, the plunger is held against the surface of the fruit and forced into the fruit with steady pressure applied by the hand to attain the necessary force necessary for breaking the flesh. The fruit may be peeled to overcome the interference of the skin with the action of the plunger. The force recorded on the scale indicates the maturity of the fruit. Typical range of pressure values of one variety of apples at different maturity stages is given below:

Degree of maturity/ripeness	Pressure test reading (lb) Delicious apple
Hard	17-20
Firm	14-17
Firm-ripe	11-14
Ripe	8-11

4.4.2 Instron Testing Machine

This is a versatile instrument capable of obtaining texture profiles of different types of objects. The machine consists of two parts: i) the drive mechanism, which drives a moving cross head in a vertical direction in selected speeds of 0.05 to 50 cm / min and ii) the load sensing and recording system for loads in the range of 2g to 5,000 Kg. There are different types of fixtures like flat compression plates, cylindrical compression box, assortment of needles and punches, a single star-shaped needle etc. A careful selection of the fixtures permits the measurement of different texture parameters. The instrument measures force- deformation of force- time functions. It is extensively used to measure the texture of fruits, vegetables and processed food products.

4.4.3 Measurement of Jellying Property of Pectins

Jams, jellies and marmalades are important commercial products. Pectin is commonly used to obtain the characteristic jelly like texture to the products. Therefore, the jellying quality of the pectin used determines the product quality. There are different methods for assessing the quality of pectin. Physical methods for determining jelly strength are two types. The first group of methods measure the breaking strength of jellies when they rupture after exceeding their elastic limits and the second group of methods measure jelly strength by taking into account the deformation of jellies within their elastic limits. Here one method in each group is described.

Pectinometer

The Luers-Lochmuller Pectinometer (Figure 4.10) measures the force required to pull a disc embedded in the jelly being tested upwards. The apparatus is shown below. It consists of a moving load (weight) put on one arm of a balance and the disc in the jelly attached to the other arm through a double pulley arrangement. The jelly container (corrugated) is held in a fixed position on the base of the balance (B). The disc (A) is suspended in the corrugated container (C). The jelly being tested is poured hot into the container and allowed to cool for at least one hour before the test is carried out. Now, weights are applied on the pan (W) till the jelly breaks. The corrugated sides of the container prevent slipping of the jelly in the container. The indicator (I) measures the extent of compression of the jelly. Breaking values pf jellies range from 200 to 300 g depending on the type of jelly. For quality control purposes a narrow range (± 15g) is usually fixed.

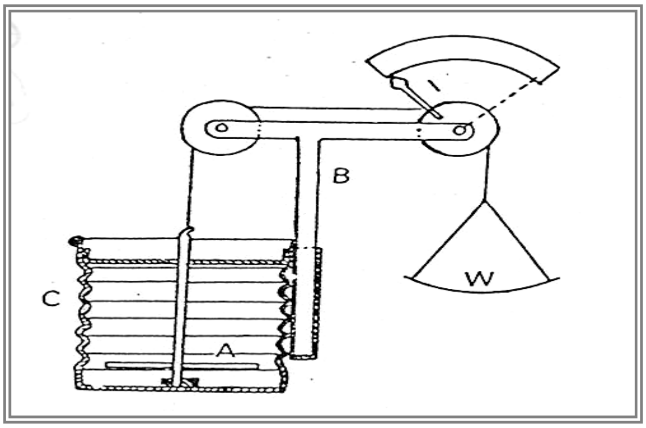

Figure 4.10: Luers and Lochmuller pectinometer

Ridgelimeter (Cox-Higby Sag Method)

Ridgelimeter measures the percentage sag or slump occurring when a test jelly is removed from its supporting container and inverted upon a glass plate. The Fig. below shows the instrument with a sample of jelly in measuring position and jelly glasses (containers). The glasses are of standard sizes of 3.125 in (79.4 mm) depth. The instrument as such has only a micrometer screw fixed on a stand. The screw has 32 threads to an inch so that one revolution moves the point by 0.03125 in., which is equal to 1% of the height of the jelly. Therefore, if the depression of the jelly as measured by the instrument is 0.03125 in. it is equal to 1% sag. For determining the jelly strength of a pectin sample, the following procedure is followed.

Weigh 48.8 g of tartaric acid in distilled water and make up to 100 ml in a volumetric flask. The quantity of pectin to be taken for the test depends on the assumed grade of the pectin. For example commercial pectin is usually supplied as 150 grade. Therefore, the assumed grade of the pectin is taken as 150. Since jellies should contain 65% sugar (TSS) i.e. 65 g sugar in 1000 g jelly, the weight of pectin to be used is 650/assumed grade of the pectin (650/150 = 4.33 g). Weigh 646 g sugar and 4.33 g pectin. Mix the weighed pectin with about 20-30 g of the weighed sugar in a dry beaker. The tare weight of a stainless steel saucepan along with a stirrer (about 1 lit. cap.) is noted and 410 ml of distilled water is taken in the pan. The pectin-sugar mix is added to the water in the pan and stirred. The pan is placed on a hot plate and heated to boil the solution. The remaining sugar is added and heating and stirring continued till the sugar dissolves completely. Heating is continued until the net weight of jelly is 1015 g. If the net weight is less, distilled water is added in slight excess and boiled down to exact weight. The entire heating time should not exceed 5-8 min. The material is allowed to stand for 1 min., any foam or scum is skimmed off and allowed to cool to 95°C (check with a thermometer) while stirring gently. Pour the hot jelly into three Ridgelimeter glasses (after fixing gummed tapes to a height of 0.5 in. above the rims) almost to overflowing, each containing 2 ml of the tartaric acid solution. After 15 min., the glasses are covered with metal lids and allowed to cool for 20-24 hr. at $25^{o} \pm 3^{o}$C.

After cooling, the lids are removed and the gummed tapes are tore off. The jelly exposing beyond the brims of the glasses is sliced off with a stretched wire. Now the jelly from one glass is removed with the help of a spatula and directly placed on to the glass plate provided along with the instrument. Start a stopwatch as the jelly is placed on the glass plate, and place the jelly directly below the micrometer screw. After exactly 2 min. bring the point of the micrometer screw just into contact with the jelly surface. Read the sag to the nearest 0.1%. Repeat the measurements with the jellies in the other two glasses also and take the average. The true grade of the pectin is calculated by multiplying the assumed grade with the corresponding factor for the measured sag provided in a tabular form along with the instrument. For example if the assumed grade is 150 and the factor for the measured sag of say 25 is 0.936, the true grade of the pectin is:

$$150 \times 0.936 = 140.4 \text{ or } 140 \text{ grade}$$

4.5 LET US SUM UP

Measurement of colour, viscosity and texture of foods is very important for quality control.

When visible white light falls on an object, some of the spectral colours of the light are partially or fully absorbed by the object. The resultant coloured radiation is reflected from a solid or semi-solid object or transmitted through a liquid object, which the eyes perceive as the colour of the object. Any colour can be matched by mixing the three primary colours viz. red, green and blue in appropriate proportions. The relative amounts of the three primary colours required to match a colour is called the Tristimulus value of the colour. This is the basis of quantitative specification of colours under the CIE system. The CIE system specifies a colour in terms of its Hue or dominant wavelength, Chroma and Lightness. Based on instrumental measurement of reflectance from an object over the entire light spectrum, it is possible to arrive at the complete specification of its colour. For routine quality control of some food products like fruits, vegetables, meat etc., simple comparison of their colour with standard colour charts gives useful data. The Hunter colour system which is related to the CIE system specifies a colour in terms of L, a, b values.

Foods can exist in the liquid, semi-solid and solid state. Liquid foods are classified as Newtonian or non-Newtonian liquids depending on their flow properties. Instruments are available to measure the flow properties of liquid foods.

Texture of solid foods is related to their reaction to stress and can be divided into parameters of hardness, brittleness, chewiness, elasticity etc. Texture of foods is determined by measuring the relationship between the applied pressure and the resultant deformation of the food material. There are simple instruments like the fruit pressure tester, which measure a single parameter of texture like the pressure required for puncturing a fruit. Such data are usually sufficient for some quality control purposes. However, more detailed texture analysis is required for many other products especially for research and product development. Such texture profile analysis is possible with instruments like the Instron Testing Machine.

Jams, jellies and marmalades are important commercial products. Quality control of such products require measurement of their jell quality. The gel quality is mainly determined by the quality of the pectin used for their preparation. The jell strength of pectin and the products are determined using simple instruments. The instruments are either based on measuring the force required to break a gel or the sag (loss of rigidity) of a gel on standing.

4.6 KEY WORDS

Hue : The colour attribute denoted by red, green, blue and so on.

Saturation : The depth or strength of hue.

Lightness : The brightness of colour.

Dominant wavelength : Wavelength of the spectrum light that, when combined in suitable proportions with the specified achromatic (colourless) light yields a match with the light considered.

Tristimulus values : The amounts of the three primary colours required to match a colour.

Rheology : Study of flow and deformation of materials.

Newtonian fluids : Fluids for which the shear stress required to maintain its flow is proportional to the shear rate.

Texture profile analysis : Determination of various texture parameters like hardness, cohesiveness, elasticity, adhesiveness, fracturability, gumminess, chewiness etc.

4.7 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:
   - Appearance property
   - Absorption of some spectral wavelengths
   - Reflection and transmission of light
2. Your answer should include the following points:
   - Hue
   - Saturation
   - Lightness
3. Your answer should include the following points:
   - Primary colours
   - Tristimulus values
   - Chromaticity coordinates
   - Chromaticity chart
   - Dominant wavelength
   - Standard illuminants
   - Standard observer
4. Your answer should include the following points:
   - L,a,b values
   - Colour difference

Check Your Progress Exercise 2

1. Your answer should include the following points:
   - Ratio of shear stress to shear rate constant
   - Power law equation
   - Flow behaviour index
2. Your answer should include the following points:
   - Flow meter
   - Flow per unit time

3. Your answer should include the following points:

   - Deformation due to application of force
   - Hardness
   - Cohesiveness
   - Elasticity
   - Fracturability
   - Gumminess
   - Chewiness

4. Your answer should include the following points:

   - Magness-Taylor Pressure tester
   - Force required for puncturing

5. Your answer should include the following points:

   - Drive mechanism
   - Load sensing and recording system
   - Texture profile

6. Your answer should include the following points:

   - Standard jelly
   - Measurement of per cent sag

UNIT 5 TESTING AND EVALUATION: CHEMICAL AND MICROBIOLOGICAL

Structure

5.0 OBJECTIVES

After reading this unit, you should be able to:

- describe the methods for determining crude fat, protein, pectin and tannins in food products;
- discuss various aspects of bacteriological examination of water;
- describe procedures for assessing surface sanitation; and
- explain the salient aspects of microbiological examination of spoiled canned foods.

5.1 INTRODUCTION

Analytical food chemistry deals with the methods for determining the chemical composition (quality) of foods. It employs both qualitative and quantitative methods for the purpose. A qualitative method yields information about the nature of the component and a quantitative method provides numerical information on the content of the component in the sample.

For the analysis of foods, chemical methods are more often employed even though physical methods are also proving to be very useful. The analytical methods based on the physical properties of food components are collectively known as “Instrumental Methods of Analysis’, which you will be learning in the next Block.

You will be learning and performing several analytical methods in your Practical exercises under Courses III and VII. In this unit, you will learn a few other methods, which are, either too time consuming or could not be included under the Practical exercises because they require more sophisticated facilities which are available only in specialised laboratories.

Microbiological quality of foods is equally important. A major portion of microbiological methods will be covered under Course V 'Food Microbiology". Therefore, in this Unit, only a selected few methods are discussed.

5.2 CHEMICAL ANALYSIS OF FOODS

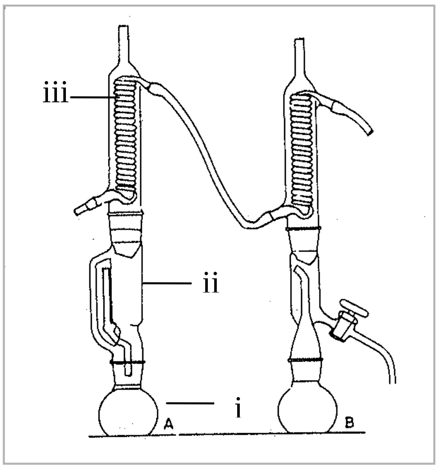
The quantitative analysis of food raw materials and their products may be classified into **proximate analysis** and **ultimate analysis**. Proximate analysis provides information on the nutritional and biochemical composition, while ultimate analysis or detailed analysis determines the content of a particular component in the food material.

The proximate analysis, especially for fruits and vegetables consists in determining the percentages of the moisture, ash, acidity, crude fat or ether extractives, protein, sugars and crude fibre. Their sum total subtracted from 100 represents primarily the amount of carbohydrates other than sugars, but includes starch, pectin, etc.

Among the above constituents, all except **crude fat, protein** and **pectin** are covered in the Practical exercises**.** Therefore, these methods are described in this unit. Tannin, which is another component of importance to fruits and vegetables, is also included here.

5.2.1 Crude Fat or Ether Extractives

As you have learnt already, food products contain water-soluble and water insoluble constituents. Among the water insoluble constituents, the ether soluble materials such as the tri- glycerides, phospholipids, sterols, essential oils, fat-soluble vitamins and pigments are very important. The first step in determining most of the individual components is extracting the food material with ether using a Soxhlet extraction apparatus (Figure 5.1). The Soxhlet extraction apparatus is an all glass simple assembly consisting of a Soxhlet flask to the top of which a Soxhlet extraction tube and a condenser are attached through standard glass joints. The Soxhlet extraction tube has provision for siphoning off the solvent used for the extraction when the level has reached a particular level.



i. Soxhelt flask
ii. Soxhelt extraction tube
iii. Condensor

Figure 5.1: Soxhlet apparatus (A) for fat extraction and (B) for solvent removal

Ether extractives are determined on samples after moisture determination (please see 'Moisture determination' under Course III Practical exercises). The dried sample is transferred to a thimble. The thimble has a tubular structure like a large test tube (having diameter and length suitable to occupy the Soxhlet extraction tube) made of cellulose filter pad. The top of the thimble is plugged with a wad of pure cotton and placed inside the Soxhlet extraction tube, which is then attached to the Soxhlet flask. About 75 ml of anhydrous ether is poured through the sample in the thimble, which percolates through the sample into the flask. The condenser is then attached and the whole assembly is placed in a heating mantle or water bath. Heat is applied just enough to boil the ether. The evaporated ether condenses and falls into the thimble containing the sample and extracts the ether soluble components. When the ether level reaches the siphon outlet level, it is siphoned off into the flask. The distillation process is allowed to continue for about 16 hours. At the end of the extraction period heating is discontinued and the thimble is removed. The ether-extracted sample is used for crude fibre estimation (please refer Practical exercise under Course III). After removing the thimble, ether is distilled off into the Soxhlet tube and poured out before the level reaches the siphoning level. Ether may be distilled off using the assembly B shown in the Fig. When the ether in the flask has reached a small volume, it is transferred into a weighed beaker with repeated rinsing with small portions of ether. The ether in the beaker is evaporated on a steam bath, dry at 100 ^{o}C for 1 hr, cooled and weighed. Crude fat is calculated by:

$$\% \text{ Crude fat} = \frac{\text{Weight of ether-soluble material}}{\text{Weight of sample}} \times 100$$

5.2.2 Protein Estimation

Protein content of food samples is usually determined by the Kjeldahl method, which is based on the determination of the amount of reduced nitrogen present in the sample. The nitrogen compounds are converted into ammonium sulphate by boiling with concentrated sulphuric acid. The ammonium sulphate formed is decomposed with sodium hydroxide and the liberated ammonia is absorbed in excess of neutral boric acid solution and titrated with standard acid.

The food sample is digested (destruction of organic matter) with conc. H_2SO_4 in a Kjeldahl flask that is a long neck round bottomed flask. To facilitate digestion and efficient conversion of all the reduced nitrogen into ammonium sulphate, small quantity of a catalyst is added. The catalyst consists of a mixture of selenium dioxide, potassium sulphate and copper sulphate in the ratio of 1:40:8. The digested and cooled sample is made up to a known volume with distilled water and an aliquot of it is distilled in a micro-Kjeldahl distillation apparatus (Figure 5.2).

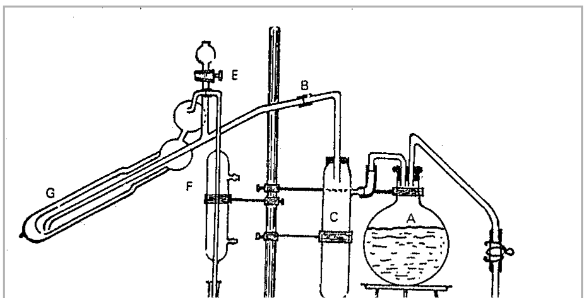


Figure 5.2: Distillation apparatus for micro-Kjeldahl determination of nitrogen
***A* steam generator, *B r*ubber tubing, *C* steam trap, *D* pinch clamp, *E* funnel, *F* condenser, *G* distillation flask**

This is a glass unit with only one short rubber tube joint (B). This rubber joint makes the unit less rigid and reduce the danger of breakage. The steam generator A is a 1-litre round-bottomed flask with a side arm for refilling. The other components of the assembly are the steam trap C, sample delivery funnel E, condenser F and sample holder for steam distillation G.

After initial cleaning of the system with steam, an aliquot of the acid digested sample and strong sodium hydroxide solution are let into the distillation flask and steam distilled. The liberated ammonia is absorbed in a known volume of dilute neutral boric acid solution containing an indicator (mixed indicator) placed below the condenser. On completion of distillation, which takes about 5 min the ammonia absorbed boric acid solution is titrated with 0.01 N HCl. From the titre value, the nitrogen content in the sample is calculated. The function of boric acid in the estimation is only to absorb the liberated ammonia and does not react chemically with it. The titration reaction is:

$$NH_4OH + HCl \rightarrow NH_4Cl + H_2O$$

Calculations:

1000 ml 1 N HCl = 1 g mole of nitrogen = 14 g nitrogen

or 1 ml 1 N HCl = 14 mg nitrogen

Therefore

$$\%\text{ N in the sample} = \frac{\text{Titre x normality of HCl} \times 14 \times 100}{\text{Aliquot of digest taken} \times \text{weight of sample} \times 1000}$$

For calculation of protein content from the nitrogen value, a multiplication factor of 6.25 is usually used. This factor is based on the assumption that plant proteins contain 16 % nitrogen. Therefore, protein content (%) = % N × 6.25.

5.2.3 Pectin Estimation – Calcium Pectate Method

Pectin is an important constituent of fruits. Processing wastes of fruits like citrus peel and pomace, apple pomace etc. are used for commercial, production of pectin. Knowledge of the pectin content of fruits used in jam and jelly manufacture is necessary to calculate the quantity of pectin to be added. Therefore, estimation of pectin content of the raw materials is important.

Pectin extracted from plant materials is usually estimated as calcium pectate. For the estimation, the pectin sample is saponified with alkali and precipitated as calcium pectate from an acid solution by the addition of calcium chloride. The calcium pectate is washed free of chloride, dries and gravimetrically estimated.

Pectin extraction from plant materials: 50 g sample is weighed into a 1000 ml beaker and extracted with 400 ml 0.05 N HCl for 2 hr at 80 – 90^{o}C. Water lost by evaporation is frequently replaced. After cooling the suspension, it is transferred to a 500 ml volumetric flask and made up to volume with distilled water. Subsequently, it is filtered through Whatman No. 4 filter paper.

100-200 ml of the filtrate is taken in a 1 lit beaker and 250 ml distilled water is added to it. The solution is neutralized with 1 N NaOH using phenolphthalein as the indicator and allowed to stand overnight. The next day, 50 ml 1 N acetic acid is added to the solution, stirred and after 5 min, 25 ml 1 N calcium chloride solution is added with stirring. After 1 hr, the solution is boiled for 1-2 min and filtered through a previously dried and weighed (in a covered dish) filter paper circle. The precipitate in the filter paper is washed with almost boiling water till free of chloride. Presence of chloride in the filtrate is tested with silver nitrate solution. The filter paper containing calcium pectate is transferred to the covered weighing dish initially used, dried overnight at 100^{o}C, cooled in a desiccator and weighed. Calcium pectate is calculated as follows.

$$\text{\% Calcium pectate} = \frac{\text{Weight of calcium pectate} \times 500 \times 100}{\text{ml of pectin extract taken} \times \text{Wt. Of the sample}}$$

The theoretical yield of calcium pectate from pure pectinic acid is about 110%.

5.2.4 Estimation of Tannins

Tannins are widely distributed in fruits and vegetables. They belong to the general group of polyphenols called flavonoids and cinnamic acid derivatives. Tannins are responsible for the undesirable astringency of cashew apple or desirable astringency of apple and apple juice, amla etc. They are responsible for the typical taste and aroma of tea and cocoa. Polyphenols play important role in protecting ascorbic acid in some fruits and can act as a anti-oxidants. Of late, polyphenols have been shown to have several health benefits including prevention of diseases like heart attack, cancer etc.

Tannins can be estimated either by volumetric or by colorimetric method.

Volumetric method

The volumetric method of estimation of tannins is based on the oxidation of tannins by potassium permanganate.

Reagents

1. 0.04 N Potassium permanganate solution (1.40424 g $KMnO_4$ per litre).
2. Indigo carmine solution: 1.5 g indigo carmine in 1 litre water containing 50 ml conc. H_2SO_4.
3. Gelatin solution: Soak 25 g gelatin in saturated sodium chloride solution for 1 hr, heat to dissolve, cool and make up to 1 litre with saturated sodium chloride solution.
4. Acid sodium chloride solution: To 975 ml saturated sodium chloride solution, add 25 ml conc. H_2SO_4.

Procedure

An aliquot of the filtered fruit juice or extract (10 to 20 ml containing about 0.01 g of tannin) is taken in a porcelain dish and 20 ml of the indigo carmine solution is added followed by 500 ml water. From a burette the potassium permanganate solution is added to the dish with vigorous stirring until the colour becomes light green. Then the permanganate solution is added drop wise till the colour changes to bright yellow. The titre value is noted as *A*. Now, another aliquot of the juice or fruit extract (50 ml equal to 10 ml of original juice or extract) is taken in a 250 ml volumetric flask and 25 ml of the gelatin solution is added and made up to volume with the acid sodium chloride solution. It is transferred to a conical flask, a little of filter aid is added, shaken well and filtered. To 50 ml of this filtrate, 20 ml indigo carmine solution is added and titrated with the permanganate solution as done previously. The titre value is noted as *B*.

Calculations

A = Total tannin like materials

B = Non tannin materials

$A - B$ = True tannins

One ml of 0.04 N $KMnO_4$ = 0.00168 g tannin (Gallo tannic acid)

$$\% \text{ Tannin} = \frac{(A - B) \times 0.00168 \times 100}{\text{Volume of sample}}$$

Colorimetric method

The colorimetric method for estimation is based on the measurement of blue colour formed by the reduction of phosphotungstomolybdic acid by tannin like compounds in alkaline medium. The following reagents are required for the estimation.

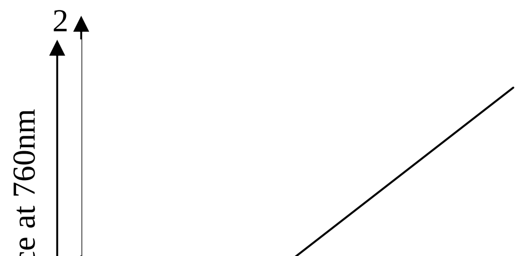
i) Folin – Dennis reagent: A mixture of 100 g of sodium tungstate ($Na_2WO_4.2H_2O$), 750 ml water and50 ml 85% phosphoric acid (H_3PO_4) is refluxed for 2 hr, cooled and diluted to 1000 ml with water.

ii) Saturated sodium carbonate solution: 35 g anhydrous sodium carbonate is dissolved in 100 ml warm (70-80^{o}C), and cooled. The clear supernatant solution is used for the estimation.

iii) Tannic acid standard solution: Dissolve 100 mg tannic acid in 1 litre water (1 ml = 0.1 mg tannic acid)

Standard curve

To a series of 100 ml volumetric flasks containing 75 ml water, 0 to 10 ml aliquots of the standard tannic acid solution is pipetted followed by 5 ml Folin-Dennis reagent and 10 ml saturated sodium carbonate solution. Make up to volume with water, mix and measure the absorbance (colour) of the solutions after 30 min in a colorimeter or spectrophotometer at 760 nm. A standard curve is prepared by plotting mg tannin in the x axis and the corresponding absorbance on the y axis.



Mg of tanin

Tannin estimation in sample

Liquid samples can be used as such. Solid samples (about 5 g) are boiled with water for 30 min, cooled and made up to a known volume.

An aliquot of the prepared sample (containing about 0.1 mg tannin) is used for colour development as in the case of standard. Note the tannin content from the standard curve and the tannin content in the sample is calculated.

Calculations

Weight of sample taken	= W ------- g
Sample extract made up to	= V ------- ml
Volume taken for colour development	= V_1 ------- ml
Tannin content in V_1 ml extract (from standard curve)	= a ------- mg

$$\text{Tannin as \% tannic acid} = \frac{a \times V \times 100}{V_1 \times W \times 1000}$$

If liquid sample is taken for estimation as such:

$$\text{Tannin as \% tannic acid} = \frac{\text{mg tannic acid in sample aliquot} \times 100}{\text{ml sample aliquot take} \times 1000}$$

5.3 BACTERIOLOGICAL EXAMINATION OF WATER

Large quantities of water are used in the food processing industries for various purposes. Some of the chemical qualities of the water are discussed in another course. Bacteriological quality of water is equally or more important from the public health point of view. The main objectives of bacteriological examination of water required for the food processing industry are to check whether:

i) the water is safe for human consumption,
ii) the water requires treatment,
iii) the treatment followed is adequate.

The following parameters are usually included in the bacteriological examination of water:

i) plate count,
ii) coliform count,
iii) faecal Streptococci test.

Sampling of water: Care should be taken to collect samples of water for bacteriological examination of water. Water should be collected fresh in sterilizes glass bottles and closed properly.

5.3.1 Plate Count

Plate count or total plate count is determined by mixing a known volume of the water sample with a solidifiable culture medium and incubating it for a specified time to allow formation of visible colonies.

Requirements

i) Nutrient agar sterilized in 15 ml quantities in plugged culture tubes.

ii) Sterilized Petri dishes of 10 cm diameter.

iii) Ringer's solution (full strength): Dissolve 9 g sodium chloride, 0.42 g potassium chloride, 0.48 g calcium chloride and 0.2 g sodium bicarbonate in 1000 ml distilled water. Suitably diluted solution is sterilized at 15 psig for 20 min before use.

iv) Dilution bottle each containing 90 ml of quarter-strength Ringer's solution.

v) Sterilized 1 ml and 10 ml pipettes.

Procedure

You have already learnt sample dilution, plating etc. The agar plates are incubated at 37^{o}C for 24 ± 3 hr. After incubation, the colonies formed are counted using a colony counter. The results are expressed as **"plate count per ml at 37^{o}C in 24 hr."** Properly filtered and chlorinated water will not have total plate count in excess of 10 per ml.

5.3.2 Coliform Count

As you have learnt already, presence of coliforms in water indicates the possibility of faecal contamination and hence is strictly monitored. Coliform counts involve three tests viz. i) presumptive test, ii) confirmed test and iii) completed test.

Presumptive test: E-coli is one of the few bacteria, which is able to ferment lactose (lactose broth) with production of acid gas. Therefore, a positive test indicates 'presumptive' evidence for sewage contamination in the water sample. It is only 'presumptive' because several non-faecal bacteria also answer this test. Hence, this test must be 'confirmed'.

Confirmed test: Positive 'presumptive' test sample is plated on eosin-methylene blue (EMB) agar and incubated at 37^{o}C for 24 hr and examined. Typical E-coli colonies will have dark to black centres, button-like in appearance and will often be surrounded by a greenish metallic shine. If positive 'presumptive' sample inoculated into brilliant green lactose bile broth and incubated at 37^{o}C for 24 hr shows gas formation also, it is confirmatory evidence for the presence of E-coli.

Completed test: Completed test for E-coli is performed by transferring a typical colony from EMB agar plate to a nutrient agar slant and lactose broth tube and incubating for 24hr at 37^{o}C. A stained mount of the agar culture is examined under a microscope. A completed test for E-coli should show a pure culture of Gram-negative short rods, and gas formation in the lactose broth tube.

5.3.3 Faecal Streptococci Test

The genus Streptococcus constitutes a diverse group of cocci widely distributed in nature. Some are dangerous pathogens. Streptococci found in faeces are called faecal Streptococci or Enterococci of which Streptococcus faecalis is typical. Streptococci usually occur in pairs of ovoid cocci or in short chains. Unlike many other Streptococci, these grow well in ordinary laboratory media in the presence of bile salt. They produce deep red pin pointed colonies in MacConkey agar and ferment glucose, lactose and mannitol, producing acid but no gas. While most Streptococci are susceptible to heat (55^{o} C for 15 – 20 min), Streptococcus faecalis offers relatively high resistance destructive agents such as heat and can withstand a temperature of 60^{o} C for 30 min. In examining water for the presence of faecal Streptococci, advantage is taken of its relative heat resistance, its ability to form acid in MacConkey broth, and grow in the presence of a concentration of sodium azide sufficient to prove inhibitory to most coliform bacteria. As some anaerobic spore forming bacilli also produce acidity in sodium azide medium, a confirmatory test is also performed. In the confirmatory test, a heavy inoculum from the positive azide tubes is plated on MacConkey agar and incubated at 37^{o} C for 48 hr. The growth of minute pin pointed red colonies is a strong evidence of the presence of faecal Streptococci. On Gram-staining and observing under the microscope, the Streptococci appear as Gram-positive.

5.4 ASSESSMENT OF SURFACE SANITATION

Bacterial counts on utensils, equipment, working surfaces, walls, floors etc., are useful means of assessing the standard of hygiene and the efficiency of cleaning procedures in food factories. The **'Swab Rinse Method'** is useful for the purpose.

For the swab method, pre-sterilized cotton swabs are used. The sterile swabs are dipped in sterile Ringer solution and rubbed over the required surfaces. The rubbed swabs are allowed to stand in sterile Ringer solution for 20-30 min and shaken. This solution is used to make plate counts with yeast extract agar. The Ringer solution inoculated into MacConkey broth should not show positive test for coliform organisms for well-sanitised surfaces. For bins and large utensils, sterile Ringer solution is used to rinse them. The rinsed solution is plated and inoculated in MacConkey broth as above.

5.5 MICROBIOLOGICAL EXAMINATION OF FOOD SPOILAGE

Microbiological spoilage of foods and its examination is an extremely wide area. Therefore, in this section, microbiological examination of spoilage of canned vegetable products, which is the most important, is discussed.

Canned Products

Canned food spoilage has both monitory loss and public health implications. Microbiological spoilage of canned fruits and vegetables is due to either under processing or post processing contamination (leakage). Under processing is due to insufficient heat treatment resulting in failure to destroy all microorganisms capable of subsequent growth in the product. Leakage is due to contamination of the product, mostly during the cooling process due to faulty seam or damage to the can. Microbiological examination of the spoiled cans help in identifying the cause of spoilage and take remedial measures.

The nature microorganisms associated with spoilage of canned fruits and vegetables is related to the pH of the products. As you have learnt, the spoilage of acidic foods like most fruit products is less critical from safety point of view. The pH of most canned fruits ranges from 3.7 to 4.5. In such products, spoilage is usually caused by aerobic and anaerobic spore formers, though Lactobacilli and Leuconostocs are also encountered occasionally. Tomato is a critical product having pH in the borderline between acidic and low acid foods. Butyric anaerobes and aciduric flat sours are important spoilage organisms of tomato products.

Spoilage in low acid (pH more than 4.5) canned products like vegetables; vegetable soups etc., spoilage due to under processing are caused by thermophiles. Some of these organisms and the type of spoilage are given below.

Bacillus stearothermophilus	:	Causes flat sour spoilage
Cl. thermosaccharolyticum	:	Causes hard swell
Cl. nigrificans	:	Causes sulphur stinkers
Mesophilic spore formers	:	Cause putrefaction

Spoilage due to can leakage is characterised by the presence of a variety of organisms including non-thermophilic organisms like various cocci including Leuconostoc and micrococci. The presence of micrococci and/ or yeasts is almost certain evidence of can leakage.

Examination of can spoilage is an elaborate process. The first step is sampling. If the spoilage is widespread, about 6-12 cans from each batch may be sufficient. Other wise the number of cans required will be quite large. The sampled cans are subjected to the following examinations.

Physical examination: The following parameters are recorded.

i) Name of the product

ii) Code mark

iii) Can size (A1 tall, A2 ½, A10 etc.)

iv) Gross weight

v) Physical condition of the can like mechanical defects, pin holes, swell etc

vi) External seam dimensions

Incubation: The cans are incubated at different temperatures depending on the pH category as below before further examination. Incubation facilitates the multiplication of the surviving organisms, which helps in the subsequent examinations.

Fruit products (pH 4.5 and below): 37^{o} C for 3 days

Vegetable products: Some at 37^{o} C and the remaining at 55^{o} C for 3 days

The cans are examined periodically during incubation and if any cans are swollen, they are removed. After incubation, the cans are cooled before opening.

Opening the Can and Sampling

The cans have to be opened under sterile/ aseptic conditions using sterilizes implements and gas flame. Special type of punches and openers are available for the purpose. Sample is drawn out using sterile glass tubing into a sterile container.

Sample Examination

The sample is used for direct microscopic examination, culturing, pH determination etc. The can under examination is emptied and observed for it's inside appearance and the seam dimensions are examined.

pH determination is important when flat- sour is suspected. As a routine procedure, the net and drained weight of the can is determined and the product quality is visually examined. Test sample should never be tasted. Combustible nature of the gas (hydrogen) in swollen cans can be checked by puncturing the can and directing the gas to a flame. The can interior of hydrogen swelled cans will show heavy corrosion. In the case of sulphur stinker, the can interior will show black or purplish black stain.

Direct Microscopic Examination

The sample taken from the can is smeared on glass slides and stained with methylene blue or carbol fuchsin and examined under the microscope for general morphology of the organisms. Separate slides are also Gram-stained.

The presence of Gram-positive rods suggests under processing while cocci, yeasts etc., suggests leaker spoilage. If spoilage is due to bacteria surviving heat process, not more than one or two types would be present except in gross under processing. In the case of products having pH above 4.0, container leakage would usually show mixed flora. The presence of micrococci and/or yeast is a sure evidence of container leakage. Based on the information, preventive measures such as increasing the process time if under processed or rectification of the can seam if leakage is the cause are undertaken.

Culturing of the can contents is required to identify the microorganisms for further investigations on the spoilage. This is an elaborate process and is not carried out in routine quality control work.

5.6 LET US SUM UP

As you have learnt, food quality assessment is based on physico-chemical, microbiological and sensory methods. Sensory methods for quality assessment are described under a separate unit.

Analytical food chemistry makes use of physico-chemical methods for determining the composition of foods. In food analysis, proximate analysis is routinely carried out to determine the proximate composition of foods. Proximate composition gives a general idea of the major components of foods. In ultimate analysis, individual compounds of the food are determined.

Many of the analytical methods commonly followed in food analysis are described in the Practical Manuals, which you will be performing. A few of those physico-chemical methods, which could not be covered in the practical Manuals, like determination of 'Crude fat', 'Protein', Pectin' and 'Tannins' are described in this unit.

Crude fat and protein are important parts of the proximate composition of foods. You have already learnt the nutritional importance of fats and proteins. Crude fat includes all fat-soluble constituents like tri-glycerides, phospholipids, sterols, essential oils, fat-soluble vitamins and pigments. Therefore, crude fat extracted from foods is used for determining those constituents also.

Microbiological quality of water used in food processing is very important from the food safety point of view. Potable water should conform to certain microbiological quality standards. The major parameters are plate count, coliform count and faecal Streptococci count. If water from a particular source is found unsafe, it should be treated suitably.

In the food processing industry, surface sanitation of the machinery, utensils etc. used should be thoroughly sanitized before use. The method followed to assess the efficiency of sanitation viz. Swab Rinse method is described in this unit.

Spoilage of foods cause monetary loss and may result in public health hazards. Canned low acid foods are of particular concern. Canned foods are generally spoiled either due to under processing or can leakage. The general procedure for examining microbiological spoilage in canned foods include, proper sampling of cans, physical observation of the cans, incubation at specified temperatures, opening the cans under sterile/ aseptic conditions, sampling the contents of the can (spoiled food material), microscopic examination and some times culturing the sample. Microbiological examination of spoiled cans helps in preventing their recurrence.

5.7 KEY WORDS

Proximate analysis : Nutritional and biochemical composition.

Ultimate analysis : Analysis of specific compounds and elements.

Crude fat : Lipids and fat-soluble components.

Tannins : Flavonoids and cinnamic acid derivatives.

Presumptive test : Tentative or unconfirmed test.

Flat sour spoilage : Spoilage in cans with acid formation without Bulging.

Hard swell : Can spoilage with hydrogen swell and heavy corrosion.

Under processing : Insufficient heat processing of cans.

5.8 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:
   - Nutritional and biochemical composition
   - Detailed analysis, analysis of individual compounds
2. Your answer should include the following points:
   - Tri-glycerides, phospholipids, essential oils, sterols, fat-soluble vitamins
   - Soxhlet apparatus
   - Ether extraction
3. Your answer should include the following points:
   - Acid digestion
   - Micro-Kjeldahl distillation method
   - % Protein = % Nitrogen $\times$ 6.25
4. Your answer should include the following points:
   - Acid extraction of pectin
   - Precipitation as calcium pectate
   - Gravimetric determination
5. Your answer should include the following points:
   - Antioxidant
   - Health benefits

- Oxidation of tannins by potassium permanganate

Check Your Progress Exercise 2

1. Your answer should include the following points:
   - Total count
   - Coliform count
   - Faecal Enterococci count.
2. Your answer should include the following points:
   - Nutrient agar
   - Ringers solution
   - Plating
   - Incubation
   - Counting
3. Your answer should include the following points:
   - Presumptive test
   - Confirmed test
   - Completed test
4. Your answer should include the following points:
   - Cotton swab
   - Ringers solution for rinsing
   - Plating
   - Incubation
   - Counting
5. Your answer should include the following points:
   - Can sampling
   - Incubation
   - Can opening
   - Sterile conditions
   - Product sampling
   - Microscopic examination
6. Your answer should include the following points:
   - Spore formers
   - Gram-positive
   - Micrococci
   - Yeasts
   - Under processing
   - Leakage

UNIT 6 SENSORY ANALYSIS OF FOODS/ BEVERAGES

Structure

6.0 OBJECTIVES

After reading this unit, you should be able to:

- differentiate between sensory analysis carried out by a trained panel and casual testing by consumers; and
- explain the methods that should be used in the two situations as both are important in analysing food/ beverage.

6.1 INTRODUCTION

Food / beverage quality is composed of four major components. They are: (i) Intrinsic factors as nutrition, safety which are hidden, (ii) economic factors as investment and profit for a producer (iii) sensory quality noticed by the people as colour, appearance, taste, flavour etc. and (iv) affective quality which decides its ultimate acceptance and use due to like/dislike to a product. The producer is most interested in the last two components to see repeat purchase and good sale of his product. Definite methods to test the intrinsic quality and cost benefit analysis are available for the first two components. These involve human responses and are often confused as one and same. At the outset it should be understood that the two are different. The sensory component testing refers to stimulation of sense organs (Iyendria) and it purely refers to responses in analytical way. The consumer or affective test refers to response by a population, their like/dislike. It is a test for acceptance or rejection, preference or liking of a product (Indria) and not critical analysis.

The senses used in analysis of foods/ beverages by people are, the eye, which includes colour and appearance, the nose for the sense of smell/ aroma as felt by smelling or while swallowing the food, and by the tongue and interior of the mouth for the four basic tastes of sweet, sour, salt and bitter. The teeth while biting and feel on the tongue or by finger is another important sensory quality of food, as for example, softness of fruits, crispness of biscuit and papads etc. Figure 6.1 gives the idea of the sensations that foods create.

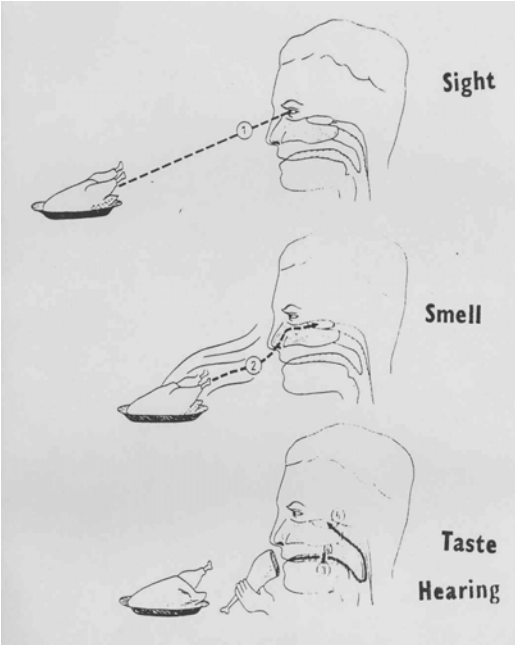

Figure 6.1: Sensory impressions by food

6.1.1 DEFINITION

Sensory analysis is a scientific discipline used to evoke, measure, analyse and interpret the reactions to food as perceived by sense of sight, taste, smell, touch and hearing. The sensory analyst will be equal to an analytical instrument, and will use his 'Iyendrias' (senses) as a tool. It is the 'Iyendria Moulya Maapan' only and not referring to personal likes and dislikes.

The ultimate use of food/beverage is achieved when people consume it. All human beings are endowed with sense organs and use them to judge colour, appearance taste, flavour and texture of food automatically. Is it not true we all look at the food we eat at home or outside for its sensory quality? Think and remember!!

However, this being a psychological response, it can be influenced by several factors. It is therefore important to test the product under careful conditions and in a scientific way.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. What are food qualities tested by people as tools called?

   a) Intrinsic quality test
   b) Economic quality test
   c) Sensory quality test
   d) Affective (consumer) qualities test

2. Give the definition of Sensory Analysis of foods.

   ……………………………………………………………………………………

   ……………………………………………………………………………………

   ……………………………………………………………………………………

   ……………………………………………………………………………………

   ……………………………………………………………………………………

6.2 APPLICATION

Sensory analysis tests are used in foods/beverages, personal care products as cosmetics, perfumes, and also in textiles for examination of texture, smoothness, etc. Sensory tests are needed in production, research centres and in consumer studies as in market research or survey. We all have seen sensory quality discussed in basmati rice, instant coffee, shampoo, soap etc.

6.3 CONDUCTING SENSORY TESTS

We know sensory tests are carried out by a panel leader and can be either analytical test done by trained people or as affective test done by consumers. The following remain common to both.

6.3.1 Identification of Problem

The first factor to be considered by panel leader is to identify the problem to be looked into i.e., aim of the test should be known. Since sensory organs are simulated simultaneously, for example, aroma and taste, colour and appearance, etc. the objective of testing has to be clear and focussed. The judge has to look for these attributes only.

6.3.2 Selection of Method

Sensory analysis testing for food quality valuation has been in practice from a long time. It has been used for complex products as tea and coffee, whisky by special blenders and also for simple products as sweetness by flow calorie sweeteners. The choice of test method, however, is very specific to the objective of testing. International and national standards are now available to use uniform pattern of testing. This is given in detail under 4.6.

6.3.3 Panellists

Panel Selection

The panel of judges for laboratory sensory testing are usually selected from people with normal sensitivity and not super tasters. They are from office, co-workers in factory, research group and management staff. They are collected through circulars or personal contacts. People from both sexes are used. The eagerness to participate is the first requirement, as they have to be interested in it. Initial information on age, sex, health status, likes and dislikes, educational background, availability is necessary. In consumer tests, the target population should be selected. We have to see who uses the product and decides to buy it and they have to test it. For example chewing gum flavour is best tested by teenagers and quality of cooking oil by housewife.

Panel Training

In laboratory sensory analysis, the level of training required depends on the type of test used. It is first done to select a group of people who are sensitive to the required level. For example, ability to test off odour has to be done by carefully selected and trained people. Where more intricate analysis is required, more training with examples are used. The panel leader will select the degree of training needed. In consumer tests, no specific training is given to panellists and only method to fill up the answer sheets/ pro forma will have to be explained.

Check Your Progress Exercise 2

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Sensory tests are done only for foods. Yes No
2. Aim of testing should be clear first. Yes No
3. Panel members should be super tasters. Yes No
4. Which of the tests need more training and why?

…………………………………………………………………………….

…………………………………………………………………………….

…………………………………………………………………………….

…………………………………………………………………………….

…………………………………………………………………………….

6.4 FACTORS CAUSING BIAS IN SENSORY TESTS

In sensory tests since human subjects are used as tools, care must be taken to use bias-free conditions. Bias means bad influence. Several difficulties can come up which will disturb the analysis and affect the results. They can be due to physiological factors or psychological factors.

6.4.1 Errors Due to Physiological Factors

Errors due to physiological reasons could be the following:

i) *Health:* People with common cold cannot perceive smell and taste. Textural properties, particularly biting quality cannot be judged by people with artificial molar teeth.

ii) Age is another factor which will influence sensory perception. With proper training and motivation it is possible to use panellists of all ages but care must be taken to avoid too young and too old age group.

iii) Adaptation can occur in sensory in nose or tongue when a product is to be tested continuously. For example testing of pungent compounds or bitterness can make a panellist more tolerant of sensation in a product.

iv) Enhancement of sensation can occur in some situations, for example perception of sweetness can be increased with some other substances as sourness. This is commonly observed in testing gooseberries or bitterness in coffee with added chicory.

v) Suppression of taste sensation is the opposite effect of enhancement and commonly observed in foods. This effect will modify the taste sensation. This is observed in combination of pungent and salt tastes or even addition of oil or fat to a food.

6.4.2 Psychological Factors

In sensory testing, psychological factors play an important role. We all know each of us is capable of thinking and imagining. Some common psychological factors, which bias judgement, are as follows.

i) Anticipatory or expectation errors. This occurs due to the panellist starting to test with a pre-conceived idea. Information received earlier can influence judgement. For example, this may happen in testing sweet tasting low calorie foods.

ii) Stimulus error can occur due to other sensory impression in the same product, for example intense colour in fruit juice is considered strong in flavour. Even irrelevant issues can cause bias in judgement as packaging of product can give a bad influence.

iii) Logical error can come up due to the imagination of panellist. For example, cakes with lot of holes may be expected to be soft and spongy or chapathi with brown spots will be considered soft and well cooked.

iv) Halo effect is another situation of bias where the testing is to be done on 3 to 4 attributes and confuse the panellist if he/she is not careful.

In addition to these factors, testing sequence can also cause bias, as for example first sample tested will be seen critically. Over eagerness to perform well in tests or cross talk can influence the test. The panel leader should minimize these factors, which can bias judgement. The panellists should remain calm and interested to concentrate on the test.

In consumer tests, testing place as in a school or shopping area or home may be a bad influence if wrongly selected.

6.5 PHYSICAL SET UP FOR CONDUCTING SENSORY TEST

6.5.1 Laboratory Set Up

Three main areas are required for sensory testing of foods. They should be away from busy corridors and separated by wall or wooden partition. They are: (i) briefing room, where the panellist is told all about the product to be tested, testing method and number of samples (ii) testing room with table to keep the samples and write the score card. Lighting and ventilation should be good. Each panellist should be separately seated and not in the visual reach of each other (iii) the third area should have sufficient place to keep all plates and cups used in test. All samples should be presented in uniform containers and coded numbers. Figure 6.2 gives a picture of a testing room in a laboratory set up.

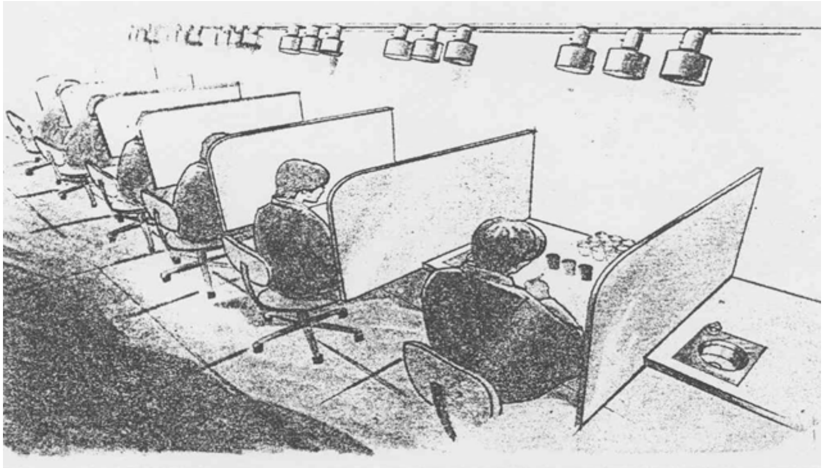

Figure 6.2: Laboratory setup for sensory testing

6.5.2 Consumer Testing

The physical set up depends on product and target group of consumers. It can be a central location testing in shopping area, college campus, hospital, etc.; it can be in club house or homes of friends. Essential requirement in all is to have similar cups and plates with code numbers for all products tested.

Check Your Progress Exercise 3

1. Bias in sensory test (wrong influence can arise due to a) Physiological, b) Psychological factors.

Yes No

Give two examples for both.

……………………………………………………………………………………

……………………………………………………………………………………

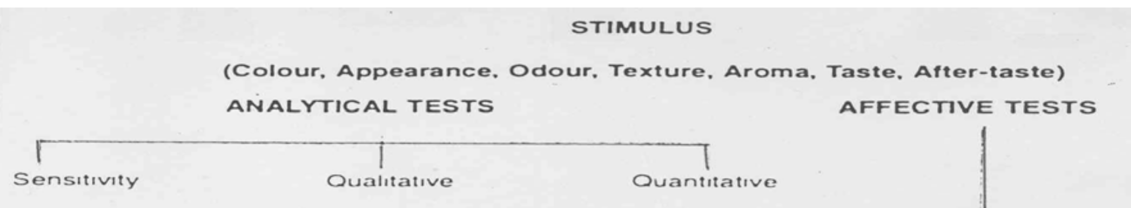
……………………………………………………………………………………

……………………………………………………………………………………

6.6 SENSORY TEST METHODS

Bureau of Indian Standards follows the internationally standardised sensory test methods also. The Table 6.1 gives the test methods adopted. The first distinction is between analytical methods i.e., laboratory test method and second is the affective or consumer test method.

Table 6.1: Sensory testing methods



6.6.1 Analytical Tests

These are the laboratory methods used to test the product for its sensory quality.

Sensitivity Test

This refers to basic difference test. It can be performed as threshold test to identify a sensory impact. Threshold tests are used, for example, to select people with normal sensitivity to sweetness or saltiness. It can be used to detect adulteration Samples are tested in a line till they find out the sensation.

Sensitivity tests can also be done as discriminative test in pairs or triangle. These two-sample tests are simple. We all know it is possible to compare one with just another easily with out confusion. The order of examining, which is first? which is second? should be properly planned to avoid the bias that first is always best. For example think of comparing a new orange drink with fresh juice. Paired test is by testing two samples at same time and see if they are same or different. Figure 6.3 shows how the samples are arranged. You will see 4 pairs of sample arranged for testing. Plain water is used in between samples. Only small quantity of test sample is given under coded numbers.

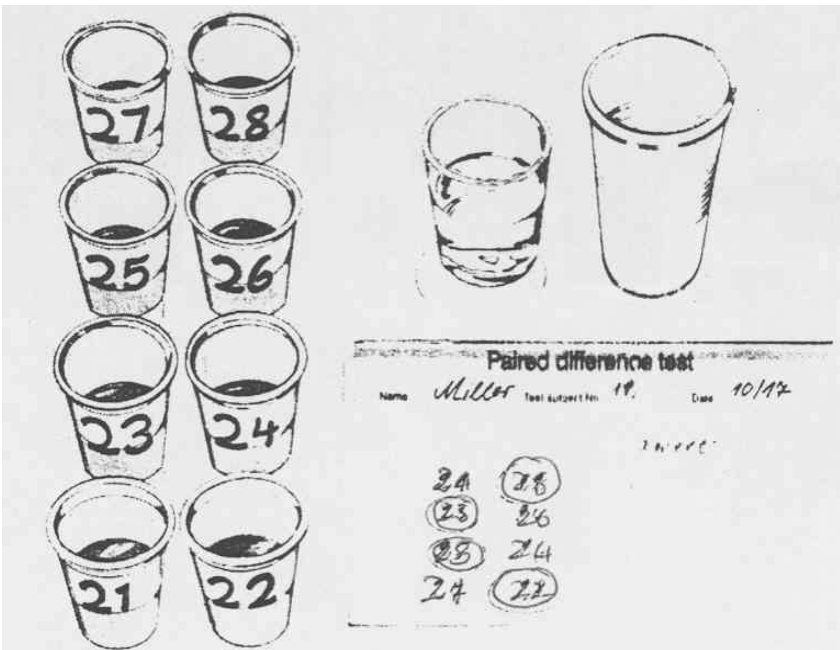


Figure 6.3: Paired comparison test

Minimum 7-10 panellists should examine the samples. Test results are checked for significance of difference by referring to statistical tables.

Triangle test is another method for difference test. The samples are presented in groups of three. Here two are identical and one is odd. The test is to identify the odd sample. For analysing the data, the total number of correct identification is counted and referred to table for significance of difference.

Qualitative Tests

Many times more than two samples will have to be tested for more attributes. For this qualitative tests can be used. This test is useful for working with semi-trained panel of 7-10 members. One of the methods is to arrange the tested foods in the order of increasing intensity (e.g. strong or week aroma), or quality (e.g. good or bad aroma). Ranking is another method. For examples in chocolates, four to five brands can be tested for colour and appearance, texture, flavour and overall quality in one session. The panellist will have to arrange the samples in order of 1st rank for best colour then for best texture etc. Each attribute is tested separately. Classification method is another method. These can be for a specific category of sensory attributes for example as depth of yellowness in pineapple juice. The data in these tests is analysed using non-parametric method. The samples should be tested as coded samples and in random order to prevent bias.

Quantitative Test

In sensory tests to get information on 'how' and 'why' the foods are different, marks for the sensation felt has to be given. The panellists have to be trained more to do these tests and a minimum of 7 panellists are required. They have to be trained both to identify the sensation and give marks to it. This method is very useful for factory and research people. The methods are scoring, rating and time-intensity tests.

In scoring test, numbers as in figures or descriptive scores are used. These scores are useful when the panellists are well trained. For example in a product as jam, ketchup etc. scoring and grading for colour, consistency, set and aroma is useful. Similarly duration of sensory feeling can be matched with time-intensity as in natural and artificial sweeteners. The data is analysed for arithmetic mean and standard error. These quantitative tests can be tested further by detailed statistical tests. Indian standards institution has given details of these tests.

Quantitative description method, popularly called as QDA is another very useful methods for testing foods and beverages. It is a complete and detailed system of panel training, selection of range of products and vocabulary development in simple language. 8-10 well trained panellists can participate. For example description of Dosa or Samosa can be completely obtained and tested by this method. A reference can be maintained as a standard and any number can be tested by a panel. The method can be used to get difference, defects and desirable sensory quality. Recently available computer aided data analysis is very useful for testing.

Check Your Progress Exercise 4

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Which are the two groups in sensitivity tests?

   ………………………………………………………………………………

   ………………………………………………………………………………

   ………………………………………………………………………………

   ………………………………………………………………………………

   ………………………………………………………………………………

2. For two samples ……………….. and …………………. tests can be used.

3. Qualitative test can be done with > 2 samples.

   Yes No

4. Significance of difference is decided by referring to statistical tables.

   Yes No

5. Which tests are used to know 'How' and 'Why' foods are different? What are the methods used to give marks?

   ………………………………………………………………………………

   ………………………………………………………………………………

   ………………………………………………………………………………

   ………………………………………………………………………………

   ………………………………………………………………………………

6.6.2 Affective Test

This group of tests is used to get the reaction of the consumer for the food. It tests the users opinion of the product. Three common methods are acceptance, preference and degree of liking. These tests need careful planning and the objective of the test should be known. Question should be asked accordingly. Selection of people who do the tests should be correct, for example baby foods should be tested by mothers and traditional family food should be tested by all at home. Consumer attitude will also change and it is better to check the target population periodically. The number of samples in consumer tests should not be more than two. Consumer response study should never be less than 50 number and 100 will be best. The questionnaire should be as simple and focussed as possible and related to the objective. Consumer tests can be handled for the four types of problems given below:

Acceptance Test

Acceptance is the simplest decision making job for the consumers but only one sample should be tested in one session. They should be asked to concentrate on attribute like for example, overall quality or aroma of new variety of rice, etc Since consumers will relate it to other factors as price, it can be done only at a central location in a shopping complex, college campus, etc., A new product can be tested here. These tests can be done at home also for example, a new masala mix for rice. Results are given as percentage of people accepting it.

Preference Test

Preference test is another possibility in consumer tests. Not more than three samples should be tested at a time. This can be as 1st, 2nd, and 3rd preference. It should be done by consumers who are familiar with the product. For example cola a type of drink, by college students and instant coffee by office staff.

Hedonic Test

Hedonic test is a direct reference to personal like/dislike to a product. The test is done on 5 or 7 point scale of 'like very much' to 'dislike very much'. The actual users will have to test the food/beverage. New product for example, noodles, shakthi drink etc., can all be tested by this method. Here also a minimum of 100 responses will have to be collected. Figure 6.4 shows one sample of score card for children's food. Here results are as percentage liking it or not.

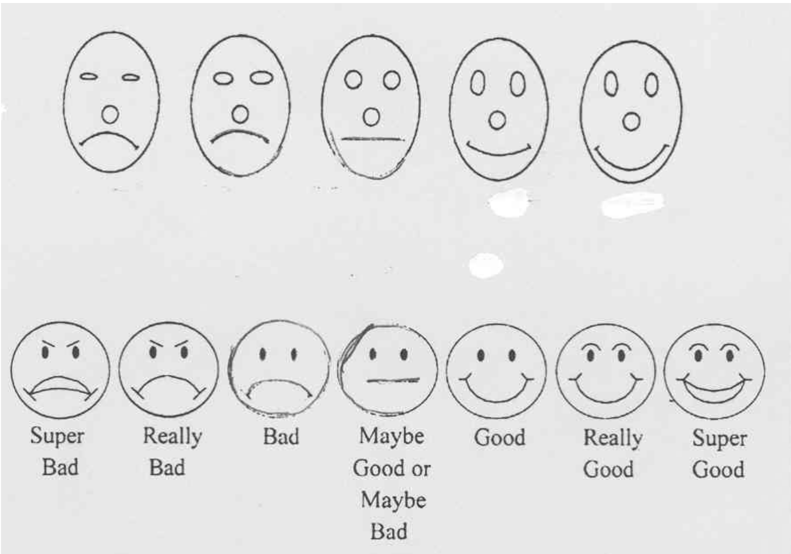

Figure 6.4: consumer evaluation card

…………………………………………………………………………………

…………………………………………………………………………………

6.7 SENSORY TEST AND INSTRUMENTAL MEASURES

The sensory test when carried out by scientific method will be useful to support instrumental tests. The following are some corresponding tests.

6.7.1 Visual Examination

Visual examination is by the rods and cones in the eye where colour, shape, structure, freshness, etc. are observed. The human eye can distinguish up to 1500 different hues/shades of colour. For example, degree of colour in fruits from green to over ripe fruits, the shades of brownness in chocolates, etc. The instrumental measures for matching what the eye can see are in the visual range of 380–780 nm as L*a*b* tristimulus values in CIE system. The average level of difference as seen by people can be used to describe the colour. Shapes of foods are easier to be measured in terms of geometry of height, length, etc. This can be shown as example in cakes that are baked, sweetmeats as jelabi, etc. Degree of freshness can be noticed in some products by checking for bubbliness, in some beverages as soda and orange.

6.7.2 Texture Examination

Auditory (hearing) sensation in foods is caused by stimulation of ear drum by the sound waves. This is called as texture as crispness of papads or fresh fruits as in apple, etc. It is what the teeth feel when biting the food. It is closely related to structure and movement of food in the mouth. There are advanced texture measuring instruments to study the hardness, softness of food and viscosity of beverages.

6.7.3 Olfactory – Sense of Smell

Olfactory or sense of smell is a chemical stimulation of the receptors in the nose and upper oral cavity. Human odour memory is short but can be trained to recall. Up to 150 odour types can be differentiated. The air carries the chemicals that give the smell. It is difficult to understand how nose can pickup differences in mango variety or bad smell due to toxins. Instrumental measures as gas chromatography or headspace volatiles are used to analyse the individual chemicals. Recently electronic nose is developed to match human response.

6.7.4 Gustatory – Sense of Taste

The sense of taste noticed by tongue and parts of oral cavity are developed early in human beings. Preference for sweet taste is seen even in one week old babies. Instruments for measuring salt content, sweetness and sourness are available. The simple ones are Brix (sugar content), sodium chloride content and pH (food acid content). Special methods are also there.

6.7.5 Flavour

Flavour is the common term for the total effect of odour, taste and touch experienced by people. It is a sensation more closely related to aroma when the food/beverage is put in the mouth. Highly trained panel only can test this. No single instrument can measure this sense.

Check Your Progress Exercise 6

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Sensory tests for colour, shape and texture can be related to instruments.

   Yes No

2. What causes smell in the nose and how do they reach the nose?

   …………………………………………………………………………………

   …………………………………………………………………………………

   …………………………………………………………………………………

   …………………………………………………………………………………

   …………………………………………………………………………………

3. No single instrument can measure total flavour test.

   Yes No

6.8 LET US SUM UP

In this unit we learnt that sensory analysis of foods and beverages refers to using humans as instruments/tools. The analytical tests for colour shape, aroma/odour, taste and texture of foods are done by trained people called panellists. Like/dislike, acceptance/rejection are tested by normal consumers is affective tests and done by consumers. Tests have to be carried out under bias free conditions i.e., without wrong influence. Specific methods of testing and analysing data is given by Indian Standards. There are three major types of analytical tests. We need not use any super taster but people like you and me can do the test. There are three types of consumer tests. For analytical tests seven to ten members are needed and for consumer test at least 50 people should be used. For all sensory tests, some instrumental analysis is possible but not for total flavour and acceptance or liking. Only human beings can tell this.

6.9 KEY WORDS

Senses of humans	:	Eye for Colour and shape, teeth and flow in the mouth for texture and viscosity, nose and back of throat for smell and aroma of food. Tongue for taste.
Analytical sensory Tests	:	Tests done by trained people.
Consumer tests	:	Tests done casually in markets, schools etc.
Sensitivity tests	:	Threshold and two sample tests.
Qualitative test	:	More than two samples for arranging in order.
Quantitative test	:	Tests where marks are given.

Iyendria	:	Senses (analytical).
Indria	:	Likes/ dislikes (affective).
Sensory analysis	:	Iyendria Moulya Maapan.
Bias	:	Bad influence.

6.10 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. b) Sensory quality test
   d) Affective quality test

2. Sensory analysis is a scientific discipline used to evoke, measure, analyse and interpret the reactions to food as perceived by sense of sight, taste, smell, touch and hearing. The sensory analyst will be equal to an analytical instrument.

Check Your Progress Exercise 2

1. No
2. Yes

2. Shanthi Narasimhan and D. Rajalakshmi (1999), Sensory evaluation of fermented foods, in Biotechnology: Food Fermentation, Vol. 1, Ed. V.K. Joshi and Ashok Pandey: Educational Publishers and distributors, Asia Teca Publishers Inc. New Delhi, p.346-382.

UNIT 7 ANALYTICAL INSTRUMENTATION – ANALYTICAL BALANCE, pH METER & CHROMATOGRAPHY

Structure

7.0 OBJECTIVES

After reading this unit, you should be able to:

- explain the principle of measurement of mass;
- describe the different types of analytical balances;
- explain the principle of pH measurement;
- explain the principles of chromatographic techniques; and
- describe the instrument details if gas chromatograph.

7.1 INTRODUCTION

In Unit 3.2.1, you have learnt some of the analytical and quality control methods based on the physical properties of food components. You have also learnt that instrumental methods are becoming the preferred methods over the classical volumetric and gravimetric methods. Some of the instruments are becoming more and more sophisticated and capable of automatic analysis. Even the simple analytical balance used for all analytical determinations has gone through a lot of developments and has become highly complex and refined. Therefore, all those engaged in analysis and quality control of food and food products should have some basic knowledge of the instruments, which they will be using.

In the following two units, you will be learning about a few important instruments. Microscope, a very important instrument, will be dealt with in another unit along with microbiological techniques. Some methods like texture measurement and reflectance colour measurement require more theoretical explanation to understand. Therefore, they are covered under physical methods in Unit 3.2.1. It is presumed that gadgets and equipments like gauges, hydrometers, ovens etc. are so simple that they can be straight away handled.

In this unit, you will be learning about modern analytical balances, pH meter and chromatography.

7.2 MEASUREMENT OF MASS

In the course of most chemical/ food analysis, an accurate and reliable measurement of the mass (weight) of a sample is required. The terms **'mass'** and **'weight'** are often used synonymously but they are different. Mass is a fundamental quantity which is an invariant measure of the amount of matter in an object. Weight is the force of attraction that exists between an object and its surroundings, mainly the earth. Therefore, the weight of an object varies with the altitude of the place where it is weighed. For example the weight of a coin is less in Shimla than in Mumbai whereas the mass of the coin remains constant in both the places. Weight and mass are related by the expression:

$$W = M\,g$$

Where, **W** is the weight of the object, **M** is its mass and **g** is the acceleration due to gravity. In order to free the results from dependence upon altitude, a **balance** compares the weight of an object with the weight of a set of standard mass. Because g affects both unknown and known masses equally, an equality between their weights indicate an equality in mass. Therefore, measurement of mass is usually referred to as weighing and the results of weighing are called weight.

7.2.1 Analytical Balances

An analytical balance is a weighing instrument, which has a maximum capacity ranging from 1g. to a few kilograms but usually 160 to 200 g. Weighing can be made with a precision of ± 0.1 mg. Semi micro analytical balances have a maximum loading of 10 to 30 g. with a precision of ± 0.01 mg. and micro analytical balances have a capacity of 1 to 3g and precision of 0.001 mg. The analytical balance has undergone significant evolution during the past several decades. The traditional analytical balance had two pans suspended from the two ends of a lightweight beam, which was supported on a knife-edge. Single pan balance is more convenient to use and hence has almost completely replaced the double pan balance.

7.2.2 Mechanical Single Pan Balance

The two types of balances, however, have several common fundamental features. The components of a mechanical single-pan balance is shown below (Figure 7.1):

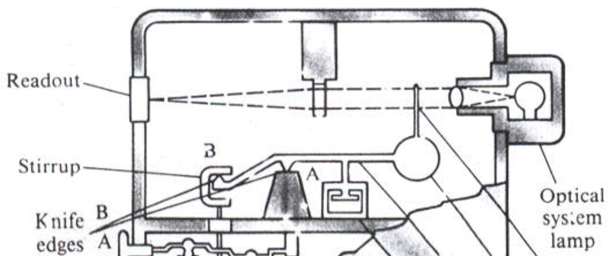

Figure 7.1: Single-pan analytical balance

A lightweight beam is supported on a hard surface (agate or synthetic sapphire) by a knife-edge A. At the left end of the beam there is one more knife-edge B from which a pan for holding the object to be weighed and a full set of weights held in place by hangers is attached. These weights can be lifted from the beam, one at a time, by a mechanical arrangement that is controlled by a set of knobs on the exterior of the balance case. At the right end of the beam a counter weight is fixed which just balances the pan and the weights on the left end of the beam.

The performance of a mechanical balance is critically dependent upon the perfection of the knife-edges. They should permit motion of the beam and pan with minimum friction. To protect the knife-edges from damage and ware when an object is placed on the pan or when the balance is not being used, the balance is equipped with a beam arrest and a pan arrest.

An air damper is mounted near the end of the beam opposite the pan. This device consists of a piston that moves within a concentric cylinder. As the beam is set in motion, air in the cylinder undergoes expansion and contraction causing opposition to the motion bringing the beam rapidly to rest. When there is no object in the pan, the beam will be in horizontal position. When an object is placed in the pan, the beam is displaced downward. Weights are then removed one by one from the beam until the imbalance is less than 100 mg. The angle of deflection of the beam with respect to the horizontal position is directly proportional to the mg. of additional weight that must be removed to restore the beam to its original position. The optical system measures this deflection and converts the angle to milligrams. A small transparent screen mounted on the beam has 1-100 mg. markings. A beam of light passes through the scale to an enlarging lens which in turn focuses a small part of the enlarged scale on to a frontal glass plate located on the front of the balance. A vernier makes it possible to read this scale nearest to 0.1 mg. Before the weighing starts, the vernier is adjusted so that the scale reading is zero.

7.2.3 Electronic Analytical Balance

The electronic balance has neither a beam nor knife-edges. The diagram of an electronic analytical balance is shown below (Figure 7.2):

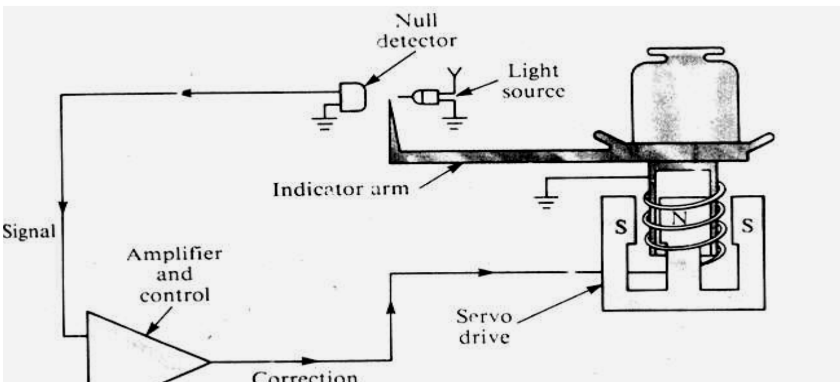

Figure 7.2: Electronic analytical balance

The pan of the balance on which the object to be weighed is placed rides above a hollow metal cylinder which is surrounded by a coil and fits over the inner hole of a cylindrical permanent magnet. An electric current in the coil creates a magnetic field, which levitates the cylinder, the pan and indicator arm. The current is so adjusted that the level of the indicator arm is in null position when the pan is empty. When an object is placed in the pan, the pan along with the indicator arm move downward, which increases the amount of light striking the photocell of the null detector. The increased current from the photocell is amplified and fed into the coil, creating a larger magnetic field, which returns the pan to its original null position. A device like this, in which a small electric current causes a mechanical system to a null position, is called a servo system. The current required to keep the pan and the object in the null position is directly proportionate to the weight of the object and is readily measured, digitised and displayed. Electronic balance is calibrated with a standard mass.

7.3 pH MEASUREMENT – pH METER

You have learnt about the importance of pH in food analysis, food preservation as well as its role in the sensory quality (flavour and taste of foods). You also know that precise maintenances of pH of biological systems is essential for their survival. Therefore, an accurate measurement of pH is of great importance. Before you learn the instruments for measurement of pH it is important to have a clear understanding of pH itself.

Pure water undergoes self-ionisation as follows:

$$2H_2O = [H_3O^+] + [H^-]$$

$$H_3O^+ \text{ is essentially } H^+ + H_2O$$

Since the extent of ionisation is negligible and hence the concentrations of $[H_3O^+]$ and $[OH^-]$ are also negligible, the ionisation constant

$$Kw = [H_3O] + [OH^-]$$

Taking the negative logarithms of both sides

$$PKw = pH + pOH$$

Kw has a value of 1.0×10^{-14} at 24°C (it increases slightly with increase in temperature, e.g. At 100°C the value is 49×10^{-14})

Since $\quad [H_3O^+] = [OH^-]$

$$Kw = [H_3O^+]^2$$

Or $\quad [H_3O^+] = \sqrt{}\ 10^{-14} = 1 \times 10^{-7}$

Therefore, $\quad pH = -\log(1.00 \times 10^{-7}) = 7.00$

At 24°C, any solution whose hydronium ion concentration exceeds 1.00 × 10^{-7}M i.e. 1.0 × 10^{-6}, 1 × 10^{-5} is acidic and any solution whose hydronium ion concentration is less than 1.00 × 10^{-7} M i.e. 1 × 10^{-8}, 1 × 10^{-9} is basic.

pH Meter

pH meters are based on the principle of potentiometry. Potentiometry is the measurement of potentials or voltages of electro chemical cells. An electrochemical cell has two electrodes namely a reference electrode and an indicator electrode or working electrode. An electrode potential of a reference electrode is known and is independent on the composition of the solution under study. The potential of the working electrode employed in conjunction with the reference electrode on the other hand is dependant on the concentration of the solute under investigation. The third component of an equipment required for potentiometric measurement (including pH measurement) is a potential measuring device.

There are three important reference electrodes. They are (1) Standard Hydrogen Electrode (SHE), (2) Saturated Calomel Electrode (SCE) and (3) Silver – Silver chloride Electrode. Even though SHE is the ultimate reference against which the potentials of all other electrodes are measured, it is not convenient to use for routine purposes. Therefore, the later two are often used. The indicator or working electrode for pH measurement is the glass membrane electrode.

7.3.1 Glass Electrode

Glass electrode is a type of ion-selective electrode (ISE). ISEs permit selective determination of numerous cations and anions. The basic principle of glass electrode for the measurement of hydrogen ion concentration is the measurement of the potential that develops across a special type of thin glass membrane that separates two solutions having different hydrogen ion concentrations. Figure 7.3 shows a typical glass electrode.

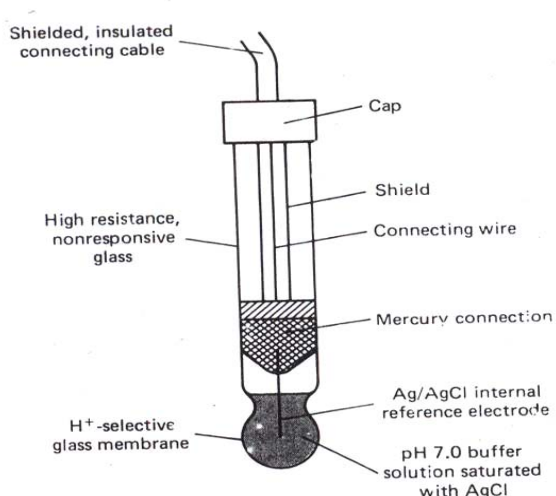

Figure 7.3: Glass electrode

The glass electrode consists of a thin, pH sensitive glass membrane sealed onto one end of heavy-walled non-responsive glass or plastic tube. The internal element consists of silver-silver chloride electrode immersed in a pH 7 buffer saturated with silver chloride. Some glass electrodes contain dilute hydrochloric acid saturated with silver chloride. A silver wire in this solution forms a silver/silver chloride internal reference electrode. The complete system consists of a glass electrode with an internal reference electrode, calomel or silver/silver chloride reference electrode and a potential measuring device. Although, the internal reference electrode is part of the glass electrode, it is not the pH sensing element. Instead it is the thin glass membrane at the tip of the electrode that responds to the pH.

Glass electrodes are available in a variety of sizes and shapes. For example, semi microelectrodes are so small that they can be used to measure the pH of solutions as little as 0.2 ml. There are also electrodes in which the glass electrode and a reference electrode like silver/silver chloride electrodes are physically combined and encased in a single tube. These **combination electrodes** have the advantage of being more compact than a separate two-electrode system. Figure 7.4 shows a diagram of a combination glass pH and silver/silver chloride reference electrode.

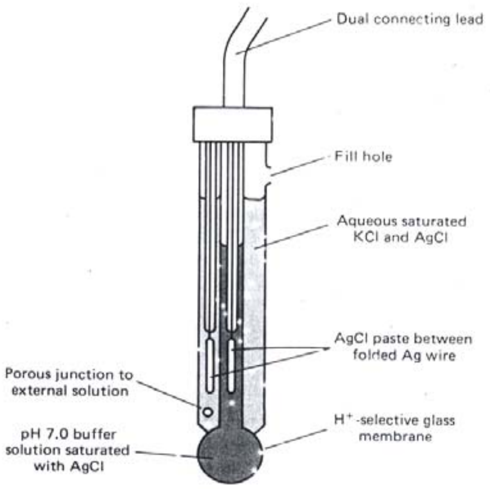

Figure 7.4: Combination pH electrode

7.4 CHROMATOGRAPHY

Chromatography is a method of separation of the components of a mixture of closely related compounds and depends upon the distribution of these components between two immiscible solvents. The separated components are detected usually as such or after converting them to coloured complexes. Other signals such as thermal conductivity, visible, ultraviolet and infrared absorption, refractive index and electrical conductance have also been employed to complete the analysis. There are a number of chromatographic separation techniques, which you will be learning in this section.

Tswett is credited with the major part of the discovery and description of chromatography. Since the initial studies were on the separation of coloured components, the method came to be known as chromatography, which means **'description of colours'** or **'writing in colours'.** However you will be learning that present day chromatographic methods are not restricted to separating coloured substances.

Even though the basis of chromatography was laid in the beginning of the 20th century, it was only in 1941extensive work on chromatography was carried out and it's vast potential was realised. This was mainly sue to the work of Martin and Synge who got the Nobel prize in 1952 for their contribution in the field. They did the developmental work on liquid/liquid partition chromatography using inert adsorbents in columns and also paper (inert cellulose) chromatography. Another development in chromatographic technique, which took place during the middle and later 1950s, is the thin layer chromatography (TLC). Stahl is credited for most of the early developmental work on TLC. Martin and Synge even suggested that there is no reason why the moving phase in chromatography should not be a gas. They used a moving gaseous phase to separate a mixture of fatty acids on a conventional liquid chromatography column. Thus gas chromatographic technique was born which has developed into a very powerful analytical tool today. However, it has to be accepted that the modern gas chromatography owes a lot to the development of high sensitivity detection systems.

7.4.1 Classification of Chromatographic Methods

In any chromatographic method, the components to be separated are distributed between two phases. One of the phases is the stationary phase and the other flows through or along the stationary phase and is called the mobile phase. The mobile phase carries along with it the mixture of compounds to be separated. The mobile phase can be either liquid or gas while the stationary phase can be a solid or liquid. **Adsorption chromatography** is in which the stationary phase is a solid and the mobile phase is a liquid. Most of the column chromatographic methods are based on adsorption. The separation process in which both the stationary and the mobile phase are liquid is called **partition chromatography.** Even column chromatography and paper chromatography in which a liquid stationary phase (mostly water) is held on the inert solid support (column filling material or paper) are basically partition chromatography. However it has to be noted that the overall separation process in liquid/ liquid chromatography is most likely due to a combined effect of adsorption and partition.

When the mobile phase is a gas, two possibilities similar to the above are possible. One is in which the stationary phase is a solid and is called **gas – solid chromatography**. The second, which is more popular, is called **gas – liquid chromatography (GLC)** in which the stationary phase is a liquid held on an inert material. Due to the wider application of GLC, quite often it is referred to as just gas chromatography (GC).

Thin layer chromatography (TLC) can also be based on liquid/ liquid or solid/ liquid principle. Somewhat unrelated separation processes viz. ion exchange chromatography and exclusion chromatography are also often included under chromatography. A schematic representation of different chromatographic methods is shown in the Figure 7.5.

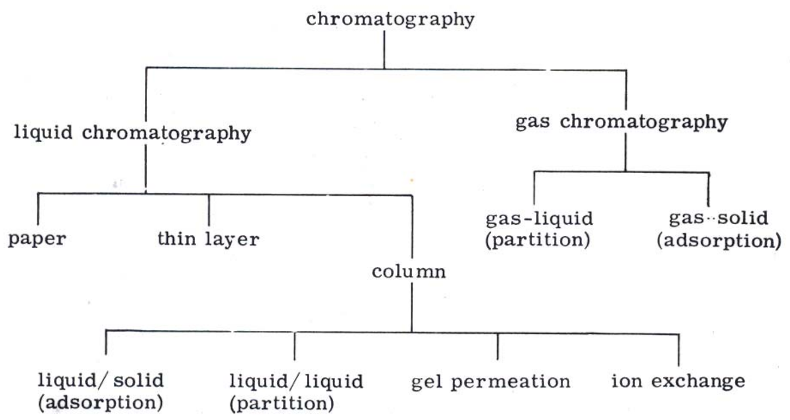

Figure 7.5: Classification of chromatographic methods

7.4.2 General Principles of Chromatography

A sample of a mixture of solutes applied to the stationary phase of a chromatographic system (column, paper or TLC) is carried by the mobile phase (liquid or gas) through the stationary phase. Depending on the nature of the mobile phase, the transfer of components from the stationary phase to the mobile phase is due to one or more of the following factors.

i) adsorption on to the stationary phase,

ii) partition into the liquid stationary phase,

iii) formation of polar bonds with ionic components of the stationary phase.

Separation of the components of a mixture by chromatography is based on the principle that the speed of movement of an individual component through the stationary phase depends on its partition between the two phases. The partition coefficient of each component depends on its sorption characteristics under the experimental conditions. If the sorption characteristics of the individual components of a mixture differ significantly, they move through the chromatographic system at different rates resulting in their separation.

The chromatographic behaviour of a solute is described generally by its retention factor (R). In chromatographic work, the retention factor is termed as Rf value.

$$Rf = \frac{\text{Distance moved by the solute}}{\text{Distance moved by the mobile phase}}$$

Rf value of a substance is more or less constant for a fixed set of chromatographic conditions and hence is used as one of the criterion for its identity.

7.4.3 Paper Chromatography

As mentioned already, paper chromatography is essentially liquid/ liquid partition chromatography. The stationary phase is the water, which is held by the inert cellulose of the filter paper. The mobile phase is a solvent, usually a mixture of solvents saturated with water. Obviously, such a system is suitable for separating hydrophilic compounds and not hydrophobic compounds. For separating hydrophobic compounds, modified filter papers are required. The paper used for paper chromatography is usually Whatman No.1 or No.2. Thicker filter papers are used for separating larger quantities of a mixture for extraction (elusion) and further studies.

General procedure: After selecting a suitable filter sheet of desired dimension, a pencil line is drawn parallel to one edge of the filter paper. Only pencil should be used for drawing the line or for making any markings because ink may dissolve in the solvent. The distance of the pencil line from the edge of the paper depends on whether one is carrying out descending or ascending chromatography. The difference between the two will be explained subsequently. For descending chromatography the line should be about 10 cm. from the edge of the paper and for ascending chromatography about 2 cm. is sufficient. In descending chromatography the pencil line should be drawn in such a way that while placing the paper in the tank assembly it should be after the antisyphon rod.

Application of sample: Sample preparation for different groups of compounds varies considerably. They are quite elaborate and are described in their respective methods available in textbooks or publications. Therefore, they are not included in this section.

Due to the simplicity of the technique, separation of a large number of substances has been achieved by paper chromatography. However, it should be kept in mind that paper chromatography is mostly used as a qualitative method, though in certain cases quantification is possible.

The samples are prepared in such a way that by applying a few **μl** of the sample is sufficient to detect the individual compounds on the chromatogram. The sample of the mixture is usually applied as a spot on the pencil line on the paper and allowed to dry by itself or by using a stream of hot air. Spots of solutions of known standard compounds likely to be present in the sample mixture are also made on the pencil line, each separated by sufficient space.

Development of the chromatogram: As mentioned earlier, there are two types of paper chromatographic techniques. Descending chromatography is one in which the mobile phase is allowed to flow down the paper by gravity. In ascending chromatography the solvent is allowed to rise on the paper. The requirements for ascending paper chromatography are rather simple. After applying the sample on the filter paper it is folded into a cylindrical form. The cylinder is fastened with thread along the sides to retain the shape. Subsequently it is placed in a petri dish containing an appropriate solvent (solvent mixtures for different groups of compounds have been developed) kept on a glass sheet and covered with a bell jar. Care should be taken to see that the solvent level is below the pencil line. The assembly is made airtight by applying grease. The solvent may take several hours to ascend to sufficient height (about ¾ of the paper). Care should be taken not to allow the solvent to reach the upper end of the paper. Subsequently, the paper is removed, and hung on a suitable support to dry. The separated spots are detected using suitable reagents if not coloured.

The assembly required for descending chromatography is more sophisticated. The tank assembly has a trough or boat on the top to hold the solvent into which the sample spotted edge of the filter paper dips. An anchor rod to hold the paper and an antisiphon rod to prevent siphoning of the solvent down the paper. A simple tank assembly is shown in the following Figure 7.6.

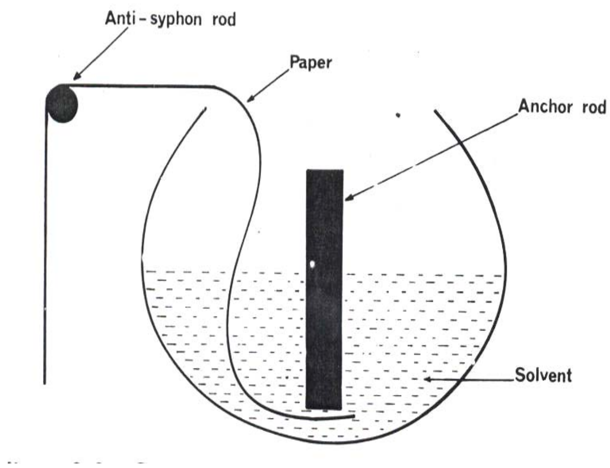

Figure 7.6: Cross section of descending chromatography trough

The rest of the sequence of operations are similar to those explained for ascending chromatography.

Some of the food constituents effectively separated by paper chromatography are: Carbohydrates, amino acids, organic acids, plant pigments, synthetic colours, vitamins, etc.

7.4.4 Thin Layer Chromatography

Thin Layer Chromatography (TLC) is similar to paper chromatography in several ways. The main difference is the nature of the chromatographic sheet. Instead of a filter paper it is a rectangular glass or plastic sheet. On the sheet, a thin layer (usually less than 1 mm.) of an inert material (coating material) like silica gel or alumina is applied. For imparting binding properties, substances like gypsum, polyvinyl alcohol is added to the coating material. For separating different groups of substances, different types of coating materials are used.

For forming a uniform layer of the coating material on the sheet, usually an **applicator** is used. The applicator has adjustment to control the thickness of the layer. The coating material is taken in the applicator as slurry and drawn over a set of sheets to form the layer. A schematic diagram of a TLC applicator is shown in the following Figure 7.7.

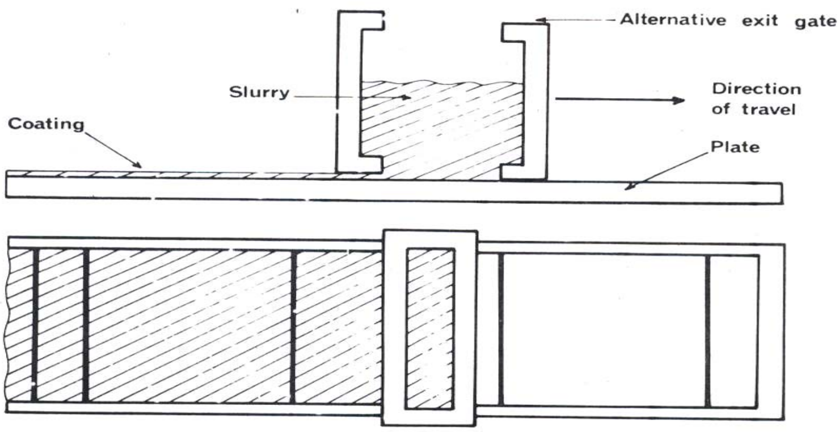

Figure 7.7: TLC applicator

After applying the slurry on the plate, it is allowed to dry in air. For adsorption TLC, the plates are subsequently activated (dried) in an oven at 110°C for 30 minutes or more.

Sample application on the TLC plate is similar to that followed for paper chromatography, except that no pencil line is drawn. The plate after applying the sample and standards spots is developed in a tank using a suitable solvent. The ascending type assembly for TLC is shown in the Figure 7.8.

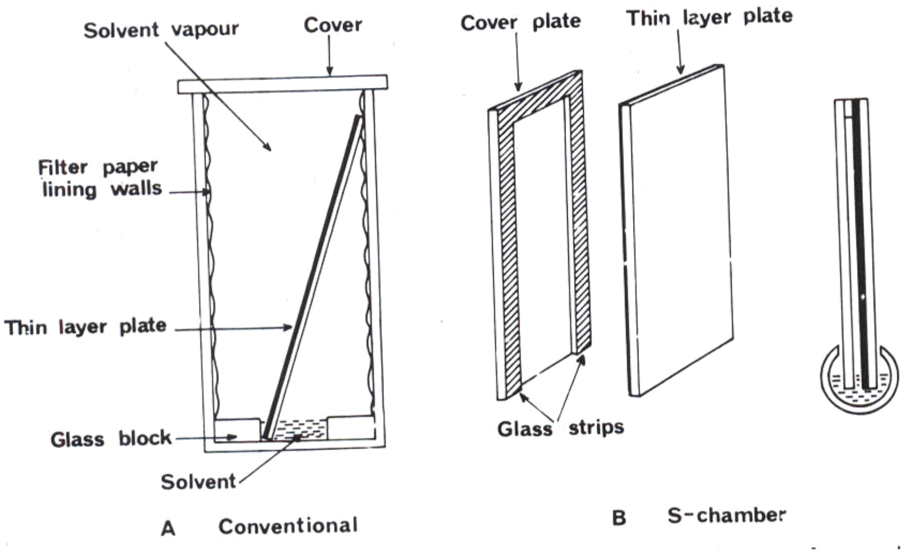

Figure 7.8: Ascending development chambers for TLC

TLC has certain advantages over paper chromatography. They are:

- TLC is far quicker than paper chromatography.
- As the support material used in TLC is truly inert unlike cellulose of filter paper, it is possible to use highly corrosive reagents for detection of components.
- TLC requires much smaller amount of sample and hence more sensitive than paper chromatography.

TLC is widely used for detection and identification of synthetic colours in foods, aflatoxin, pesticide residues besides most other substances mentioned under paper chromatography.

7.4.5 Column Chromatography

Until recently, column chromatography has been mostly employed for sample clean up (purification) prior to analysis by other methods. However, in some cases it is also used as an analytical tool and with the development of high sensitivity detectors, it has now evolved into **high performance liquid chromatography (HPLC)** having several applications.

The basic equipment for column chromatography is very simple. It consists of a vertical glass tube containing the inert material packed fairly firmly. The glass columns used are usually about 30 cm long and 1 cm internal diameter, although much longer and wider columns are used for specific purposes. The lower end of the column is tapered where a sintered disc is fixed or glass wool is placed to prevent the packing material from falling down.

Filling of the column with the packing material is a critical step. Care should be taken to fill the column firmly and evenly. The nature of the column filling material depends on the particular application. It could be alumina, silica gel, ion exchange resin, Sephadex gels, etc.

The filled column is fixed to a solvent (eluent) reservoir to hold the required solvent. A typical assembly is shown in the following Figure 7.9.

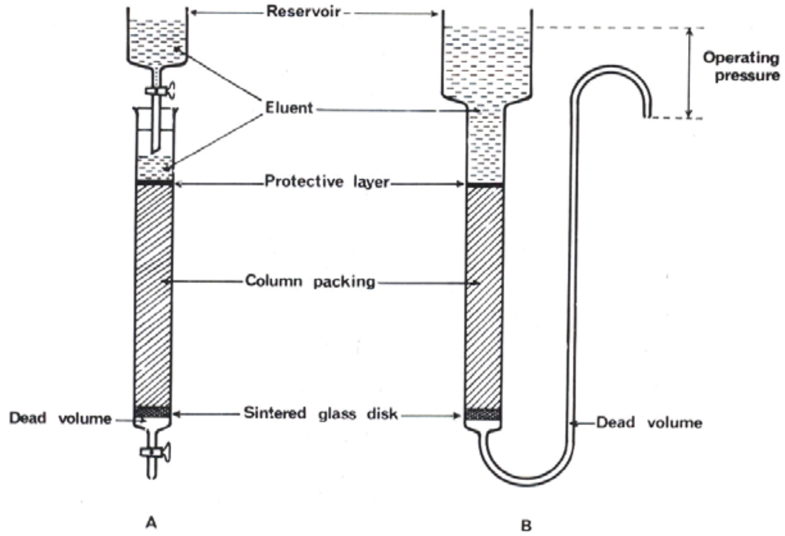

Figure 7.9: Column arrangement for liquid chromatography

After packing the column, it is washed with the intended solvent in order to wash out any impurities that may have been present in the packing material. At the top of the packing, a piece of glass wool is placed as a protective layer.

The sample is applied to the top of the column in a small volume of solvent drop by drop. The sample is allowed to penetrate into the packing material. Flow of the eluent through the column is called **elution.** Elution is normally achieved by gravity, although it may be necessary to facilitate flow by use of pumps or inert gas pressure. Flow rates of eluents for different applications have been standardised. However, flow rates of about 1 ml /min is normal.

For coloured compounds, the movement of coloured bands can be seen and each band can be collected separately in tubes and analysed. For colourless compounds, number of fractions have to be collected and analysed.

A number of methods are available for column chromatographic separation of food components. Separation of carotenoid pigments is an important method followed even today. Amino acids are separated on ion exchange columns. Peptides can be separated on Sephadex columns.

7.4.6 High Performance Liquid Chromatography

In the conventional column chromatography, the flow rate of mobile phase is usually by gravity. Therefore, to maintain satisfactory flow, the particle size of the inert column packing materials cannot be very small. Unfortunately, to get good resolution (separation) of sample mixture, very low particle size packing material is required. Systems have now available which can create pressures of the order of 600 atm. At that pressure, adequate flow rates are obtained even with packing particle as small as 2 to 3 μm in diameter. Along with this development, several detection systems were also adapted for use with liquid chromatographic columns. Liquid chromatography using these high-efficiency columns at high pressures has come to be known as **High-Performance Liquid Chromatography (HPLC)**.

Most HPLC columns are fabricated from stainless steel tubing. Usually the columns are 10 to 50 cm long with an inside diameter of 2-10 mm. The packing material used have diameter in the range of 3 to 10 μm. The detectors used in HPLC belong to one of the four basic principles viz. UV absorption, fluorescence, refractive index or conductance.

7.4.7 Gas Chromatography

In this section you will learn the details of gas-liquid chromatography, which is one of the most widely used analytical technique today. As mentioned earlier, gas-liquid chromatography is usually shortened as gas chromatography or merely GC.

There are a number of reasons why GC has become very popular in analytical work. Firstly, GC permits separation of complex mixtures including those containing closely related homologues and isomers. Secondly, it is relatively simple to prepare samples for analysis because unlike for other analytical methods, GC does not require extensive purification of the sample. The only requirement (may be a draw back) is that the components of the sample should be reasonably volatile.

The instrument used for gas chromatographic work is called a gas chromatograph. The modern gas chromatograph is a very complicated instrument. However, all gas chromatographs have a few key components, which is illustrated in the following Figure 7.10.

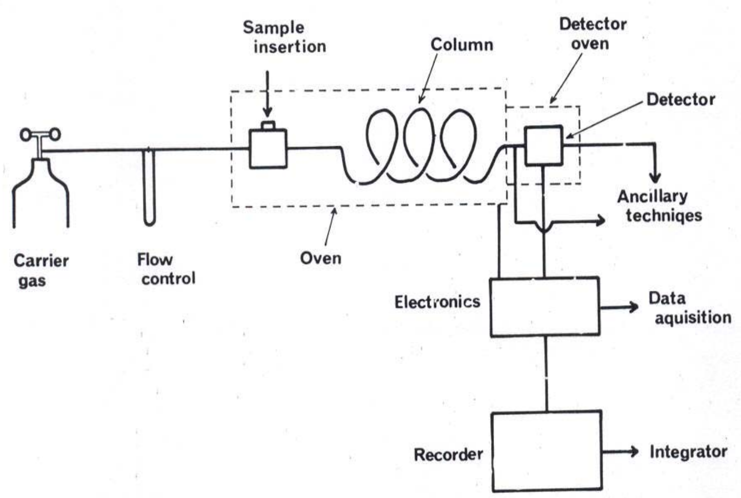

Figure 7.10: Basic components of a gas chromatograph

It can be seen from the diagram that a gas chromatograph has four major components viz. i) carrier gas supply system, ii) sample insertion (injection) system, iii) column assembly, and iv) detector and readout device.

Carrier Gas Supply System

The carrier gas used, which is the mobile phase in GC, must be chemically inert. These include helium, argon, nitrogen, carbon dioxide and hydrogen. The choice of the gas is decided to a great extent by the detector used. The gas supply assembly consists of the gas cylinder and gas flow meters. Gas flow rates play important role in the performance of a GC. Therefore, the gas flow rate is one of the parameters defined in GC procedures. The average gas flow rates for packed columns are in the range of 25 to 150 ml/ min and 1 to 25 ml/ min for capillary columns. You will be learning more about different types of columns subsequently. A soap bubble meter located at the end of the column is used to measure the gas flow rate.

Sample Injection System

Sample injection system has a sample injection port and a vaporizer. For efficient separation of sample components, it is necessary to introduce a small size sample into the column as a 'plug' of vapour. Usually a micro syringe is used for the purpose. The volume injected range from <1 to 20 μl. The sample vaporizer is usually maintained at a temperature of $50^{o}C$ above the boiling point of the least volatile components of the sample. The flow splitter allows the passage of only the quantity of the sample necessary for good resolution and the remaining is let out.

Column Assembly

Two general types of columns are used in GC. They are packed columns and open tubular or capillary columns. Packed columns are made of 1 to 10 m or longer stainless steel tubing having 1.5 to 5 mm internal diameter. Usually they are coiled for compactness. Capillary columns are much longer ranging from 10 to 100 m having very small diameter of the order of 0.1 to 0.5 mm. They are usually made of glass or silica.

The solid support in a packed column serves to hold the liquid stationary phase in place so that as large a surface area as possible is exposed to the mobile phase. The most widely used support material is prepared from diatomaceous earth. The particle size of the support material is usually in the range of 60 to 100 mesh.

Capillary columns are of two basic types viz. wall-coated open tubular (WCOT) and support–coated open tubular (SCOT). In WCOT columns, the inside of the capillary is coated with the stationary phase. In the SCOT columns, the inner surface of the capillary is coated with a thin film of the support material such as diatomaceous earth and over which the stationary phase is applied. Due to coating of the support material, SCOT columns can hold several times more of the stationary phase than in WCOT columns. Therefore, the efficiency of the SCOT columns is better than WCOT column.

Stationary Phase in the Column

The stationary liquid phase used in GC columns (both packed and capillary) are of different types. They are selected based on the nature of the compounds separated on the column. Some of the stationary phase substances are listed below.

Material	Trade name	Common application
Polydimethyl siloxane	OV-1, SE-30	Hydro carbons, steroids, polynuclear aromatics etc.
Poly (phenyl methyl) siloxane	OV-17	Pesticides, glycols, steroids, etc.
Poly (phenyl methyl dimethyl) siloxane	OV-3, SE-52	Fatty acid methyl esters, alkaloids, halogenated comps, etc.
Poly (trifluorophenyl dimethyl) siloxane	OV-210	Chlorinated aromatics, nitro aromatics, alkyl substituted benzenes, etc.
Poly (dicyanoallyl dimethyl) siloxane	OV-275	Poly unsaturated fatty acids, free acids, alcohols, etc.
Polyethylene glycol	Carbowax-20M	Free acids, alcohols, esters, essential oils, glycols, etc.

Detectors

Like in any chromatographic separation process, in GC also, the separated compounds have to be detected and quantified if necessary. An ideal detector should have some of the following characteristics.

- Adequate sensitivity.
- Good reproducibility.
- Wide range of linear response to analyte concentrations.
- Detection with out destroying the sample.
- Response to all types of compounds.

Unfortunately, an ideal detector is yet to be developed. Therefore, for different purposes, different detectors are used. There are a few types of detectors; two of the important ones are described below.

Flame Ionisation Detector (FID)

FID is one of the most widely used detectors for GC. In a flame ionisation detector, the effluent from the GC column is mixed with hydrogen and air and ignited electrically. When organic compounds are burnt at the high temperature, they produce ions and electrons that can conduct electricity through the flame. The current produced is amplified and measured.

Thermal Conductivity Detector (TCD)

TCD is based on the principle that the thermal conductivity of a gas stream is changed by the presence of analyte molecules. The sensing element in a TCD is an electrically heated element (platinum, gold or tungsten) whose temperature at constant electric power depends on the surrounding gas. The thermal conductivities of helium and hydrogen are about six times greater than those of most organic compounds. Therefore, in the presence of even traces of organic materials, a relatively large decrease in the thermal conductivity of the column effluent takes place. Consequently, the detector undergoes a marked increase in temperature. One major advantage of TCD as against FID is that it is non-destructive meaning that the compounds separated are not disintegrated and hence can be used for further analysis if required. Besides, TCD can detect both organic and inorganic compounds and hence has a wider range.

Signals from the detector are amplified and recorded by suitable electronic instruments. The output in the form of a graph having different peaks for the components is called a **gas chromatogram**. The chromatogram also provides the retention times, height and area of each peak.

Applications of GLC

Even though, GC is an excellent tool for tentative identification of components of a mixture, confirmation of their identity is rather difficult. Therefore, an important trend has been in combining the remarkable fractionation qualities of GC with the superior identification properties of such instruments as **mass spectrometer (MS)**, **infrared (IR)** and **nuclear magnetic resonance (NMR) spectrometers**. Mass spectrometer is very complicated and not meant for routine analytical purposes, hence will not be described in this unit.

7.5 LET US SUM UP

Modern analytical methods demand very accurate determination of mass. Consequently, considerable developments have taken place in increasing the sensitivity and simplicity of the analytical balance. This resulted in the modern single pan mechanical balance which can weigh with an accuracy even of ± 0.001 mg. Simultaneously, development in electronics have resulted in the evolution of electronic balances which have done away with the knife-edges which are the critical and wearable components of mechanical balances.

Measurement of pH of food systems is very important for various reasons. PH indicators based on colour change of certain chemicals have obvious drawbacks. Potentiometric method for the determination of pH is more reliable. The development of the glass electrode is one of the major breakthroughs in the instrumentation for pH measurement.

Chromatography, which started mainly as a separation technique, has assumed much more importance in food analysis. In addition to the simple techniques like column, paper and thin layer chromatography, gas chromatography and High-performance liquid chromatography have become very powerful tools for qualitative and quantitative analysis of food products.

7.6 KEY WORDS

Mass	:	Invariant measure of the amount of matter.
Weight	:	Force of attraction between an object and earth.
Chromatography	:	Writing in colours or separation of a mixture of compounds based on adsorption and partition.
Partition	:	Distribution of solutes between two phases.
Retention factor	:	Ratio of distance moved by the solute to distance moved by the mobile phase.
Eluent	:	Solvent used as the mobile phase.
Carrier gas	:	Gas used as the mobile phase in gas chromatography.
FID	:	Flame ionisation detector.
TCD	:	Thermal conductivity detector.

7.7 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

- Invariant measure
- Dependent on gravitational force

2. Your answer should include the following points:

- Single pan and set of weights on one end of beam and counter weight at the other end
- Air damper
- Optical system

3. Your answer should include the following points:

- No beam
- No knife-edge
- Servo system

4. Your answer should include the following points:

- Ionisation of water
- Ionisation constant of water
- pH = - log [H^+]

5. Your answer should include the following points:

- Glass electrode
- Calomel or silver-silver chloride reference electrode
- Potentiometer

Check Your Progress Exercise 2

1. Your answer should include the following points:

- Separation of the components of a mixture
- Adsorption
- Partition

2. Your answer should include the following points:

- Liquid column chromatography at high pressure
- Electronic detectors

3. Your answer should include the following points:

- Carrier gas
- Sample injection system
- Column assembly
- Detector and readout device

UNIT 8 ANALYTICAL INSTRUMENTATION BASED ON ELECTROMAGNETIC RADIATION

Structure

8.0 OBJECTIVES

After reading this unit, you should be able to:

- explain the properties of electromagnetic radiation;
- describe different types of spectroscopic methods;
- describe the components of a colorimeter and spectrophotometer;
- differentiate between atomic absorption and emission spectroscopy; and
- explain the principle and instrumental details of refractometer and polarimeter.

8.1 INTRODUCTION

Majority of the modern instrumental methods of analysis are based on interaction of electromagnetic radiation with matter (elements and molecules). They include emission, absorption, scattering, fluorescence, refraction, reflectance and rotation of radiation. You have learnt reflectance colour measurement of materials like fruits in the previous unit.

Spectrometry is a general term describing various methodologies dealing with the production, use and measurement of electromagnetic radiant energy or radiation. Electromagnetic radiation can interact with matter to produce measurable signals, which are made use of for qualitative and quantitative measurements. In this unit, you will be learning about some of the instruments based on these principles. In order to understand the nature of these interactions, it is necessary to have some basic knowledge of the propagation of radiation.

8.2 PROPERTIES OF ELECTROMAGNETIC RADIATION

Electromagnetic radiation is a type of energy that is transmitted through space at enormous velocities. For simplicity of understanding, the transmission can be viewed to be of a transverse waves consisting of discrete energy packets called photons. The waves oscillate in all the planes perpendicular to the direction of propagation.

There are a few important terminologies associated with the propagation of electromagnetic radiation. They can be explained easily with the aid of the waves of a plane-polarised light shown below (Figure 8.1). Plane polarised light (radiation) is one in which the wave oscillation is only in one plane. You will learn more about polarisation later.

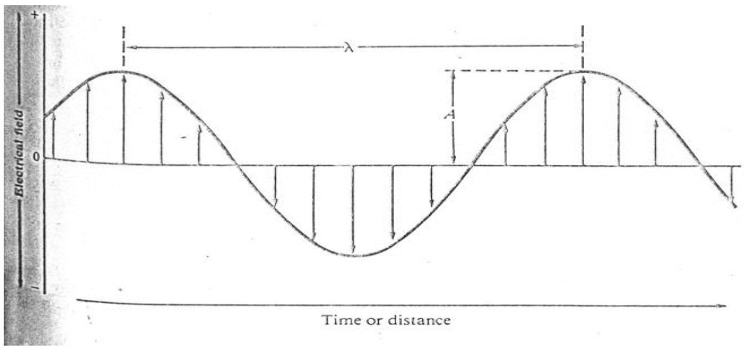

Figure 8.1: A beam of plane polarised monochromatic radiation of wavelength λ and amplitude A

The **amplitude, A** of the wave is defined as the maximum height of the wave. The length of one wave or the distance between two successive maxima or minima of a wave called the **wavelength, λ** of the radiation. The reciprocal of the wavelength, or the number of waves per unit length is called the **wave number, ν.** The time required for one wave to pass a fixed point in space is called the **period, p** and its reciprocal, the **frequency, υ** which is the number of waves passing a fixed point per unit time. A simple relationship exists between the length of a wave (wavelength) and the time required for it to move past a fixed point in space. This relationship says that the product of the wavelength and frequency equals the **velocity of propagation of the wave, c.** In vacuum, the velocity of propagation of radiation (usually referred to as **speed of light**) is approximately 3.0×10^8 m/s. The velocity of radiation in any other medium is always less because of interaction with matter. Since the radiant frequency is invariant and fixed by the source, the wavelength of radiation decreases as it passes from vacuum to a medium containing matter. In air, the velocity is only marginally less (0.03%). Chemists in characterising radiant energy most often use wavelength and frequency.

The power, P of radiation (frequently also called intensity) is the energy of beam that reaches a given area per second. P is related to the square of amplitude, A. Electromagnetic radiation is continuous over all possible wavelengths. It is sub divided according to how the radiation reacts with matter. The visible portion of the spectrum i.e. those wavelengths to which the human eye produces a sensation called colour, is only a tiny part of the spectrum (750 to 380 nm) as shown in the following Figure 8.2.

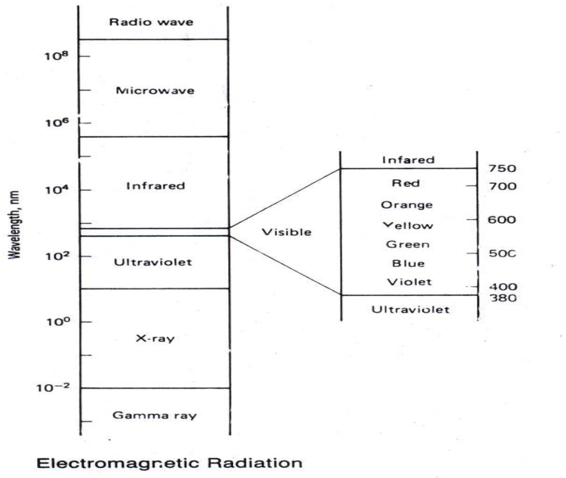

Figure 8.2: The electromagnetic spectrum

You have learnt that the interactions of electromagnetic radiation with matter cause certain responses (phenomena). Optical spectroscopic methods are based on measuring these responses.

8.3 SPECTROSCOPY

Historically spectroscopy referred to a branch of science in which visible or ultraviolet light is resolved into its component wavelengths, thus producing spectra, which were then used for theoretical studies on the structure of matter or for qualitative and quantitative analysis. However, with passage of time, the meaning of spectroscopy has broadened to include other types of electromagnetic radiations also. Currently, spectroscopy even includes studies with other types of radiations including ions (mass spectrometry), electrons (electron spectroscopy), and sound waves (acoustic spectroscopy).

Among various interactions between radiation and matter, absorption of radiation is the most important for analytical work. Visible and ultraviolet radiations are the most widely used for the purpose. Therefore, visible and ultraviolet absorption spectroscopy will only be dealt with in detail here.

8.3.1 Absorption of Radiation

In spectrometry, absorption is a process in which a chemical species in a transparent medium selectively attenuates (decrease the intensity of) certain frequencies of electromagnetic radiation. The absorbing characteristics of a chemical species are described by means of an absorption spectrum, which is usually a plot of some function of the attenuation versus wavelength, frequency or wave number.

In absorption spectrometry, one encounters both atomic absorption and molecular absorption. Atomic absorption relates to absorption of radiation by atoms and ions (especially the metals) and the consequent responses. Methods based on this phenomenon fall under **atomic absorption spectroscopy (AAS)**. The second is called molecular absorption spectroscopy, which has found maximum application in qualitative and quantitative analysis.

Molecular Absorption Spectroscopy

You have learnt that a beam a radiant energy is reduced in power as it passes through a solution containing absorbing substances. The attenuated radiation is transmitted. At this stage it may be of interest to know why a coloured solution has a particular colour. For example a red coloured solution is red not due to the molecules of the solute impart red colour to the solvent. Instead the solute molecules absorb the green component of the white radiation and transmit the red component. Thus, green colour is called the complimentary colour for red. You will learn subsequently in visual colorimetry the complimentary colours are used to measure the absorption characteristics of the coloured solutions.

Wave-length range (nm)	Colour	Complimentary colour
400 – 435	Violet	Yellow – Green
435 – 480	Blue	Yellow
480 – 490	Blue-green	Orange
490 – 400	Green-Blue	Red
500 – 560	Green	Purple
560 – 580	Yellow-green	Violet
580 – 595	Yellow	Blue
595 – 650	Orange	Blue – Green
650 – 700	Red	Green – Blue

Important terms used in Absorption Spectroscopy

The terms can be explained using the simple diagram below (Figure 8.3):

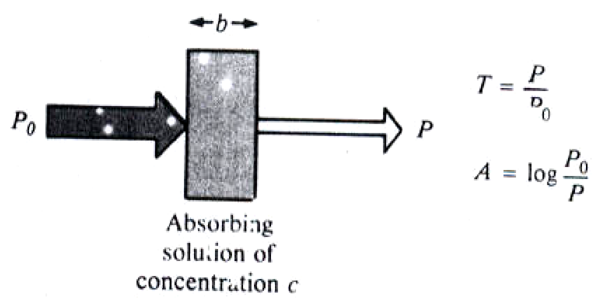

Figure 8.3: Attenuation of radiation by an absorbing solution

The Figure shows a beam of radiation before and after it has passed through a layer of solution with a **thickness, b cm** and a **concentration of c** of an absorbing solution. The power of the beam is attenuated from P_0 to P. The **transmittance, T** of the solution is defined as the fraction of the incident radiation transmitted by the solution.

$$T = P/P_0$$

Transmittance is usually expressed as a percentage (%T).

Absorbance, A of a solution is defined by the expression

$$A = -\log T = \log P_0/P = \log 1/T \text{ or } \log 100/\%T$$

$$A = \log \frac{P_0}{P}$$

$$\Rightarrow \quad A = \log P_0 - \log P$$

Since P_0 always set at 100% and log P is % T

$$A = \log 100 - \log \% P$$

$$A = 2 - \log \% T$$

i.e. $$A = 2 - \log \%T$$

Please note that in contrast to transmittance, the absorbance of a solution increases as the attenuation of the beam increases.

Relationship between absorption and concentration

The relationship between the amount of radiation absorbed or transmitted and the amount of absorbing substance is called Beer's Law or sometimes Beer's-Lambert Law.

$$A = \log P_0/P = abc$$

Where **a** is a proportionality constant called the absorptivity and **b** is the path length of the radiation through the absorbing media and c its concentration. When the concentration is expressed in moles per litre and b is in cm., they absorptivity is called **molar absorptivity** ε i.e.

$$A = \varepsilon bc$$

Where ε has the units of $l\ cm^{-1}\ mol^{-1}$

Instruments for Absorption Spectroscopy

Absorption spectroscopic instruments have 5 basic components i) a source of radiant energy, ii) a wave-length selector that allows the radiation of a restricted wave-length region, iii) one or more sample holders, iv) a radiation detector or transducer which converts radiant energy to electrical signal, and v) signal processor and read-out (Figure 8.4).

Figure 8.4: Basic components of a spectrometer

Radiation sources: The basic requirements of a radiation source for spectroscopic studies are (1) should generate a beam of radiation with sufficient power for easy detection and measurement and (2) its out-put power should be stable for reasonable periods. No single source is suitable for all the spectral regions of interest to analytical work. For the visible spectroscopy, the most common energy source is a tungsten filament lamp which has an out-put (325 nm to 3000 nm) which covers the entire visible region of the spectrum and also part of the ultra violet and infrared regions. For ultra violet spectroscopy, the preferred energy source is deuterium discharge lamp which has an out-put in the range of 160 nm to 380 nm.

Wavelength selector: Since the radiation sources are continuous, it is necessary to select the required wavelength at which the measurement is to be made. As it is practically impossible to isolate a single wavelength, a very narrow band of wavelength is usually isolated. Two types of wavelength selectors are available, namely, filters and monochromators.

Filters: Filters operate by absorbing all but a restricted band of radiation from a source. A filter is characterised by its nominal wavelength, maximum percent band width and its effective bandwidth. (Figure 8.5)

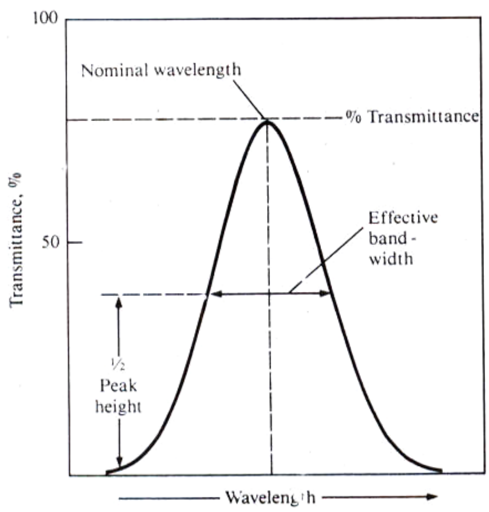

Figure 8.5: Output of a typical filter

Absorption filters are the most common type of filters. Absorption filter consists of a coloured glass piece that removes part of the incident radiation by absorption. Obviously, absorption filters are limited in application to the visible region.

Monochromators: Monochromators have mostly replaced filters in spectrometers due to their ability to produce very narrow band of wavelength over a considerable spectral range from radiation source. Such measurements are called spectral scanning. Monochromators as the name implies are capable of passing radiation of almost a single wavelength called monochromatic radiation. The components of a monochromator are i) an entrance slit that provides a rectangular optical image of the radiation ii) a collimating lens or mirror which produces a parallel beam of radiation iii) a prism or grating that disperses the radiation into its component wave-lengths iv) a focusing element that reforms the image of the slit and focuses it on a planar surface called a focal plane and v) an exit slit that isolates the desired spectral band. The following figure shows the assembly for the two types of monochromators.

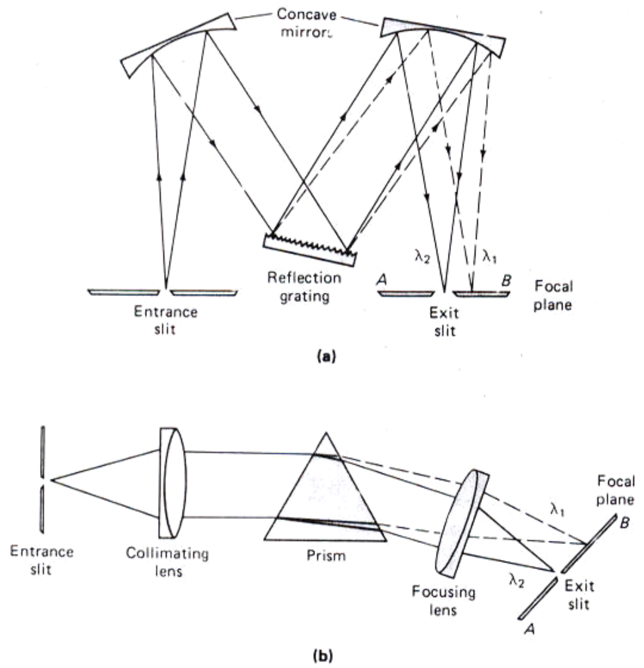

Figure 8.6: Two types of monochromators

Sample holders: Sample holders are called cells or cuvets, which come in a variety of shapes and sizes appropriate for various instruments and experiments. The rectangular cell of 1 cm light path is the most widely used. Glass cells are used for measurements with visible radiation but cannot be used with ultra violet because of their strong absorption. Quartz or fussed silica cells, though more expensive are suitable for both UV and visible spectrometry.

The remaining two components of a spectroscope are the radiation detector and read-out device. The components of spectroscope described above have been assembled in various ways to produce a number of designs of instruments. Some are simple but other are very sophisticated. Therefore, their costs also vary widely. No single instrument is best for all purposes and selection must be based on the type of work for which the instrument is intended and by the economics of its application.

There are some common names for spectroscopic instruments. A **photometer** is a simple instrument that can be used for absorption, emission and fluorescence measurements with ultra violet, visible or infrared radiations. A photometer is distinguished by its use of absorption or interference filters for wavelength selection and a photoelectric device for measurement radiant power. Instruments used for absorption measurements with visible radiation are sometimes called **photoelectric colorimeter** or simply **colorimeter**. A photometer that is employed for fluorescence measurements exclusively is called a **fluorometer**. A spectrometer is a spectroscopic instrument equipped with a monochromator. A spectrometer equipped with a photo transducer is called a **spectrophotometer**. Fluorescence spectrometers are often called **spectrofluorometers**.

Spectrophotometers: Numerous spectrophotometers are available to choose from. Some are designed for the visible region only, where as others are for both visible and ultraviolet regions. Spectrophotometers meant for the visible region are called **photoelectric colorimeters.** They can be used in the wavelength range of 380 to 800 nm. **Spectronic 20** is a typical commercial model of a photoelectric colorimeter (Figure 8.7).

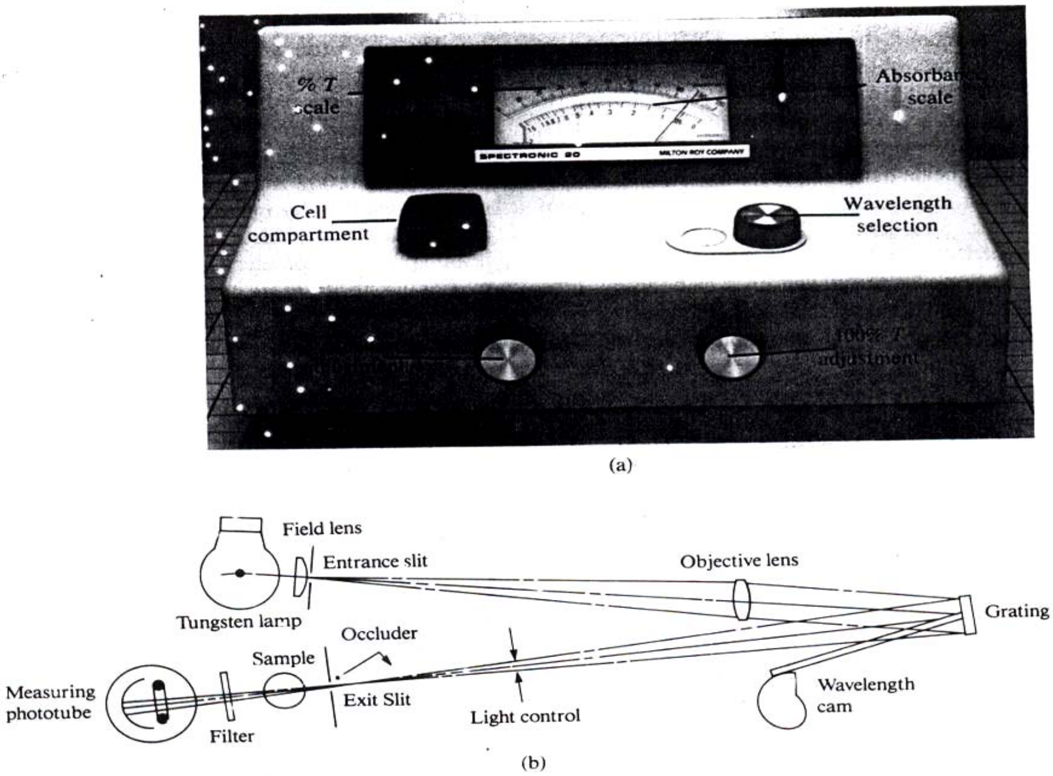

Figure 8.7: a) Spectronic 20 spectrophotometer, b) its optical diagram

The instrument employs a tungsten filament lamp light source, and a reflection grating for wavelength selection. The selected wavelength of radiation is passes through the sample tube and to a phototube. The amplified electrical signal then powers a meter calibrated in % transmittance and absorbance.

Single and double beam spectrophotometers: Single beam instruments are simple and less expensive than double beam instruments. In this type of instruments, the cells containing reference and sample solutions have to be placed alternatively to tale measurements. Double beam spectrophotometers have two optical paths, which pass through the sample and reference solutions simultaneously. Such instruments also have provision for measurement of absorbance or transmittance of solutions continuously.

8.3.2 Atomic Spectroscopy

In the previous section, you have studied molecular absorption spectroscopy. Atomic spectroscopy is based on absorption, emission and fluorescence phenomena. Atomic spectroscopy is used for the qualitative and quantitative determination of more than 70 elements. Sensitivities of atomic methods are very high of the order of parts- per- million (ppm) to parts- per- billion (ppb). The reason that thermal emission methods are little used for determining molecular species is that most molecules decompose at the temperatures required for producing atomic spectra.

Atomic absorption spectroscopic methods are characterised on the basis how the sample is atomised. The most convenient and common method followed is by using a suitable flame. Therefore, the instrumentation based on flame atomisation only will be discussed in this section. There are three methods under flame atomisation, viz. i) atomic absorption spectroscopy (AAS), ii) atomic emission spectroscopy (AES), and iii) atomic fluorescence spectroscopy (AFS). Among the three, AAS and AES have a lot of similarities, but it is important to know the differences.

Atomic Absorption and Emission Spectroscopy

Both AAS and AES are extremely important and valuable analytical techniques. It is well known that coloured radiations are produced when salts such as those of sodium, calcium, copper etc. are introduced into normal flames. Talburt investigated similar flame spectra of strontium, and lithium. In 1960, and 1961 Bunsen and Kirchoff discovered the elements caesium and rubidium by observing their flame spectra. It is the emission of such characteristic radiation and the determination of the intensity of this, which form the basis of atomic emission photometry. Atomic absorption spectroscopy deals with the external radiation absorbed by an element in a flame under certain conditions.

Flame atomisation: The critical component of a flame spectrometer is the flame atomiser. A flame atomiser consists of a pneumatic nebulizer, which converts the sample solution into a mist that is then fed into a burner. The most common type of nebulizer is based on aspiration in which the sample is sucked through a capillary tube by a high-pressure stream of gas flowing around the tip of the tube.

Burning a fuel with air or an oxidant like oxygen or nitrous oxide produces the flame in the burner. Air fuel mixtures produce flame having temperature in the range of 1700 to 2400°C, which is suitable for exciting only alkali and alkaline earth metals. For heavy metals, fuel- oxygen or nitrous oxide flames, which produce temperature in the range of 2500 to 3100 ^{0}C, are required.

Emission and absorption spectra for both atoms and elementary ions are obtained from the flame. When atoms and ions are heated in a flame, they are excited to various stages of energy levels. The excited species on relaxation produces the emission spectra and the unexcited species can absorb energy from an external source for producing absorption spectra. The external source for producing absorption spectra is usually a hollow-cathode.

Hollow-cathode lamp: The most useful radiation source for AAS is the hollow-cathode lamp. It consists of a tungsten anode and a cylindrical cathode sealed in a glass tube containing an inert gas such as argon. The cathode is made up of or coated with the metal to be analysed. Application of a high potential across the electrodes causes ionisation of the argon and generation of a current. The argon cations migrate towards the cathode and strike with sufficient energy to dislodge some of the metal atoms producing an atomic cloud. Some of the metal ions in the cloud in the excited state emit their characteristic wavelengths as they return to the ground state. The emitted radiation is allowed to be absorbed by the unexcited atoms/ions of the same species in the flame and the extent of absorption is measured. Hollow-cathode lamp for a large number of elements is available. The development of the hollow-cathode is widely regarded as the single most important event in the evolution of atomic absorption spectroscopy. The remaining components of AAS or AES are similar to those present in molecular absorption spectrometers.

8.3.3 Refractometry

Refractometry involves the determination of the refractive index of a solution. It is applied to both qualitative and quantitative analysis such as identification of oils and fats, concentration of sugar solutions and total soluble solids content of fruit juices.

Refractive index is an important property of matter. You have already learnt about the propagation of light through vacuum and other media. Refractive index is defined as the ratio of the velocity of a radiation of a particular frequency in vacuum to the velocity in the medium under consideration. When a ray of light travels obliquely from one medium into another of different density, its direction is changed (bent) on passing through the interface between the two media. This phenomenon is called refraction. This phenomenon can be easily explained with the help of the following Figure 8.8.

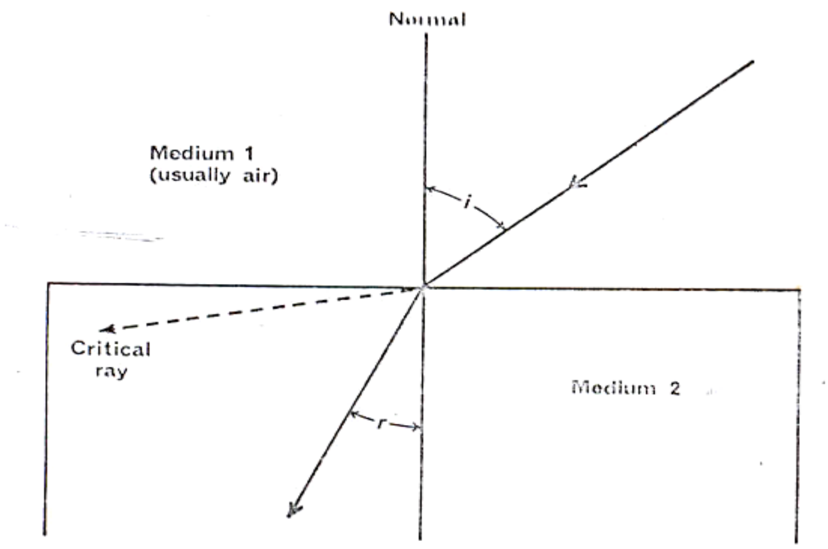

Figure 8.8: Refraction of light

The angle made by the incident ray in the first medium is called the angle of incidence, i and the corresponding angle in the second medium is termed the angle of refraction, r. sin i and sin r are directly proportional to the velocities of the radiation in the two media. Therefore, refractive index of the medium:

$$n = \frac{\sin i}{\sin r}$$

The refractive index of a medium is characteristic of that medium under constant temperature of measurement and the wavelength of the incident radiation. **Refractive index, n** of a medium is denoted by $\mathbf{n_D^{20}}$ meaning that it is measured using radiation of sodium D- line at 20°C. Water has a value of η_D^{20} of 1.3330. An instrument used to measure the refractive index (extent of bending of the radiation) of a medium is called a refractometer. The most important type of refractometer is the Abbe' refractometer.

Abbe' refractometer

A simplified diagram of the optical system of Abbe' refractometer is shown below (Figure 8.9).

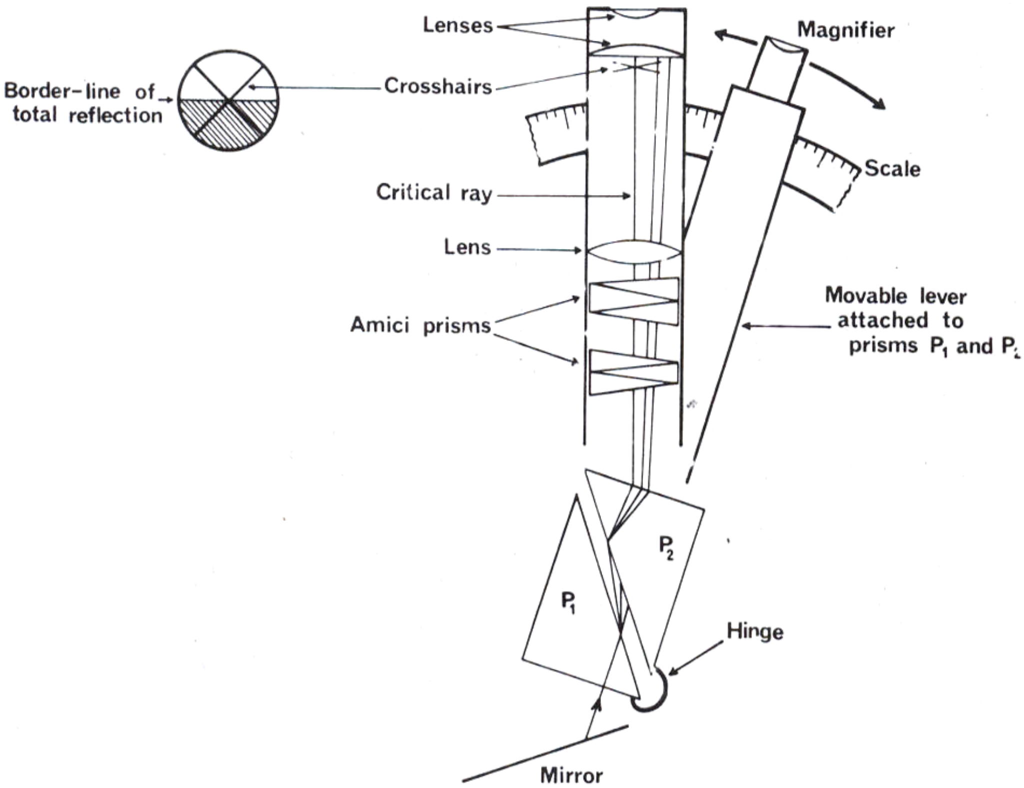

Figure 8.9: Abbe' refractometer

The most important component of the instrument is the double prism unit (P_1 and P_2). The unit can be rotated by means of a lever. At the other end, this lever moves over a fixed scale at which readings can be taken. The upper prism is made of a type of glass in which light has a velocity less than the velocity in any sample likely to be examined. The liquid sample is coated as a thin film between these two prisms. The upper prism is fixed while the lower one can be swung on a hinge to introduce sample and for cleaning.

White light entering the instrument is split by the two Amici prisms placed in the telescope of the instrument and only the sodium D-line is transmitted. Light falling on the polished surface of prism P_1 reflects an infinite number of rays through the liquid sample. The rays strike the surface of the upper polished prism, P_2 and are refracted. All light rays pass through the prism P_2, except those, which are parallel to the surface of the prism. The parallel rays are bent upwards and emerge from the prism at an angle, which is determined by the refractive index of the sample solution. The critical ray forms the border between light and dark portions of the field viewed by the observer. This border is aligned with the cross hairs of the eyepiece of the fixed telescope of the refractometer by slowly rotating the double prism unit. A fixed scale measures the angular relationship of the double prism to the telescope. Thus by moving the lever, the critical ray is scanned until it coincides with a fixed point in the instrument.

Usual Abbe' refractometer covers a range of refractive index either from 1.30 to 1.70 or from 1.45 to 1.84. The concentration of a known substance in a solution can be readily determined by measuring the refractive index of the solution. This is the basis of °Brix (% of sugar) measurement. Abbe' refractometer provides separate scale based on the same principle.

8.3.4 Polarimetry

Polarimetry involves the measurement of the optical rotatory power of a substance. This method can also be used for both qualitative and quantitative analysis. You have learnt about the optical rotatory properties (levo and dextro) of compounds especially sugars. This is the basis of saccharimetry.

You have also learnt about plane polarisation of light. Many substances are capable of rotating the plane polarised light. Such substances are said to be optically active. Examples are amino acids, sugars, steroids, terpenes etc. The extent to which the plane-polarised light is rotated by an optically active compound is dependent on the concentration of its solution and path length under constant conditions of temperature, wavelength of the polarised light and solvent used. Thus the specific rotation of a solution is given by:

$$[\alpha]_{\lambda}^{T} = \frac{\alpha}{dc}$$

where, $[\alpha]_{\lambda}^{T}$ is the specific rotation at temperature T and λ wavelength of radiation. The angle of rotation measured is α and c is the concentration of the solution (in g/ml) contained in a sample tube d decimetres in length. Figure 8.10 shows a diagrammatic arrangement of a polarimeter.

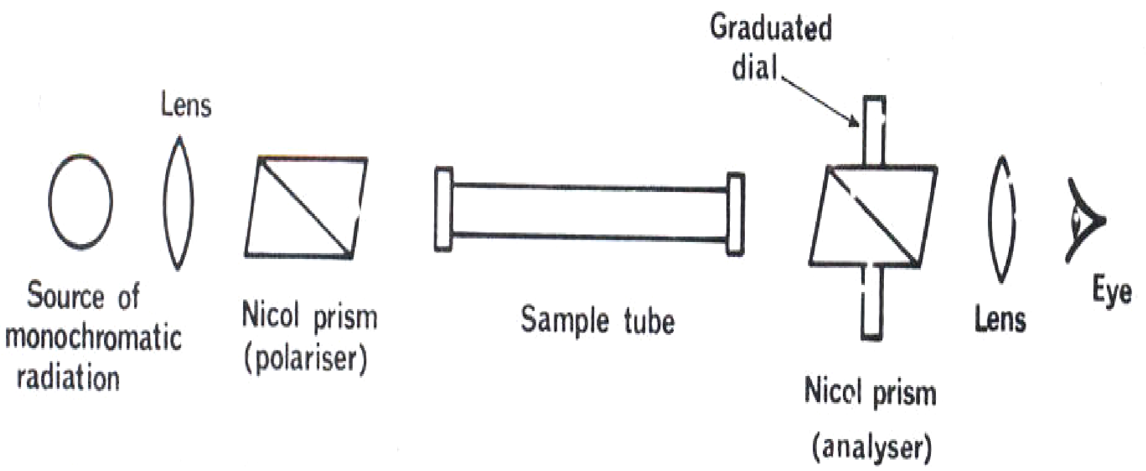

Figure 8.10: Components of a polarimeter

Monochromatic radiation from a source is passed through a Nicol prism, which polarises the radiation. Nicol prism is made of calcite or quartz crystal block cut diagonally in a special manner and cemented together. The polarised light passes through the sample when it is rotated. The analyser prism is another Nicol prism similar to the polariser prism. The prism is rotated to the extent of rotation of the radiation to allow it to be fully transmitted and observed by the human eye. The analyser is attached to a dial to indicate the number of degrees of rotation and direction of rotation.

8.4 LET US SUM UP

A number of instruments based on the interactions of electromagnetic radiations with food components are used for analysis and quality control. These interactions could be in the form of absorbance, emission, refraction, and rotation of radiation. Among the instruments, those based on absorption of radiation by solutions are widely used for qualitative and quantitative analysis of elements and compounds. While colorimeters are used in the visible range of radiation, spectrophotometers can be used with ultra violet, visible and infrared regions.

Atomic absorption and emission spectroscopy find application in the determination of elements, especially metal ions.

Refractometers are based on the principle of refraction of light radiation. Refractometer is a handy instrument for measuring the total soluble solids (^{o}Brix) of fruit products and sugar solutions.

Polarimeter is based on the principle of rotation of plane polarised light by a solution of optically active substance. A number of food components, especially oils, and sugars exhibit optical activity. Therefore, they can be easily determined using a polarimeter.

8.5 KEY WORDS

Wavelength	:	Distance between two successive waves.
Frequency	:	Number of waves passing a fixed point per unit time.
Beer's law	:	Relationship between amount of radiation absorbed and the concentration of solute in the solution.
Monochromator	:	An optical instrument to produce a narrow band of radiation.

8.6 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Your answer should include the following points:

   - Distance between two successive wave maxima or minima
   - Number of waves passing a fixed point per unit time

2. Your answer should include the following points:

   - Study of the interactions of electromagnetic radiations with matter
   - Absorption spectroscopy
   - Emission spectroscopy
   - Fluorescence spectroscopy

3. Your answer should include the following points:

   - Absorption of radiation by molecules
   - Absorption of radiation by atoms and ions

4. Your answer should include the following points:

   - Relationship between amount of radiation absorbed and the amount of absorbing substance.

5. Your answer should include the following points:

   - **Hints:** Use formula A = Ebc, Ans.33600

Check Your Progress Exercise 2

1. Your answer should include the following points:

   - Source of radiant energy
   - Wavelength selector
   - Sample holders
   - Radiation detector

2. Your answer should include the following points:

   - Instrument to produce monochromatic radiation
   - Prism or grating

3. Your answer should include the following points:

   - Absorption measurement with visible radiation
   - UV, visible and IR

4. Your answer should include the following points:

   - Emits characteristic radiations of metals
   - Atomic absorption spectroscope

Check Your Progress Exercise 3

1. Your answer should include the following points:

   - Ratio of velocity of radiation in vacuum to the velocity in the medium
   - Ratio of sin i to sin r

2. Your answer should include the following points:

   - Double prism unit
   - Amici prism and telescope

3. Your answer should include the following points:

   - Restricting the oscillations to one plane
   - Optical activity

4. Your answer should include the following points:

   - Nicol prism
   - Sample tube
   - Measuring scale

EXPERIMENT 1 DETERMINATION OF ASCORBIC ACID BY TITRIMETRIC AND COLORIMETRIC METHODS

Structure

1.1 INTRODUCTION

Fruits and vegetables are important sources of ascorbic acid (vitamin C). Ascorbic acid being unstable under different storage and processing conditions, it is important to know its residual content in food products. The most satisfactory chemical method of estimation is based on the reduction of 2,6-dichlorophenol indophenol by ascorbic acid. This can be performed either by titration or by colorimetric method. In this experiment you will be learning both the methods.

Objectives

After studying and performing this experiment, you should be able to

- prepare different types of food samples for ascorbic acid estimation;
- determine the ascorbic acid content by dye titration method; and
- determine the ascorbic acid content by xylene extraction and colorimetric method.

1.2 EXPERIMENT 1a: DYE TITRATION METHOD

1.2.1 Principle

2,6-dichlorophenol indophenol dye, which is blue in alkaline solution and red in acid solution, is reduced by ascorbic acid to a colourless form. The reaction is quantitative and can be performed by titration. This reaction is practically specific for ascorbic acid in fresh fruits and vegetables. Sulphur dioxide present in products like squashes can deduce the dye and thus interferes in the estimation. Condensing SO_2 with formaldehyde can eliminate this interference.

1.2.2 Requirements

Apparatus/Glassware

Microburette, 10 ml capacity with 0.05 ml sub-graduations

Burette stand

Volumetric flask, 100 ml

Pipette, 1 ml

Conical flask, 100 ml

Analytical balance, 0.1 mg sensitivity

Whatman No.1 filter paper circles

Glass funnel, 2" dia.

Chemicals and Reagents

i) 3% (w/v) Metaphosphoric acid (HPO_3): Prepare by dissolving the sticks or pellets of HPO_3 in distilled water.

ii) Ascorbic acid standard: Weigh accurately 100 mg of L-ascorbic acid and make up to 100 ml with 3% HPO_3 solution. Dilute 5 ml to 50 ml with 3% HPO_3 solution (1 ml = 0.1 mg of ascorbic acid).

iii) Dye solution: Dissolve 50 mg of the sodium salt of 2,6-dichlorophenol indophenol in approximately 150 ml of hot distilled water containing 42 mg of sodium bicarbonate. Cool, filter and dilute with distilled water to 200 ml. Store in a refrigerator and standardize every day.

iv) Formaldehyde, 40% solution.

v) Conc. Hydrochloric acid.

1.2.3 Procedure

Standardization of Dye

Pipette out 5 ml of the standard ascorbic acid solution into a 100 ml conical flask and add 5 ml of the 3% HPO_3 solution. Fill the microburette with the dye solution. Titrate the ascorbic acid solution with the dye solution to a pink colour, which should persist for 15 sec. Note the Titre value. Calculate the dye factor.

Volume of ascorbic acid solution taken for titration = 5 ml

Volume of dye solution required (titre) = V = ----- ml

Dye factor = mg of ascorbic acid per ml of the dye

Since 5 ml of the standard ascorbic acid solution contains 0.5 mg ascorbic acid:

$$\text{Dye factor} = \frac{0.5}{\text{Titre}} = \frac{0.5}{V} = \text{mg ascorbic acid per ml dye}$$

Preparation of Sample

Juices and liquid products: Take 10-20 g sample and make up to 100 ml in a volumetric flask with 3% HPO_3 solution. Filter through a Whatman No. 1 filter paper.

Solid or semi-solid products: Blend 10-20 g sample with 3% HPO_3 solution and make up to 100 ml in a volumetric flask with 3% HPO_3 solution. Filter through a Whatman No. 1 filter paper.

Titration

Pipette out 2-10 ml of the sample extract into a 100 ml conical flask and titrate against the dye solution as above. The volume of the sample should be such that the tire value is in the range of 3-5 ml.

If the sample contains sulphur dioxide, to the pipetted out sample extract add 1 ml of the formaldehyde solution and 0.1 ml HCl, keep for 10 min and perform the titration.

1.2.4 Observations

Weight of sample taken for extraction with HPO_3 = W = ----- g

Volume of the sample made up with HPO_3 solution = 100 = ----- ml

Volume of sample extract taken for dye titration = V_1 = ----- ml

Volume of dye required (titre) = V_2 = ----- ml

1.2.5 Calculations

Ascorbic acid in V_1 ml of the sample extract = dye factor x V_2 = mg

$$\text{Therefore, ascorbic acid in 100 ml of the extract} = \frac{\text{Dye factor} \times V_2 \times 100}{V_1} = \text{mg}$$

Since W g sample was made up to 100 ml, ascorbic acid content of the sample (mg per 100 g)

$$= \frac{\text{Dye factor} \times V_2 \times 100 \times 100}{V_1 \times W} = \frac{\text{Dye factor} \times V_2 \times 10{,}000}{V_1 \times W}$$

1.2.6 Results

Ascorbic acid content of the sample = mg per 100 g.

1.3 EXPERIMENT 1b: XYLENE EXTRACTION METHOD

1.3.1 Principle

This method is based on measurement of the extent to which a 2,6-dichlorophenol indophenol solution is decolourised by ascorbic acid in sample extracts and in standard ascorbic acid solutions. The excess dye is taken up in xylene and colour measured in a colorimeter at 520 nm. This method is particularly suitable for stored products in which considerable interfering substances are present.

1.3.2 Requirements

Colorimeter with sufficient number of sample tubes

Analytical balance, 0.1 mg sensitivity

Volumetric flask, 100 ml, and 1000 ml

Pipette, 10 ml

Conical flasks, 50 ml glass stoppered

Funnel

Whatman No.1 filter circles

Reagents

i) Acetate buffer- pH 4: Mix 500 ml of 50% sodium acetate ($CH_3COONa.3H_2O$) with 500 ml of glacial acetic acid.

ii) Dye: Dissolve 125 mg of 2,6-dichlorophenol indophenol (sodium salt) in warm distilled water, cool , make up to 100 ml in a volumetric flask and filter (stock solution). Dilute 18 ml to 100 ml with water. 1 ml of this solution should be equal to 0.1 mg of ascorbic acid. The stock solution of the dye may be stored in a refrigerator for a week.

iii) Meta phosphoric acid solution (3%): Dissolve 15 g of sticks or pellets of HPO_3 in distilled water and dilute to 500 ml.

iv) Standard ascorbic acid solution: Weigh exactly 100 mg of ascorbic acid and make up to 100 ml with 3% HPO_3 solution. Dilute 10 ml to 100 ml (1 ml = 0.1 mg ascorbic acid).

v) Xylene.

vi) Formaldehyde 40%.

vii) Anhydrous sodium sulphate.

1.3.3 Procedure

Sample extraction procedure followed for the titration method may be followed for this method also.

Standard Curve

Pipette out 0.0, 0.50, 0.75, 1.0, 1.5 and 2.0 ml of the standard ascorbic acid solution into 50 ml stoppered conical flasks. Make up the total volume in each flask to 2 ml with 3% HPO_3 solution. Add 1 ml water, 2 ml acetate buffer, 3 ml dye solution and 15 ml xylene in rapid succession. Stopper the conical flasks and shake vigorously for 10 sec to extract the excess dye into the xylene. Allow the layers to separate. With a pipette completely draw out the water layer below the xylene layer and discard. Add a small quantity (0.5-1 g) of anhydrous Na_2SO_4 to the xylene layer to remove traces of moisture. Transfer the xylene extracts to the colorimeter tubes and measure the absorbance at 520 nm. Set the instrument to 100% transmittance using xylene as blank. Plot the absorbance values (A) against ascorbic acid (mg) on a graph paper to get the standard curve. You will see that as the concentration of ascorbic acid in the reaction mixture increases, the absorbance value decreases.

Vol. of ascorbic acid (ml)	Ascorbic acid (mg)	Absorbance (A)
0.0	0.00	
0.5	0.05	
0.75	0.075	
1.0	0.10	
1.5	0.15	
2.0	0.20	

Sample

Take 2 ml sample extract in a stoppered conical flask, add 2 ml of buffer, 1 ml of 40% formaldehyde and mix. Allow to stand for 10 min. Then add 3 ml dye solution, stopper and shake for 10-15 sec. Follow the remaining steps as done in the case of standard curve preparation. From the standard curve note the ascorbic acid content (mg) in the 2 ml sample extract taken for the estimation.

1.3.4 Observations

Absorbance of the xylene extract = A_1

Corresponding ascorbic acid content from the standard curve = W_1 = ---- mg

Weight of the sample taken for extraction = W_2 = ----- g

Volume of the sample made up for ascorbic acid extraction = 100 = ---- ml

1.3.5 Calculations

From the data, W_1 mg of ascorbic acid is present in 2 ml of the sample extract.

As W g of the sample was made up to 100 ml for extraction of ascorbic acid, the ascorbic acid content of the sample (mg per 100 g)

$$= \frac{W_1 \times 100 \times 100}{2 \times W_2} = \frac{W_1 \times 5000}{W_2}$$

1.3.6 Results

Ascorbic acid of the sample = mg per 100 g.

1.4 PRECAUTIONS

The general precautions mentioned in the course 'Introduction' and those indicated in the experiments should be followed meticulously.

The colorimeter and the sample tubes should be handled with care.

EXPERIMENT 2 DETERMINATION OF SODIUM CHLORIDE

Structure

2.1 INTRODUCTION

Salt (sodium chloride) is an important ingredient in several food products like pickles, chutneys, and sauces. Brine (dilute salt solution) is the common covering liquid for most of the low acid canned products like vegetables. In products like "pickle in brine", the minimum salt content has been specified.

The approximate salt content in brine solutions can be measured using a salinometer (hygrometer). However, for more accurate determination of sodium chloride, silver nitrate titration method is mostly followed.

Objectives

After studying and performing this experiment, you should be able to

- determine the salt content of food products.

2.2 EXPERIMENT

2.2.1 Principle

When a sample extract containing sodium chloride to which a few drops of potassium chromate solution is added, is titrated with standard silver nitrate solution, silver nitrate precipitates chloride as silver chloride. Immediately on completion of the precipitation reaction, the excess of silver nitrate reacts with potassium chromate forming reddish brown silver chromate, which is the end point. The quantity of silver nitrate used for the precipitation is the measure of the sodium chloride content of the sample.

$$NaCl + AgNO_3 \rightarrow AgCl + NaNO_3$$

2.2.2 Requirements

Glassware and other items

Chemical balance	
Burette, 25 ml	–1
Conical flask, 250 ml	–2

Measuring cylinder

Whatman No.1 filter paper circles,

Funnel, 4 inch –2

Reagents

5% Potassium chromate solution (indicator)

0.1N Silver nitrate solution

Calcium carbonate powder

2.2.3 Procedure

Weigh 25 to 50 g of homogenized sample depending on the salt content. Dilute with distilled water and neutralize with 0.1N sodium hydroxide solution using phenolphthalein as indicator. Transfer to a 250 ml volumetric flask, make up to volume, shake and filter. Titrate an aliquot with 0.1 N silver nitrate solution adding about 1ml of 5% aqueous potassium chromate solution as indicator. Note the volume of silver nitrate solution required to produce the reddish brown end point colour. Carry out a blank titration with distilled water of same volume as the sample aliquot.

2.2.4 Observations

Weight of the sample	= W = ------- g
Volume made up	= V = ------- ml
Volume taken for titration	= V_1= ------- ml
Volume of silver nitrate solution required for sample	= V_2 = ------ ml
Volume of silver nitrate required for blank titration	= V_3= ------- ml
Normality of the $AgNO_3$ solution	= N

2.2.5 Calculations

1000 ml 1 N $AgNO_3$ solution = 1 g mole of sodium chloride = 58.45 g.

Therefore, % NaCl in the sample =

$$\frac{58.45\,(\text{sample titre} - \text{blank titre})\,N \times \text{volume made up} \times 100}{1000 \times \text{aliquot volume taken for titration} \times \text{weight of sample}}$$

i.e. % sodium chloride in the sample = $\dfrac{58.45\,(V_2 - V_3)\,N \times V}{10 \times V_1 \times W}$

2.2.6 Results

Salt content in the sample = Percent.

2.3 PRECAUTIONS

The general precautions mentioned in the course 'Introduction' and those indicated in the experiments should be followed meticulously.

Handle silver nitrate and its solution with care. They can leave permanent stain on the skin and cloth.

EXPERIMENT 3 DETERMINATION OF TOTAL CAROTENOIDS AND BETA-CAROTENE BY COLORIMETRIC METHOD

Structure

3.1 INTRODUCTION

Carotenoids are a group of yellow, orange and orange-red fat-soluble pigments widely distributed in nature. The carotenoids are of great nutritional importance as some of them are converted into vitamin A. Several fruits and vegetables especially the leafy vegetables are good sources for carotenoids. Therefore, estimation of their concentration in fresh and processed foods is important.

Extracting into solvents like petroleum ether and measuring the colour at 452 nm in a colorimeter most commonly estimate total carotenoids in food materials. Beta-carotene is chromatographically separated from total carotenoids on a suitable adsorbent and colorimetrically estimated.

Objectives

After studying and performing this experiment, you should be able to

- extract carotenoid pigments from food materials;
- separate beta-carotene from the total carotenoids chromatographically; and
- estimate them colorimetrically.

3.2 EXPERIMENT: TOTAL CAROTENOIDS AND BETA-CAROTENE ESTIMATION

3.2.1 Principle

Carotenoid pigments (carotenes, xanthophylls and santhophyllesters) being fat-soluble substances, can be extracted into water immiscible solvents like petroleum ether. The absorbance of the extract is measured in a colorimeter or spectrophotometer, and the carotenoids concentration is calculated using a standard curve. Beta-carotene can be separated from total carotenoids extract chromatographically on a magnesium oxide- supercel column and separately estimated.

3.2.2 Requirements

Apparatus

Colorimeter or specrophotometer

Chromatographic column, 150 x 19 mm (ID) glass tubes with constriction at one end to attach 3 mm glass tubing. The column should be fixed to a rubber cork, which should fix to a 100 ml Buchner flask.

Plunger for the preparation of the adsorption column.

Buchner flask, 100 ml	–2
Suction pump	
Analytical balance, 0.1 mg sensitivity	
Pestle and mortar	
Volumetric flask, 100 ml	–6
------ do ----- , 250 ml	–1
------- do ---------, 25 ml	–2
Pipettes, 5 and 10 ml	
Conical flask, 250 ml	–2
Funnels, 3 inch	–2
Separating funnel, 250 ml	–2

Reagents

Petroleun ether (b.p. 65-70^{0}C)

Acetone

Chloroform

Anhydrous sodium sulphate

Adsorbent: Mix one part of magnesium oxide (MgO) with three parts of supercel.

3% acetone in petroleum ether

Sea sand, purified

Surgical cotton

3.2.3 Procedure

Standard Curve of β-carotene

Weigh accurately 25 mg of β-carotene and dissolve in 2.5 ml chloroform and make up to 250 ml with petroleum ether (1 ml = 0.1 mg or 100 μg). Dilute 10 ml of this solution to 100 ml with petroleum ether in a volumetric flask (1 ml = 10 μg). Pipette 5, 10, 15, 20, 25 and 30 ml of this solution to separate 100 ml volumetric flasks, each containing 3 ml acetone and dilute to mark with petroleum ether. The concentration of β -carotene in these solutions will be 0.5, 1.0, 1.5, 2.0, 2.5 and 3.0 μg per ml. Measure the absorbance of the solutions at

452 nm using 3% acetone in petroleum ether as blank. Draw a graph by plotting absorbance against concentration. Record the data as follows.

β-carotene (μg/ ml)	**Absorbance(A)**
0.5	
1.0	
1.5	
2.0	
2.5	
3.0	

Sample Extraction

Weigh a well-blended sample (5 to 25 g) containing 10 to 500 μg total carotenoids. Grind in a pestle and mortar with acetone adding small quantity of pure sand. Filter through cotton into a conical flask. Continue extraction and filtration till the residue is colourless. Transfer the combined filtrate to a separating funnel. Add 10 to 15 ml petroleum ether followed by distilled water to transfer the pigments to the petroleum ether phase. Drain out the aqueous phase and filter the petroleum ether extract through anhydrous sodium sulphate. Make up the petroleum volume of the ether extract to 25 ml in a volumetric flask with petroleum ether. Measure the absorption of the solution at 452 nm. Calculate the total carotenoids contents using the standard curve. The results are expressed in terms of β-carotene as μg per 100 g of the material.

Chromatographic Separation of β-carotene

Preparation of column: Attach the column to a Buchner flask, apply vacuum and pack the glass column tightly with the adsorbent to a height of about 10 cm. alternatively, press the adsorbent, 2-3 times with a plunger to ensure a tight column. Add anhydrous Na_2SO_4 to the top of the column to about 1 cm height.

Sample adsorption and elution: Wash the column with 25 to 50 ml petroleum ether with suction. When the petroleum layer has almost reached the Na_2SO_4 surface, disconnect suction pump and attach the column tube to another clean and dry Buchner flask. Pipette out 5 to10 ml of the sample extract into the column and apply suction. Wash the column continuously with 3% acetone in petroleum ether (eluent) taking care not to allow the solvent layer to go below the Na_2SO_4 layer. β-carotene moves out of the column prior to all other pigments. When the β-carotene band has flowed out completely, disconnect suction and transfer the contents of the Buchner flask to a volumetric flask and make up to volume with the eluent. Measure the absorbance of the solution at 452 nm using 3% acetone in petroleum ether as blank.

3.2.4 Observations

Weight of sample taken for carotenoids extraction = W = ----- g

Volume of the petroleum ether extract of the sample = V = ----- ml

Absorbance of the solution = A

Concentration of carotenoids in the solution (from std. curve) = C = μg/ml

Volume of the petroleum ether extract taken for

Chromatography = V_1 = ----- ml

Volume of the β- carotene band made up to = V_2 = ----- ml

Absorbance of the β-carotene extract = A_1

Concentration of β-carotene in the solution (from std. curve) = C_1 = -- μg/ml

3.2.5 Calculations

Total Carotenoids

Concentration total carotenoids in the petroleum ether extract = C = μg/ ml

Therefore, total carotenoids content in V ml of the petroleum ether extract

$$= C \times V = \mu g$$

C × V μg carotenoids are present in W g of the sample

$$\text{Therefore, total carotenoids content in the sample} = \frac{C \times V \times 100}{W} = \mu g \text{ per } 100 \text{ g}$$

β-carotene

Concentration of β-carotene in the β-carotene eluate = C_1 = μg/ml

Therefore, β-carotene content in V_2 ml of the eluate = $C_1 \times V_2$ = μg

$C_1 \times V_2$ μg of β-carotene is present in V_1 ml of the extract taken for chromatography.

$$\text{Therefore, } \beta\text{-carotene content in the sample} = \frac{C_1 \times V_2 \times V \times 100}{V_1 \times W} = \mu g \text{ per } 100 \text{ g}$$

3.2.6 Results

Total carotenoids content of the sample = μg per 100 g.

β-carotene content of the sample = μg per 100 g.

3.3 PRECAUTIONS

β-carotene is unstable to light and susceptible to air-oxidation. Therefore, the sample extracts should be prevented from oxidation and light.

The general precautions mentioned in the course 'Introduction' and those indicated in the experiments should be followed meticulously.

Never handle petroleum ether near a flame. The solvents should be handled only in a well-ventilated room or inside a hood with exhaust. Avoid inhaling the solvents directly.

EXPERIMENT 4 DETERMINATION OF SULPHUR DIOXIDE

Structure

4.1 INTRODUCTION

Sulphur dioxide and sulphites are versatile food preservatives having several beneficial functions. Sulphur oxide added to food products as preservative may exist as undissociated sulphurous acid, as free bisulphite ion, as free sulphite ion, and/or as combined SO_2 in the form of hydroxy sulphonates. However, they can cause harmful effects if consumed in higher quantities. Therefore, like for all other preservatives, maximum permissible limits of sulphites in foods have been laid down. Besides, sulphites are not permitted in all foods.

There are two methods used for the estimation of sulphites in foods. Both of them make use of the reducing property of sulphur dioxide. In one method, iodine is used to oxidize sulphur dioxide (sulphurous acid to sulphuric acid in aqueous solution) and in the other method, hydrogen peroxide is used for the oxidation reaction after liberating sulphur dioxide from the product. The latter method is more reliable and hence followed widely.

Objectives

After studying and performing this experiment, you should be able to

- estimate the sulphur dioxide content of food products by the distillation method.

4.2 EXPERIMENT

4.2.1 Principle

This method measures total sulphur dioxide in food products. Sulphites present in the product are liberated as sulphur dioxide by boiling with hydrochloric acid. The liberated sulphur dioxide is absorbed in hydrogen peroxide solution, which oxidizes it to sulphuric acid. Sulfite content is directly related to generated suphuric acid, which is determined by titration with standard sodium hydroxide solution.

The reactions involved are:

$$SO_2 + H_2O \rightarrow H_2SO_3$$

$$H_2O_2 + SO_2 \rightarrow H_2SO_4$$

4.2.2 Requirements

Apparatus

a) All glass distillation apparatus for determination of sulphur dioxide shown in the diagram below.

Diagram: SR p 307

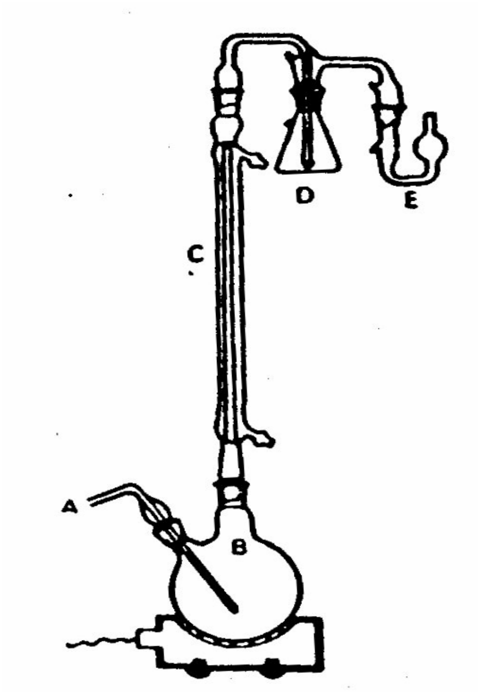

Figure 4.1: All glass distillation apparatus for determination of sulphur dioxide. A) glass inlet tube, B) 500ml round-bottomed flask, C) condenser, D) 250 ml conical flask, E) trap

b) Burette: - 10 ml

Reagents

a) **Aqueous hydrochloric acid:** -4M. For each analysis, prepare 90 ml solution by adding 30 ml HCl to 60 ml deionized water.

b) **Methyl red indicator: -**Dissolve 250 mg methyl red in 100 ml ethanol.

c) **0.05 N NaOH solution.**

d) **3% Hydrogen peroxide solution: -**. For each analysis, dilute 3 ml reagent grade 30% H_2O_2 to 30 ml with distilled water. Just prior to use, add 3 drops methyl red indicator and titrate with 0.01N NaOH to yellow end point.

e) **Nitrogen gas: -**High purity, used with regulator to maintain flow of 200 ml/min.

4.2.3 Procedure

Circulate cold water through condenser of the distillation apparatus. Add from a graduated cylinder, 20ml of 3% hydrogen peroxide solution to the conical flask (D) and 5 ml to the trap (E). Assemble the apparatus and connect condenser. Weigh 50g of blended sample into the round-bottomed flask (B) through gas inlet tube joint, using 300ml of water. Replace the inlet tube immediately, making sure all connections are well greased and tight. Remove the inlet tube, and slowly add 20ml of 4N HCl. Ensure that bubbles of nitrogen gas enter the receiving flask through the gas inlet tube. If not, check joints for leaks. Adjust nitrogen to give a flow of 15 to 20 bubbles per minute through the tube. Heat the content of the flask to boil and adjust the heater to give a slow boil. Continue boiling for 30 mins. Stop heating and disconnect the assembly and remove the conical flask and the trap containing hydrogen peroxide. Transfer the hydrogen peroxide solution from the trap into the conical flask and rinse the trap with water and transfer the rinsing to the flask.

Determination

Add 3 drops of the indicator. Immediately titrate contents of conical flask (D) with 0.05N NaOH to yellow end point that persists for about 20 seconds. Compute sulfite content, expressed in mg SO_2/Kg food (ppm).

4.2.4 Observations

Weight of the sample	= W = ----- g
Normality of the NaOH solution	= N
Volume of NaOH (titre)	= V = ----- ml

4.2.5 Calculations

1 ml of 0.05N NaOH = 1.6 mg of SO_2

$$\text{Therefore, V ml of N normal NaOH} = \frac{(V \times N \times 1.6)}{0.05} = (V \times N \times 32) \text{ --- mg } SO_2$$

Since (V x N x 32) mg SO_2 is present in W g of the sample

$$\text{Therefore, } SO_2 \text{ (mg) in 1 Kg of the sample (ppm)} = \frac{(V \times N \times 32)}{W} \times 1000$$

4.2.6 Results

SO_2 in the sample = ppm = mg per kilogram.

4.3 PRECAUTIONS

The general precautions mentioned in the course ‘Introduction’ and those indicated in the experiments should be followed meticulously.

Handle the all glass distillation apparatus very carefully. It may easily break because the joints are rigid.

EXPERIMENT 5 ESTIMATION OF BENZOIC ACID

Structure

5.1 INTRODUCTION

Benzoic acid is the second most common preservative added to fruit and vegetable products. Being insoluble in water, it is added as the soluble sodium benzoate. The method commonly followed for the estimation of benzoic acid involves conversion of the salt into benzoic acid by acidification, extraction into an organic solvent and titrating against alkali.

Objectives

After studying and performing this experiment, you should be able to

- determine the benzoic acid content of foods by the extraction and alkali titration method.

5.2 EXPERIMENT

5.2.1 Principle

In sodium chloride solution of the sample, the benzoic acid present is converted into water-soluble sodium benzoate by the addition of NaOH. When the sodium benzoate solution is acidified with excess HCl, it is converted into benzoic acid. The water insoluble benzoic acid is extracted with chloroform. The chloroform is removed by evaporation and the residue containing benzoic acid, which appears as leafy crystals, is dissolved in neutral alcohol and titrated against standard NaOH to phenolphthalein end point.

5.2.2 Requirements

Equipment and Apparatus

Separating funnel, 500 ml	–1
Beaker, 250 ml	–2
Volumetric flask, 250 ml & 500 ml	–1 each
Burette, 50 ml	–1

Pipette, 25 ml –1

Measuring cylinders, 50 ml and 10 ml –1 each

Water-bath –1

Chemical balance –1

Desiccator –1

Whatman No. 1 or No. 4 filter paper circles

Chemicals and Reagents

Diethyl ether,

Hydrochloric acid – (1+ 3)

Anhydrous sodium sulphate

Ethyl alcohol

Phenolphthalein indicator – 0.1% in alcohol

Sodium hydroxide solution – 0.05 N

Ferric chloride solution – 0.5%

Sodium chloride – saturated solution

Sodium hydroxide – 10 % solution

Chloroform

Sodium chloride – powder

5.2.3 Procedure

a) Detection

Transfer homogenized sample into a separating funnel. Acidify with 1+3 HCl. Extract with solvent ether. Collect ether in a dry conical flask. Evaporate ether to near dryness and completely evaporate under a current of dry air. To the white leafy crystals of benzoic acid add few drops of 0.5% neutral $FeCl_3$ solution. A salmon coloured precipitate confirms presence of benzoic acid.

b) Determination

Take 50-75 g of the homogenized sample in a 500ml beaker. Add 200ml saturated solution of NaCl and 50g powder NaCl and stir well. Make the solution alkaline to litmus paper with 10% NaOH. Quantitatively transfer the solution to 250ml volumetric flask and make up to volume. Shake well. Let stand 2-3 hr. with frequent shaking. Filter through whatman No. 4 filter paper. Pipette 50ml filtrate into a separating funnel. Neutralize to litmus paper with HCl (1+3). Add 5ml in excess of the acid. Extract the solution thrice with 70, 50, 30 ml portions of chloroform. Shake funnel using rotary motion with each extraction. If emulsion forms, break it by (a) Stirring $CHCl_3$ layer with a glass rod, or (b) draw $CHCl_3$ layer into a second separating funnel and give one or two sharp shake. Pool clear $CHCl_3$ extracts and transfer to separating funnel. Wash the chloroform extract with

5ml water. Draw the $CHCl_3$ layer into a 250ml conical flask. (the $CHCl_3$ extract may be passed through a bed of cotton and anhydrous Na_2SO_4 to remove traces of moisture). Evaporate $CHCl_3$ to near dryness on water bath. Dry completely under a current of dry air. Keep the flask overnight in a H_2SO_4 desiccator. Remove and add 25ml neutral alcohol. Add 6-8 ml of water and one drop of phenolphthalein indicator and titrate against 0.05N NaOH.

5.2.4 Observations

Weight of the sample	= W = ---- g
Volume made up	= V = ---- ml
Volume taken for extracting with chloroform	= V_1 = ---- ml
Titre value	= V_2 = ---- ml
Normality of the NaOH	= N

5.2.5 Calculations

1000 ml 1N NaOH = 1 g equivalent of benzoic acid = 122 g benzoic acid

or 1 ml 1 N NaOH = 122 mg benzoic acid

Therefore ppm (mg per Kg) of benzoic acid in the product =

$$\frac{\text{Vol. of alkali} \times \text{Normality of NaOH} \times \text{Vol. made up}}{\text{Vol. Taken for } CHCl_3 \text{ extraction} \times \text{Weight of sample}} \times 122 \times 1000$$

$$= \frac{V_2 \times N \times V \times 122 \times 1000}{V_1 \times W} = \text{ppm}$$

5.2.6 Results

The result is expressed as benzoic acid in ppm.

5.3 PRECAUTIONS

The general precautions mentioned in the course 'Introduction' and those indicated in the experiments should be followed meticulously.

Never handle ether near a flame. The solvents should be handled only in a well-ventilated room or inside a hood with exhaust. Avoid inhaling the solvents directly.

EXPERIMENT 6 DETERMINATION OF HARDNESS OF WATER

Structure

6.1 INTRODUCTION

Hardness of water is almost entirely due to the presence of calcium and magnesium salts. It is expressed as ppm (mg/ litre). Hardness values for water meant for different purposes have been specified.

The most common method for the determination of hardness of water is by the ethylenediamine tetra-acetic acid (EDTA) titration.

Objectives

After studying and performing this experiment, you should be able to

- determine the hardness of water.

6.2 EXPERIMENT: HARDNESS OF WATER BY EDTA METHOD

6.2.1 Principle

This method is based on the principle that when EDTA is added to a solution containing certain metal cations like calcium and magnesium, it complexes with them and make them unavailable for some reactions. One such reaction is the formation of wine-red colour between the cations and Chrome black T at a pH of 10. Therefore, for the determination of hardness of water, Chrome black T is added to the water at pH 10 ± 0.1 and titrated with EDTA solution till the disappearance of wine-red colour and formation of blue colour, which is the end point.

6.2.2 Requirements

Apparatus

Analytical balance

Hot air oven

Desiccator

Volumetric flasks, 500 ml and 1000 ml

Conical flask, 250 ml and 500 ml

White porcelain dish, 250 ml

Glass rods

Reagents

i) Borate buffer: Dissolve 20 g borax ($Na_2B_4O_7.10\ H_2O$) in about 400 ml distilled water. Dissolve 5 g sodium hydroxide and 2.5 g sodium sulphide (Na_2S) in 50 ml water, cool, mix with borax solution and dilute to 500 ml with distilled water.

ii) Indicator: Mix together 0.5 g of Eriochrome black T and 100 g sodium chloride and powder in a pestle and mortar.

iii) Methyl red indicator.

iv) 3N ammonium hydroxide solution.

v) Standard calcium solution: Dry calcium carbonate ($CaCO_3$) in an oven at 105^{o}C over night and cool in a desiccator. Weigh exactly 1 g into a 500 ml conical flask. Add dilute (1+1) HCl drop by drop until all the $CaCO_3$ has dissolved. Add 200 ml distilled water and boil for a few minutes to expel carbon dioxide. Cool, add a few drops of methyl red indicator and adjust to the intermediate orange colour by adding 3N ammonium hydroxide. Transfer to a 1 litre volumetric flask and make up to volume with distilled water (1 ml = 1 mg $CaCO_3$).

vi) Standard EDTA solution: Dissolve 4.0 g of disodium salt of EDTA in 800 ml of distilled water. Standardize against standard calcium solution. Adjust the dilution of the EDTA solution such that 1 ml = 1 mg $CaCO_3$. Store in a corning glass or plastic bottle to prevent extraction of salts from ordinary glass.

6.2.3 Procedure

Take 25 ml of the water sample in a porcelain dish and add 25 ml distilled water followed by 1-2 ml of the buffer. Add a small quantity of the Eriochrome indicator and stir with a glass rod to dissolve. If the water is hard, a red colour will be formed. Titrate slowly with the EDTA solution, stirring continuously until the red tinge disappears and a permanent blue colour is produced. If the water sample has low hardness, more volume of water may be taken for titration by adding proportionate volume of the buffer. The duration of titration should not exceed 5 min measured from the time of addition of buffer.

6.2.4 Observations

Volume of water sample taken for titration = V = ----- ml

Volume of EDTA solution required (titre) = V_1 = ----- ml

6.2.5 Calculations

Since 1 ml of the EDTA solution is equal to 1 mg $CaCO_3$, V_1 ml EDTA solution = V_1 mg $CaCO_3$.

As V_1 mg $CaCO_3$ is present in V ml of the water sample, the hardness of the water.

$$= \frac{V_1 \times 1000}{V} = \text{ppm } CaCO_3 \text{ or mg } CaCO_3 \text{ per litre.}$$

6.2.6 Results

Hardness of the water sample = ppm $CaCO_3$ or mg $CaCO_3$ per litre.

6.3 PRECAUTIONS

The general precautions mentioned in the course 'Introduction' and those indicated in the experiments should be followed meticulously.

EXPERIMENT 7 ESTIMATION OF RESIDUAL CHLORINE IN WATER

Structure

7.1 INTRODUCTION

Water is routinely chlorinated to make it microbiologically safe. When chlorine is added to water other than distilled water, initially a small amount reacts with impurities in the water and does not show as residual chlorine. This is called the chlorine demand of the water, which has no germicidal effect. Chlorine added subsequently remains as the residual chlorine (free available and combined available chlorine), which is important for disinfection. The residual chlorine levels of water used for different purposes have been specified.

The most common method for routine estimation of residual chlorine is the iodometric method, which you will learn in this practical.

Objectives

After studying and performing this experiment, you should be able to

- determine the residual chlorine content in water; and
- follow the necessary sampling procedures.

7.2 EXPERIMENT: RESIDUAL CHLORINE BY IODOMETRIC METHOD

7.2.1 Principle

Chlorine liberates free iodine from potassium iodide solution in acidic pH quantitatively. The liberated iodine is determined by titration with standard sodium thiosulphate solution. As chlorine in aqueous solution is not stable, the determination of chlorine must be performed immediately after sampling. Care should be taken to avoid excessive exposure of the water sample to sunlight and agitation.

7.2.2 Requirements

Apparatus / glassware

Analytical balance

Burette, 25 ml

Volumetric flask, 100 and 250 ml

Conical flask, 250 ml

Measuring cylinder, 500 ml

White porcelain dish, 500 ml

Beaker, 250 ml

Reagents

i) Acetic acid, glacial.

ii) Potassium iodide crystals.

iii) Starch indicator.

iv) N sodium thiosulphate solution: Dissolve 24.8192 g of sodium thiosulphate ($Na_2S_2O_5$. 5 H_2O) in 200 ml water and transfer to a 1 litre volumetric flask and make up to volume. Standardize the solution with potassium dichromate. Weigh 0.20 to 0.23 g $K_2Cr_2O_7$ and transfer to a 250 ml beaker using about 150 ml water. Add 2 g potassium iodide and mix. Add 20 ml of 1 N HCl , swirl and allow to stand for 10 min. Titrate with the thisuphate solution adding 1 ml of 1% starch solution towards the end of titration and complete titration where the solution changes from blue green to light green.

$$\text{Normality of sodium thiosulphate solution} = \frac{\text{Wt of } K_2Cr_2O_7 \text{ (g)} \times 1000}{\text{Vol. of } Na_2S_2O_3 \text{ (ml)} \times 49.037}$$

Prepare 0.01 N working standard by diluting the 0.1 N thosuphate solution.

7.2.3 Procedure

Take a suitable volume of the water sample into a porcelain dish or beaker. For water containing 1 mg / litre or less chlorine take 1000 ml and for 1 to 10 mg / litre take 500 ml. The titre value of 0.01 N thiosulphate should not be more than 20 ml. Add 5 ml glacial acetic acid followed by 1 g potassium iodide, stir and titrate with 0.01 N thiosulphate solution until the yellow colour of the liberated iodine is almost disappears. Add 1 ml starch solution and titrate until the blue colour is discharged. Do not carry out the titration in direct sunlight. Blank titration can be carried out by taking equal volume of distilled water.

7.2.4 Observations

Volume of water taken for titration = V = ----- ml

Volume of thiosulphate solution required (titre) = V_1 = ----- ml

Normality of sodium thiosulphate solution = 0.01 N

7.2.5 Calculations

1000 ml 1N sodium thiosuphate = 35.46 g chlorine (i.e.1 g mole of chlorine)

or 1 ml 1N sodium thiosulphate = 35.46 mg chlorine

or V_1 ml of 0.1 N sodium thiosulphate = V_1 x 0.01 x 35.46 mg chlorine

Therefore, residual chlorine content of the water (mg per litre)

$$= \frac{V_1 \times 0.01 \times 35.46 \times 1000}{V}$$

$$= \frac{V_1 \times 354.6}{V}$$

7.2.6 Results

Residual chlorine content of the water sample = mg per litre or ppm.

7.3 PRECAUTIONS

The general precautions mentioned in the course ‘Introduction’ and those indicated in the experiments should be followed meticulously.

EXPERIMENT 8 DETERMINATION OF TOTAL SOLUBLE SOLIDS (°BRIX)

Structure

8.1 INTRODUCTION

Total soluble solids may be determined by means of Refractometer. Brix is a measure of total soluble solids (TSS) in the case of pure sucrose solutions. Generally fruit juices contain more sugar than other soluble constituents, and hence, Brix provides useful guide of TSS or sugar content.

The concentration of sugar solutions can be determined conveniently for routine purposes using a refractometer. There are two types of refractometers viz. hand refractometers and Abbe's refractometers, the latter being tabletop instrument, which can measure both ^{o}Brix (TSS) of sugar solutions and also there is provision for maintaining constant temperature.

It should be noted that the refractometers are calibrated for sugar solutions and hence if the medium contains other soluble solutes in substantial quantities, there will be slight error.

Objectives

After studying and performing this experiment, you should be able to

- determine the °Brix of sugar solutions and TSS of food products.

8.2 EXPERIMENT

8.2.1 Principle

Refractometer measures total soluble solids (TSS) concentration based on the principle of refraction of light. When a ray of light travels obliquely from one medium to another, it is bent or refracted. The refraction occurs because light travels at slightly different velocities in different media, the extent being proportional to the density of the solution or the soluble solids concentration. The refractive index of a medium is defined as the ratio of the sine of the angle of incidence to the sine of the angle of refraction when a ray of monochromatic light is refracted from a vacuum (or, to a very close approximation, from air) into the medium. In a Brix refractometer, the refractive index is calibrated into ^{o}Brix readings. As refractive index is dependent on the density of the solution, the measurements have to be made at a specific temperature (20°C) or suitable corrections have to be applied.

8.2.2 Requirements

Equipments

Hand Refractometer or Abbe's Refractometer

Thermostatically controlled water bath.

8.2.3 Procedure

Place few drops of the sample in between the prisms of hand refractometer and note the reading at the demarcation line. Apply temperature correction for readings taken at temperatures other than 20°C using the following table.

In the case of Abbe's refractometer, circulate 20°C water in the chamber enclosing the prism from a thermostatically controlled water bath. Place a few drops of the sample in between the prisms and allow the temperature to equilibrate and note the Brix reading, which gives per cent of sucrose sugar or TSS.

If sample is thick, squeeze it through cotton and place the drop in between the prisms.

8.2.4 Results

The readings are expressed as total soluble solids (TSS) = %.

Temperature corrections for readings of per cent sucrose in sugar solution by either Abbe or Immersion refractometer at temperatures other than 20°C.

Table 8.1: International temperature correction table, 1936

8.3 PRECAUTIONS

The general precautions mentioned in the course 'Introduction' and those indicated in the experiments should be followed meticulously.

EXPERIMENT 9 CONTAMINANTS: TIN CONTENT IN CANNED FOODS

Structure

9.1 INTRODUCTION

Food contaminants are substances, which can cause harmful effects in the human system. They generally are pesticide residues, heavy metals, toxins and harmful microorganisms. Therefore, their detection and determination in foods is very important. However, the methods available for the determination of most of the contaminants require very sophisticated instruments and are time consuming. Therefore, most of these analyses are done in specialized laboratories and usually not done in the food processing industries.

One of the few estimations, which can be done easily, is tin content in canned foods. Canned food industry is one of the largest food processing industries. Dissolution of tin (can corrosion) into the canned product during storage is a common problem in canned foods. Excess tin dissolution causes discolouration and flavour change in the products and gives an unattractive appearance to can interior. Excess tin is also harmful to the human system. Therefore, maximum limits for tin content in canned foods have been specified.

Tin content in canned foods is usually determined by iodimetry.

Objectives

After studying and performing this experiment, you should be able to

- carry out ashing of food products for tin estimation; and
- perform the iodimetric estimation of tin.

9.2 EXPERIMENT: TIN ESTIMATION BY IODIMETRY

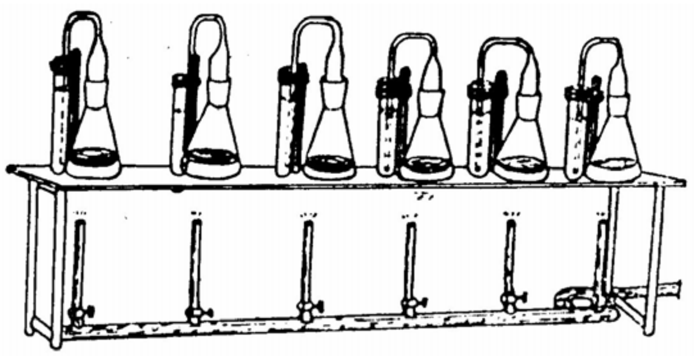
9.2.1 Principle

Canned food sample is acid digested (wet digested) to destroy the organic matter. Tin salts present in the digested sample are reduced with nascent hydrogen to stannous form. Titration of the stannous tin with potassium iodate quantitatively estimates tin.

9.2.2 Requirements

Instruments and Apparatus

Analytical balance	
Blender	
Kjeldahl digestion flask, 300 ml	–2
Pipettes, 10 ml	–2
Burette, 10 ml	–2
Volumetric flasks, 50, 100 ml, 500 ml, 1 lit	–1 each
Conical flask, 150ml with glass jointed (B24) capillary bent tube:	–2
Test tubes, 20 ml	–2
Glass beads	



Set of flasks used for reduction of tin salts

Reagents

i) Conc. HNO_3

ii) Conc. H_2SO_4

iii) Hydrogen peroxide

iv) 3N HCl: Dilute 294.6 ml conc.HCl to 1 litre with distilled water

v) Potassium iodide solution: Dissolve 0.2 g of KIO_3 and 3 g sodium bicarbonate in 100 ml of boiled and cooled water. Transfer to a reagent bottle. Add a few drops of HCl and shake. When effervescence ceases, insert stopper.

vi) Potassium iodate stock solution: Dissolve 5.3505 g KIO_3 in boiled and cooled water and make up the volume to 1 litre. Prepare working standard (0.005N) by diluting 5 ml to 100 ml.

vii) Antimont trichloride ($SbCl_3$) solution: Dissolve 1.5 g $SbCl_3$ in 50 ml HCl and dilute to 100 ml.

viii) Standard tin solution: Dissolve 0.5 g pure tin in 250 ml conc. HCl containing 2 drops of antimony trichloride solution and dilute to 500 ml (1 ml = 1 mg tin).

ix) Aluminium foil, pure.

x) 5% sodium bicarbonate solution.

xi) Starch indicator: 1% starch in 20% sodium chloride solution.

Note: The potassium iodide and iodate reagents should be freshly prepared.

9.2.3 Procedure

Empty the contents of the can immediately to a container after opening to avoid further tin pick up. Blend the product in a blender and digest a suitable quantity of the sample.

Wet digestion: Weigh 50 g sample and transfer to a Kjeldahl digestion flask using distilled water. Add a few glass beads and 10 ml conc. H_2SO_4 and 10 ml or more conc. HNO_3. Heat gently until the liquid darkens. Continue addition of HNO_3 in small proportions (1 to 2 ml) and heating until the solution fails to darken. At this stage, all the organic matter would have been oxidized. Cool and add 10 ml of hydrogen peroxide (30%) drop wise and heat until the digest is colourless. Cool and make up to 50 ml in a volumetric flask with distilled water.

Pipette out 20 ml of the digest into the 150 ml conical flask having glass joint. Add 1 drop of antimony trichloride solution, 30 ml of 3N HCl and about 0.3 g aluminium foil. Connect the flask by mean of B24 joint and a capillary bent tube to a "suck-back" test tube containing sodium bicarbonate solution. Sodium bicarbonate sucked into the conical flask, liberates CO_2 to maintain inert atmosphere.

Heat the flask gently until evolution of gas commences. When the aluminium foil has almost completely dissolved, heat again. Boil till the liquid is colourless. Cool the flask in ice water, disconnect the side tube and add about 4 ml potassium iodide solution along the sides of the flask from a pipette to wash down the digested solution. Add a few drops of starch indicator and titrate rapidly with 0.005 N potassium iodide solution to a blue end point. Run a blank determination with the regents at the same time. The blank titre should not be more than 0.2 ml of 0.005 N potassium iodate.

9.2.4 Observations

Weight of the sample taken: = W = ----- g

Volume of the digest made up to: = V = ----- ml

Volume of the digest taken for tin estimation: V_1 = ----- ml

Volume of potassium iodate required (titre): = V_2 = ----- ml

Blank titre: = V_3 = ----- ml

Normality of potassium iodate solution: = 0.005 N

9.2.5 Calculations

1000 ml 1 N KIO_3 = 59.35 g Sn (tin)

or 1 ml 1 N KIO_3 = 59.35 mg tin

Actual volume of the standard iodate required by the sample = (sample titre – blank titre) = $(V_2 - V_3)$

Therefore, tin content in the canned product (mg / Kg or ppm)

$$= \frac{\text{Actual titre} \times \text{Normality of } KIO_3 \times \text{Total volume of digest} \times 59.35 \times 1000}{\text{Volume of digest taken for tin estimation} \times \text{Weight of sample}}$$

$$= \frac{(V_2 - V_3) \times 0.005 \times V \times 59.35 \times 1000}{V_1 \times W} = \text{mg / Kg}$$

9.2.6 Results

Tin content in the product = ppm or mg per Kg.

9.3 PRECAUTIONS

The general precautions mentioned in the course ‘Introduction’ and those indicated in the experiments should be followed meticulously.

Handle the flask assembly with are to prevent breakage.

EXPERIMENT 10 SENSORY EVALUATION OF FOOD PRODUCTS – HEDONIC RATING TEST

Structure

10.1 INTRODUCTION

Sensory quality of food products is of great importance to both the producer or processor and the consumer. Good quality products attract the consumer by satisfying his aesthetic and gustatory senses. Therefore, it is always the endeavour of the processor to produce the best quality product or produce a product having certain qualities accepted by the consumer in a product already available in the market.

You have already learnt the importance and various aspects of sensory analysis in the theory unit 7.2.4 "Sensory analysis of foods/ beverages". Please brush up before performing this test. There are different sensory test methods to suit specific purposes. One of the frequent requirements of the processor while developing a product is to find out the relative acceptability of his product compared to three or four market sample or to develop a product close to the best in the market. One of the simplest sensory test methods to generate such information is the Hedonic rating test. In this exercise you will learn the method and carry out the test.

Objectives

After studying and performing this experiment, you should be able to

- carry out Hedonic rating test on a set of food products; and
- analyse the data to find out the order of their quality of consumer preference for the samples.

10.2 EXPERIMENT: HEDONIC RATING TEST FOR KETCHUP SAMPLES

10.2.1 Principle

The Hedonic rating test is used to measure the consumer acceptability and preference of food products. The panellist is asked to rate the acceptability of the product on a scale of 9 points, ranging from "like extremely" to "dislike extremely". The data are analysed to find out the average of the panellists ratings from which the order of preference if found out.

10.2.2 Requirements

The primary requirement for any sensory test is the panel of members (panellists). For many sensory tests including the Hedonic rating test, a semi-trained panel is sufficient. The minimum number of panellists required for this test is ten. They should be selected from a larger number of people and should be familiarised (trained) with the quality attributes of the product being tested (or they should be familiarised by proper briefing) and the procedure. They should also have at least average sensitivity to the sensory quality attributes like colour and appearance, flavour and taste etc. Besides, they should be willing to spend the time to do the test.

The other requirements are a well-lighted (white light) room with tables (preferably white tops) and chairs. Assuming that 4 samples (tomato ketchup as in this test) are evaluated and 10 panellists are going to evaluate the products, the following glassware and other items are also required.

White porcelain saucers	:	12 (These are sufficient for serving a set of the four samples to three panellists. The saucers can be cleaned and reused)
Teaspoons	:	12
Glass tumblers for water	:	10
Bread	:	1 loaf
Evaluation cards (Sample shown below)	:	10

Specimen evaluation card

HEDONIC RATING TEST

Name…………………… Date……........

Product: Tomato ketchup

Taste the four samples of tomato ketchup and check how much you like or dislike each one. Use the appropriate scale to show your attitude by checking at the point that describes your feeling about the sample.

Scale	**Ketchup samples**			
	Code No.	**Code No.**	**Code No.**	**Code No.**
Like extremely				

Like very much				
Like moderately				
Like slightly				
Neither like nor dislike				
Dislike slightly				
Dislike moderately				
Dislike very much				
Dislike extremely				
Reason for like/ dislike				

(Signature of panellist)

Three columns are provided to accommodate more than one sample if all of them fall at the same point.

10.2.3 Procedure

In this test, four tomato ketchup samples are tested for the preference. One sample could be the one prepared in a factory and the others are the three market samples. Otherwise, all the four samples could be market samples. The ketchup bottles are first marked with code numbers. It is preferable to have three digit random number codes to avoid bias. Single digit numbers like 1,2,3, 4 are likely to cause bias. For example, some panellists may have a tendency to assume No. 1 is the best and No.4 is the worst and vive versa. Random numbers can be taken from random number tables or generated from a calculator. An example of assigning random numbers to four samples is shown below.

Ketchup sample	Code No.
A	897
B	281
C	951
D	418

In the same way, the sets of four saucers are also numbered and small quantities of the ketchup samples are taken in them. Before starting the evaluation, the panellists are briefed about the test procedure, what to look for in the quality of tomato ketchup, two or more samples may be given the same rating if found so etc. Each product has its own quality attributes. For example, in the case of tomato ketchup, good quality attributes are bright characteristic tomato red colour, thick consistency, does not flow easily when the saucer is tilted, does not show separation of serum around the ketchup sample in the saucer etc.

The set of four saucers containing the samples is given to each panellist along with the evaluation card. Drinking water to rinse mouth in between tasting of two samples to clear the taste of the previous sample is provided. Similarly, cubes of bread are provided for eating for the same purpose. If a panellist requires more samples, the same should be provided. On completion of the evaluation, the evaluation cards are collected and the data are analysed as shown below.

10.2.4 Observations and Calculations

To analyse the results, numerical values are assigned to each point on the scale, 1 is usually given to 'like extremely' and 9 to 'dislike extremely'. The scores received for each sample from all the panellists are averaged and compared. The data are tabulated as shown in the following table. The numerical values given in the table are only examples. You have to enter the actual values.

Panellist	Sample-A	Sample-B	Sample-C	Sample-D
1	3	3	6	5
2	4	3	4	5
3	3	1	4	4
4	2	2	3	4
5	3	1	2	3
6	3	2	7	6
7	2	2	3	5
8	3	2	3	8
9	5	3	7	7
10	3	2	4	6
Total	31	21	43	53
Mean score	3.1	2.1	4.3	5.3

10.2.5 Results

Since the numerical scores are assigned in the reverse order i.e., 1 for the highest quality and 9 for the lowest quality point, lower the score total or score average higher the preference. Therefore, the rating of the quality (preference) of the four tomato ketchup samples is in the following order:

Sample-B > Sample-A > Sample-C > Sample-D

10.3 PRECAUTIONS

The general precautions mentioned in the course 'Introduction' and those indicated in the experiments should be followed meticulously.

UNIT 1 BEING AN ENTREPRENEUR: WHAT DOES IT INVOLVE?

Structure

1.0 OBJECTIVES

After reading this unit, you should be able to:

- differentiate between Wage-employment & Self- employment;
- assess the benefit of self-employment;
- evaluate the risk taking behaviour in goal setting;
- become aware of business opportunities; and
- appreciate the linkage between economy & entrepreneurship.

1.1 INTRODUCTION

"Being an entrepreneur" a Career option. "Self-help is the best help" applies in case one chooses to become an entrepreneur. It is not only running and managing an enterprise but also creating jobs for others. It also means taking challenges by utilizing all available resources. Let us now understand how an entrepreneur goes through this process

1.2 BECOMING AN ENTREPRENEUR

As you grow up you have to think about what you would like to do in order to earn your living. If you look around you will find that different people are doing different activities to earn money to look after their family and to lead a decent life. They are choosing different careers based on their knowledge, and experience. For young persons like you, there are two career alternatives:

a) **wage-employment,** i.e. taking a job and serving the boss for a monthly salary

b) **self-employment**, i.e. to start any economic activity of your own for being self-employed. In self-employment, once the activity grows it can also generate wage-employment for others, then it is called **entrepreneurship.** The person who practises entrepreneurship is called an **entrepreneur.**

An entrepreneur is defined as "person in effective control of commercial undertaking; one who undertakes a business or an enterprise".

The economic activity in self-employment may be a small business, a manufacturing unit or a service-cum-repair unit. Individuals generally choose self-employment for the following reasons:

i) Self-employment provides a solution to the problem of unemployment. Unemployment exists to a large extent in rural and urban areas and among the educated and uneducated in India. Hence, the need to promote self-employment.

ii) One self-employed individual can also offer employment to others. The best scope for self-employment exists in a variety of small business like, retail trade, small stores, repair-cum-servicing units, newspaper stalls, dealership-based business activities, small catering places, franchise-based soft-drink vending, ice-cream and small servicing stations, small manufacturing units, etc.

1.3 NEED FOR ENTREPRENEURSHIP

Let us understand the need for and significance of entrepreneurship.

- **Increases national production**

  More and more entrepreneurs are developed they contribute directly to product and process development which in turn increases national economy. For example, more entrepreneurs in the area of food processing sector would be able to maximize the uses of raw material, and the products in food industries would increase.

- **Balanced area development**

  As more entrepreneurs are developed both in rural and urban sectors, it will decrease the dispersal of the people from rural areas to urban areas. It will also help the rural industries to grow as well as the industrially backward areas in the country.

- **Dispersal of economic power**

  It is a process of empowering people. People can have "power" either through muscle, status or money. Entrepreneurship helps to balance "power" through participation, economic gain and position in the society.

- **Reinvestment of profit for the welfare of the area of profit generation**

  It has been observed that entrepreneurial community or people in a particular area would reinvest their profit for the development of roads, infrastructure as well as for the welfare of the people. Take for example, what contributions have been made by the well-known entrepreneurs like Tata's, Birla's and Reliance.

- **Development is a function of motivation and human resource**

  Any development requires participation of human resources. These people have to be motivated for contributing towards development. Entrepreneurship truly contributes to development through the participation of people who are motivated, energetic and have a concern for growth.

- **Entrepreneurial awareness**

  There is a need for creating mass awareness among the people whether they are students, unemployed youth, artisans, retired personnel, or housewives to be aware about entrepreneurship. More and more entrepreneurs lead to economic development.

1.4 BENEFITS TO THE SELF-EMPLOYED

a) Self-employment offers perhaps the best opportunity for gainful use of one's own capabilities and time.

   It is gainful because it generates income for the self-employed individual. In short, one can earn livelihood based on self-employment.

b) Self-employment develops initiative and ability to plan and manage business activity on the part of the individual.

   Thus, it offers scope for development of the individual.

c) In a self-employment situation one learns many things 'on the job' because one has to take all the decisions and also manage the business.

   One learns and develops through self-employment.

d) In self-employment one can grow and expand one's own business and be innovative.

   One learns to be innovative and growth-oriented. Thus, self-employment develops initiative and ability to plan, decide and manage one's own business. The saying "self-help is the best help" applies here also very well.

1.5 WHO IS AN ENTREPRENEUR?

Once you are self-employed you may like to grow and expand so as to become big to achieve great heights in life, one needs to take initiative and be on one's own. If you look around you will find that all those who have become rich and have earned a big name have become so by starting their own enterprises rather than by seeking jobs. In this way, the educated person does not become a burden on the nation but rather builds the nation by starting a small enterprises, which may be a small industrial enterprise to start with, but over a period of time it becomes a large industry. These are the people who are called entrepreneurs.

i) Becoming an Entrepreneur would mean to own one's tasks\jobs, organize activities, and manage and run an enterprise assuming the risk of a business.

ii) Being an entrepreneur would mean independence and having control over one's own life?

iii) Being an entrepreneur would mean being innovative and reaching towards excellence.

iv) Being an entrepreneur would mean creating job opportunities for others.

v) Being an entrepreneur would also mean sensing economic opportunities.

Entrepreneurs have specific qualities; they have special strengths which they draw upon for their foray into business. If you want to start your own enterprise and make it a success, you will have to play different roles at different times and at different stages of the growth of your enterprise. Let us understand some of the special qualities that an entrepreneur needs to develop.

1.6 SETTING CHALLENGING GOAL – RISK TAKING

Risk-taking is an important aspect of entrepreneurial life. Entrepreneurs are calculated risk-takers. They do not aim at goals that can be very easily accomplished. They like challenges. They also do not aim at tasks that are very difficult to accomplish, as they would enjoy a sense of success attained only after accomplishing a challenging goal. They are moderate risk-takers. Moderate or calculated risk-taking involves a number of processes, stated below:

a) Understanding the situation

b) Gathering as much information as possible

c) Assessing one's own resources

d) Setting challenging goals for oneself, on the basis of the information and resources

e) Testing one's own abilities

f) Modifying the goals set on the basis of previous experience (one's own and others).

To be personally responsible for the risks involved in the establishment of an enterprise may be considered as one of the important dimensions of entrepreneurial behaviour. Entrepreneurs have, however, certain characteristic attitudes towards risk. Generally, the choice of an occupation is because of the 'fear of failure'. However, in the choice of an entrepreneur, the fear of failure forms the least important consideration. The entrepreneur bears the risk of launching a new business. Nonetheless, while opting for a risk, he does not like to play the gambler.

1.6.1 The Entrepreneur and the Gambler

The difference between a gambler and an entrepreneur needs to be clearly understood for a proper appreciation of entrepreneurial behaviour.

When a gambler takes risks, the person is primarily concerned with the pay off which is solely determined by the result of a "chance". The gambler operates without using the earlier experience. In gambling, such event is independent of any pay off.

On the other hand, even though the entrepreneur also stakes and hopes, he continuously intervenes to influence the outcome. In such a situation, the person is aware that any intervention, even in the most certain situations, makes all the difference to the outcome. Such awareness is confirmed by experience. It would be appropriate to say that an entrepreneur takes only such risks where one cannot control the outcome. The feelings or awareness, which is confirmed that the outcome can be controlled by interventions, marks the demarcating line between gambling and the calculated risk-taking.

In gambling, learning is not possible, whereas entrepreneurial risk-taking is mainly governed by learning. In the former, it is not possible to calculate long-term objective probabilities or odds. Such objective probabilities may be almost denied or not available to the entrepreneurial activity. Only the denial of the objective calculation of risk, however, does not make all the difference between gambling and an entrepreneurial venture. The sense of control, the possibility of learning, and the presence of moderate risk and subjectivity lead to entrepreneurial activity.

1.6.2 Moderate Risk Taking

The concept of taking a challenge or stretching explains better the concept of moderate risk-taking. One takes a challenge if the goal is personally meaningful, the outcome is dependent on one's effort, and the goal is a little beyond one's capabilities, holding in store a lurking possibility of even a failure. The same is true of the concept of' stretching'. One is likely to stretch oneself if the goal appears a little beyond one's reach, if it is personally meaningful, i.e. if it has any personal marginal utility, and its attainment largely depends on one's effort. Stretching results from the hope of success. On the other hand, a person with a low hope of success or a high fear of failure is likely to choose goals, which are well within one's capacity, thereby ensuring a low probability of failure. In the latter case, the concern is not about success or achievement, but about non-failure. Very often, by congenital standards, these people appear to be succeeding. In effect, they have chosen to operate well within their natural capacity. A person operating from the hope of success, however, is likely to increase the capacities because of inclination towards stretching.

1.7 SENSING OPPORTUNITIES

Let us understand yet another important problem faced in entrepreneurial life, “Sensing Opportunity” what is opportunity? It may be a chance to do something new; it may also be a way of getting something for nothing? or it may be a job or admission to a school or college. While these are, no doubt, opportunities, there is another type of opportunity that exists in our environment, which we most often fail to notice. We call it by the general term: problem Problems, pose a challenge to entrepreneurs, and in solving them, they find opportunities. For an entrepreneur it is like saying “If you have a problem, then it is my opportunity”.

Opportunities for launching new enterprises exist in the environment everywhere but all of us are not able to perceive them. Even if we do, we only see an opportunity in retrospect. The good idea was there but it is usually a case of “Why didn’t I think of it first?” Entrepreneurs however, perceive opportunities quickly, synthesize the available information and analyze emerging patterns that escape others. They are people with a vision, capable of persuading others such as customers, partners, employees and suppliers to see the opportunity, share it and support it. For them the opportunity exists, as we have seen before, in the environment in the form of needs and problems of people and society. After spotting the opportunity, they evolve a strategy to find a creative solution to the problem or need.

Apart from perceiving an opportunity that already exists in the environment, it is also possible to create or craft business opportunities. Many great inventions like the microwave and the mobile phones are the examples of created opportunities. They are born out of fantasies of entrepreneurs about products or services they would love to have in their lives. It requires lot of ideas which can be generated. We will now try to understand how these ideas can be generated and what are its sources?

1.7.1 Sources of Idea

By following different ways for generating ideas an entrepreneur collects a number of ideas. The process of generation of ideas can be streamlined by developing awareness for different 'Idea fields'. This helps the entrepreneur in enlarging the scope of thinking, at the same time structuring the ideas according to convenient frames of reference. Thus idea fields can be described as convenient frames of reference for streamlining the process of generation of ideas.

a) *Natural resources*

Ideas can be generated based on natural resources. A product or service may be desired from forest resources, agriculture, horticulture, mineral, marine or aqua mineral, animal husbandry, wind, sun and human resources. A further exercise with a field may generate many useful product ideas. For instance, if we are getting ideas in the field of forest resources, we can think of forest produce, wood-based product, bio-fertilizer etc. Similarly if it is horticulture, we can generate a number of ideas for food preservation, canning, freezing, juices, squashes, pulp, jam pickles etc. Similar exercises can be done with almost all the other natural resources.

b) *Existing products or services*

There is also a continuous and consistent effort on the part of all entrepreneurs to improve the products and services already in the market. When black and white computer screen came into use, immediately entrepreneurs started thinking of introducing colour monitors. There are new techniques and strategies being developed in every service like teaching, medicine, management etc.

So thinking about existing products and services can generate a number of ideas to improve them or to provide a cheaper substitute or to bring about a reduction in price. It can also help in deciding whether similar projects can be established, whether new products can work as raw material for existing units, whether new products can be developed from the waste or by products of existing units and whether there is scope for packaging and other services for existing products. For example, when an automobile unit is established in an area, attempts can be made to ascertain whether a few parts or components for the automobile can be produced in the small scale sector. Similarly where a perfume unit is functioning, there is scope for growing and supplying aromatic plants. Or essential oils can be purchased from existing units and final products such as medicine or cosmetic products can be manufactured. These types of backward and forward linkages of existing business activities are a good source of new ideas.

c) *Market-driven or demand-driven ideas*

We have already seen that one important method for generating ideas is to carry out a market research. Such a study yields valuable data about trends of supply, demand, consumer preferences etc. Sometimes information related to different products is available with associations and organizations, which carry out routine market surveys. Whatever the source of information about the market, it is a promising field for generation of ideas.

For instance, if through a market survey we learn that there is a gap between supply and demand for stationery in the beginning of school or college year, it can be a good opportunity to start a venture using this information. Similarly if the market survey reveals that a particular product is being imported, efforts can be made to find an import substitute. Indian space technology has witnessed a tremendous boost because of the development of indigenous technology.

In the service sector, it is booming time. There are many ideas that have transformed into reality. For instance, too much of pesticides, which is harmful for health, has given idea for organic farming. If for instance, a survey reveals that the call centres which are catering to the international clients are facing problems because of different accents like French, Italian American, a consultancy service to update employees of call centres through training in pronunciation may become a successful project. Similarly, if the market demands more of cheap detergent cakes, it will be a good opening for small-scale entrepreneurs. Though we are looking at market-driven ideas as an important field of entrepreneurial ideas, we should remember that market would always exert its influence on all enterprises. So entrepreneurs in all sectors have to be always knowledgeable about market dynamics.

d) *Trading related ideas*

Trading these days is not limited to ordinary grocers or distributor outlets. With increasing consumerism, the scope and nature of trade has enlarged; local trade, imports and exports, e-commerce etc. are all making trading a very wide area of enterprise. Trade in simple terms is buying goods and services, and selling them to consumers at a profit. One big advantage that trading has over other types of business is that it is easier to launch and less risky.

It is, however, necessary for a prospective trader to be aware of the trends in an economy. With the opening of the market to international companies, large size departmental stores, chain shops and umbrella markets have become ubiquitous – competition has become intense and to survive in the market new entrants will have to acquire skills, competencies and knowledge required to launch, manage and expand business opportunities. The basic concept, as we have already seen, is that if a business is to be successful, it must satisfy a need of enough consumers. A trade that is based on this concept is more likely to be successful than a trade that is launched without adequately studying the consumer needs.

e) *Service sector ideas*

What is the difference between entrepreneurs and employees? We have already examined this issue. Most of the people seek jobs to earn a living. They work for someone else and get salary or wage for their services. Such people are called employees. Entrepreneurs, on the other hand, are both owners and employees. So, when we talk about service sector ideas we should bear in mind this difference. We are not considering different options in service sector to launch a business venture that involves sale of services for a profit. The entrepreneur himself may provide the service sold or he may provide it through his employees. The key element is that he owns the enterprise and is hence ultimately responsible for its success or failure.

As said earlier, entrepreneurial opportunities are not restricted only to the manufacturing field. Service sector is the most growing field these days the world over, thanks to emerging knowledge societies and advances in information technology. Understanding the linkages to different business activities can identify so many new opportunities. For instance, with the existing industrial enterprises we can think of several service-based units like transport, workshop, painting, maintenance, security, catering, recruitment, training, communication etc. Similarly we can get ideas about linkages with commercial establishments like photocopy, courier service, printing, book-keeping, computer centre, telecom centre, advertisement etc. Many services that have the purpose of helping establishments satisfy their day to day needs like bill collection, water supply, water tank cleaning, travel arrangements, repair and maintenance etc. They can provide many useful options for prospective entrepreneurs.

1.7.2 Creating Efforts

We have understood that creativity is an important and key component of the talents and abilities needed for an entrepreneur. Apart from applying creativity to spot and harness opportunities, it can also be applied to develop new products and services. Such a function is often called inventive entrepreneurship. In a sense this field of opportunities overlaps with all other fields. There are basically five ways in which creative ideas can be generated:

1. Develop a new product or service.
2. Improve an existing product or service.
3. Find a new process or resource for manufacturing a product.
4. Find a new use for a product or service.
5. Find new markets for existing products or services.

A very useful concept to bear in mind is that most often creative products and services are born as a result of problem solving. Someone found that while tightening screws on fixtures, over tightening often resulted in damage to the fixtures. Here was a problem and the solution came in the form of a self-adjusting screwdriver, which prevented over tightening. Similarly when doctors found the monitoring of dosage of medicine to be administered to patients on a regular basis through the traditional method using a syringe cumbersome, a pharmaceutical firm developed a new process of implanting the required medicine in the patient for constant discharge of regulated and required dosage into the blood stream. When Israeli farmers faced the problem of raising fruit trees in arid and semi-arid conditions, they developed the now much-in-use drip irrigation system. An enterprising villager in our country adopted this system extensively to produce record yields on farms.

Another type of invention is to produce something completely new like computer, television etc. Even if an entrepreneur does not invent a product or service himself, he can spot good inventions, buy the rights, manufacture the product and sell it. We have already seen an example of this kind of opportunity in Trever Baylis clock-work powered portable radio.

1.7.3 SWOT Analysis

Once an idea for a business gets generated, it is important for an entrepreneur to go in for a SWOT Analysis about the idea. This is important as it helps the entrepreneur to make a feasibility study before starting the business. This is crucial and important.

Let us understand from a case study how a business opportunity can further be analyzed for making a final decision. Read the case and try to do the following exercise.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

CASE STUDY

The Pickle Maker

Ramvati hailed from a village of Uttar Pradesh and was married to Sanatan of Rajasthan. Ramvati always wanted to do some work and earn money to increase the family income. After seeing the women in her village mostly engaged in some activity or the other, Ramvati also thought of making pickle and selling it to the market. She thought it would be a good idea as she knew how to make good and tasty pickle and moreover, she need not have to go out of her house to make it. She may not need to invest a lot of money and the technique needed for making pickle was also very simple.

There was a potential market nearby her village and she thought that her pickle could be sold there. She felt that she should brand the product (like Ramvati Pickle) so that selling becomes easy and fast. She also found out that people in the town and nearby villages use lot of pickle as a regular food habit. She thought she can make a variety of pickles to suit different customers taste – “extra spices”, “sweet pickle” and “pickle of various vegetables”. However, Ramvati realized that the raw materials needed for making pickles are mostly seasonal and therefore, she needs to have a large stock. There was also a problem as pickle can be spoiled if not prepared properly. It has to be consumed very fast. Her husband Sanatan also told her that she needs to go for a licence as it is a food item. Ramvati thought she would visit the market and find out something more about the product. She also discovered that there are many women who are making pickles and selling them in the market. She also realized that people who buy pickles mostly go for a brand name which is common and popular. After coming home Ramvati started thinking whether she should go in for pickle making or not!

Try to fill in the following box. Identify the Strengths, Weaknesses, Opportunities and Threats for the Pickle business for advising Ramvati. This is known as SWOT analysis.

SWOT Analysis

Strengths	Weaknesses
Opportunities	**Threats**

Look at the answers at the end of the Unit.

1.8 ENTREPRENEUR AND ECONOMY

The growth of economy in any country is largely dependent on its people and these people are using resources for a productive purpose. The entrepreneur is an economic leaders. According to Joseph Schumpeter, who regarded entrepreneur basically as an innovator who carries out new combinations to initiate and accelerate the process of economic development, Innovation may assume the following forms :

i) Introduction of new goods;
ii) Introduction of new methods of production;
iii) Opening of a new market;
iv) Conquest of new source of raw materials or half manufactured goods; and
v) Carrying of new organization of any industry.

The innovator differs from the manager of a firm who runs the business on established lines. The entrepreneur is the engineer of change, not its product. Profits are the premiums for innovation and continue only when one keeps one step ahead of rivals with innovations.

Schumpeter's theory is based on certain assumptions like existence of capitalist society with private property, private initiative, money and banking system, etc. The applicability of this theory is doubtful in under-developed countries where the poor infrastructure and lack of capital may block the innovativeness. In such countries even imitator entrepreneurs have a distinct role to play. Such entrepreneurs provide a fillip to the process of economic growth by adopting business practices already discovered and applied. They reduce the shortage of goods and services and create additional jobs for the unemployed.

India is a country where entrepreneurial initiatives are now encouraged. There are lots of institutions, Organisations, both technical and non-technical, are giving training to young people to become entrepreneurs and create job opportunities for others. So, why not become an entrepreneur to bring a positive change to the society.

1.9 FOOD PROCESSING BUSINESS

In order to understand what it means to be self-employed in food processing, let us see what one needs to know and needs to do.

Food processing business has to consider the availability of raw material, quality, packaging, and preferences of consumers. Generally, we all prepare food at home, and also make food items, which are preserved for a long time. In rural and urban areas, men and mostly women make dried, fermented, and fried products for their family consumption. Adding some skill and knowledge of preservation, anyone can start a business in food items.

It is important to have an idea of

First

- Where one could get trained in food processing
- Where one could get training in business management.
- Where one could get awareness business aspects of the project.

Second

- Raw materials
- Availability of raw material in local market
- Availability of the raw material outside local market
- Price
- Transport
- Equipment

Third

- Packaging
- Type of packaging
- Attractive labelling

Fourth

- Storage
- Preservatives
- Space

Fifth

- Marketing the Product
- Distribution
- Publicity

Sixth

- Preparation of Project report
- Arranging Finance

SENTENCE COMPLETION TEST

Tick any one

1. To succeed in life, one needs

   a) money
   b) friends
   c) self-confidence
   d) good luck
   e) skill

2. If there is a good demand, it requires ….. to earn in business

   a) proper instructions
   b) quality product
   c) intensive and good advertisements
   d) capacity to store goods
   e) own control over market

3. My main aim in running industry should be

   a) to keep workers happy
   b) to earn good profit
   c) to improve quality of products
   d) to remain undisturbed by strikes and unrest
   e) to work hard

4. To continue progress, it require

   a) hard work
   b) new and progressive ideas
   c) honesty and trustworthiness
   d) education
   e) systematic and though work

5. He became a successful industrialist because

   a) he knows how to maintain relations
   b) he has dependable friends and relatives
   c) he has vision and enterprising nature
   d) market fluctuations were favourable to him
   e) he is a gentleman and a good businessman

6. I want to start a new business because

   a) I should earn
   b) I would be popular in society
   c) I want to do something new
   d) The state wishes that we should do something
   e) I want to serve my caste and society

7. Slow economic progress of the country is because of

   a) Faulty policies of the government
   b) Lack of good facilities
   c) Lack of someness venture
   d) Labour unrest
   e) Lack of increasing opportunities

8. If I will face difficulties in my work, then

   a) I will leave it and will start a new work
   b) I will take advice of known and proper person
   c) I will think why it happened, and then again will work with new Enthusiasm
   d) I will blame my colleagues
   e) I will blame my self

9. If business fails or there is a loss, then

   a) I shall try to pay less tax to reduce the loss
   b) I will accept it with sportsmanship and try again
   c) I will sell goods at cheaper price so that everything is sold out
   d) I will join with somebody in partnership
   e) I will try to find out who is responsible for the failure

1.10 LET US SUM UP

Deciding a career is important. However, there are lots in benefits in becoming a self-employed person. It generates income and this is responsible for livelihood. It helps to be innovative and growth-oriented. The growth in a self-employed situation reflects certain entrepreneurial behaviour. In this process, an individual learns to imbibe many entrepreneurial qualities and to acquire certain entrepreneurial skills.

'Risk' is inevitable in the life of an entrepreneur "Risk" in other words refers to challenges but the risk taken by an entrepreneur has to be moderate and calculated. However, entrepreneur's risk is different from gambler's risk although gambler also undertakes risk. But remember that an entrepreneur depends on "effort" for the outcome, while the gambler depends on "chance".

The success of an entrepreneur depends upon the goal setting with a hope of success. This leads to stretching to one's own capacity. The capacity would include how one senses opportunity. The sensing of opportunity involves understanding problems in the environment, and identifying a solution, think about ideas, products and services. All opportunities have to be analyzed through SWOT analysis. The feasibility of a business can only be understood through that process.

Becoming an entrepreneur also means a contribution to the economy of a country through new products, new methods, new markets, and new sources of material. This involves innovations. However, in a developing country like India "imitators" can also be entrepreneurs.

1.11 KEY WORDS

Accelerate	:	Begin to move more quickly
Attainment	:	Success in accomplishing
Conquest	:	The action of conquering
Distinct	:	Recognizably different in nature
Gambler's risk	:	primarily concerned with the" pay off" which is solely determined by the result of a "chance".
Imitator	:	Copier of a model
Inclination	:	Natural tendency or urge to act or feel in a particular way
Innovate	:	Make changes in something already existing
Oriented	:	To direct towards
SWOT	:	A process through which the feasibility of a project/business idea is assessed
Sensing of opportunity	:	understanding problems in the environment, and identifying a solution, thinking ideas, products, services.

1.12 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

CASE STUDY

SWOT Analysis Chart

Strengths	**Weakness**
• The Pickle can be made tasty • Low investment • Skills easily available • Simple technology	• Seasonality of raw materials (needing large stocks) • Product is perishable • Licensing formalities are cumbersome
Opportunity	**Threats**
• Large Market • Brand selling possible • Variety could be made to suit customers 'Tastes'	• Large no. of competitors • Establishing brand is difficult • Customer tastes may change

Remember that Weakness can be converted into Strengths and Threats can be converted into Opportunities

Check Your Progress Exercise 2

GET YOUR SCORES FOR SENTENCE COMPLETION TEST

1. To succeed in life, one needs: self-confidence (c)
2. If there is a good demand, it requires: Quality Product (b) to earn in business.
3. My main aim in running industry should be to earn good profit (b)
4. To continue progress, it requires new and progressive ideas (b)
5. He became successful industrialist because he had vision and enterprising nature (c)
6. I want to start new business because I should earn (a)
7. Slow economic progress of country is because of lack of someness venture (c)
8. If I will face difficulties in my work, then I will take advice of known and proper persons (b)
9. If business fails or there is loss then I will accept it with sportsmanship and try again (b)

Make a total of the statements tick marked in the answer sheet by you. Then follow the table given under for final scoring.

Table

0 – 3	=	1 mark
4 – 6	=	2 mark
7 – 9	=	3 marks

Note: If your scoring is in category 7-9 you get 3 marks: **It suggests that your understanding about entrepreneur and entrepreneurship is towards right direction.**

If your scoring is in category of 4 to 6 you get 2 marks: **It indicates medium score.**

If your scoring is in category of 0 to 3 you get 1 mark: **It is a low score.**

In order to improve the score read lot about entrepreneurs, try to meet them, watch Television programmes on them. Try to locate new food products in the market. Try to find their source.

UNIT 2 ENTREPRENEURIAL SKILLS

Structure

2.0 OBJECTIVES

After going through this unit, you should be able to:

- appreciate the requirement of becoming an entrepreneur;
- explain the concept of entrepreneurial skills;
- describe entrepreneurial values, attitude and motivation; and
- state various entrepreneurial skills.

2.1 INTRODUCTION

Entrepreneurship is the quality and skill required to become an entrepreneur. It refers to identifying and innovating ideas and services; mobilizing resources; organizing production and services; and finally marketing them, covering the risk by constantly trying for growth and development.

In this unit we will try to understand the concept of entrepreneurial skill and different skills that an entrepreneur needs to develop.

2.2 THE JOY OF BEING AN ENTREPRENEUR

In the previous Unit you have understood who an entrepreneur is. However, let us also understand the joy that a person gets after becoming an entrepreneur. In entrepreneurship the individual is the most important element. He/she takes a decision to start an enterprise and strives to make it a success. In this process, it is an experience of challenge, joy as well as fulfilment. Let us look at the reasons why this is an experience of fulfilment.

- An entrepreneur is an independent being; entrepreneurship provides an opportunity for self-expression and the realization of one's passion for doing something new and different – a scope for innovation.

- There are numerous opportunities for self-development.

- An entrepreneur makes his/her own decisions and acts on them.

- Working on one's own and thus getting rewards yields immense satisfaction and pleasure for more than what one can get in a job.
- Monetary rewards can be more that commensurate with one's capacity, capabilities and work.
- An entrepreneur with a science and technology background can introduce new technologies, develop substitutes for imported components.
- An entrepreneur generates employment for others.
- An entrepreneur can make significant contributions to the development of the country.
- An entrepreneur can be doubly fulfilled. He/She realizes both goals, of individual success as well as of contribution to society.
- Above all he/she can be an achiever, realize his/her goals and prove his/her one's achievements to the world.

The following example shows how a person with determination and strong desire to be on his own can become an entrepreneur and be successful:

Balachandran was born in a lower middle class family of Madurai. He completed his graduation in commerce by attending evening classes and doing part-time jobs during the day. Later, he worked as a part-time accountant and also became an insurance agent. He left this job due to some problems and enrolled himself in a post-graduate course in Commerce. But his heart was not really in it. It was at this time that he came across an advertisement for an Entrepreneurship Development Programme (EDP) to be organized by ITCOT (Industrial and Technical Consultancy Organization of Tamilnadu Ltd.) He applied for participation in the same and was selected. During the EDP he identified a project, but could not mobilize the financial resources needed. However, he was determined to set up his own industry and with this objective he left for Chennai in 1988 with just Rs. 500 in his pocket.

He was unfamiliar with that city, but somehow found an inexpensive place to stay. In order to servive, the first priority was to earn some money. With some knowledge about the market for used cartons, he purchased used empty cartons at a cheap rate from liquor shops and sold them. This went on for some time; then through a friend he got a job, as an assistant to a commercial artist, which paid him Rs. 300 per month.

But his ultimate aim was to establish his own enterprise. So before joining he tried to find out whether a job would provide him experience, which could help him, set up his own enterprise. When he found that there was a good market for advertising, he joined. His job was to procure orders for the artist and on the very second day of his employment, he procured a very large order. But his salary was too small to survive on, so he procured small orders for himself on the side and executed them. Very soon, dissatisfied with his salary he took up another job with a liquor company inspecting liquor shops, but continued with his work for advertising companies. And when he felt that he had enough work to survive on, he resigned his job.

In December 1988, with a sum of Rs. 24,000 borrowed from his brother-in-law, he was finally able to launch his own advertising enterprise in rented premises. The first order was from Kwality Ice Cream. Working capital was a problem, but with persistence he obtained Rs. 5,000 from a bank. Fortunately the machinery and equipment required were few and not very expensive, so he had some money left over for the working capital. The business grew steadily.

By 1990, he had diversified into acrylic glow sign boards and was executing orders for big companies like Cadbury's, Kwality Ice Cream, etc.

He thus grew steadily, took more loans from banks, diversified into name plates, menu boards, engraved works, screen-printing and bulk order paintings.

From humble beginnings, step-by-step, with hard work and perseverance, today he is an entrepreneur with a turnover in lakhs. Two years ago he launched a confectionery unit. But the story does not end there for Balachandran. He has ambitious plans for setting up other industries too, and with his skills and motivation, he is bound to succeed and realize all his dreams.

So, does this case motivate you to become an entrepreneur?

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

Tick the right answer

1. Do you feel motivated? … (Y/N)
2. Do you sincerely believe that you have to work hard? … (Y/N)
3. Can you identify some entrepreneurs, from your surroundings, who are reaping the fruits of their labour? … (Y/N)
4. Do you put your belief into action? … (Y/N)
5. Can you identify the types of work you have to do? … (Y/N) List them.
6. Can you work for long without getting tired or bored? … (Y/N)
7. If the answer is 'NO' to 7, have you adopted any strategy to improve it? … (Y/N)
8. Is your work related to the attainment of your goal? … (Y/N)
9. Do you call yourself a hard worker? … (Y/N)
10. If 'Yes' to 9, do you have reasons for thinking so? (Y/N) Write down the reasons.
11. Is there any gap between how you want to pass a day and how you actually do it? … (Y/N)
12. Have you mastered the play theory of work? … (Y/N)
13. If 'Yes' to 14, do you have any concrete evidence? (Y/N) list out the evidence.

2.3 WHAT IS REQUIRED TO BE AN ENTREPRENEUR?

Once you are motivated you will start your business. It is often said that in order to start a business one need to have three things: knowledge, attitude and skills. For example, if a person wants to start a fruit juice corner, he should have proper knowledge about "processes" involved in fruit juice making. What kind of fruits make juice, in what season, which fruits are available etc. are the knowledge part. Apart from this the skill to prepare fruit juice, using machinery etc. is important, this is the skill part. To prepare oneself, to 'Be' a fruit juice stall owner, to have the right mind set and willingness to be independent and value each and every job involved in this business. This is referred as attitude.

It is the attitude that matters

Why is it so? There is nothing wrong with rummy or any other thing. The difference lies in the attitude of the players. You associated the idea of boredom with rummy because you learnt to hate it; others associated it with pleasure as they learnt to love it.

It is implying this. Turn the switch in your mind. The boring job turns out to be the most interesting: Change! Does it come easy? With time, anybody can change. Given the will, you too can change!

You have to change your attitude. You have to find interest in your work – whatever you are called upon to do. It is all because you have not got used to it at all. That is why it is wasted. Start using it and interest will develop.

Right now start finding your work interesting and enjoyable. No matter if it does not seem to be so. You simply start thinking it is wonderful. You know that drops of water wear away the hardest of stone. Likewise, each day of your practice will carry you closer to your goal.

Every day, while you work, try to visualize the goal you are striving for. Each spell of work will take it nearer to its fruition. The intensity of your desire should be so strong that it will take away all the rigours of your so-called hard work. Then it will turn into mere play and sheer fun. Imagine, feel and experience that fun, that joy!

Make work fun!

Believe that you can do it!

Start doing it right now!

Brush aside the initial difficulty, if any!

Create enough zeal and enthusiasm for your work!

Each day, conquer it with greater determination!

A simple book on 'Yogic exercises' warns the beginners: "In the beginning, you will not be able to perform some of the poses perfectly. Regular practice for some days will bring perfection. Patience and perseverance, earnestness and sincerity, are needed."

Contd…

We interviewed a circus star. Since childhood, she had put in many years of strenuous practice. It took time, patience and devotion to achieve perfection. Practice makes for perfection.

Entrepreneurs who are already successful, about whom you hear or read stories, benefited from many years of informal training. Real education does not necessarily mean university education, alone.

These many years of informal training you do not have. And in your case, it is this training we are going to replace with a compressed course. Naturally, you can imagine the importance of following each instruction faithfully, as well as the amount of work you have to do in order to obtain the desired result in the shortest possible time.

There is another difference. Our entrepreneurs had their informal training in its most natural form, whereas you have to be deliberately induced into it. Therefore, quite possibly, you may have to exert a lot more than they did.

That is why it is all the more important that you should turn the tedious task of exertion into an interesting play. Obviously it has other benefits as well. That way, you will learn better and quicker. It should provide an ideal substitute for another man's informal training.

2.4 CONCEPT OF ENTREPRENEURIAL SKILLS

If you decide to become an entrepreneur, it is natural that you need to develop certain entrepreneurial skills to translate your dreams into action. What are these skills and how they are developed are certain questions that might bother you. However, we will first try to understand entrepreneurial skills.

Entrepreneurial skills refer to the ability and the capability of an entrepreneur to initiate, launch and sustain the process of enterprise building. These skills are not necessarily born but can be developed.

However, these entrepreneurial skills are the result of certain set of values, attitudes and motivation.

2.4.1 Entrepreneurial Values Attitudes and Motivation

Values

Values refer to one's own belief towards life in general. It helps an individual to focus towards goal. However, some of the entrepreneurial values are as under:

- Innovativeness
- Independence
- Seeking Perfection, and
- Respect for work

Attitudes

Attitude refers to ones own in born and developed tendency to think and act in a particular way. The entrepreneurial attitudes are:

- To use imagination/intuition
- To take moderate risk
- To enjoy freedom of expression & action
- To look for economic opportunities
- To find satisfaction from successful completion of tasks
- To believe that one can change the environment
- To take initiative
- To analyse situation & Plan Action
- To involve in work

Motivation

Motivation is generally understood as the driving force towards the attainment of the goal. Because of certain entrepreneurial values and attitudes specific motivations get developed within a person. Such as:

- Constantly striving for success in attaining certain standard of excellence.
- Desire to set some standard and to excel it.
- Need to excel the standard already set by others.
- Concern for achieving something unique.
- Urge to succeed in achieving long-term career goals.
- Need to influence environment, individuals & situation for achieving set goals.

In the next unit you will know more about Motivation with particular reference to Achievement Motivation.

2.4.2 The Work Ethics

The Primary Motive of an entrepreneur is related to his/her work or task and therefore, the basic philosophy of work is important for an entrepreneur. Let us understand about the work ethics.

Who works? The man who has a need. Everybody in the world from a Sadhu and a politician down to the writer, builder and carpenter, and whosoever, works with a motive. There is no work without a motive. Not even the so-called “nishkama karma”. However, motives differ from man to man. A sadhu has a motive different from that of a politician.

We are mainly concerned with economic motives. We are interested in economic wants and our work is economically directed towards productivity, prosperity and plenty.

Want, necessity, need or desire – whatever you may call it – is the great force behind all human motivation. No skyscraper would have been built, nor better living conditions created, had there been no felt-need.

Needs may arise because of:

a) a desire for material gain;

b) a desire for winning love;

c) a desire for gaining a sense of freedom and power;

d) a desire to be better than your neighbour;

e) a desire for social and national service;

f) a desire for self-expression and recognition.

Identify the ground (or grounds) for your need. Specify them. This will serve as your motivators.

The biggest source of energy – far greater than all potential sources of energy combined together – mankind could so far find, is the desire of the human heart. It fuels the gigantic engine of progress. Any man fuelled by the fire of desire moves to ever greater achievement. The man devoid of the fire of desire rots in the same groove he was born.

Invent your necessity

Invention is not first. Necessity is the first. And desire comes ahead of development.

In order to rise higher, to achieve greater success, develop your fuel first. Before you build anything, build up as your desire.

L.N. Kirloskar was a petty drawing instructor at Victoria Jubilee Technical Institute (VJTI), Bombay. Since the time of Kirloskar, if not earlier, many such drawing instructors retired from service and died as drawing instructors. At present, a few hundreds, if not more, such instructors are serving in different institutions in the country. Probably they too will retire and die as drawing instructors.

But Kirloskar did not retire as a drawing instructor. And he did not die too as one because he had the courage to desire something much more than the pittance he was getting at VJTI. He had a dream to fulfil. He had the will to work for it. As a result he died as a renowned industrialist. Remember, today's conditions are much better than those in Kirloskar's time.

Y.R. Nanda was a small-time trucker. He fell in love with a girl named Dolly. She told her young fiancé in plain terms that she would never marry a truck driver'. Nanda set up Escorts Limited in 1949 in order to win his fair lady's hand. This is no fairy tale. It is a true story.

It does not matter what you are at present. It matters what you want to be.

Spell out your wants, necessities and desires. Make them strong and intense. If you are armed with a burning desire, only then will you be able to work wholeheartedly with a tenacious singleness of purpose, and win. The stronger the desire, the higher you will reach.

2.5 UNDERSTANDING ENTREPRENEURIAL SKILLS

In order to initiate, launch and manage the enterprise, the entrepreneur is motivated to imbibe certain skills. Let us try to understand these skills, which are important for success.

Positive self concept

An achiever directs his energies towards accomplishment of worthwhile goals and sets standards of excellence in what he is doing. This is based upon the awareness of his strengths and weaknesses. He uses positive knowledge to support his thinking. He is rarely negative. He has self-confidence.

No entrepreneur has all these qualities. But most of them possess at least some of them. So the first step for a person aspiring to entrepreneurship is to make an inventory of the traits he possesses. This self-awareness analysis will help define your strengths and overcome your weaknesses.

Creativity and innovation

The anchor of an entrepreneur's career is creativity and innovation. Innovation is the process of applying **"new knowledge"** to practical use. It does not necessarily mean trying new ideas for the first time but it also means applying the same or a similar idea at different places or in new settings. As an entrepreneur you may have to develop the quality of picking up new ideas and adopting them faster than others.

Risk taking

Many of us have new ideas, knowledge and resources. But we do not start an enterprise because we lack the quality to take risk involved in it. As an entrepreneur you have to develop faith. No venture is possible without certain amount of risk. An entrepreneur assesses the risk and favours taking calculated moderate risk (neither very high nor very low). Risk means stretching ones own capacity where the chance of success is greater than the chance of failure.

Using feedback

Entrepreneurs like to have immediate feedback on their performance. They seek prompt and accurate data, and it does not make any difference whether or not the information they get is favourable. In fact, they are stimulated by unfavourable feedback into pouring more energy into attaining their objectives.

Opportunity seeking

Common people just wait for opportunities to come along. Majority does not even recognize opportunities until these become obvious. An entrepreneur actively looks for, seeks, recognizes or creates business opportunities even under crisis.

Information seeking

Seeking relevant and precise information is important for success. It enables you to take risk, helps improve the quality of decision that you make and provides basis for efficient management. An entrepreneur inculcates the habit of gathering information from all sources and considers expenses for seeking information as investment.

Being high achiever, an entrepreneur has ability for seeking and using feedback about his own performance. Based on the feedback, the person mends his ways. Often money (profit or loss) is an indicator of the performance.

Concern for standard/quality of work

The concern for excellence is the key quality of an entrepreneur. By attaining certain standard of excellence in his work, and proving his worth he gets satisfaction. Sub-standard performance is not acceptable to him. The standard of work performance is not limited to products and services, but extends to efficiency, to do things better, faster, with fewer resources.

Problem solving orientation

One of the important entrepreneurial qualities is the problem-solving orientation. While pursing any business goal, an entrepreneur makes the basic assumption that problems are bound to be there. As a matter of fact, he believes that real pleasure comes in solving these problems. Accordingly, entrepreneurs develop a lifestyle of solving problems.

Faith in planning

To be a successful entrepreneur you need to develop skill in planning and a firm faith that planning is a must for successful completion of any task. You develop and use logical step-by-step plans to reach your goal. Through planning an entrepreneur prevents the wastage of scarce resources, ensures success by anticipating possible hurdles, locates new sources of help and resorts to alternative activities to reach the goal.

Persuasive and influencing quality

One of the important functions is to influence the environment comprising individuals and institutions for mobilizing resources, procuring information, organizing production/services and marketing your products and services. For all these you need to develop skills and attitude for persuading, influencing and convincing others.

Long term commitment

This is one of those characteristics, which distinguish you as an entrepreneur, as the creator and builder of an enterprise from the promoter of quick money. The commitment to a long-term entrepreneurial goal helps an individual to give highest priority to getting jobs completed.

Coping with stress

As a central figure in your enterprise, you will have to cope with many situations at the same time and make the right decisions, which may involve a lot of physical and emotional stress. All this can be done, if you have the capacity to work long hours and keep cool under a lot of tension.

Check Your Progress Exercise 2

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

CASE STUDY

Let us study the case of Ajay. Can you list out some of the qualities in him which have made him a successful entrepreneur.

Story of Ajay

Ajay after his higher secondary started working in a Private Company. However, he nurtured a dream to have his own enterprise. The training during November, 2001 in an EDP on Food Processing organized by a consultancy organization helped his dream to be come true with the aid of Cooperative Agricultural and Rural Development Bank Ltd. Ajay set up his enterprise “DELICIOUS” Food products in December 2001 at village Hariharpur, (Midnapore). However, like any other entrepreneur, he had initial difficulties in launching the enterprise. This process made him strong and determined and he was able to start the enterprise with an initial investment of Rs. 2 lacs with a matching loan of Rs. 2.50 lacs. He collected information about a machine developed by IIT Kharagpur at the Department of Food and Technology; this was a motorized oil-extracting machine, which he felt would help him to create a healthy snack item. The capacity per day of this machine was 300 kgs. He purchased the raw material from the wholesale market of Kolkata as quality and cost effectiveness were his prime concern.

The food item that he produced got picked up by the market and within a period of 2 years, the unit could establish its identity and reputation. For Ajay there was no looking back and he expanded his market to Bihar and Orissa, apart from the local market and identified about 26 distributors with 19 full time workers. As time passed, Ajay expanded his business and identified more smack items. After a training program me during March 2002 by the KVIC, he decided to diversify his business. His colleague Vipin, a Food Processing Expert of Kolkata helped him to add value to his product.

At the present moment Ajay is happy with his reputation in the market but the fund flow and cash liquidity is not helping him to fulfil his next dream. He is aware that these are the problems of any business when it grows and he has to persevere.

Ajay is ready with his new venture of starting a unit of grinding mill with Vipin as his partner. The Bank is ready to finance the Project but is insisting on a market study done by an established organization. The dilemma at this stage for him is whether to invest money on a Market Study or to concentrate on present business. He strongly feels that this consultancy organization being the Promoter of his initiative should give him concession in consultation charges. The journey to becoming an entrepreneur has made him tough and he is open for negotiation.

Perhaps it is time for Ajay to consolidate his business strategy and review the marketing expansion for his principal business. For an established entrepreneur nothing comes free, but perseverance is tested.

(Case extracted from a report of NIESBUD)

In case you have identified a few skills in Ajay, Check the same with the answers given at the end of the Unit.

Check Your Progress Exercise 3

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

"Entrepreneurial Skill Assessment Quiz"

This quiz is designed to determine the latent skills in you. Read each question and respond by indicating 'T' for true or 'F' for false. Give your immediate reaction. Be completely honest so that the quiz will really be useful to you. Complete the quiz in one sitting free from distractions.

True/False

1. When faced with a problem, I always find a new way of overcoming it ________
2. When a decision has to be made, I can make it easily even though I am not sure of the outcome ________
3. I have a strong need for social interaction ________
4. After learning how to do something right the first time, I don't change my approach ________
5. I have a plan where I want to be financially ten years from now ________
6. When I am placed in a new situation at work I quickly sort out what needs to be done ________
7. I see potential problems as challenges ________
8. Constantly having to deal with problems wears me down ________
9. I revise my goals from time to time in the light of changing situations ________
10. It is important for me to know that I have a dependable income ________
11. When I am dealing with a problem, I tend to to get struck easily ________
12. If I were laid off, I know I could find some other source of income ________
13. I thrive on the challenge of solving different problems ________
14. I don't enjoy being directed by others ________
15. I take courses on how to improve what I do ________
16. Once I've met a challenge I am usually satisfied and don't need to look for an other project ________
17. I normally start off my day with a list of things to do ________
18. I don't enjoy working alone ________
19. The fear of losing my job causes me great apprehension ________
20. I am not good at dealing with a multitude of problems at the same time ________

21. I consider myself to be very resourceful in tight situations __________
22. I usually have a plan of action before starting a project __________
23. I am good at finding creative ways of solving problems __________
24. The idea of being my own boss appeals to me __________
25. At times, I don't feel completely comfortable with myself __________
26. I worry about what will happen if my plans to do not work out __________
27. When I come up against un-expected obstacles, I prefer not to continue __________
28. I have a strong desire to improve myself in everything I do __________
29. I read books on how to achieve success __________
30. I need to keep taking on challenges and feeling myself overcoming them __________
31. I think of a glass as being half-empty rather than half full __________
32. I get disappointed when things do not go my way __________
33. I believe in the saying "If anything can go wrong, it will" __________
34. My friends would call me an optimist __________
35. I always look at the bright side of the life __________

2.6 LET US SUM UP

Most individuals are looking for many things when they venture out on their own. Some of the charms of becoming an entrepreneur are:

- Opportunity to gain control over your own destiny
- Opportunity to realize your full potential
- Opportunity to reap unlimited profits
- Opportunity to contribute to society and be recognized for your efforts.

To become successful as an entrepreneur, one needs to have specific skills. These skills get developed in a person by certain set of values, attitudes and motivation. Values are certain beliefs, which give direction. Attitudes are defined as certain tendencies to act. Motivation is the driving force, which helps an individual to acquire certain skills, which are functional, and helps the individual to perform.

The entrepreneurial skills are important as they help the person to prepare himself for the external environment. These skills can be learnt and can be developed through proper training and interventions. Some of the skills are important to launch any business whereas some are important to manage the enterprise. or example seeking and using feedback, concern for standard/ quality work, problem solving orientation, persuasive and influencing talents are very important in sustaining the entrepreneurial initiative.

2.7 KEY WORDS

Entrepreneurship : The quality and skill required to become an entrepreneur.

Entrepreneurial skills: The ability and the capability of an entrepreneur to initiate, launch and sustain the process of enterprise building.

Values : One's own beliefs towards life in general

Attitude : One's own tendency to act towards the goal and direction.

Motivation : The driving force towards the attainment of the goal.

Innovation : The process of applying "new knowledge" to practical use.

Risk : Stretching one's own capacity where the chance of success is greater than the chance of failure.

Persuade : Cause another to do or think in a desired way through reasoning or argument.

Convince : Cause another to believe firmly in the truth of something.

Influence : The capacity to have an effect on the character or behaviour of someone or something, or the effect itself.

Achievement Orientation : Desire to do something, which is new or better, and to be the best in competition.

2.8 ANSWERS TO CHECK YOUR PROGRESS EXERCISEs

Check Your Progress Exercise 1

Clues

1. It should be a continuous process.
2. For 2 to 11, 13 and 14, a "Yes" answer indicates good progress.

   For 11 and 14, proofs will confirm your 'Yes' answer.

   Any contradiction among 6, 9, 10, and 11 will indicate that you are not able to judge yourself properly.

'No' answer in 12 proves that your action and will are perfectly matched. Your will power is quite strong. Keep it up.

A 'Yes' answer to 12, you have to take remedial action for reducing the gap.

Check Your Progress Exercise 2 – Case Study

Story of Ajay

The following qualities\skills have made Ajay an Entrepreneur.

- Having a dream (Achievement Orientation)
- Strong
- Determined
- Hard Working
- Information seeker
- Long-term commitment
- Risk Taker
- Persevering
- Problem Solver
- Planner
- Persuasiveness

Check your Progress Exercise 3 – Self Exercise

Check Your Score

(Tick mark as per your response True\False)

SKILLS

Innovation	1(T), 4.(F), 11(F), 5(T), 21 (T)
Tolerance to Uncertainty	2(T), 6 (T), 10 (F), 12 (T), 19. (F)
Desire for Independence	3(F), 14 (T), 18 (F), 24 (T), 25 (F)
Continuous Goal Setting	15.(T), 9 (T), 16 (F), 17 (T),, 20 (T)
Persistent Problem Solving	7 (T), 8 (F), 13 (T), 22 (F), 23 (T)
Achievement Oriented	26 (F), 27 (F), 28 (T), 29 (T), 30 (T)
Positive Outlook	31 (F), 32 (T), 33 (F), 34 (T), 35 (T)

The result

Add up your tick marked scores in each category of skills. The score obtained may help to understand your position & status on different skills. If your score is 5, congratulations!! If your score is less than 3 it suggests that you need improvement in that skill. Find out the way for developing the same. However, the next unit will help you to see the way of developing these skills.

6. Nalinaksha Mutsuddi (1996) You Too can become an Entrepreneur, Wheeler Publishing.

7. Raju, U.B. and Rani, C. (Ed.) (2002) Women Entrepreneurs in India, Published.

8. Raymond, W.Y. Kao Tan Wee Liang (2001) Entrepreneurship and Enterprise Development in Asia, Prentice Hall.

UNIT 3 DEVELOPING ENTREPRENEURIAL SKILL

Structure

3.0 OBJECTIVES

After going through this unit, you should be able to:

- explain the stages of developing the mind set for becoming an entrepreneur;
- describe about Locus of Control; and
- state the steps of planning for success.

3.1 INTRODUCTION

As we have understood from our previous units that it is possible to acquire Entrepreneurial skills, in this unit we will understand the process of acquiring them. Remember the saying" GOD help those who help themselves" it holds true in the case of becoming an entrepreneur.

3.2 RIGHT MINDSET

In order to become an Entrepreneur, all you need to develop is the right mindset, the appropriate knowledge and required skill. I am sure you will agree that it is not so difficult to collect information in the era of internet, apart from books and journals, which are the old device. Acquisition of skill related to business function is important and it can be learnt. However what is most crucial in this is to develop a right kind of mindset. Let us look into the following.

3.3 STRATEGY TO BRING DESIRABLE CHANGES IN THE "MIND SET" THROUGH TRAINING

It is possible to bring desirable changes through a purposeful training intervention. We have talked about this in the previous unit. The specialist trainer organizes specialized training. However the major responsibility lies with the learner for this to succeed. The attempt is made to provide an opportunity to explore the "Behaviour "and experiment with new Behaviour conducive to entrepreneurial performance. These lead to getting entry into the process of "self- learning" and "self-acceptance". Now let us understand this process of change, during training

3.3.1 To Know "What You Are?"

The question could be answered in a variety of ways. One of the ways commonly followed is the attempt to reflect oneself keeping in view the image of an achievement-oriented person. In such a situation it is possible to visualize an "ideal self"; against the "real self" i.e. what is reality or the real image? The gap between the ideal self & the real self sets the Process of change in motion. It is possible to realize the gap and enhance willingness to fill up the gap through action. For example, Raju's real self is that he hates math's, but the ideal self is that he wants to become a Chartered Accountant. Now it is for Raju to fill this gap by taking steps.

Let us examine the steps:

- Reviewing one's failures and successes, fears and aspirations.
- Looking at the relation between one's own desires and what society. (Family & Culture) expects.
- Examining one's characteristic modes of behaviour resulting from understanding, attitude, opinions and beliefs.
- Looking at the self through the eyes of others.
- Studying fantasies\dreams and the actual behaviour.
- Identifying the internal potentialities.

3.3.2 To Know Your Destination

Once you know or discover the discrepancy between the ideal and real self it may create enough anxiety or discontentment and you may soon desire to change towards the ideal. This is important, as through discontentment, you may like to find alternative solutions. For this the following aspects may be kept in mind.

- Explore alternate ways of thinking and action and collecting factual information in relation to the consequences of these choices.
- Ensure quick feedback concerning the new Behavioural patterns and understand their significance.
- Evaluate progress in the desired direction.
- Try out the new Behavioural pattern in the real world outside the training experience.

3.3.3 To Believe that You Are The Master of Your Own Destiny

Fundamental to all the other conditions for change is growing conviction in you that you can change, take control and direct your own life. There are different ways through which any person can realize how powerful he is, rather than a pawn being pushed around by others. Try this simple strategy to bring about:

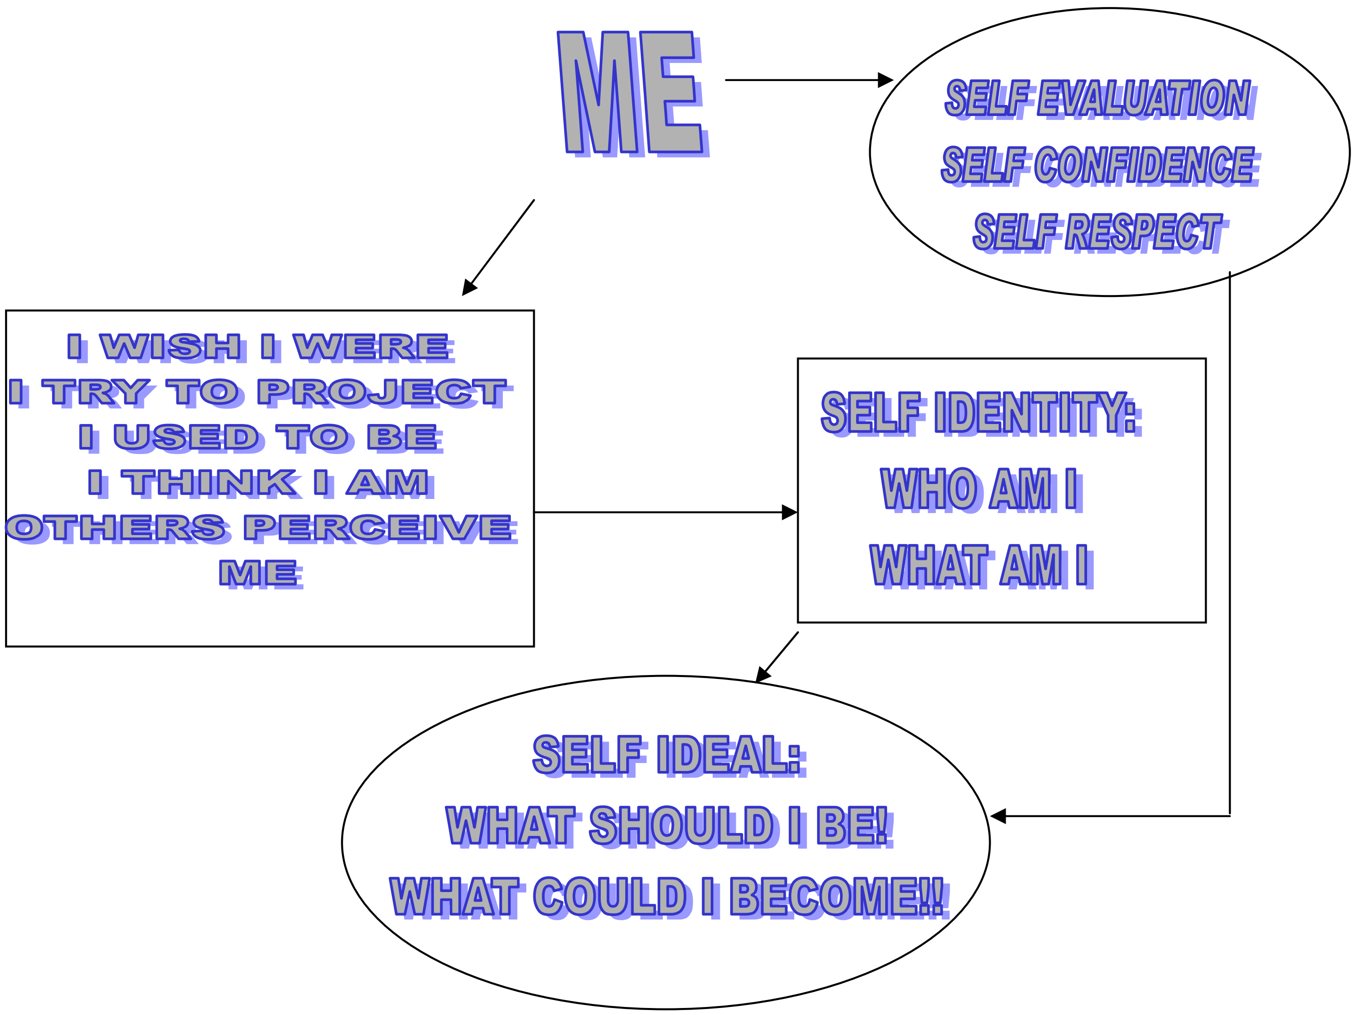
- Have belief in your capacity to help others and to learn from others.
- Have a constant desire to strive for change.
- Take a decision regarding pursing any change on your own rather than following prescription by others.

These will facilitate your thinking and help you towards building an entrepreneurial profile. Any desirable change in thinking will lead towards actions conducive to entrepreneurial performance.

3.3.4 To Develop a Positive Self Image

In order to develop an image of self, let us look at this diagram. The central focus is **'ME'**. This 'ME' is formed on what I think about myself, what I wish to become, how others perceive me and most important how I project myself. Based on this, I develop my own identity of "Who I am". However, this ME constantly goes through a continuous self-evaluation, which contributes to self-confidence and self-respect. Based on this evaluation the "Ideal self" is formed which helps the person to move forward towards the goal.

Remember this can make a person more focused. This leads to self-effectiveness and increased internal power or control.



Research has shown that a person desiring to be an entrepreneur has a goal where he is continuously engaged in some activity rather than just aiming at a goal where there is a lack of clarity. Further it has been found that such persons have tendency to solve rather than avoiding problems. They possess internal resources in the form of confidence, ability, capacity etc. rather than depending upon external resources or have a feeling of lack of resources. Similarly they are found to take initiative rather than wait for a direction from others to do the task. A content analysis of the essay on "Who I am?" can help in understanding and developing this concept.

3.4 LOCUS OF CONTROL

What is Locus of Control?

It means that the factors responsible for any event or an outcome of any action. The responsibility may be of external factor or internal factor. The internal factor may be under one's control but the external factor is not within one's control.

Let us take an example, Ravi has not scored well in his 10th Board exam. This is an event. Now for Ravi, he may justify the outcome in three ways

a) The paper was tough
b) I did not prepare properly for the exam
c) My luck was bad

For the response (a) and (c) the locus of control is **external** and for response (b) the locus of control is **internal**.

The persons who are more internal are more effective in whatever they do in their lives. They perform better than others as they believe in their own potential.

3.4.1 Effort, Performance and Outcomes

Let us try to understand the diagram further:

The relationship between self-effectiveness and locus of control and their effect on performance may be best summed up in the following diagram:

Effort (E) leads to performance (P), which then leads to outcome (O). An individual's belief that if they exert effort they will succeed, is their self-efficacy. Locus of control on the other hand, is their belief that they can perform in such a way as to achieve the desired outcome

$$E \xrightarrow[\text{Efficacy expectation (Self-efficacy)}]{\text{Leads to}} P \xrightarrow[\text{Outcome expectation (Locus of Control)}]{\text{Leads to}} O$$

It is possible to assess one's self-efficacy and plan for necessary changes if required. A simple task of writing an essay about "who I am" brings out significant dimensions, which are as follows: -

- Goal Setting
- Tendency to solve problem
- Locus of resources
- Source of initiation

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

LOCUS OF CONTROL - THE ENTREPRENEURIAL ORIENTATION INVENTORY*

Instructions: This Inventory contains twenty pairs of statements. In each pair, you may agree with one statement more than the other. You have five points to distribute between the two statements in each pair, to indicate the extent to which you agree with each of the statements. You may distribute the five points in any combination (0-5, 1-4, 2-3, 3-2, 4-1, 5-0). If you agree slightly more with statement "a" than with "b", then assign three points to "a" and two points to "b". If you agree completely with "a" but do not agree at all with "b", assign five points to "a" and zero to "b".

You may not divide your points equally (i.e., 2.5) between the two choices. You must choose one statement with which you agree more and then distribute the points.

		Points
1.	a) How successful an entrepreneur will be depends on a number of factors. One's capabilities may have very little to do with one's success.	....
	b) A capable entrepreneur can always shape his or her own destiny.	....
2.	a) Entrepreneurs are born, not made.	....
	b) It is possible for people to learn to become more enterprising even if they do not start out that way.	....
3.	a) Whether or not a salesperson will be able to sell his or her product depends on how effective the competitors are.	....
	b) No matter how good the competitors are, an effective salesperson always will be able to sell his or her product.	....
4.	a) Capable entrepreneurs believe in planning, their activities in advance.	....
	b) There is no need for advance planning, because no matter how enterprising one is, there always will be chance factors that influence success.	....

5. a) Whether or not a person can become a successful entrepreneur depends on social and economic conditions. ……….

   b) Real entrepreneurs can always be successful, irrespective of social and economic conditions. ………..

6. a) Entrepreneurs fail because of their own lack of ability and perceptiveness. ……….

   b) Entrepreneurs are bound to fail at least half the time, because success or failure depends on a number of factors beyond their control. ……….

7. a) Entrepreneurs are often victims of forces they can neither understand nor control. ……….

   b) By taking an active part in economic, social and political affairs, entrepreneurs can control events that affect their businesses. ……….

8. a) Whether or not you get a business loan depends on how fair the bank officer you deal with is. ……….

   b) Whether or not you get a business loan depends on how good your project plan is. ………..

9. a) When purchasing raw materials or any other goods, it is wise to collect as much information as possible from various sources and then to make a final choice ……….

   b) There is no point in collecting a lot of information; in the long run, the more you pay, the better the product is ……….

10. a) Whether or not you make profit in business depends on how lucky you are. ……….

    b) Whether or not you make a profit in business depends on how capable you are as an entrepreneur. ……….

11. a) Some types of people can never be successful as entrepreneurs. ……….

    b) It is possible to develop entrepreneurial ability in different types of people. ……….

12. a) Whether or not you will be a successful entrepreneur, depends on the social environment into which you were born. ……….

    b) People can become successful entrepreneurs with effort and capability irrespective of the social strata from which they originated. ……….

13. a) These days, people must depend at every point on the help, support, or mercy of others (governmental agencies, bureaucracies, banks, etc.) ....

b) It is possible to generate one's own income without depending too much on the bureaucracy. What is required is a knack in dealing with people. ....

14. a) The market situation today is very unpredictable. even perceptive entrepreneurs falter quite often. ....

b) When an entrepreneurs' prediction of the market situation is wrong, that person can blame only himself or herself for failing to read the market correctly. ....

15. a) With effort, people can determine their own destinies. ....

b) There is no point in spending time planning or doing things to change one's destiny. What is going to happen will happen. ....

16. a) There are many events beyond the control of entrepreneurs. ....

b) Entrepreneurs are the creators of their own experiences. ....

17. a) No matter now hard a person works, he or she will achieve only what is destined. ....

b) The rewards one achieves depend solely on the effort one makes. ....

18. a) Organizational effectiveness can be achieved by employing competent and effective people. ....

b) No matter how competent the employees in a company are, if socio-economic conditions are not good, the organization will have problems. ....

19. a) Leaving things to chance and letting time take care of them helps a person to relax and enjoy life. ....

b) Working for things always turns out better than leaving things to chance. ....

20. a) The work of competent people always will be recognized. ....

b) No matter how competent one is, it is almost impossible to get ahead in life without contacts. ....

3.5 ACHIEVEMENT MOTIVATION

Motive

The basic question 'What is Motive?' has to be answered and understood before we discuss the various motives characterizing human behaviour and development. To put it in simple language, 'motives' can be defined as various psychological needs in varying degrees of strength which are reflected in the continuous concerns an individual has, and his thoughts as occupied with such concerns.

What is important for you as an entrepreneur is one motive and that is the motive for achievement. Achievement motivation can be described as 'an urge in an individual to do something new, unique, an urge to excel in what he/she does and a long term involvement'. Before you move on you must understand that achievement motivation is necessary.

Though we are mainly concerned here with achievement motivation as related to entrepreneurship, we feel that you should know something about the sources of development of achievement motivation. They are:

Literature

As children, whatever we see, hear or read, influences us and our life. And when we grow up, our motivation depends on what we were exposed to in childhood. If we have been exposed to literature in any form which instills in us a desire to be independent, we exhibit a motivation to take our own decisions, to do something worthwhile in life, to have a goal, be an achiever. And this is further reinforced by what we read, see or hear, as well as our environment, as adults. To quote an example of a country, Japan, after its crushing defeat in the Second World War bounced back to become a rich and highly industrialized country. The reason was the literature which reflected the values of hard work and achievement in life.

Research in the field has shown that achievement motivation, as found in stories, newspapers and folk tales was reflected in the wealth or economy of a country and if and when it was not, the country started declining.

Child-Rearing

The way a child is brought up or reared, making him/her 'achievement-oriented', is also important, not only for the child but also for the community and country in general.

This early orientation, making a child independent in his/her thinking, involving him/her in decision-making at home and rearing him/her to take risks on his/her own, makes the child an achiever in life, thus influencing the country as a whole.

Here in our country we have street children who have to fend for themselves, which results in their becoming independent and develops in them the quality of decision-making.

As we have discussed in earlier units about the traits and qualities of an entrepreneur, achievement motivation is highly relevant to entrepreneurship. If you have achievement motivation of a certain degree, if you have a spark, it can be developed to make you a successful achiever, entrepreneur. But one word of caution: having high achievement motivation alone may not be sufficient to make you a successful entrepreneur. There are certain other requirements too, which you will know about as you read on.

Achievement Motivation and Internality

The 'Internal Locus of Control' refers to the belief that whatever happens to you is to a large extent, caused by you and that you have control over the outcome of your actions. This does not mean that the external environment does not influence the outcome of your efforts. But you should believe that ultimately success or failure depends on how you are able to do certain things and the awareness that you can intervene to influence the outcome of external factors. In order to possess such an attitude, you should identify your strengths, concentrate on them and be confident of using the same to influence the outcome.

Developing Achievement Motivation

'Suppose I do not have achievement motivation, can I develop it?' Yes, you can. There is a specialized training programme called 'Achievement Motivation Training' which is based on experiential learning. The other alternative is introspection and an analysis of your strengths, weaknesses, opportunities and threats (SWOT). After going through the chapters on entrepreneurial traits and competencies, based on self-learning you can try to improve yourself in the areas where you find yourself weak, and convert the weaknesses to strengths. Achievement motivation can also be developed by thinking in the language of achievement. Your entire thought process (imagery) has to be achievement oriented.

3.6 ACHIEVEMENT PLANNING AND BUSINESS GOAL

One of the most crucial skills for an entrepreneur is to plan and implement action towards business goal. Why is this important? Let us examine.

Through planning, you will be able to clearly specify your goals, identify various activities, anticipate obstacles, enlist resources and also anticipate consequences. Often people having no patience for planning, jump to work and get stuck when faced with obstacles. Therefore, to be a successful entrepreneur, you need to develop skill and insight in planning and firm faith that planning is a must to ensure success in accomplishing goal.

Entrepreneurs always set challenging goals, which are realized with difficulty but bear unique fruits. They are often governed by achievement motivation, which has concern to attain certain standard of excellence. For this reason the planning practised by entrepreneurs are often called 'achievement planning'. This should not be mistaken for project planning. *Achievement planning provides for the necessary psychological preparation of the entrepreneur to pay adequate attention to those significant dimensions of his/her action areas, which contribute to his/her eventual effectiveness.*

Let us understand how planning can be effective from this case study.

CASE STUDY

Jhora Medhi (34) a shy, homely lady decided to enter the field of entrepreneurship. She belongs to a family where service is the main occupation. After completing her HSLC, she discontinued her study and got married. She always wanted to do something to be financially self-dependent. After her marriage she felt that she had to supplement her husband's income for the economic well being of her family. She could do this by starting some income generating activity in her home itself. She observed that varieties of fruits were available in her locality. But fruits get wasted most often during the harvesting season. She had a hobby of making jams, jelly, pickle etc. for use in her own home. She felt that she could convert her hobby into a profitable source of income generation. She discussed her idea with her husband. Her husband also liked the idea of doing something to generate additional income. She started to make jams, jelly, and pickle and sold them to her friends and relatives. The products were good. Her friends and relatives began to appreciate them. This encouraged her further to continue her effort to make jams, jelly etc. In the meantime IIE organized an EDP at Nagaon. She came to know about the programme and wanted to participate in it. She was admitted in the training. The training gave her further confidence to convert her income generating activity into an entrepreneurial activity. But to do so, she needed money, machines, manpower etc. She could approach bank for loan. But she was not certain if she could get a loan from bank. For machines she could not depend on the local market.

In addition, she also needed to know the formalities for starting a food processing unit. But money was the most important resource for her to start her enterprise. She thought it worthwhile to start her enterprise on her own without any finance from bank. She had about Rs. 20,000/- in her savings account. With this initial investment of Rs. 20,000/- she started a fruit processing unit at Nagaon. This small amount of money was inadequate to run her unit. She then approached her friends and relatives to get money for running her unit. The problem of finance and machine could be solved. Now there was the problem of marketing. It is now not an income generating activity for her. It was an entrepreneurial activity.

She had to be able to market her products not only in the local market but also the outside market. She employed two salesmen to sell her products. The salesmen used to travel from place to place to sell the products. They took the products to different places in the morning and returned in the evening. In this way she could get the market of central Assam. Jhorna also used to travel to different towns and villages at regular intervals to establish contact with the sellers to sell her product. This helped her a lot in popularizing her products. In addition, she also used to put up advertisements to create awareness of her food processing unit and the quality of her product. Now there are ten persons working in her unit. Initially she faced the problem of getting FPO licence. She had to take a lot of trouble to overcome the problem. Her annual turnover during 1999 – 2000 was about Rs. 2 lakh.

What is the secret of her success in her entrepreneurial activity? She stated that hard work, foresight and planning are the major contributing factors in the success of her enterprise. Establishing linkage with market and her strong determination to be a successful entrepreneur contributed to her success.

*(**Source:** Women Entrepreneurs in India, Published by NISIET, Hyderabad 2002)*

We have understood from the case how planning is important for setting up an enterprise. However, planning also requires systematic analysis and careful implementation. In other words, planning is also known as the "blue print for the entrepreneur. Let us look at the various steps of planning.

3.6.1 How to Plan

The planning has to have some strategies. In order to achieve the desired goal, it involves nine steps:

- Analysis of Situation
- Goal Setting
- Enlisting Activities
- Anticipation of Potential Obstacles
- Location of resources
- Generating alternatives
- Anticipation of consequences
- Action Planning, and
- Feedback.

We will try to understand each of these one by one

Analysis of situation: Entrepreneurs analyze situation to perceive the emerging change and the problems that people will be facing to adjust to such changes. Such problem areas offer you the entrepreneurial/business opportunities.

Goal setting: Look for new ideas, product or services that people need. Use creativity and be innovative in setting challenging goal. Efforts should be made to make the goal crystal clear.

Enlisting activities: Being action oriented you as an entrepreneur will enlist activities needed to move towards goal.

Anticipation of possible obstacles: Every action is resisted. Entrepreneurs anticipate such barriers, which may arise within entrepreneurs themselves or in the environment.

Location of resources/help: If barrier exists then there must be some source/help somewhere to overcome it. You need to locate them.

Generate alternatives: Using the resource new activities are generated as alternatives.

Anticipate consequences: Before actual operation an entrepreneur anticipates the consequence based on previous experience and information.

Action planning: Action planning is a device meant to help the entrepreneur to crystallize the short tem and intermediate goals; and to visualize corresponding actions which, in his\her view, will ensure the movement towards the goals.

ASSIGNMENT-1

If you want to make a good plan of action, you should be able to answer questions such as:

- What action is to be taken?
- Why must it be done?
- Where will it take place?
- Who will do it?
- How will it be done? and
- How much control (kind and degree) should be exercised.

See if you can respond to all the questions at one attempt. find out which question is taking longer than others. Perhaps then you have to spend a little more time. Remember there are no right or wrong answers. What is more important is your clarity and focus. Try this after six months and you will see the difference in your response.

3.6.2 Feedback

Feedback is essential feature of achievement planning. An entrepreneur seeks feedback and uses it to effect change in the course of action to ensure accomplishment of goal.

3.6.3 Planning a Habit

Make it a habit to clearly set goal and plan its accomplishment by stating activities, possible obstacles, resources to overcome barriers and suggesting alternatives. This will ensure you success in your entire venture.

Check Your Progress Exercise 2

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

Fill up the gap with appropriate words that you have learnt through these units.

Do match answers given at the end of the unit after you have completed.

1. Entrepreneurship is concerned with ----------- and putting it into social use against pay off.

2. ---------------- is used by entrepreneur to make innovation available to users/people.

3. Entrepreneurship contributes directly to national economy by increasing -------------- and --.

4. Entrepreneurship brings about changes in people's orientation towards solving ----------------- Taking ------------------ enhancing concern for ---------------.

5. Entrepreneurial opportunities are sensed by scanning the ---------------.

6. For selecting an enterprise, entrepreneurs consider its suitability to three Es including Entrepreneur, E------------ and E----------------.

7. Entrepreneur works for --------------- and accordingly believes in -------- before action.

8. Entrepreneurs perceive ---------------- faster than common persons.

9. Through planning entrepreneurs assess ---------------- required, quantity of -------------- to be produced, and ----------------------- where products/services are to be sold and the total ------------- that has to be made and finally the -------------- that is expected.

10. A business plan is the -------- ------------ ready with entrepreneur before actually launching a project.

ASSIGNMENT-2

(Achievement Planning and Business Goal)

Do this exercise on your own:

Identify an important task that you are required to complete by a specific date in the future.

1. Think about the task(goal).

2. Clearly state the goal. (Why you want to this?)

3. List out the activities needed to accomplish your goal.

4. List the problems you may face or which may arise in the "environment."

5. Suggest possible sources of help (from friends/parents\teachers} to overcome obstacles.

6. What are your chances of success or failure (indicate in%}.

7. Suggest alternative plans of action.

8. Draw plan of action.

3.7 LET US SUM UP

Developing entrepreneurial skills in us is possible. It requires right mindset to develop a strategy. Understanding oneself, own goal in life and identifying strengths and weaknesses are very crucial.

The locus of control both internal and external are important. In any task when we put our efforts, it leads to performance and further leads to outcome. Thus believing in one's own self-efficacy and ability is crucial. The recognition of external locus of control can help to develop the tendency to solve problems, taking help and openness to feedback for improvement.

However in order to achieve success we must plan for success. We must follow the steps in planning. Let us remember that in planning, anticipation and alternative plan of action is important.

3.8 KEY WORDS

Locus of control : Factors responsible for any event or an outcome for any action. The responsibility may be external factor or internal factor. The internal factor may be under one's control and the external factor is not within one's control.

Self-efficacy : Utilising one's own full potential for performance.

Achievement planning : necessary psychological preparation of the entrepreneur to pay adequate attention to those significant dimensions of his/her action areas, which contribute to his/her eventual effectiveness.

Acquisition : A recently acquired asset or object, the act of acquiring.

Accomplishing : Achieving or completing successfully.

Accomplishment : Something that has been achieved successfully, an activity. That one can do well.

Anticipate : Be aware of and take action regarding something likely to come about in the future.

Blue Print : A design plan or other technical drawing. Something which acts as a plan, model

Conducive : Contributing or helping towards.

Crystallize : Form or cause to form crystals, make or become definite and clear.

Discrepancy : An illogical or lack of compatibility.

Discontentment : Lack of satisfaction.

Enhance : Increase

Loci : Particular point or place.

Perceive : Become aware of or conscious of.

Recognition : Knowing again.

Visualize : Form a mental image.

3.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

(The Entrepreneurial Orientation Inventory Scoring Sheet)

Name --- Date -----------------------------

Instructions: Transfer your point allocations from the inventory form onto this scoring sheet.

Internal Locus of Control	External Locus of Control
1 b --------------	1 a --------------
2 b --------------	2 a --------------
3 b --------------	3 a --------------
4 a --------------	4 b --------------
5 b --------------	5 a --------------
6 a --------------	6 b --------------
7 b --------------	7 a --------------
8 b --------------	8 a --------------
9 a --------------	9 b --------------
10 b ------------	10 a ------------
11 b ------------	11 a ------------
12 b ------------	12 a ------------
13 b ------------	13 a ------------
14 b ------------	14 a ------------
15 a ------------	15 b ------------
16 b ------------	16 a ------------

17 b -------------	17 a -------------
18 a -------------	18 b -------------
19 b -------------	19 a -------------
20 a -------------	20 b -------------
Total Internal ------------------	Total External -----------------

Determine the ratios of your internal/external locus of control scores by dividing the total internal score by the total external score. Record the amount here -------

Internal/external ratios above 3.0 indicate a high level of entrepreneurial internality; the chances are high that such individuals will initiate entrepreneurial activities. Ratios below 1.0 indicate that the respondent has a more external (less entrepreneurial) locus-of-control orientation. There is a need for this type of person to become more internal in order to be able to initiate and sustain entrepreneurial activities. Ratios above 1.0 indicate possible entrepreneurs. The higher the ratios above 1.0, the more internal the respondent is.

* Test developed by T.V. Rao. Reproduced from the 1985 Annual, “Developing Human Resources”, Leonard D. Goodstein and J. William Pleiffer Edition. San Diego, California University Associates.

UNIT 4 BUSINESS IDEA – HOW TO GET IT?

Structure

4.0 OBJECTIVES

After studying this unit, you should be able to:

- make a distinction between economic and non-economic activities;
- understand the meaning and nature of business;
- identify various business opportunities, which a businessman may come across;
- describe the various sources from which a businessman may derive business ideas;
- understand as to how to generate the business ideas; and
- comprehend the evaluation procedure of a business idea.

4.1 INTRODUCTION

All of us are always engaged in some activity or the other. In the morning when we get up we brush our teeth, take bath, offer prayers and have our breakfast. Then, you as a student go to your Study Centre for studies. Your parents go about their own occupations. In the evening somebody may watch television or go for playing. The point, which needs to be stressed here is, that every human being is busy in some activity or the other.

A person may do a particular piece of work just to derive happiness or peace within himself. This is a non-economic activity. Another activity, may be to earn money. This is an economic activity. Business falls in the category of economic activity – the objective being to earn money.

A business can be started by any person. It can be pursued as a career by him. He may start a business with any amount of money. The range of investment may be as low as Rs. 100 or as high as Rs. 1,00,000 or even more depending upon how enterprising and courageous he is. But have you ever thought of the aspect which we all need the most to start a business? Well, it is the idea of – **What to Do?**

A businessman needs to decide upon the type of activity, which he will be interested in pursuing. Let's change your role for a moment. Visualize the following:

You have just completed the present Diploma Course. You want to start your own business. The pertinent question here is – which business you want to be involved in. Whether you want to manufacture something or simply want to start a trading business. Are you in a dilemma? If the answer is yes, here is a hint for you.

Look around yourself and try to identify an opportunity. May be you get your answer by keenly observing the environment i.e. consumers, producers, products, competitors, government, society etc. Well, this is exactly what a businessman does.

The businessman starts the initial work of identifying various business opportunities, which he may come across. He then evaluates these opportunities and gives a shape to his business idea.

4.2 WHAT IS BUSINESS?

In this Unit we shall discuss about business, business opportunities, business ideas and other related aspects.

As already mentioned, business is an economic activity. The objective of doing any business is to earn profit. Business involves a wide range of activities like manufacturing, trading, transportation, warehousing etc.

Definitions of business

1. *According to B.O. Wheeler:* "Business is an institution organized and operated to provide goods and services to society under the incentive of private gain."

2. *As per Section 2 (13) of the Income Tax Act, 1961:* "Business is any trade, commerce or manufacture or any venture in the nature of trade, commerce or manufacture."

Features of business

Let's discuss the features of business one by one

1. *Economic activity*

   Business is an economic activity because it involves production, exchange and distribution of goods and services for profit, e.g. Arun sells goods worth Rs. 1,000 to Bhanu for Rs. 1,200 – it is a case of business activity. In case Arun donates Rs. 11 to a temple it is not a business activity.

2. *Profit motive*

   The main aim of a businessman is to earn profit. If a businessman is manufacturing cloth or is dealing in purchase or sale of wheat – the main reason behind this activity is some kind of gain or reward.

3. *Goods or services*

   A businessman deals in goods or provides services.

The *goods* in which he may deal are of two types:

(i) Consumer Goods;
(ii) Producer Goods

Consumer goods are those goods, which are used by consumers to satisfy their needs and wants directly. In this case goods are used or consumed after their purchase. The examples are – bread, milk, cloth, pulses, furniture etc.

Producer goods, also known as capital goods, are those goods, which help in the manufacture of consumer goods. These goods are used by manufacturers and not consumers. Examples are – tools and equipment, machinery boilers, wheat used as seeds for further growing, etc.

The *services* in which a businessman may deal in, can be grouped as below:

- Transport
- Warehousing
- Advertising
- Marketing
- Banking
- Insurance

4. *Production of goods and services*

A businessman endows utility to a material by making it more useful and suitable. A businessman can satisfy human wants only if he makes something useful e.g. cotton as such is of no use to consumers. But if the same cotton is converted into cloth by a manufacturer, the needs and wants of the customers are satisfied. This way, the businessman by manufacturing, processing or altering the material creates 'form utility' to make the product more useful.

5. *Distribution of goods and services*

Have you ever thought of how wheat cultivated by the farmer reaches the final consumer i.e. you and your family and others in society? Well, it is due to the distribution function of trade. Distribution of goods and services is a function, which facilitates the flow of goods and services from the manufacturer to the ultimate consumer.

6. *Risk*

Every kind of business involves risk – whether small or big, whether manufacturing or selling, whether done in rural areas or urban areas.

A business involves risk due to uncertain factors. The businessman does not have full control over his environment e.g.:

- The tastes and fashions may change;
- Level of competition may rise;
- Government policies, commercial, fiscal etc. may change in the country;
- Technology of production may change;

There is a direct relationship between the risk and profit. Higher the risk, higher the profit. In a way, profit is the reward for risk-bearing. Profit is termed as the compensation for risk undertaken by the businessman.

7. *Sale, transfer and exchange*

   Buying, selling and exchange of goods and services are the essential features of any business. Sale and exchange for a price is a must if the activity is to be considered as a business activity.

Forms of business activities

Business activities, *inter-alia*, may take the following forms:

- Agricultural activities – growing of crops, preparing harvest for the market, preservation etc.
- Manufacturing activities – manufacture of pickles, jams, papads, biscuits, chutneys, spices, sauces, pump sets, agricultural implements, spare parts etc.
- Trading activities – buying and selling in wholesale, retail or barter
- Service activities – transportation, warehousing, insurance etc.
- Reproducing and multiplying activities – nurseries which multiply and sell plants, plant materials
- Mining activities – exploration, extraction of minerals, iron ores, gold, diamonds etc.
- Constructing activities – construction of buildings, warehouses, cold storages, silos, etc.

4.3 BUSINESS OPPORTUNITY – IDENTIFICATION AND ASSESSMENT

Business opportunity identification

Let’s begin with identifying various business opportunities.

As we are all aware one should know how to swim before plunging into the water or else the person will get drowned. Same is the case with a person who wishes to start a business of his own he should acquire necessary knowledge. Even when he thinks of expanding his existing business, he has to update his knowledge.

The process begins with an effort to think out an attractive set of opportunities for the firm. In case the firm has too many opportunities, the task will be to select from among them.

A businessman can choose an opportunity from his environment. As long as there are unsatisfied needs and wants, there will be opportunities. Identification of such opportunities requires imagination, sensitivity and realistic assessment of what a businessman can do. For example, in the modern world the need to develop new sources of energy, to improve agricultural methods etc.

By going through the following examples, you'll understand more will throw up many possibilities clearly how a businessman can identify business opportunities.

Example I

Nanak discovers that there is no wholesaler dealing in sugar in his area. Nanak sees an opportunity in becoming wholesaler himself.

Example II

Rakesh, a student living in Shahibabad, is undergoing a Diploma Course on Value Added Products from Fruits and Vegetables conducted by IGNOU. One of his cousins Amar works as a gardener in AIIMS in New Delhi. Casually Amar discloses to Rakesh that affluent families in Delhi living in big bungalows maintain a kitchen garden in their courtyards but they find difficulty in obtaining seeds of good quality of various fruits and vegetables, green/flowering plants and high quality manure. Here, Rakesh is face-to-face with a business opportunity of selling good quality seeds (even imported ones), green/flowering plants and manure in Delhi and nearby areas. He can also act as Garden and Landscape consultant.

Example III

A commercial bank announces a loan scheme under which loan can be obtained for business purposes at a reasonably low rate of interest. The loan can be repaid in easy installments. Ravi, a money-starved young businessman who owns a juice shop reads about the loan scheme on a visit to a branch of that bank. He has identified an opportunity for expanding his juice shop.

Activity

Scan your environment thoroughly. Think. And then identify five business opportunities and list them in a serial order in the space provided below:

Sl. No.	Business opportunity identification
1.	
2.	
3.	
4.	
5.	

Opportunity assessment

After the businessman has identified various opportunities, the next step is to evaluate these opportunities. The opportunities need to be assessed before the best one is transformed into a business idea.

Let's now study the procedure of assessing an opportunity, which has been identified.

i) *To choose the relevant opportunities*

The businessman has to make a choice of the relevant opportunities out of the various opportunities available in the environment. Certain opportunities (and not all) will be relevant only if they meet the purpose, objectives and growth strategies of the firm.

For example, Darshan Kumar, a manufacturer of vegetable sauce, finds that the Finance Minister has announced slashing of excise duty on steel. This is an opportunity, which a businessman may find to be quite useful but it has no relevance to Darshan Kumar because he is in the business of manufacturing vegetable sauce using various vegetables and not steel.

In other words, business opportunities should be consistent with the purpose and objectives of the firm.

ii) *To evaluate the sales potential of each opportunity*

After identifying the available relevant opportunity, the businessman should evaluate the sales potential of each opportunity. In this context, following questions need to be considered:

a) Who would buy the product;

b) How much the potential customers can pay;

c) How many customers would buy the product;

d) Which strata of society would buy the product;

e) Who will be the competitors;

f) How would the product be distributed.

iii) *To evaluate the financial aspect of each opportunity*

Each identified opportunity is required to be evaluated in terms of financial aspects. This will lead to proper and detailed estimation of cost. The various items on which long-term funds can be committed are:

a) Cost of land and site development

b) Cost of building

c) Cost of plant and machinery

d) Money required for working capital

iv) *To evaluate the technical aspect of each opportunity*

Evaluation of each identified opportunity in terms of technical aspects is also an essential step. The various technical elements to be evaluated are:

a) Type of raw material to be used – agricultural product or livestock product or mineral product;

b) Manufacturing process;

c) Plant capacity required;

d) Technology for manufacturing – whether to purchase or make it available through *joint venture* arrangement.

e) Availability of infrastructure – power, transportation, water and communication.

v) *To evaluate the marketing aspect of each opportunity*

Each business opportunity should also be analyzed from the point of view of how to enter the market. The company should make an effort to know what its competitors are offering to the consumers and in which way can the consumers be satisfied.

The businessman should bank upon that opportunity which is most feasible and promising.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Read the following paragraph, identify the relevant business opportunity and fill your answer in the space provided.

   Manoj is a young enterprising man. He owns a sweet shop. He is well versed with Indian culture and festivals. He knows that on the occasion of various festivals people make different kind of sweets and namkeens. Here, he finds a good business opportunity to be turned into a viable business idea. He may ……………………………………………………………….

   ………………………………………………………………………………

2. You are Kailash Nath and you own a *chakki* shop. Through your customers, you come to know that packed masalas (i.e. packed spices) available in the market are not of good quality as they are thought to be adulterated. In the following space write down the relevant business opportunity, which you will identify.

   ………………………………………………………………………………

   ………………………………………………………………………………

   ………………………………………………………………………………

   ………………………………………………………………………………

4.4 SOURCES OF BUSINESS IDEA

Once an opportunity has been identified and assessed, the next step for a businessman is to translate the business opportunity into a viable business idea. In this respect the businessman has to seek the sources from where he can get his business idea so that the available opportunity is translated into a profitable venture.

A businessman should keep his mind open. According to Promod Batra, a management expert "A closed mind is like a gloomy cave made gloomier by the cobwebs of ignorance and prejudice, whereas an open mind is like a green meadow where fresh ideas spread and blossom. The businessman should therefore, step out of the morass of stagnant thoughts into the open field of bold new opportunities. He should soar high on the strength of an exploring mind to reach unknown heights of achievement and success."

The various *sources* from where a businessman can derive business ideas are presented in Figure 4.1.

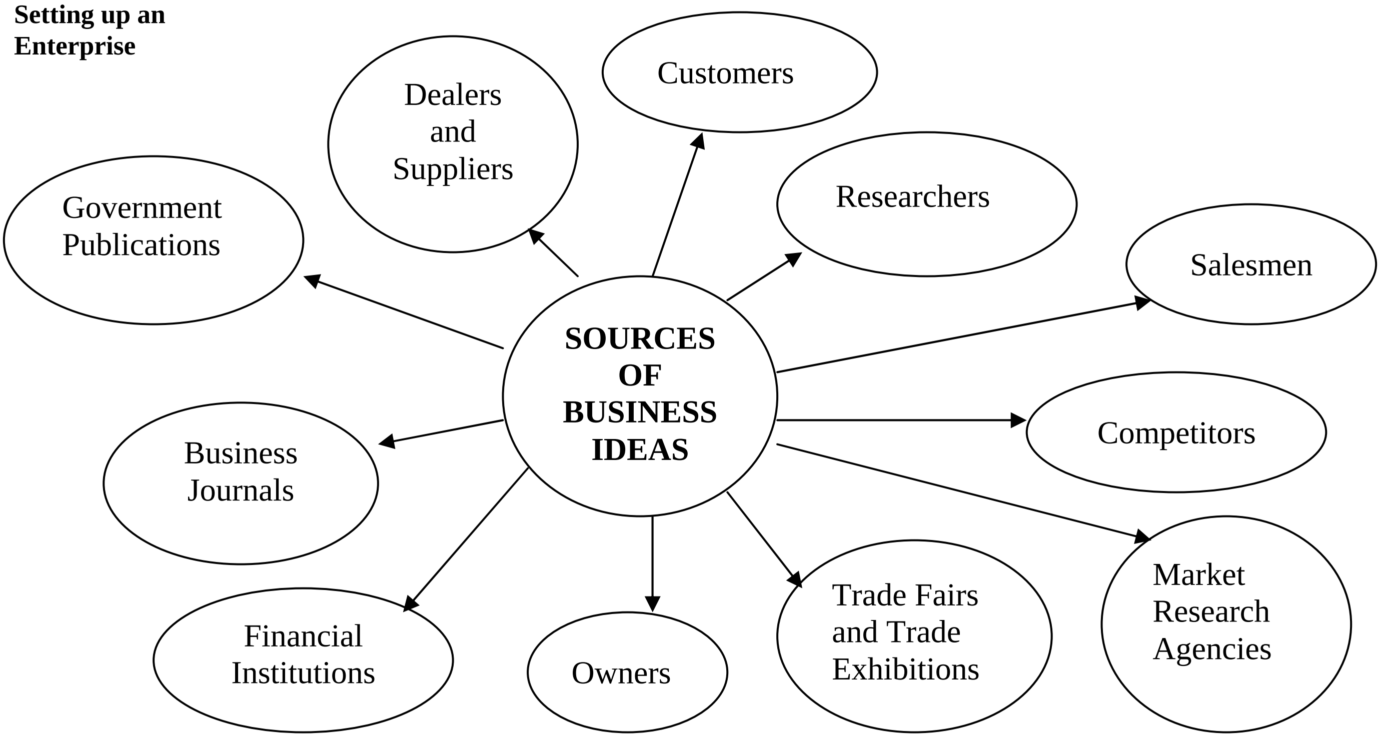

Figure 4.1: Diagrammatic presentation of sources of business idea

These are detailed in the following paragraphs.

1. *Customers*

Customers, whether Indians or foreigners, are the primary source of business idea. Customers, as we know, are the pivot around whom the entire marketing process revolves. Customers are those persons who use or consume the product and therefore, are the best judge. The ideas or the criticism provided by these esteemed customers are valued greatly by the business firms. The business unit can identify customers' needs and wants through surveys, group discussions, suggestion system etc.

2. *Researchers*

Researchers are those talented scientists, who because of their various scientific research programmes conducted in the labs, try to bring out something new – it can be a new product or modification of an existing product or a new form of packaging material. Big companies maintain R & D department for this purpose only. R & D labs carry out research and hence become a source of business idea.

3. *Competitors*

A businessman should never undermine his competitors. He should monitor the activities and strategies used by them carefully specially in connection with bringing out new products, new methods of selling, and new promotional measures. A businessman should try to add some value to their product and build a far better product than his rivals.

4. *Salesmen*

Salesmen or sales-managers or sales representatives – with whatever name we may call them – are the ones who come in direct contact with the final consumers. Whether it is a multi-national company (MNC) of Nestle or

Kellogg fame or a local chat-papri shop – the customers interact only with the salesmen while buying the product. In this process, the sales persons happen to get exposed to complaints and problems faced by the customers while using the product. They also come in contact with the unsatisfied needs of the customers as well. They can lead the owners of the business firms on to the right track. Therefore, they are a good source of business ideas.

5. *Owners*

The owner of an enterprise can be a single person or a group of persons depending upon the form of business ownership. They are also a major source of business ideas. They may have a creative and innovative mind churning out new ideas to take their enterprise to the top.

6. *Government publications*

Government Publications are also an important source of business ideas. Data, provided in various Government publications, act as a harbinger for business improvement. The scope of further investment can also be estimated. The various publications like Economic Surveys published by the Ministry of Finance, Guidelines to Industries published by the Department of Industries, Annual Reports of the various Ministries etc. provide information about structure, location, licensed and installed capacity etc. of various projects. Through analysing the available statistics regarding exports and imports a trend of foreign trade can be judged. Idea about import substitution can be generated by analysing the data of imports and possibility of exports can be estimated through export data.

7. *Business journals and financial newspapers*

Information regarding business idea can also be gathered from business journals, business bulletins, business magazines, financial newspapers etc. Some of these are:

- Indian Textile Bulletin
- Indian Packaging Directory
- Glass Udyog
- Glass Gazette
- Business India
- Business World
- Economic Times
- Financial Express
- RBI Bulletin

8. *Financial institutions*

Commercial banks, RRBs, State Co-operative Banks, State Financial Corporations, EXIM Bank, IDBI, SIDBI etc. are there to promote development of Industries, to conduct studies and to offer valuable suggestions to potential entrepreneurs.

9. *Market research agencies*

Market Research Agencies (MRAs) are also an important source of business ideas. These agencies conduct marketing research covering different segments of the market. They prepare research reports for their clients. Some of the MRAs are Indian Market Research Bureau (IMRB), Marketing and Research Group (MARG), Operations Research Group (ORG), National Council of Applied Economic Research (NCAER), Marketing Operations, Design and Enquiry Service (MODE), and Pathfinders India.

10. Trade fairs and trade exhibitions

Trade Fairs and Trade Exhibitions also contribute in searching for a business idea. Direct interaction takes place among the manufacturers, dealers, suppliers and customers through these fairs and exhibitions. National and International trade fairs provide an excellent opportunity to know about new products and development of existing products. A lot of information/data can be collected which may be used for evaluation purposes.

11. Dealers and suppliers

Business ideas given by Dealers and Suppliers are also an important source. Therefore, their viewpoint should also be considered because they have first hand exposure to customers' unsatisfied needs and complaints.

12. Performance of existing industries

The profitability and return on investments of various industries (region wise) are also one of the important sources for gathering business ideas. The potential for investments in the particular industry (e.g. fruits and vegetable processing industry) can thereby be analysed and judged.

Activity

In the following Table you will find unsatisfied needs and other problems of the customers as well as the relevant product to mitigate the problems. Scan the environment and fill in the Brand Name of the Product:

Customers' unsatisfied needs and problems	*Relevant product*	*Brand name of the product*
1. Heart Problem	Edible Oil	
2. Diabetes	Sugar Free Tablets	
3. Travelling	Sauce in sachets	
4. Hygiene	Water	

(**Hint:** 1. Saffola Gold, 2. Equal, 3. Kissan and 4. Bisleri)

1. Name two financial newspapers from which the businessman may get a business idea.

   i) ....

   ii) ....

2. Customers are an important source of business idea because:

....

....

....

4.5 GENERATION OF BUSINESS IDEA

Identification of business opportunity and its assessment leads the businessman to generate business ideas, which can translate the opportunity into a profitable venture.

Business idea can never come from a vacuum. Instead it originates from a creative and enthusiastic mind feeding on an active environment.

The process of identifying business idea should always be done in a systematic and rational way. It is always better "To think at leisure and never repent" and not "To act in haste and repent at leisure." That is why, the businessman should sensibly scan the environment, which consists of himself, his prospective customers who will buy from him, his prospective suppliers, his prospective competitors whom he has to face, etc.

The businessman can generate a business idea to sense a business opportunity in different ways. But before detailing them out let's go through some of the examples given below. These examples contain the opportunity and its transformation into a business idea.

Example 1

Business opportunity	Business idea generated
A cold storage is built in a village.	The businessman gets an idea to deal in off-season fruits and vegetables as well.

Example 2

Business opportunity	Business idea generated
Indian Railways starts a new train on a new route.	The businessman (dealing in flowers i.e. florist) gets an idea to expand his business by delivering the flowers through the new train to other areas, which were hitherto not tried.

Example 3

Business opportunity	Business idea generated
State Government announces the plan to provide free mid-day meals in primary schools in a village.	The businessman puts in efforts to take the contract of supplying vegetables to the contractor.

Figure 4.2: Diagrammatic presentation of generation of business idea

Now, let's discuss the generation of business idea.

1. ***Product imitation:*** The businessman can think of manufacturing any product, which already exists in the market. In other words the businessman may think of making a product, which already has a market. He wants to bank upon the efforts put in by his rivals. Product awareness and product acceptability are already there. Acquisition of an existing product obviates the costly and time-consuming process of building resources and reputation. For example, Suresh plans to manufacture instant Gulab Jamun mix. Here, Suresh is saved from putting in extra efforts and money to launch a totally new product as the customers are aware of this product and have accepted this mixture through which instant Gulab Jamun can be made.

2. ***Manufacturing of a new product (Product innovation):*** A businessman can plan to make a non-existing product, which is not available in the market. Well isn't it a big deal? Every businessman cannot do such an act. One needs to be extra bold, courageous, risk taker and adventurous, for it can be a risky proposition. Can you think of a new product, which has been recently launched in Indian food markets? Yes, there are products like Tomato Puree, Ginger-Garlic paste, instant cake mix etc. But there are

certain other new products also (though not linked with food industry) like mobile phones with camera, solar cookers, Jackets with in-built fans, etc. which were previously unheard of. Now-a-days some new types of namkeens like roasted wheat, roasted Kabuli (white) Chana, roasted moong dal etc. (cooked without using oil) have emerged in the market.

3. ***Manufacturing of an existing product but after adding more value to it or improving it:*** At times, a businessman thinks of manufacturing an existing product but with a difference. He tries to make that product slightly different from the product of his rivals by making some changes in the product. For example, 'Marie' biscuits are now in the market as 'Marie Gold' biscuits enriched with wheat fibre and with a slogan "better tastier and healthier". Some of the other examples are given below:

   - Pickles are sold with a new and better package;
   - Custard powder is now sold with some added ingredients;
   - Double Folding Umbrellas are an improvement over the single folded umbrellas in as much as they can easily be accommodated in ladies' purses;
   - Sauces, herbal shampoos are sold in sachets.

4. ***Manufacturing of a product after listening to the needs and wants of the customers:*** With liberalisation and globalisation processes, the entire environment is changing. The life and life style of people are changing. People, by and large, are buried neck deep in their responsibilities and duties, entrusted to them by their bosses so that they hardly get time for themselves and for their family. More and more women are working and they have less and less time for their family. In this changing life style, they want products tailor-made to suit their requirements. The businessman can therefore, find more ideas by asking customers to describe their problems with the current product. He can also identify customers' needs and wants through customer surveys, group discussion, suggestion system and letters received from them. The products, which have taken birth after listening to customers' woes, are:

   - Ready to eat food;
   - Ready to eat mushroom soup, tomato soup etc.;
   - Cake mix;
   - Sprouted Dals;
   - Roasted Namkeens;
   - Pudding Syrups.

5. ***Finding new uses for an old product***

   At times, the businessman may find some more and new uses of the product to increase his turnover. For example, 'Ready to Mix' product – a mixture of Badam-Pista flavour; of chocolate flavour; and of strawberry flavour, was launched for making milk shakes of different flavours. But, later on a number of uses were added the product could be used in ice creams, puddings, cakes etc.

6. ***Own problems and use of hobby:*** Sometimes, a person may face a particular problem in real life like preparing lunch for taking to office. He may, after leaving the job, start the business of supplying packed lunch during lunch-time at various offices. Recently, a fat lady was totally upset as she was not getting ready-made clothes of her size. She thought of this problem and started making over-sized clothes meant for fat people.

   A hobby can also be converted into a full-fledged business with proper planning and care. For example, a hobby of collecting flowers can be converted into making designer bouquets. Similarly, a hobby of making pickles and chutney can be converted into a Pickle and Jam business.

7. ***Untapped natural resources:*** Nature is very kind to mankind. It has given us plenty of resources like air, water, minerals, vegetation etc. Human beings satisfy their needs and wants through these natural resources. Here comes the role of a businessman. He can tap these natural resources and thereby satisfy the needs of the customers. For example, some of the products made through tapping solar energy are solar cookers, solar heaters etc.

8. ***Latest fashion and changing life styles:*** Latest fashions and designs and changing life-styles also contribute to the generation of business ideas. Nothing is permanent except change. Due to globalisation and liberalisation the common man especially the youngsters are a more aware and informed lot. The life-style of persons has also changed. An idea can be generated by observing keenly the latest fashions in the city. The businessman can therefore, make that product which goes well with the current market trend.

   Earlier pizza was not thought of as a common item to be consumed by all sorts of people. Similarly 'pasta' and other popular fast food items like 'momos', 'macaroni' etc. were also not in common use. But now-a-days, due to changing life styles, all these items are liked by the common man and their consumption is quite frequent.

9. ***Research and development programmes:*** Many business units hope to find new ideas through their scientific research programmes.

10. ***Consumption in foreign countries:*** Observing consumption in foreign countries may also lead to generation of new ideas. Each country has its own culture, and different food habits. In India we like spicy and fried foods while in western countries boiled, baked and non-vegetarian food is preferred. These consumption habits of people living in different countries may be used by the businessmen to generate an idea, which may suit the needs and wants of the people living in our country.

Activity

Let's do some fieldwork. Visit five houses in your neighbourhood. Ask the occupants, (women and children preferred) about any kind of improvement they would like to see in a particular product (fruit and vegetable products preferred) and fill the boxes given below:

Sl. No.	Name of the occupant	Age	Name of the product	Required improvement
1.				
2.				
3.				
4.				
5.				

Check Your Progress Exercise 3

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. State True or False;

   i) Acquisition of an existing product obviates the costly and time-consuming process of building resources and reputation.

   ii) A businessman should never plan to make something new, as it will always result in losses.

   iii) The customers want customized products due to changing life-style.

   iv) The company can identify the needs and wants of the customers through surveys and discussions.

   v) Less business ideas are generated due to liberalisation and globalisation.

2. You are the manufacturer of "Delicious Biscuits (salted)". Think and write in the space provided below any two new uses of the product.

   i) ....

   ii) ....

4.6 EVALUATION OF BUSINESS IDEA

Consequent upon the generation of business idea, begins the important task of its evaluation. Before the businessman gives a green signal to his project, he has to do some spadework. He should critically analyse his business proposal in question. This becomes imperative, keeping in mind the money involved – may be his life time savings - the physical and human resources used by him, utilisation of natural resources which may involve environmental degradation etc.

A businessman would always wish to turn his dream project into a reality and not a nightmare. Let's now discuss the series of steps essential for any businessman to evaluate a business idea. These steps are as below:

1. *Evaluate one-self*

   The businessman should have certain personal qualities. These qualities will help him to survive in the market, face the competition, to diversify etc. The qualities, which are very essential for any businessman, are as follows:

   - Good health
   - Sound mind
   - Bold and confident spirit
   - Knowledge of skill to be used in business
   - Good interpersonal relations
   - Dynamic attitude
   - Innovative mind
   - Cautious nature etc.

2. *Collection of information*

   The next important step is to collect information about the environment in which the businessman plans to operate. The businessman may gather information directly. He may conduct surveys of the market and try to feel the pulse of the market and business methods of his rivals. He would assess the current tastes and fashions prevalent in society-motive for buying total demand, unsatisfied needs etc. Information can be collected through some other sources also like telephone directories, offices of Registrars of small-scale units, Census of India, RBI Bulletins, Journal of Indian Banks' Association, Economic Surveys etc.

   Market Surveys conducted by the businessman are a costly affair, whereas information collected from other sources may not be fully reliable, accurate, or comprehensive. Therefore, it must be carefully examined.

3. *Reviewing the limitations*

   Though an entrepreneur is bold in taking risks and facing challenges, he wants to make doubly sure and safe before he ventures into a new project. Therefore, he analyses those activities, which may act as hurdles at a later stage. His apprehension can be related to:

   - Availability of required amount of capital;
   - Availability of required land;
   - Availability of required skilled and unskilled workers
   - Strategies of the competitors etc.

4. *Detailed investigations*

   "Think before you leap" is what the wise men say. A wise businessman is one who puts each new step cautiously. Before finalizing his business proposal, he should investigate about the following points, which if left unattended may prove fatal to his business:

   - Investigation No. 1 (Capital Requirement)

     The businessman should assess his capital needs. He should analyse whether the capital requirements are within the manageable limits or not. He can obtain funds from the following sources:

i) His own savings;
ii) Friends and relatives;
iii) Commercial banks;
iv) Regional Rural Banks;
v) Co-operative Banks;
vi) Agricultural Co-operative Societies etc.

A businessman may require money as fixed capital and as working capital. Fixed capital is required to purchase fixed assets like building, plant, machinery etc. and working capital is required to finance day-to-day operations.

Activity

Baldeo plans to open a local bakery shop and make 'biscuits and other bakery items'. List the various items of expenditure for which he will be committing his capital as fixed capital and working capital:

Fixed capital required for	Working capital required for
1.	
2.	
3.	
4.	

(**Hint:** Fixed Capital required for – Small Building/Shed, Grinder, Vehicle, Furnace, Utensils. Working Capital required for – Expenses incurred for purchasing Raw Material like maida, sugar etc., Salary and wages to workers, Repair expenses of grinder, Monthly Rent to Landlord.)

- Investigation No. 2 (Location)

  Location refers to a fairly broad area. It can be a village, a local area, a city, an industrial zone or a coastal area. Site is a specific piece of land where the project will be set up. A manufacturer will decide about the location of site of his factory and a trader of his shop. The cost of production and saleability as well as profitability of the concern depend much on its location.

  A factory located far away from the place of availability of raw material or far away from the port town (in case of exports) will result in increasing the cost of production.

  The choice of location depends upon certain other aspects also like availability of infrastructure (e.g. power, transportation, water, communication system etc.), government policies, pollution control, climatic conditions etc.

- Investigation No. 3 (Sources of Raw Material)

  As per the needs of his business, the businessman shall require various raw material like cotton, jute, oil seeds, pulses, whole spices etc. The place from where raw material is to be obtained should also to be investigated. It is quite possible that prices of the required raw material may be different at different places. It may also happen that a particular dealer may offer some discount etc. Raw material can also be purchased from the wholesaler or directly from the producer. Transportation charges or delivery charges are also to be kept in view before finalizing the decision on the source of raw material. Quality of raw material is also to be considered. In addition, the question whether the dealer will be able to provide a regular supply of raw material – even when there is a shortage – should also be given full consideration.

  Raw material can also be imported from the country of its origin. In this respect cost of freight levy import duty and the time lag involved should be given due consideration.

- Investigation No. 4 (Sources of Labour)

  The businessman before starting his business needs to decide upon the place from where he would take his workforce. Recruitment of labour will depend upon the type of work, the businessman wants to start. He may require technical, skilled, semi-skilled, unskilled or highly educated workers depending upon the nature of work to be undertaken by him.

  He should enquire about the places from where he would get the right kind of labour. He should also look into the past trend in labour rates, prevailing labour rates, labour attitudes and practices etc.

- Investigation No. 5 (Availability of Technology)

  Choice of technology is an important factor for manufacturing a product. Choice of technology is influenced by many considerations like capacity of the plant, investment outlay, production cost, principal inputs, ease of absorption etc. In a nutshell, the technology should be such as has been proven to be successful by other manufacturers.

- Investigation No. 6 (Availability of Machinery)

  The requirement of machinery will depend upon the plant technology and plant capacity. The businessman will enquire from various manufacturers and dealers about the price, quality and other terms and conditions (e.g. warranty period, after sales service etc.) regarding the machinery to be purchased. He can also think of importing a particular machine, if required. The businessman will work out through cost-benefit analysis and decide accordingly. If he plans to buy machinery from a foreign party, then he should work out a detailed analysis of the proposal because the cost may escalate due to import duty, transportation, insurance etc. and the exporter may be unknown to him. The machinery purchased should be of desired quality and capacity and should be purchased from a reputed supplier.

- Investigation No. 7 (Availability of Adequate Power Supply)

  Supply situation of power, coal etc. needs to be thought of. The businessman needs to analyse whether power supply for his business proposal can reasonably be obtained from external sources? Whether he needs to install generator set. If yes, of how much capacity, etc. also the cost of the power.

5. *Consistency with government priorities*

   The idea must be feasible from the point of view of national goals and government regulatory framework. The entrepreneur should ask himself whether there would be any environmental effect contrary to government regulations, He should also visualise the foreign exchange requirement, if any.

6. *Cost reasonableness*

   The businessman has to take into account the cost of the project in hand. The cost structure should be such that it enables him to realize an acceptable profit with a competitive price. He should examine cost of material, labour cost, general administration cost, service cost, selling cost etc.

7. *Adequacy of the market*

   The businessman should analyse that the size of the present market must offer the prospects of adequate sales volume and a reasonable return on investment. Moreover, there should be potential for growth. He should analyse the total present domestic market, competitors and their market share, sales and distribution system, barriers to the entry of new units etc.

8. *Assessment of risks*

   The desirability of a project is critically dependent on the risk inherent in it. The businessman should analyse the threat from competitors, vulnerability to business cycles, competition from importers etc.

9. *Scale of operation*

   To decide the scale on which the business is to function is an important aspect that needs to be emphasized. The businessman can operate on small, medium or large scale depending upon his finances, abilities and entrepreneurship as also size of the market etc.

10. *Form of business ownership*

    The form of business ownership is yet another dimension which is to be thought upon before commencing the business. The important forms of business ownership are sole proprietorship, partnership, company (private or public), co-operative society etc.

11. *Compliance with legal formalities*

    The businessman should also evaluate the business in terms of legal formalities, which need to be fulfilled. A variety of licences, approvals, clearances etc. may be required to be obtained from the authorities depending upon the nature of business. Some of the examples are given in the following Table:

Nature of the business	Relevant authority
Packed Foods	Directorate of Marketing & Inspection, Ministry of Agriculture
Excisable Products	Central Excise Department
Bakery Items	Local Authority/Health Department
Confectionery Shop	Local Authority

Conclusion

After going through critically and analytically the various investigations and other relevant points related to the evaluation of a business idea, it is then time for the businessman to select the best idea. Now, a question arises as to which is the best project.

In this respect, it may be noted that the project which will give the maximum profit with least input should be given a green signal. In other words, the optimum business idea should be selected.

Check Your Progress Exercise 4

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Mr. Khanna always insures his goods while transporting them from his godown to his shop. Name two qualities reflected by Mr. Khanna.

   i) ....

   ii) ....

2. Match the following:

Nature of the business	Ideal location of the business
1) A project meant for manufacturing a perishable product	a) To be located near to the centres from where raw material is easily available
2) Factory	b) To be located near to the port
3) A project based on imported raw material	c) To be located near to the centres of consumption

4.7 LET US SUM UP

Every human being is busy in some activity or the other, categorised as economic activity or non-economic activity. Business is an economic activity, prime motive being to earn profit. The businessman earns profit by satisfying the needs and wants of the customers through marketing. The process of marketing begins with an effort to develop an attractive set of opportunities for the firm. A businessman can choose opportunity from his environment. After the identification of various opportunities, the businessman may evaluate these opportunities in the light of sales potential; financial, technical and marketing aspects. Further the businessman should take steps to translate the identified business opportunity into a viable business idea. The various *sources* from where a businessman can derive business ideas are customers; researchers; competitors; salesmen; business journals; financial institutions; market research agencies etc. Identification of business opportunity and its assessment thereof leads the businessman to generate business ideas, which can translate the opportunity into a profitable venture. The businessman should, thereafter, evaluate the various aspects of business idea. He should, thereafter, choose a project, which will give him the maximum profit with minimum of input resources.

4.8 KEY WORDS

Business environment : It is a total of all external factors, which affect the organisation and operations of business. Consumers, suppliers, competitors, government etc. constitute the business environment.

Business risk : A Possibility of loss due to some unforeseeable, unpredictable or unfavourable events which may occur in future.

Fixed capital : Amount of money invested in purchasing non-recurrent assets, which will give benefits to the business for a relatively longer period of time.

Location : A fairly broad area like a city, industrial zone or a coastal area.

Trade : Buying and selling of goods and services.

4.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

1. Bhushan, Y.K. (2005) Fundamentals of Business Organisation and Management. Sultan Chand and Sons, New Delhi.

2. Chandra, Prasanna (1996) Projects, Planning, Analysis, Selection, Implementation and Review, Tata McGraw-Hill Publishing Company Limited, New Delhi.

3. Kotler, Philip (2004) Marketing Management – Analysis, Planning and Control, Prentice Hall of India, New Delhi.

4.11 ASSIGNMENTS

1. Why should business risks be assessed while evaluating the business idea?

2. List any two examples of risks, which a businessman may have to bear.

3. “A businessman has to be innovative”. Justify the statement.

4. Name two purposes for which a businessman may need fixed capital.

5. What are the benefits of product imitation?

6. Explain briefly the various sources from which business idea can be generated.

7. “A businessman should not keep his mind locked”. Do you agree? Give reasons.

8. How can business opportunities be assessed?

UNIT 5 MARKET ASSESSMENT

Structure

5.0 OBJECTIVES

After studying this unit, you should be able to:

- get a clear view about the needs for market assessment;
- distinguish between needs and wants of the consumers;
- understand the meaning of market and marketing;
- identify and comprehend the process of market assessment;
- know about market segmentation and market targeting; and
- understand the market size for the business idea.

5.1 INTRODUCTION

Market assessment is referred to as an important step in the setting up of a business and its successful continuation. The key to success in a business lies in getting into the right business at the right time. This is easier said than done. Its accomplishment is difficult because good business opportunity tends to be elusive. Identification of such opportunities requires imagination, sensitivity to environmental change and realistic assessment of what the firm can perform.

Identification of opportunities and their assessment have been discussed at length in the previous unit. After the business opportunity is translated into an effective business idea, then starts the work of market assessment. You may note that before the commencement of any business (either a new business or the expansion of existing business) the need for assessment of market always exists. Need for market assessment will arise in:

- Survival of the business;
- Growth and development of the business;
- Diversification of the business;
- Desire for higher revenue;
- Facing competition
- Building brand recognition.
- Maintaining reputation and prestige of the business;
- Keeping customers;

- Changing tastes and fashions;
- Maintaining good relations with Government Departments and other relevant factors.

5.2 CONCEPT OF MARKETING

In this Unit we will study the various aspects of market assessment.

The concept of marketing cannot be understood in isolation. The meaning of marketing is inter-woven in the concept of human needs and wants, products, exchange process and the market. Let's start our journey of finding the meaning of the term marketing through these concepts.

Concept of needs and wants

Every human being living on this planet earth is a bundle of needs and wants. All of us –keep on working throughout the day in order to fulfil a purpose – the purpose being to satisfy various needs and wants.

What is a Need: A need is a state of felt deprivation of some generic satisfaction arising in the human conditions. People need air, water, food, clothing, shelter etc. These are basic needs, which have to be fulfilled for very survival. Man's needs are few and limited.

What is a Want: Wants are desires for specific satisfiers of the ultimate needs. A person needs food to survive but the same person may want a pizza, burger, cake or biscuits to satisfy his wants. A person may need water to quench his thirst but may want to have a drink of cola, apple juice, rose sherbet, tea or coffee.

As compared to man's needs, which are few and limited, his wants are unlimited. The list of wants is large and keeps on growing.

The wants of human beings are not static. They keep changing depending upon changing social patterns and life-styles, income etc. A person today may be contented with Maruti 800 but say, two years later the same person may want to own a Honda City or a Sonata.

Activity

In the following Table, three types of needs are given. Based on this, think and list four types of wants, which a person would like to fulfil.

Needs	Wants
a) Men's clothing	1. 2. 3. 4.
b) Women's clothing	1. 2. 3. 4.

c) Shelter	1. 2. 3. 4.
d) Relaxation	1. 2. 3. 4.

Hint:

A. Safari, Silken Kurta Pyjama, Designer Suit, Jeans
B. Silk Saree, Leather Coat, Jamawar Shawl, Expensive Evening Gown
C. Flat, Farm House, Big Bungalow, Haveli
D. Dancing, Yoga, Meditation, Gym

Concept of product

A human being is in a position to satisfy his needs and wants through a product.

A product includes any object, service, activity or place through which a need or a want may be satisfied.

For example a product can be an 'object' like apple juice or it can be 'service' like showing of a play at a theatre or it can be an 'activity' like taking part in dancing during harvesting season, festivals etc. or it can be a 'place' like visiting 'tea gardens' at Palampur.

Concept of exchange

As already said, a person is in a position to satisfy his need through a product. How is the product to be made available to him? The product can be made available to any person through the process of exchange. The exchange can be through:

Barter: A person in need of wheat offers rice to another person and exchanges wheat for rice with him.

Money: For example, a hungry person may give money to get a cheese patty i.e exchange money for a cheese patty.

Getting a service: A person gets his clothes washed by another, giving him food in return.

After understanding these terms, we can now proceed to discuss what market and marketing mean.

Concept of market

The word market has its origin in the Latin word "Marcatus". It means merchandise, ware or trade. A market is the set of all actual and potential buyers of a product.

Traditionally, the term market was used to refer to a place where buyers and sellers met for exchange. But now, due to the growth and development of technology, buyers and sellers can conduct business without meeting at a place. Dealings can now be done through telephone, mail, Internet, etc.

Internet has no doubt created a revolution. It has given rise to a virtual market through which a seller can reach any customer anywhere, anytime; and so can the buyer reach the seller.

The term market in a wide sense is the set of all actual and potential buyers of a product. It takes into account the fact that whenever there is a need or a want and the wanted product is available for sale or exchange - a potential for trade: there is a market.

The term market can be looked upon from many directions.

Place of business: The term market, in common language, is used for a place where business is conducted. It is a place where customers go to purchase various goods to satisfy their needs and wants e.g. Lajpat Nagar market in Delhi and find sellers offering those goods for sale or exchange.

Nature of the products: The term 'market' may also suggest the nature of the product, which is traded there. For example, subzi market, cloth market, etc.

Volume of trade: The term 'market' is also at times used to indicate the volume of trade, which takes place between the buyer and seller. The place where goods are traded in bulk is called wholesale market and where goods are sold in small quantities is called retail market.

Concept of marketing

Marketing means working in and for markets. It can be referred to as an exchange transaction that takes place between the seller and the buyer. The needs and wants of the buyer and seller are met through the exchange transaction. Marketing is, therefore, a human activity directed at satisfying needs and wants through exchange process.

According to Philip Kotler, marketing is a "social process by which individuals and groups obtain what they want through creating, offering and freely exchanging products and services of value with others."

5.3 HOW TO ASSESS MARKET FOR ANY BUSINESS IDEA

A number of factors are to be considered for the assessment of the market (Figure 5.1). A businessman must take these factors into consideration while assessing the market. Following diagram depicts the factors affecting the assessment of market.

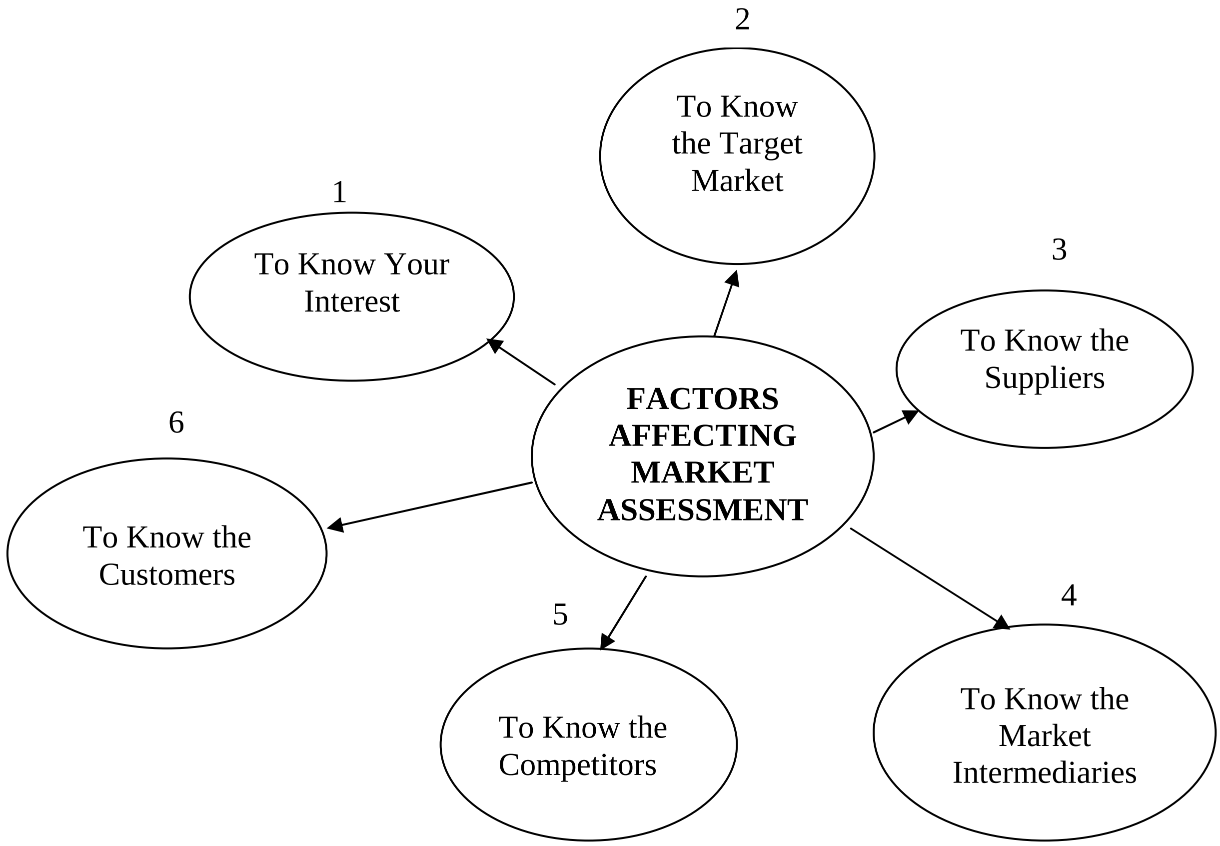

Figure 5.1: Diagrammatic presentation of factors affecting market assessment

Let's now discuss these factors:

1. To Know Your Interest

Before assessing the market, the businessman must first assess himself – he being a part of the market as well.

Have you ever pondered over whether all the people who thought of starting and running a good business were able to do so? Were they all successful in their mission to enter the market and then grow and develop, face the competition and so on.

Well, the answer is that a few businessmen did succeed in their objective whereas there were unlucky ones who did not. They could not muster any grip over the market, made wrong decisions and had unhappy experiences.

What were the consequences of the above-mentioned happenings? Gradually their business showed losses year after year and the saying "started with a boom and ended with a whimper" fully suited them.

Did these people really look into themselves before they started? Did they realize that they were poor planners or did not have an alert and dynamic mind, were visionless etc.

Because of their weaknesses resources (money, human workforce, natural resources etc.) got wasted leading to personal, social and national wastage.

Therefore it is the duty of every person who is thinking of starting a business to ask himself:

- Is he really ready to face the market?
- Is he able enough to survive in the market?
- Can he plan a strategy to save himself from losing in the competition?
- Will he be able to fulfil all the economic, social, national objectives of entering business?

A businessman needs to have certain qualities. Some of the qualities may be inherent in his nature, whereas a few of them can be imbibed. Without these qualities, it will be difficult for a businessman – whether working on a small scale or large scale – to survive, grow and expand his business.

The qualities, which are very essential for any businessman are as follows:

Personal Qualities:

- Equable temper
- Pleasant behaviour
- Considerate nature
- Openness

Physical Qualities

- Good health
- Stamina
- Impressive personality

Mental Qualities

- Clear mind
- Confidence
- Enterprising
- Practical skills
- Rational judgment
- Good memory

Education and Training

- Minimum qualification required for that particular kind of activity
- Training in required skills
- Knowledge of business methods
- Knowledge about maintaining accounts and
- Complying with legal and government regulations

Qualities to Tackle Customers (Customer Oriented Qualities)

- Should act as a friend, philosopher and guide
- Maintain good interpersonal relations
- Have patience

Competition Oriented Qualities

- Dynamic
- Flexible
- Alert to opportunity
- Quick reflexes

- Creative
- Innovative
- Foresighted

Moral Qualities

- Honest
- Truthful

Managerial Qualities

- Good planner
- Rational decision maker
- Good motivator
- Good leader
- Good communicator
- Good listener
- Good organizer
- Careful – not rash
- Willing to accept challenges
- Risk taker

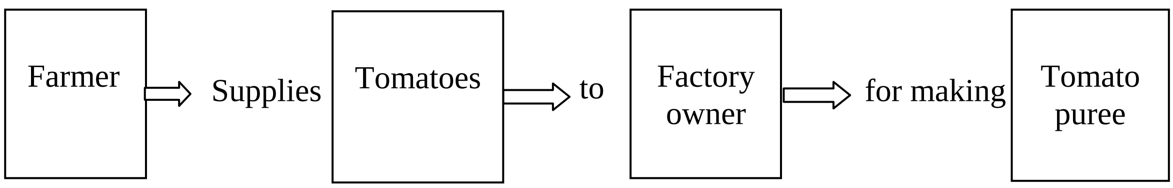
2. To Know the Type of Target Market

The businessman needs to decide on the market, which he wishes to cater to or enter. He may find two types of markets:

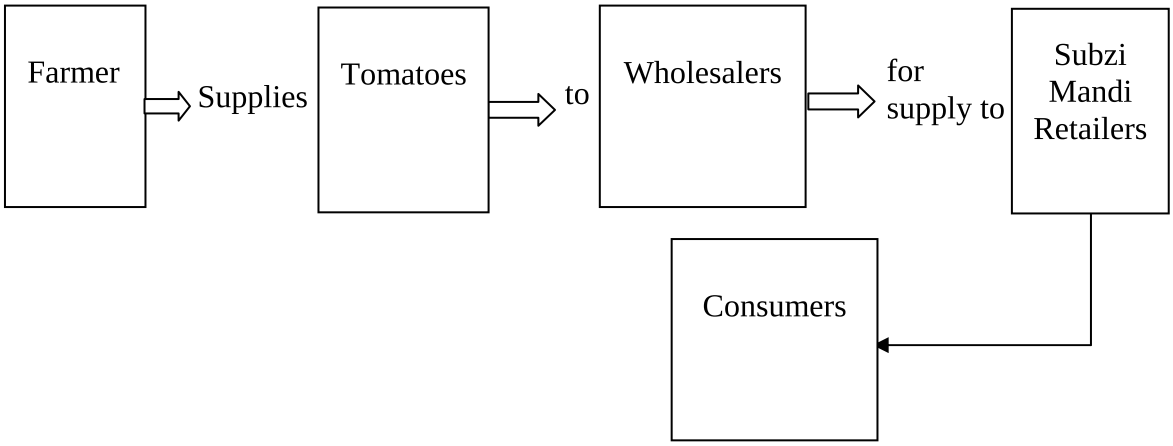
a) Producer Market; and
b) Consumer Market.

These are explained in the subsequent paragraphs.

a) *Producer market:* The goods supplied to industrial market are usually in the form of raw material and for further production not for final consumption. The raw material is processed and converted into finished product. It is then sold to the consumers. For example, tomatoes are processed in the factory, and converted into tomato puree. This process is depicted through the following diagram in which the farmer (i.e. businessman) supplies tomatoes (i.e. raw material) to the factory owner (i.e. industrial market) for converting into tomato puree (i.e. output):



b) *Consumer market:* The 'consumer market' comprises various consumers. The goods purchased from this market are for direct consumption. The buyer of the product is the final user. He purchases the finished product to satisfy his needs and wants. This process is depicted through the following diagram in which the farmer (i.e. businessman) supplies tomatoes (i.e. finished product) to wholesalers (i.e. middlemen) for further supply to subzi mandi (i.e. consumer market) and for final consumption by the consumers:



3. To Know the Suppliers

The businessman in order to produce something must acquire a number of inputs needed in the production process. These are made available through a number of suppliers.

There are many kinds of suppliers for various inputs.

Input No. 1 – Money: There are various sources for arranging finance. The businessman can pool his own savings. Money can also be obtained from other sources like friends and relatives, commercial banks, co-operative societies, Regional Rural Banks etc.

Input No. 2 – Manpower (Human resources): The number and type of workers needed by a businessman depends upon the nature and scale of his business operation. A large-scale business may need clerical staff, managers, accountants, workers etc. whereas a small businessman may need only a couple of helpers.

Input No. 3 – Material: The businessman should know the type of material required to make the product. The businessman needs to deal with the suppliers of raw material. The raw material like oil seeds, cotton, fruits, vegetables and other agro-based products can be obtained from the cultivators or Agricultural Produce Market.

Input No. 4: Machines: The tools, equipment, machines etc. can be purchased directly from the manufacturers of these items or their agents. Some of the machines can be imported also depending upon the cost-effectiveness.

Input No. 5 – Information: The businessman needs to gather information as to the latest machines available or latest methods of production etc.

For a bird's eye view let's look at the following diagram, which shows the various types of suppliers. These are also known as five M's of marketing.

M **E** **N**	**M** **A** **T** **E** **R** **I** **A** **L**	**M** **A** **C** **H** **I** **N** **E**	**M** **O** **N** **E** **Y**	**M** **E** **T** **H** **O** **D** **S** **(Information)**

(Five M's of Marketing)

The businessman should also keep in mind the strength of suppliers. At times, the suppliers of above inputs are in a dominant position and dictate their own terms and conditions to the businessman.

Activity

Roop and Swaroop are two close friends living in a small town of Uttranchal. They are planning to deal in following types of packed spices:

- Red Chili Powder
- Turmeric Powder
- Dhania Powder
- Chana Masala Powder
- Chaat Masala Powder

How will they assess their market in terms of their suppliers? The market assessment may be filled in the following Table:

Sl. No.	**Inputs**	**Decisions regarding the availability of inputs**
A.	Men	1. 2. 3. 4.
B.	Material	1. 2. 3. 4.

C.	Machine	1. 2. 3. 4.
D.	Money	1. 2. 3. 4.
E.	Method	1. 2. 3. 4.

Hint:

A. Production Manager, Marketing Manager, Workers etc.
B. Red Mirchi, Turmeric, Dhania Seeds, Spices
C. Grinding Machine, Sieves, Packing Machines, Other Tools and Equipment
D. Own Savings, Funds from Friends and Relatives, Borrowings from Banks, RRBs
E. Offices of SSI, Economic Survey of India, FICCI, CII, STC

4. To Know the Marketing Intermediaries

Marketing Intermediaries act as the middlemen or 'go-between' for the businessmen and the market i.e. the consumers. They help in the distribution of the output of the businessmen to the market. To make this clearer, let's study the case of Neelam.

25-year old Neelam lived in Himachal Pradesh. She was a born painter. As a hobby, she made, lovely landscapes, portraits, other paintings using vegetable colours as the medium. To improve her standard of living, she thought of selling those paintings and soon thereafter, she along with her husband, started selling them to the rich families of nearby areas. Sale of the paintings was a morale booster for her. At this stage, an idea struck her mind. If she could make more paintings and sell them to a wider range of people? With full determination she started doing the work and in the next two months she made twenty-five beautiful paintings using vegetable colours. It was the time for the tourists to flock to these cool refreshing hill stations. Within a week's time she and her husband were able to sell off all the paintings. This made them to earn an unimaginable figure of Rs. 15,000.

One of the tourists hailing from Delhi was greatly impressed by her paintings. Luckily, he was known to Neelam's neighbours. He suggested to Neelam to sell the paintings in hi-fi shops of Delhi. He said that she would fetch a handsome price for these lovely creations of hers. Neelam and her husband liked the idea but there was nobody to guide them and help them in selling paintings in Delhi. This made them sad. But the tourist solved their problem. He said that he was a very influential person and knew a lot about the market and people of Delhi. He could take her paintings to Delhi and sell them to the hi-fi shopkeepers on commission basis. Accordingly, the deal was made.

Now, who is this Mr. Tourist? What is his role in the entire process of exchange? Well, he is acting as an intermediary. He is the middleman between Neelam and the shopkeepers of Delhi, whom Neelam does not know.

There are three kinds of intermediaries as explained below:

i) *Merchant middlemen:* They are business units (like wholesalers and retailers). They buy, obtain title to the merchandise and sell them further.

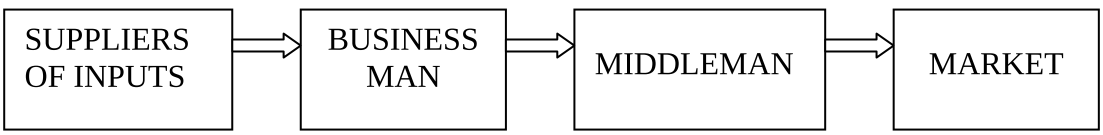
ii) *Agent middlemen:* They are the business units (like brokers and sales representatives). They negotiate purchase or sale of merchandise but do not take possession of title thereto.

iii) *Facilitators:* They are business units that assist in the performance of distribution function. They neither take possession of title to goods nor negotiate purchase or sales of merchandise e.g. transporters, warehouses, bankers etc.

The businessman seeking distribution of his goods must either use established marketing intermediaries or set up his own system of distribution. The existing marketing intermediaries have the experience. However, if the businessman finds these intermediaries to be inadequate for his needs, he can establish his own network. Direct marketing can be the way to reach the final consumers through:

- Sales force
- Direct mail
- Telephone
- Internet

The role of intermediaries can be represented with the help of the following diagram:



5. To Know the Competitors

I think you'll agree with me if I say that a particular businessman is not standing alone as a seller in the market. There are others too in the trade.

For example Babu sells oranges on his 'Thela'. Now, is he the only person selling oranges? No, there are many others on the same street, in the colony or in the entire area.

The businessman must realize that other businessmen are also putting in equal amount of hard work, efforts, and dedication. There are a number of things, which the businessman should know, to compete with his business rivals or competitors. He should:

- Know about the number of firms in the same industry;
- Know about the market share of the top few firms;
- Know about the degree of homogeneity and differentiation in respect of his product;
- Know about the entry barriers operating in the market;
- Compare his product with the substitutes in terms of quality, price and appeal;
- Know about the market policies and practices.

The strength and weakness of the competitors also need to be found out and analysed. The businessman will compete most closely with those competitors who occupy a similar position or niche in the market. The businessman should therefore identify and monitor most closely those competitors who are seen to be close to him in the minds of the consumers.

6. To Know the Customers

Customers consist of all the individuals and households who buy or acquire goods and services for personal consumption.

There may be different types of customers in the market like old and young, poor and rich, illiterates and educated etc. The businessman should be able to distinguish different groups and develop products tailored to their particular needs. For example, a new type of custard powder or ice cream may be developed to attract the young generation.

With a view to knowing the customers, the businessman should ponder over the following aspects:

- *What do people buy?*

  The customers may buy the following kinds of goods:

  i) Durable Goods: These are tangible goods, which can be used again and again, comparatively for much longer period of time. These may include furniture items, utensils etc.

  ii) Non-durable Goods: These are the goods, which are usually consumed in one go or are meant for few uses – say, fruits, vegetables, ketchup etc.

  iii) Convenience Goods: These goods are purchased very often for immediate use by the customers. The consumers will not compare the product with any other product before purchasing e.g. bread, buns, sugar, salt, food-grains etc.

  iv) Shopping Goods: These goods are purchased after due comparison with other products in terms of quality, price etc. e.g. tea, sherbets, shoes, cosmetics, furniture, etc.

  v) Specialty Goods: These are the goods, which have some unique features and brand identification. The buyer will make a special effort in purchasing these items e.g. Chocolate, sauce, Badam-Pista mixture, imported chocolates, ready-to-eat curries, olive oil, Badam rogan, television, washing machine, car, imported fruits, etc.

Activity

Visit the nearby market in your area and gather the following information for completing the Table given below:

Product	Available brand	Price	Size/weight
Tea			
Strawberries			
Imported Fruits			

- *When do consumers buy*

  The businessman should analyse the timing of purchase. A consumer may buy a product frequently or the consumption rate may be low e.g. a family with young children may buy more of chocolates, potato chips etc. compared to roasted dalia.

  The consumer may also buy at the time of festival e.g. sweets at the time of Deepawali, new clothes at the time of Rakshabandhan, rock salt and kutu atta during the 'Navratri days' when people keep 'fast', sewyian during Id, etc.

- *What do consumers want*

  The consumers purchase goods to satisfy a variety of their needs. These needs may be physiological, spiritual, social, psychological, etc. Each product offers the buyers certain amount of utility. The customers weigh whether utility derived from the product matches the price paid by them.

- *How do consumers buy*

  The businessman should study the buyers' decision-making processes that lead to a particular 'buying decision'. The businessman must try to understand the various cultural, social, and personal factors that operate to shape the life-styles of the customers. For example, in the case of apple jam, a person living in urban area may like to purchase it but the same may not appeal to a person who is living in rural area. A villager may like more to use mango chutney. Other factors, which may influence 'buying decision', include features of the product, its price, its quality, after-sales service provided by the seller, etc.

  Buying process starts when the consumer feels the need for a product. Thereafter, he generally continues with the following buying process:

  i) In order to fulfil his needs the consumer seeks information from his environment. He tries to gather more awareness about the product that would satisfy his need;

ii) The consumer after securing information develops an attitude – positive or negative – towards the product;

iii) If a favourite attitude towards the product is developed, the consumer tries the product on a small scale;

iv) Finally, if the trial is successful, he may buy the product – he may even become loyal to the product or brand.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Read the following and answer the questions that follow:

   "Raj Kishore has a mango garden in his village. He sells the mangoes grown in his garden to a firm of Sonepat namely, "Home-made Pickles" for making mango pickles.."

   i) Will the mangoes sold to "Home-made Pickles" be used by the owner of the firm and his family for personal consumption?

   …..……………………………………………………………………….

   …..……………………………………………………………………….

   …..……………………………………………………………………….

   ii) Why is the firm buying the mangoes?

   …..……………………………………………………………………….

   …..……………………………………………………………………….

   …..……………………………………………………………………….

   iii) If Raj Kishore plans to sell mangoes in the fruit market, who do you think will be the final users?

   …..……………………………………………………………………….

   …..……………………………………………………………………….

   …..……………………………………………………………………….

2. Krishna Kumar wants to make and sell vegetable sauce. List the kind of workers, he will employ:

   i) ……………………………………………………………………….

   ii) ……………………………………………………………………….

   iii) ……………………………………………………………………….

   iv) ……………………………………………………………………….

   v) ……………………………………………………………………….

3. Why has the businessman to identify and monitor his competitors?

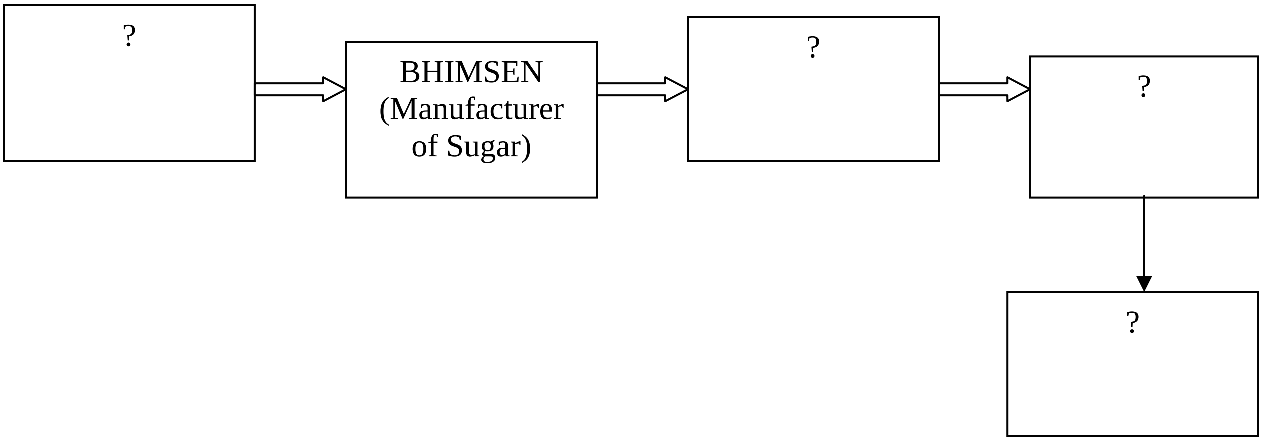
…………………………………………………………………………………

…………………………………………………………………………………

…………………………………………………………………………………

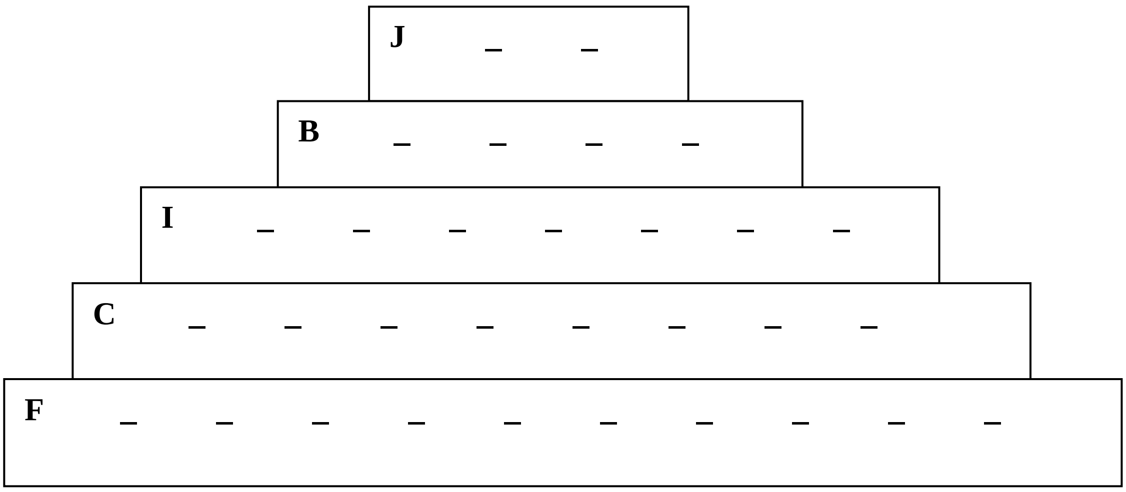
…………………………………………………………………………………

4. Bhimsen is a businessman owning a sugar mill in District Meerut. Identify his suppliers of raw material, middlemen and the market and complete the process given below:



5. Fill the following pyramid on the basis of under-mentioned information:

- A business unit that assists in the performance of distribution. (11 letters)
- A source from where money can be arranged. (5 letters)
- A source of direct marketing. (8 letters)
- The individuals who buy goods for personal consumption. (9 letters)
- A sweet consumer product, which is manufactured using fruit as a raw material (demographic segmentation – small children). (3 letters)



5.4 WHAT CONSTITUTES THE MARKET FOR YOUR BUSINESS IDEA

Market consists of consumers. A market for any businessman comprises those persons who he thinks will buy his product. A businessman desiring to cater to the consumer market should understand the fact that consumers vary widely in their characteristics. They may differ in age, geographical location, income, education level, taste, product requirements, buying attitudes (a family may buy bananas only on Mondays), etc. Any of the above aspects can make a difference in customers' fancy or in the capacity of the firm to effectively serve that customer.

From the above it can be interpreted that the consumer market is not fully homogeneous but is heterogeneous in nature. The heterogeneous market can be broken down into a number of homogeneous units. This division of market is called market segmentation. The businessman through market segmentation, aims to satisfy the needs of the customers in a much better way. He tries to focus sharply on each of the different customer groups or any one of the customer groups within a market. Market segmentation leads to market targeting. In this Unit we will study about market segmentation and market targeting.

MARKET SEGMENTATION

A business unit normally is not able to serve all the customers. It may be due to the fact that there are too many customers in the market. Again, all of the customers are widely scattered. Moreover, some competitors will be in a better position to serve the customers in the market.

If the resources are limited, then the business unit should try to identify those market segments that it can best serve in terms of segment preferences, patterns of competition and the strength of the business.

There are many ways in which a market can be segmented. These are discussed below:

1. *Geographical segmentation (Geographical markets)*

   In geographical segmentation, the businessman divides the market into different locations – neighbourhood towns, cities, districts, states, country and international markets. The businessman will target a particular geographical market keeping in mind the market potential and the costs incurred to reach the market e.g. Amul initially marketed its products only in Gujarat.

2. *Demographic segmentation*

   Under demographic segmentation, the businessman divides his customers on the basis of age, gender, family size, city size, religion, language, occupation, educational level etc. For example, in the case of chocolates and beverages, the target customers are young children and adolescents.

3. *Buying behaviour segmentation*

Under buying behaviour segmentation, customers are divided on the basis of purchase decisions made by them. The idea behind this is that different customer groups expect different benefits from the same product and as such their motivation in owning it and their behaviour in buying it will be different.

4. *Benefit segmentation*

Under benefit segmentation, the consumers are classified according to the benefits they derive from the product. For example, benefits derived from 'Amla Murabba'.

5. *Volume segmentation*

The quantity of purchase is another basis used for dividing the customers. There may be bulk buyers, small-scale buyers, regular buyers and one-time buyers.

6. *Economic segmentation*

Under economic segmentation, customers are divided on the basis of their income level. For example, Mother Dairy ice creams are available in different price ranges so that anybody according to his income level may purchase the same. In bakery shops we may find a variety of cakes like vanilla cake, chocolate cake, truffle cake, etc. A customer may buy a particular cake, which suits his income level.

7. *Psychographic segmentation*

This kind of market segmentation is done on the basis of customers' attitude, opinion, interests etc. or a combination thereof.

MARKET TARGETING

Market segmentation leads to market targeting. Market targeting is the process of fixing target market.

You may note that process of market segmentation opens up not one but several market segments. These segments will have varying potential, profitability and the degree of risks. The firm must evaluate the worth of each segment in terms of whether it is sizeable, accessible, attractive and profitable. The firm may not be interested in all the segments. Some may give high profitability but may need heavy initial investments. Some may have potential but the firm may face tough entry barriers. Thus, the firm needs to select one or more segments as the target market. The segment selected as target market must be most appropriate to the firm. This is what constitutes the market for a particular business idea.

With the help of market targeting, the businessman is in a position to identify the markets and the group of target customers for whom he plans to produce products. Market targeting is the act of evaluating and comparing different identified groups. After evaluation and comparison the businessman may select one or more of the identified groups as the prospective customers with the highest potential. Thereafter a suitable marketing mix may be devised that will give the best return on sales.

Check Your Progress Exercise 2

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. State True or False:

   i) The businessman must look at each market segment as a distinct marketing opportunity.

   ii) Market segmentation must be relevant and profitable to the businessman.

   iii) Market targeting leads to market segmentation.

   iv) Consumer market is fully homogeneous.

   v) Target market can be fixed at random.

2. Match the following:

i) Location	A) Economic segmentation
ii) Age	B) Geographical segmentation
iii) Quantity	C) Buying behaviour segmentation
iv) Income level	D) Demographic segmentation
v) Purchase decision	E) Volume segmentation

3. 'Swadeshi Beverages (Pvt.) Ltd.' is planning to launch a health drink for old people. On which base would they segment their market?

   ……………………………………………………………………………………

   ……………………………………………………………………………………

   ……………………………………………………………………………………

5.5 MARKET SIZE FOR YOUR BUSINESS IDEA

Meaning of market size

Market size means the actual volume that is currently being purchased by the customers. It can be measured in terms of rupees or units. It is always smaller than the total market potential.

Meaning of total market potential

Total Market Potential is the maximum amount of sales that might be available to all the firms in an industry during a given period under a given level of marketing effort and given environmental conditions. It is also measured in rupees or units.

Assessment of market size

Assessment of market size depends upon the following two factors:

i) Market demand: This means the total volume that would be bought by a customer in a defined time period. A product should have a demand in the market. A demand is said to be there when a person has some interest in that product and he also has the purchasing power i.e. necessary resources for purchasing the product.

To assess the market size, the businessman should undertake *demand forecasting*. Some of the methods, which a businessman may use for demand forecasting, are:

- *Survey method:* Under this method the businessman tries to gather information in respect of demand for his product. In this connection he obtains information from sales representatives, prospective customers, suppliers, experts etc. Based on the information collected, he calculates the demand for his product.

- *Leading indicator method:* Some leading indicators may show the trend of future. Now-a-days frozen vegetables (like peas) have a huge demand. This being a leading indicator, the supplier of packaging material, in which the frozen vegetables are packed, may anticipate that there will be huge demand for packing material also.

- *Statistical methods:* Certain statistical methods like multiple regression analysis and time series may be used to forecast the demand.

ii) Price: The size of the market will vary with price. A high price of a product may create a small market whereas a low price of the product may fetch a larger market. This is due to the fact that more people can afford to purchase the product.

Check Your Progress Exercise 3

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Fill in the blanks:

   i) ----------- is the maximum amount of sales that might be available to a businessman.

   ii) ----------- is the actual volume that is currently being purchased.

   iii) A product should have a --------------- in the market.

   iv) High price shall have ------------- market.

   v) ---------------- is the total volume that would be bought by the consumers.

2. Name any one unit of measurement, which may be used to measure the market size.

5.6 LET US SUM UP

For setting up a business and its successful continuation, market assessment has an important role to play. Before understanding the term market assessment, it is a must to understand concept of needs and wants, concept of product, concept of exchange, concept of market and concept of marketing. A number of factors affect market assessment. These factors include knowledge of self (i.e. self-assessment); knowledge of the type of target market; knowledge about the suppliers; knowledge about the intermediaries; knowledge about the competitors, and knowledge about the consumers. Market consists of consumers. Consumer market is not fully homogeneous but is heterogeneous in nature. The heterogeneous character of the market may be broken down into a number of homogeneous units and this kind of division of market is called market segmentation. Market can be segmented on the basis of geographical segmentation, demographic segmentation, buying behaviour segmentation, benefit segmentation, volume segmentation, economic segmentation and psychographic segmentation. Market segmentation leads to market targeting. With the help of market targeting, the businessman can identify the market and the group of target customers. Market size also plays an important role. Assessment of market size depends upon market demand and the price of the product.

5.7 KEY WORDS

Market segmentation	:	Division of market on certain bases.
Product	:	Any object, service, activity or place which helps in satisfying a need or a want.
Wholesaler	:	A middleman who purchases goods from the manufacturers in bulk and sells to the retailers.
Retailer	:	A middleman who purchases goods from the wholesalers and sells to the ultimate consumers.

5.8 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

Your answer should include following points:

1. i) No ii) For making pickles iii) Consumers

2. i) Persons in the factory ii) Clerical staff iii) Accountant
   iv) Receptionist iv) Marketing Manager

3. To gain and maintain loyalty of the consumers.

4. Farmer; Wholesalers; Retailers; Consumers

5. Words to be filled in the pyramid are:

   - Facilitator
   - Banks
   - Internet
   - Consumers
   - Jam

Check Your Progress Exercise 2

1. Gupta, C.B. and Rajan Nair, N. (2000) Marketing Management, Sultan Chand and Sons, New Delhi.

2. Kotler, Philip (2004) Marketing Management – Analysis, Planning and Control, Prentice Hall of India, New Delhi.

3. Ramaswamy, V.S. and Namakumari, S. (1998) Marketing Management (Planning, Implementation and Control – The Indian Context), Macmillan India Limited, Delhi.

4. Varshney, R.L. and Gupta, S.L. (2000) Marketing Management (An Indian Perspective); Sultan Chand and Sons, New Delhi.

5.10 ASSIGNMENTS

1. Elaborate the term ‘market’ and ‘marketing’.

2. Mention in brief the procedure, which a consumer may follow in buying the product.

3. What is the difference between wholesalers and agents?

4. What is Market Segmentation? In which ways can a market be segmented?

5. Classify the following products into convenience goods, shopping goods and specialty goods:

   i) salt
   ii) sugar
   iii) shoes
   iv) air conditioners
   v) clothes
   vi) bread
   vii) cars

6. Explain the following:

   i) Geographical Segmentation;
   ii) Demographic Segmentation

7. Distinguish between convenience goods and specialty goods on the basis of price and sale effort.

8. Name the two factors on which the size of market depends.

9. Enumerate the various qualities, which a businessman needs to assess himself.

10. Explain briefly the methods of demand forecasting.

UNIT 6 WHAT DOES MARKETING INVOLVE?

Structure

6.0 OBJECTIVES

After studying this unit, you should be able to:

- refresh the understanding of marketing;
- identify the various marketing functions;
- understand the concept of marketing mix;
- comprehend and analyse the 4 P's of marketing mix; and
- apply the elements of marketing mix to the practical world.

6.1 INTRODUCTION

Marketing, as you are all aware of, starts with the consumer and ends too, with the consumer. The businessman takes the consumer to be the king and therefore, the consumer becomes the focal point of all of his marketing decisions. The businessman has become sensitive to the attitudes of the consumer. He therefore, tries to materialize his goals through consumer satisfaction.

Marketing is the central function of any business. The entire business is organized around the marketing function. The businessman emphasizes identification of market opportunity and seeks to convert customer "needs" into "products". The entire business is a customer satisfying process.

The businessman has to get involved in a number of activities to satisfy his customers and thereby earn profit. Marketing consists of all those activities, which involve working through markets. It covers all those activities and processes by which the products are matched with the market. Marketing functions refer to a series of specialised activities involved in the marketing of goods and services.

Let's try to understand these marketing functions in the subsequent paragraphs.

6.2 MARKETING FUNCTIONS

Production of goods by the business gains importance only when they are sold. Marketing enables a businessman to sell his goods to the consumers.

The functions of marketing make goods and services of use to the society by creating form, place, time and possession utilities. Goods are to be processed into different forms to suit the needs of the consumers, creating thereby the form utility. Goods are required to be transported from the place of production to the place of consumption, thereby creating place utility. Surplus goods are also required to be stored in warehouses for deferred consumption, thereby creating time utility. Sale and transfer of goods create possession utility.

The functions of marketing may be broadly divided into three categories:

I) Functions of Exchange;
II) Functions of Physical Supply; and
III) Facilitating Functions.

The diagrammatic presentation of marketing functions (Fig 6.1) is as follows:

MARKETING FUNCTIONS

Functions of Exchange

- Buying
- Assembling
- Selling

Functions of Physical Supply

- Transportation
- Storage (i.e. warehousing)
- Inventory control;
- Order processing

Facilitating Functions

- Marketing Research
- Product Programming and Development
- Standardisation and Producing
- Packaging
- Branding
- Promotion
- Pricing
- Financing
- Risk taking

Figure 6.1: Diagrammatic presentation of marketing functions

Let us now discuss these functions in detail.

I. Functions of exchange

The functions of exchange include activities performed in the transfer of ownership from sellers to buyers. They include:

1) Buying
2) Assembling
3) Selling

1) *Buying function:* A marketer is engaged in the process of transformation. He takes inputs from the environment, converts them into a finished product and then supplies it back to the environment. Buying involves transfer of ownership of the product from seller to buyer.

   A manufacturer buys raw material from the suppliers for using the same in producing goods whereas a trader procures finished goods from the various manufacturers. A trader can be a wholesaler or a retailer. A wholesaler buys the goods for resale to retailers whereas a retailer buys the goods for resale to the ultimate consumers. Efficient buying is very important for success in marketing.

   Goods can be sold at a profit only when they are of right quality and quantity. The following points, known as five R's of best buy, should be kept in mind before any purchase:

   - Right source
   - Right quantity
   - Right quality
   - Right price
   - Right time

2) *Assembly function:* The work of assembly begins only after the goods have been purchased. It implies gathering of products purchased from different producers/manufacturers at some central place. Some times firms assemble goods in big lots, grade them and give their own brand name after packing the goods.

   For example, Niharika Agro Products purchases rice from various farmers, grades them according to the quality, packages in small lots, gives a brand name (Raja Chawal) and sell it to the wholesalers.

3) *Selling function:* Selling is a very important function of marketing. It is vital to the success of any firm because the revenue is earned by the businessman through selling. The businessman on the one hand, earns profits while on the other hand, he makes available the goods and services to the consumers. Selling can be defined as "effecting transfer of ownership in goods by the seller to the buyer in exchange for money".

Selling involves many activities like locating buyers, finding their preferences, persuading them to buy, negotiating the terms of sale, receiving payment and making delivery, and providing appropriate after sale services.

An enterprise may sell goods directly or through agents, wholesalers and retailers.

II. Functions of physical supply

The functions of physical supply refer to the activities involved in the physical movement of the goods. These functions are:

i) Transportation

ii) Storage (i.e. warehousing)

iii) Inventory management

iv) Order processing

v) Delivery

The details of these functions are given as under:

i) Transportation: Transportation is physical movement of material and goods from one place to another. The function of transportation is quite important because goods are not consumed at the place of their production. Customers are located at far away places. Therefore, goods have to be transported. Transport serves as a link between the producer and the consumer. Proper arrangement for the transportation of the product to market is important to the process of marketing. Transport helps to widen the market; to increase the scale of production and to stabilize the prices. The essence of transportation is that the right product reaches the right destination at the right time. Transportation includes decisions like:

- Choice of mode of transport
- Route planning
- Freight consolidation
- Vehicle scheduling

It may be noted that choice of mode of transport depends upon relative costs of different modes, their speed, reliability, frequency etc. Road transport is suitable for short distances and for rough terrains like mountains. Rail transport is ideal for bulky goods and also if the goods are to be sent over long distances. When goods are costly or of perishable nature and where speed counts, air transport should be preferred. Water transport is the cheapest but it slower.

The various means of transport can be depicted in the following diagram (Fig 6.2):

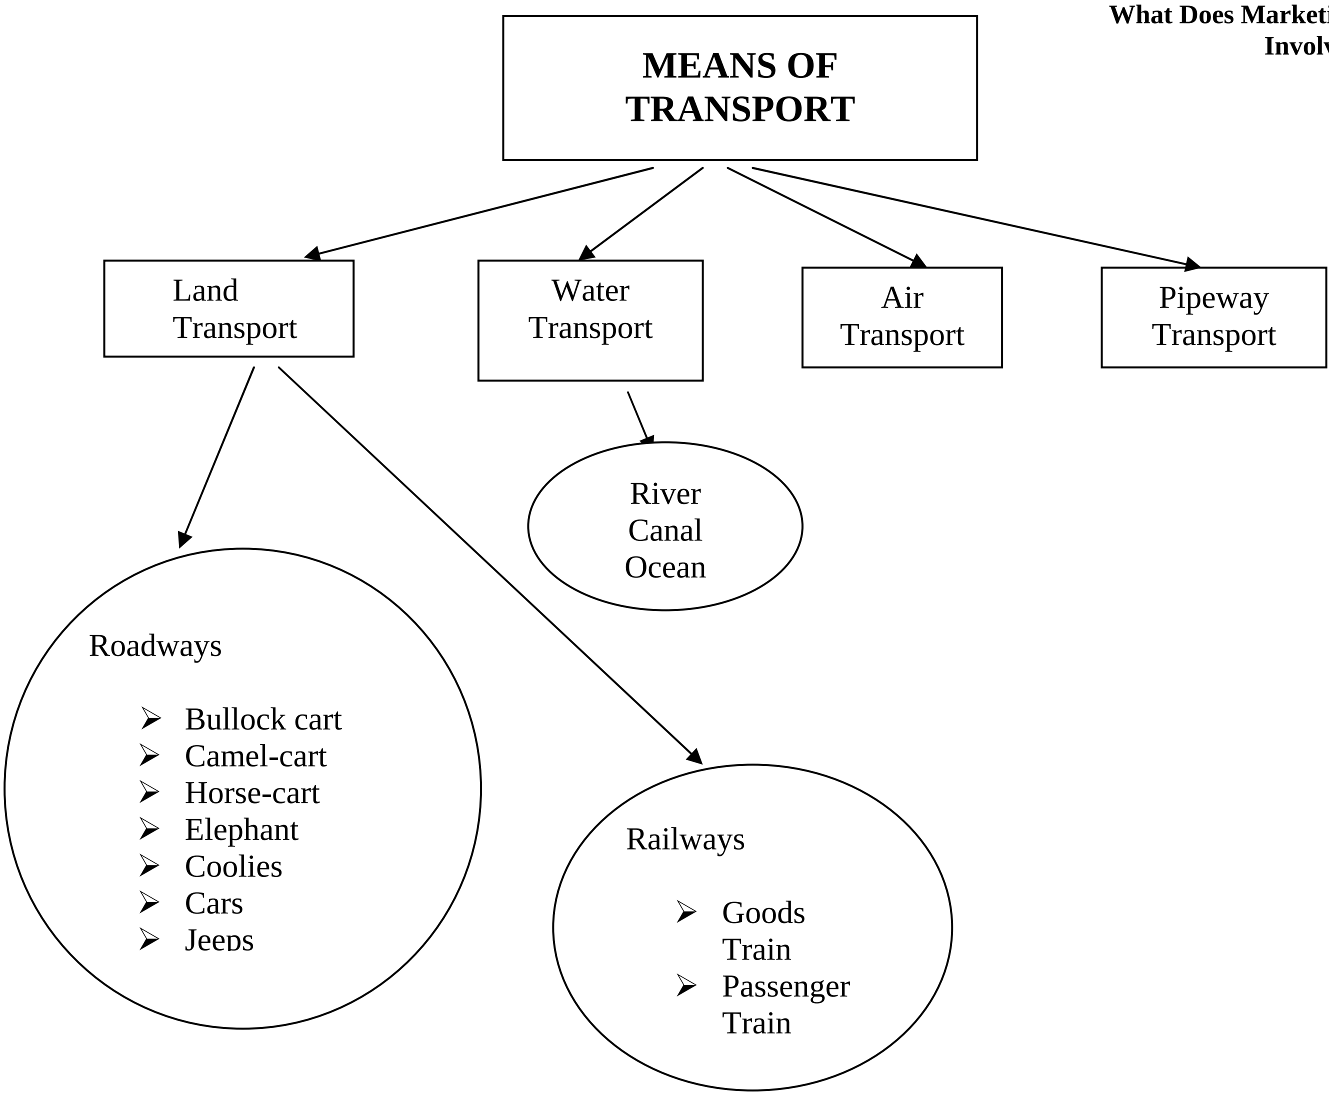

Figure 6.2: Diagrammatic presentation of means of transport

Activity

Tick the appropriate option:

Particulars	Road	Railways	Water	Air
1. Amarnath wants to transport 100 quintals of rice from Bihar to Rishikesh in Uttranchal.				
2. Vinay wants to transport 10 quintals of wheat from Ghaziabad to Bulandsahar.				
3. Ram Singh wants to transport 500 tons of sugar to London				
4. Suraj Nath plans to send 500 kilos of onions from Azadpur Mandi to Okhla Mandi (both places are in Delhi.				
5. Sham Lal wants to send 100 kgs. of rose flowers from Delhi to Chennai.				

(**Hint:** 1. Railways; 2. Road; 3. Water; 4. Road; 5. Air)

ii) *Warehousing:* Another function of marketing process is warehousing. It involves the making of proper arrangements for retaining the goods in a perfect state till the time consumers need them for consumption. Warehousing function is important because there is usually a time lag between production and consumption. With the help of warehouses where goods are stored, uninterrupted supply is maintained so that there is no inconvenience to the user and there is stability in prices. Modern warehouses provide facilities for packing, blending, grading, labelling etc. of stored goods. A manufacturer can secure wider distribution of goods by holding stock at different places. Further the goods get protected from the following risks:

- Fire
- Theft
- Leakage
- Pests, rodents and insects
- Weather changes
- Moisture

The owners may maintain their own warehouses or take the services of warehousing companies. Perishable products like fruits, vegetables etc, are stored in cold storages.

Benefits of warehousing

There are a number of benefits in warehousing. These are:

- Goods can be manufactured or processed in bulk and stored.
- Goods can be stored safety in warehouses.
- It helps in making available the product to the buyers as and when needed.
- It helps in maintaining price stability by adjusting supply with the demand.
- It helps in purchasing goods from far off places as well.
- Commercial banks make available loan on the security of warehouse receipts.
- More imports are possible.
- It facilitates exports.

iv) *Inventory management:* The firm needs to maintain a particular level of stock to ensure product availability as and when customers demand. Holding of inventory involves cost of storage, cost of capital tied up in inventory, cost of adverse price movements, cost of spoilage etc. Inventory control implies control over the size of the inventory. The business firm should weigh the benefits of maintaining inventory against the cost and optimum level should be decided.

iv) *Order processing:* The following steps may be taken to process the order:

- Receipt of order.
- Acknowledgement/Acceptance sent to the customer on receipt of order.
- Customer credit check.
- Inventory scheduling i.e. collection, packing etc.
- Dispatch of goods.

III. Facilitating functions

Facilitating functions refer to the activities involved in helping the process of exchange (Figure 6.3). Following are some of the important functions, which facilitate buying and selling of goods. Every trader is required to take these steps judiciously and carefully.

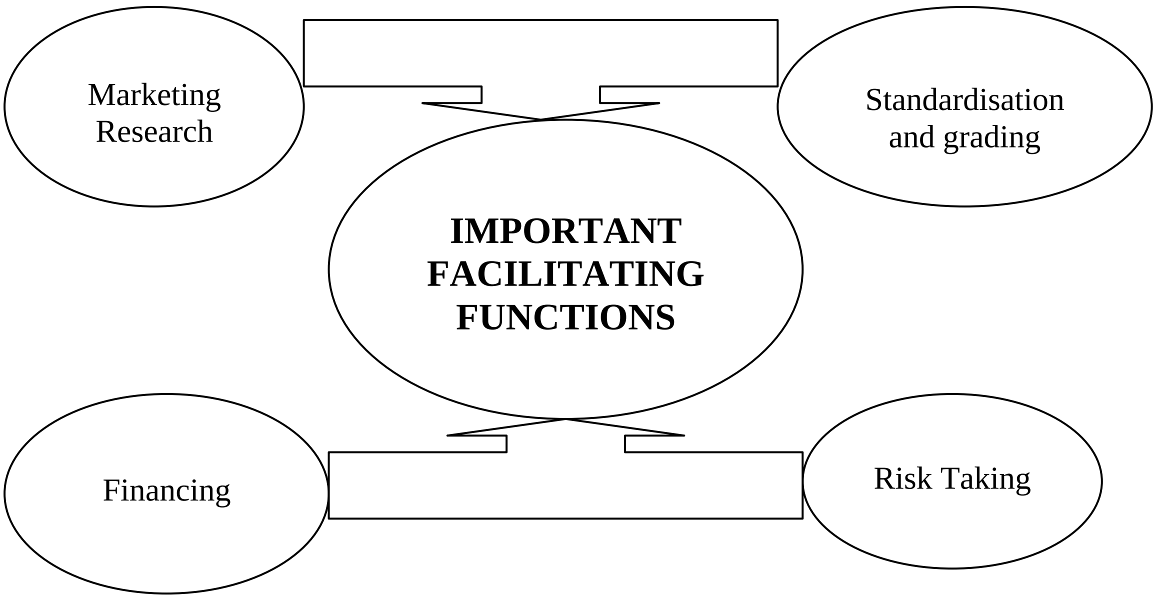

Figure 6.3: Diagrammatic presentation of important facilitating functions

1) Marketing research

American Marketing Association has defined Marketing Research as "gathering, recording and analysing of all facts about any problem relating to the transfer and sale of goods and services from the producer to consumer."

The term 'marketing research' means application of research process in solving marketing problems. Marketing Research equips the marketer in taking all-important decisions correctly. It provides the right information at the right time in the right place and to the right person, which is vital in decision-making.

Uses of marketing research

A businessman can conduct marketing research for the following purposes:

a) *To recognise the needs of the customers:* Marketing Research can be used to identify the various needs and wants of the customers. It involves the study of the market and the customers.

b) *To understand the buying motives:* Marketing Research can be used to understand buying motives of the customers. A customer may buy a product for more than one reason, protection, style, status etc.

c) *To decide the brand name:* A product should have a suitable name. An attractive name always fetches plenty of customers and helps in bringing reputation to the firm. The manufacturer should conduct proper marketing research to decide the brand name of the product.

d) *To decide the size of the package:* The size of the package should be the one, which is convenient in lifting, carrying and storing. A proper size of the package enables proper handling of the product. Ideal size can be ascertained through marketing research.

e) *To decide the method of advertisement:* Advertisement has a great impact on the minds of the customers especially children and adolescents. A good advertising campaign certainly leads to high profits. Marketing Research helps the businessman in deciding the suitable method of advertising.

Classification of marketing research problems

The various marketing research problems can be classified based on the subject matter of research as shown below:

a) *Research on Product:* It includes:

- Reviewing product line, product quality, product features etc.
- Study of the actual uses of a given product;
- Study of the new uses of an existing product;
- Study of packaging, packing material etc.
- Testing of new products.

b) *Research on Markets:* It includes:

- Study of the market size;
- Study of the market segments;
- Short range and long range sales forecasting;
- Study of the overall business trend;
- Analysis of market share.

c) *Research on consumers:* It includes:

- Study of consumer profile;
- Study of the consumer tastes;
- Study of the consumer brand preferences;
- Study of consumer dissatisfactions;
- Study of the consumer reactions.

d) *Research on Advertising and Promotion:* It includes:

- Media research;
- Assessing the impact of advertisement;
- Assessing the effectiveness of sales promotion measures;
- Cost benefit analysis.

e) *Research on Distribution:* It includes:

- Measuring relative effectiveness of different types of distribution intermediaries;
- Measuring dealers' reaction to the firm;
- Measuring warehouse efficiency.

f) *Research on Pricing:* It includes:

- Assessing the general pattern of pricing followed by the industry;
- Evaluating the pricing strategy of the firm;
- Measuring price elasticity of demand.

g) *Research on Sales Methods:* it includes:

- Testing new sales programmes;
- Analysing problems of selling;
- Measuring the effectiveness of salesmen;
- Study of sales compensation.

h) *Research on Competition:* It includes:

- Study on competitive structure of the industry;
- Study on the competitive structure of the individual competitor;
- Study of competitor's product, prices;
- Study of the competitor's promotion programme, channels policies, etc.

Steps involved in marketing research

The researchers have to go through several steps in order to apply marketing research to solve any marketing problem. The major steps are as follows:

1. *Defining and Analysing the problem:* The marketing problem should be clearly identified and defined. If the definition of the problem is faulty the research results will be misleading e.g. research should be conducted to analyse the effectiveness of advertisement.

2. *Developing a research design:* After the marketing problem has been clearly defined, the researcher should develop a proper research design. He should decide on how to collect data, the various research instruments to be used, sampling plan etc.

3. *Collection of data:* Data is the foundation of all marketing research. Data can be primary data or secondary data.

   Primary data is the data collected by the researcher himself and that too for the first time. It can be collected through salesmen, dealers, consumers etc. The researchers can also refer to the reports like sales turnover reports, advertising reports etc. The important reports can be collected through various research instruments like tape recorder, cameras, questionnaires, telephone interviews, e-mails etc.

   Secondary data is the data collected earlier by some other agency or body and used by the researcher. It can be gathered through magazines, journals, government publications, annual reports of companies, etc.

4. *To analyse the data collected:* The next step is to extract meaningful information from the data collected. It can be done through:

   - Averages;
   - Measures of dispersion;
   - Measures of correlation and co-efficient of variation;
   - Goodness of fit.

5. *Report preparation and implementation:* This is the last step in the research procedure. The major findings and recommendations, which are inferred from the study, should be properly prepared.

The findings should be written in concise, succinct simple and clear language. It can be supported with graphs, tables and examples .It should then be properly presented, thoroughly discussed and decision should thereafter, be taken rationally.

Activity

You are required to fill the following questionnaire after interviewing at least 5 consumers regarding their tastes and preferences in respect of consumption of potato chips. You may use Photostat copies of the questionnaire.

1. Name:
2. Age:
3. Sex: ☐ Male ☐ Female
4. Address:
5. Questions:

   ☐ Self-employed ☐ Housewife

   ☐ Govt. employee ☐ Private Sector employee

   ☐ Student ☐ Any other, Specify____

6. Monthly Income:

   ☐ Below Rs. 5,000 ☐ Rs. 5,000-10000

   ☐ Rs. 10,000-15,000 ☐ Above Rs. 15,000

7. Do you consume potato chips? If yes, how frequently:

   ☐ Less than 3 days in a week

   ☐ Between 3-5 days in a week

   ☐ Above 5 days in week

8. Which flavour of potato chips do you like most?

   ☐ Plain salted flavour ☐ Chilly flavour

   ☐ Masala flavour ☐ Tomato flavour

9. How much importance do you give to a brand while asking for a packet of potato chips?

   ☐ Quite a lot ☐ Medium

   ☐ Not much

10. Which brand of potato chips do you like the most? (Rank your preferences):

    ☐ Ruffle Lays ☐ Uncle Chipps

    ☐ Cheetoes ☐ Haldiram

    ☐ Any other, Specify_______________

11. What aspect do you consider most while choosing potato chips?

    ☐ Brand name ☐ Quantity

    ☐ Taste ☐ Price

    ☐ Colour of the Pack ☐ Free gift inside the pack

    ☐ Advertisement of the manufacturer

2) Standardisation and grading

a) *Standardisation:* Standardisation means production of such goods as will be uniformly of the same specifications with regard to shape, size, colour, material, performance etc. If the goods are not standardised it will have a negative impact on the minds of the consumers. The customers will lose faith and trust in the product and may shift to an other brand. The uniform specifications should be such that the customer is not required to examine the product each time before purchasing it.

b) *Grading:* Grading is division of product into classes made of units possessing similar features of size, shape, colour and quality. Grading is usually done in raw materials and agricultural products. For example, rice, wheat pulses, fruits, vegetables, eggs etc. are graded.

3) Financing

The role of finance in any business cannot be under-estimated. Finance acts as a lubricant, which makes the wheels of business move faster and faster. Finance is required for marketing the various goods and services. A businessman may need finance for short-term purposes or long-term purposes. Short-term purposes may include paying salary to salesmen or paying expenses on conducting surveys etc. Long-term purposes may include purchasing of computers or constructing a godown or purchasing vehicles for delivering goods etc.

The various sources of finance are:

- Own Capital
- Friends and relatives
- Commercial banks
- Co-operative banks
- Agricultural credit societies
- Government agencies etc.

4) *Risk taking*

Business risks refer to the possibility of inadequate profit or even losses due to unexpected events, which are beyond control. Risk is part and parcel of business. There are plenty of risks involved in any business. Risks arise due to unforeseen circumstances, natural calamities, wrong planning, irresponsible human behaviour etc. An enterprise has to bear innumerable risks in the process of marketing goods and services. Some of the examples are as below:

- Risk due to fire
- Risk due to theft and negligence
- Accidents
- Change in government policies
- Drought, famine, lightning and earthquakes
- Wrong estimation
- Change in tastes and fashion
- Technology changes
- Trade cycle risks etc.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Give one word for the following:

   i) A process of transferring of ownership of the product from seller to the buyer.

   ii) Movement of men and material from one place to another.

   iii) Activities involved in helping the process of exchange.

   iv) A place where storing is done.

   v) Possibility of losses due to unforeseen circumstances.

2. Match the following:

Type of product	Mode of transport
1) Logs of wood	A) Air plane
2) Imported Fruits	B) Elephants
3) Coal	C) Water
4) Wood-planks	D) Train
5) Sugar bags	E) Lorry

3. Give two examples for each of the following:

   i) Products which can be graded;
   ii) Short-term finance required;
   iii) Primary Data (source)

iv) Research instruments;
v) Means of Road transport.

i) …………………………………………………………………………...

ii) …………………………………………………………………………...

iii) …………………………………………………………………………...

iv) …………………………………………………………………………...

v) …………………………………………………………………………...

4. Warehousing is important because:

i) …………………………………………………………………………...

ii) …………………………………………………………………………...

iii) …………………………………………………………………………...

5. What kind of research can be done on products and consumers? Mention two points each.

Products:

i) …………………………………………………………………………...

ii) …………………………………………………………………………...

Consumers:

i) …………………………………………………………………………...

ii) …………………………………………………………………………...

6.3 WHAT IS MARKETING MIX?

The business firm usually develops a marketing plan to achieve its various marketing objectives. Developing a plan is becoming more and more important keeping in view the ever expanding global scenario, tight competition, changing needs and wants of the customers, technological changes etc.

Marketing mix is a plan designed to analyse the marketing problems. In fact, marketing mix is the ingredients or variables, which the marketer mixes in order to interact with a particular market.

Marketing mix is the term used to describe the combination of four inputs, which constitute the core of a firm's marketing programme. The four areas are as follows:

- Product Mix
- Price
- Place (Distribution)
- Promotion

These are popularly known as four P's of marketing mix (Figure 6.4).

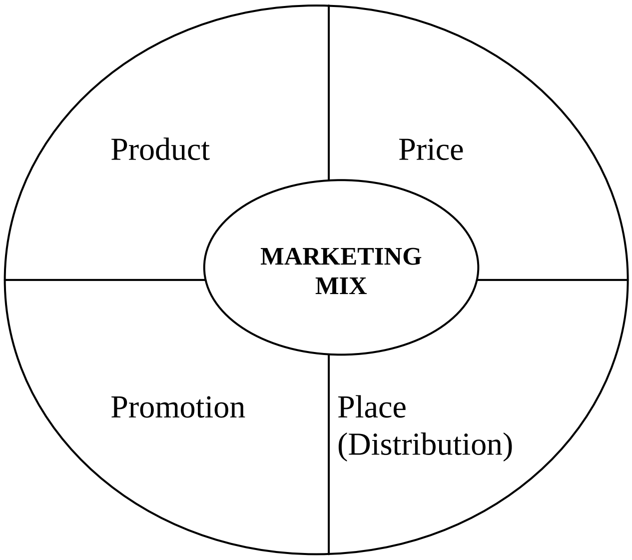

Figure 6.4: Diagrammatic presentation of 4 p's of marketing mix

The idea behind development of a marketing mix is to have greater consumer satisfaction. Marketing mix refers to various decisions taken in the context of product, price structure, promotional activities and the distribution system. A bird's eye view of these decisions, being sub-elements of 4 P's of marketing mix, is depicted in Figure 6.5.

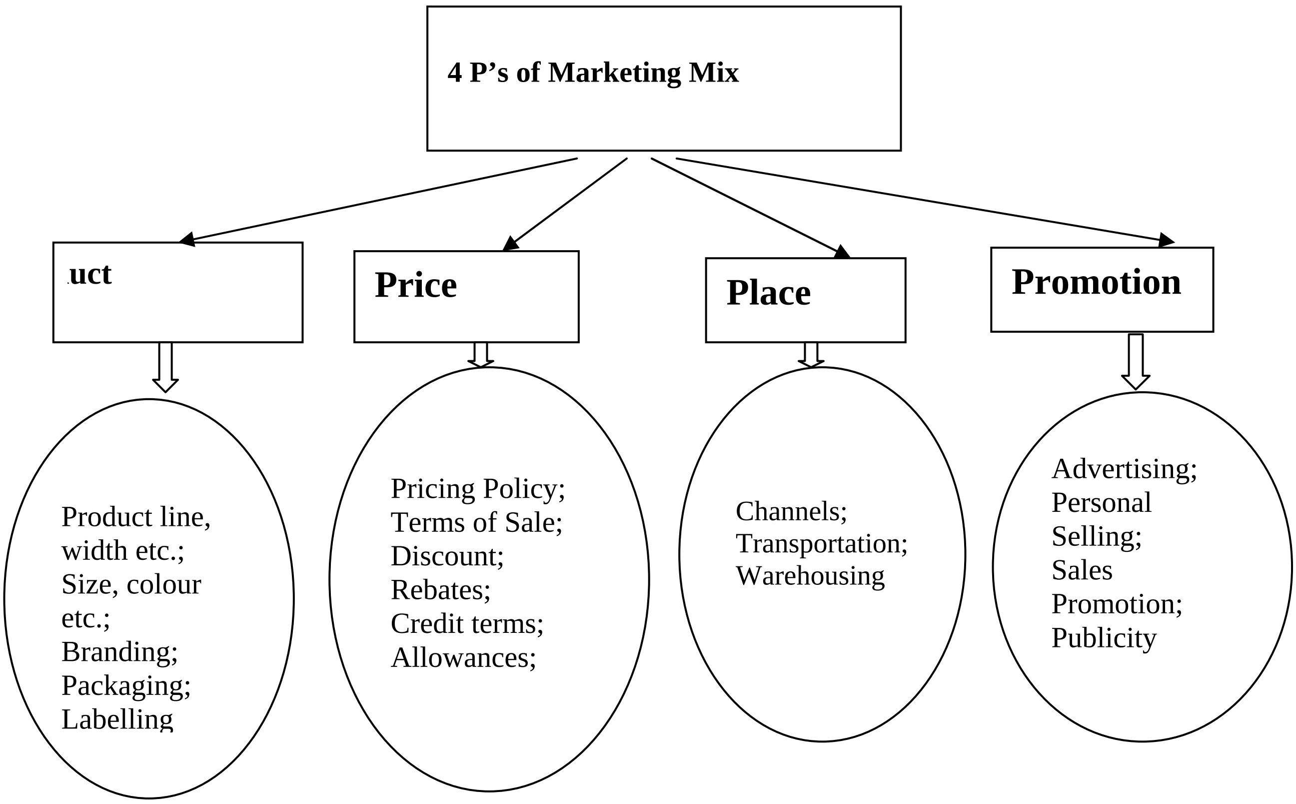

Figure 6.5: Chart showing 4 p's of marketing mix with their sub-elements

Let's explain the above-mentioned P's of marketing in the subsequent paragraphs.

6.4 MARKETING MIX – PRODUCT

Product mix refers to a combination of various features relating to the product or service to be offered for sale. It also refers to total number of products and items a businessman offers to the market. But, what is a product?

Product has a very special position in the marketing mix of a firm.

Product in the narrow sense: In this sense, the term 'product' denotes a physical commodity – a mere non-living object. The needs of the consumers are satisfied by using these products. These products can be designed as a need-satisfying entity e.g. a bottle of Kissan's orange squash; a packet of Amul's butter; a Cadbury chocolate bar etc.

Product in the wider sense: In this sense, a product is something more than a mere assemblage of matter. It takes into account the brand name, package etc. that go into the personality build up of the product. It is a source of providing material social and psychological benefits to the customers.

People derive satisfaction from the non-utility aspect of the product as well e.g. Kellogg flakes are consumed to satisfy hunger needs in the morning; but it is also used because of its brand name, packaging, prestige etc. A person feels that he has a better standard of living in consuming flakes manufactured by Kellogg's than by a local company.

Do not all of us get attracted to buy potato wafers of 'Uncle Chipps' than purchasing any other local product? Therefore, it can be said that 'product' is the total package of benefits, which the customer receives when he buys it.

Sub-elements of product mix

Various sub-elements of product mix are discussed below:

I. The nature of product

The nature and characteristics of the product which are contained in the mix are related to:

a) *Product Line:* It refers to a group of products within a product class e.g. in the case of Amul Co-operative Society, butter constitutes one product line, cream constitutes another, milk, a third one; and so on.

b) *Product width:* The width of the product mix denotes the number of product lines that the businessman offers to the market. For example, Amul has a wider product mix whereas MDH has a narrow product mix.

c) *Product length:* It refers to the number of product items that are carried in a product line. The length of product line denotes the number of items in the line e.g. Amul carries a number of product items in a butter line – it offers 'white butter' and 'salted butter'. Similarly Amul cheese may be 'cheese spread', 'sliced cheese'.

d) *Product Depth:* It refers to the total number of variants that are offered in each product item in the product line. In the case of Hindustan Lever Limited, the soap Lux may be Pink, white or Lux international.

II. *Features of a product*

The decisions regarding features of a product are mentioned below:

- *Size:* The size of the product should be easy to handle. It should be convenient to carry. For example, pack of Cadbury chocolate comes in manageable size.

- *Colour:* The colour of the product should be appealing. For example, the yellow colour of Brown & Polson custard.

- *Flavour:* The flavour of the product should have a wide variety of flavours: Priya Gold Biscuits are found in many flavours – pine-apple, elaichi, orange etc.

- *Weight:* A product should not be too heavy. For example Saffola oil comes in one litre pack, Amul butter comes in 100 gms. pack.

- *Durability:* A product should have a longer shelf life. For example Kissan tomato puree has a shelf life of 12 months.

- *Shape:* Solid products can be round (like Milk Bikis cream biscuits manufactured by Britannia); square (like Krack jack biscuits of Parle); rectangle (like Cadbury's Five Star chocolate) etc. In the case of liquid eatables they can take the shape of their containers. For example Pepsi, Coke, Kissan sauce, Kanodia Mustard oil etc.

III. *Branding*

A brand is a name, term, sign, symbol, or design or a combination of them, which is intended to identify the goods or services of the seller and to differentiate them from those of other competitors. A brand distinguishes a product from similar other offerings. A successful brand is a major asset for a company.

- *Brand Name:* It is that part of a brand which can be vocalized or uttered e.g. Five star chocolate, coca-cola, etc.

- *Brand Mark:* It is that part of a brand that can be recognised. It is not utterable since it is in the form of symbol; design etc. e.g. Nestlé's 'Nest' or Mother Dairy's 'Drop'.

- *Trade Mark:* When brand is given legal protection, it is called 'trade mark'. A trade-mark is a legal term protecting the seller's exclusive rights to use the brand name or brand mark. R in circle (i.e. *®)* is used to show that the trademark is registered.

Examples of branding

(To be scanned – Please refer Hard Copy)

Benefits of branding

- The customers find it easier to identify and handle the product.
- It gives the assurance of quality to the customers.
- Less time and energy is wasted in shopping because the customer has to just go to the market and name the brand. Thus, it makes shopping easier.
- A Purchase of a socially visible brand gives immense psychological satisfaction to the buyer.
- The quality of the product may also improve due to competition.

Selecting a brand name

Following aspects should be taken into account while selecting a brand name:

- It should reflect some benefit and functions of the product e.g. Good Knight, a mosquito repellent suggests that one can have a good sleep at night without mosquitoes.
- It should be distinctive. It should portray status, power etc e.g. Badshah Masale; Everest spices; Shakti-bhog Atta.
- It should be easy to pronounce and remember e.g. Taj Mahal Tea, Jagat Basmati rice.
- It should be legally protected.

IV. Packaging

Packaging may be defined as all the activities involved in designing and producing the containers or wrappers for a product.

Material used in packaging

- Wooden Boxes – Fruits
- Metal Containers – Processed food, oil
- Plastic – Rice, Ghee, Chocolate,
- Paper – Toffees
- Glass – Coke, Jam, Sauce
- Aluminium (foil) – Tea, Coffee

- Jute Sacks – Rice, Wheat
- Tetra pack – Fruit juices, Fruit drinks
- Durable rubber tanks and drums (made from high tenacity polyamide plastic matrix) – Food grains, oil

Forms of package/container

- Tube – Fruit Jelly
- Bottle – Cold Drink
- Small unit package (200 gm, 50 gm) – Tea, Spices
- Sachets – Candy, soups, pan masala
- Re-usable containers (Jars) – Desi Ghee, Edible oil
- Refill packs – Coffee, Chocolate powder, Tea

Benefits of packaging

- It helps in keeping the product safe from pests, rodents, moisture, rain etc.
- It helps in storage.
- It helps in product differentiation.
- It helps in increasing sales.
- It increases the shelf life.
- It ensures visibility of the product if the packaging is transparent.

Activity

Match the following:

Type of package	Product
1. Tetra pack	A) Kissan Jam
2. Glass	B) Frooti
3. Plastic	C) Pineapple Slices
4. Tin	D) Rice

(**Hint:** 1. B; 2. A; 3. D; 4. C)

V. Labelling

The term labelling means putting labels on the package or the product. A label is a small slip to provide information to the customers e.g. the name of the product, price etc. A specimen of labelling is given below:

(Specimen of Labelling*)

Functions of labelling

Labelling serves the following functions:

- Identification of a product is easy for the customer.
- The manufacturer is able to grade the products into different categories, e.g. Hindustan Lever Limited (HLL) sells different types of tea under yellow, red and green label.
- It is a carrier of information.
- It provides information, which is mandatory by law.
- It attracts the buyers and draws them to buy the product.

6.5 MARKETING MIX – PRICE

Pricing is one of the most important decision-area of marketing. This is the only area from where revenue is earned by a businessman. Pricing is crucial to profit as well. Price is the exchange value of a product.

Factors influencing pricing policy

- *Consistency:* Pricing has to be consistent with overall objectives of the firm, e.g. the firm's objective may be profit maximization or to achieve a high turnover. Accordingly, it may be a higher price or lower price.
- *Public image:* If the public image of the product is high the price may be kept high.
- *Purchasing power of the consumers*: If the purchasing power of the consumers is low, the price should be kept low.
- *Price control measures:* The prices of certain products are controlled by the government. The businessman should fix the price keeping in mind the prevailing policies of the government.
- *Pricing policy of the competitors*: The businessman should fix the price keeping in view the pricing policy of the competitors.

* (The sample has been used for educational purpose only and not for any other use).

- *Availability of substitutes:* The price may be kept higher in case there is no substitute available in the market.
- *Ability to postpone purchase:* If the consumer can think of postponing the purchase of a particular product the price of such product should be kept low.
- *Cost of production:* The price fixed should be such as would recover all the costs including a fair return to the businessman.
- *Demand and Supply:* If the demand of the product is higher than its supply the price may be fixed at a higher level. In case supply exceeds the demand, the price should be fixed al low level.
- *Current fashion and tastes:* If the product matches the current fashion and tastes, a high price may be fixed.

Decisions regarding terms of sale

The terms of sale, which the businessman may decide, shall include the following:

- Ex-works price
- Ex-warehouse price
- Cash sale price
- Credit sale price
- Instalment facility etc.

Decisions regarding discounts and rebates

The businessman, keeping in view the trends of business, may offer certain types of discounts and rebates. The may include:

- Trade discount
- Cash discount
- Off-season rebate
- Festival rebate
- Rebate for cash down purchase etc.

Activity

In the following Table two brand names of five products are given. Visit a local grocery shop; enquire about the MRPs of these products and on that basis fill the column relating to MRP.

Product	Brand/ Company	MRP	Brand/Company	MRP
1. Jam	Tops		Kissan	
2. Milk	Mother dairy		Parag	
3. Edible Oil	Dhara		Saffola Gold	
4. Biscuits	Parle G		Priya Gold	
5. Bread	Britannia		Harvest	

6.6 MARKETING MIX – PROMOTION

Promotion of the product is another important element of marketing mix. Marketing depends heavily on effective communication flow between the business firm and the consumer. It involves informing the potential customers about the availability of product and stimulating them to buy it. The businessman usually chooses a combination of communication effects. This is called development of communication mix.

The following are the communication tools (or promotional measures), which a seller can follow:

a) Advertising

b) Sales promotion

c) Personal selling

d) Publicity

A combination of these techniques is used by the businessman depending upon the nature of the product, type of customers, degree of competition, etc.

a) Advertising

Advertising is a potent promotional tool of marketing communication. It is any paid form of non-personal presentation and promotion of ideas, goods or services by an identified sponsor. The businessman tries to spread his ideas about his product among his customers through advertising.

Benefits of advertising (for consumers)

- It provides information regarding price, availability, quality etc.
- Comparison with other products becomes easier.
- It acts as a guarantee regarding quality.

Benefits of advertising (for manufacturers)

- It increases the sale of the product.
- It helps in easy introduction of new product.
- It establishes contact between manufacturers and consumers.
- It helps build the image of a product.
- It enables them to face competition.

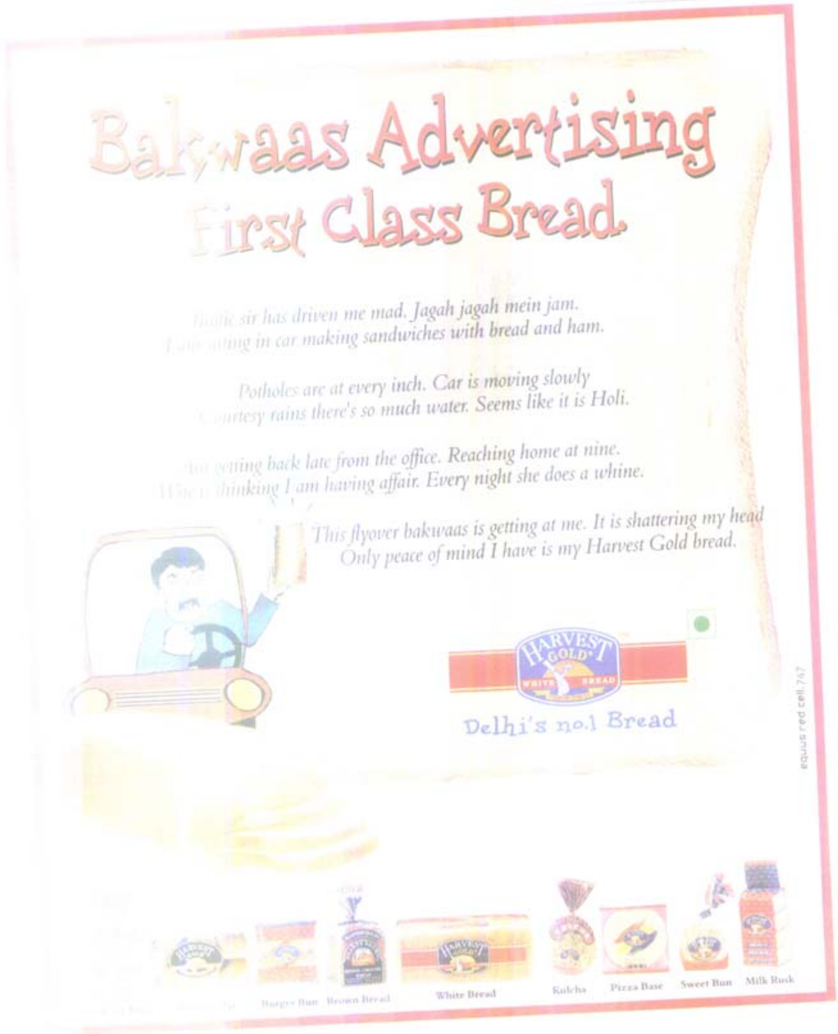
Media of advertising

The following Table shows the various kinds of media of advertising, which a manufacturer may resort to.

Print media	Electronic media	Outdoor display	Direct mail
Newspapers	TV	Bill boards	Price list
Direct mail	Video	Hoardings	Catalogues
Folders	Radios	Balloons	Letters
Journals	Cinema	Electric poles	Circulars
Magazines	Internet	Fairs and exhibitions	Pamphlets

Examples of good advertisements

1. Harvest Gold Bread
2. **P** mark Sarson Oil
3. Balrampur Chini



(Advertisement No.1*)

(Advertisement No.2*)

Activity

Scan your environment and write the method of advertising used by the following companies to advertise their products:

* (The sample has been used for educational purpose only and not for any other use).

Company/Brand	Media
1. Horlicks	
2. Pepsi	
3. Badshah Masala	
4. Heinz Tomato Sauce	

b) *Sales promotion*

Sales promotion is an effort to stimulate consumers to purchase more and more of a particular commodity. It draws quick response from the target audience. It serves as a short-term incentive.

Various means of sales promotion (At consumer level)

Following are the various means of sales promotion at consumer level:

- Distribution of free samples
- Organisation of various contests
- Offer of refund of money if the product is not up to the satisfaction
- Offer of free gifts along with the product
- Offer of discounts and rebates
- Offer of quantity deals like 'buy two get one free'
- Demonstration
- Instalment payment

c) *Personal selling*

It is the oldest method of selling a product. It means selling personally. It is oral, face-to-face interaction between a seller and prospective customers for the purpose of making sales. It leads to 'on the spot sales'.

The salesman usually goes door to door, presents and demonstrates the product and tries to negotiate a deal. He also acts as a guide as he informs about the product.

A well-trained and competent salesman can be an effective communication instrument. His knowledge about the product, the company, its future plans, familiarity with customers, level of his motivation will be the determining factors in his role as a communicator.

d) *Publicity*

Publicity is not easily controllable by the firm. It is not paid for by an identified sponsor. Large firms normally try to control, through constant press releases, press conferences etc. Such activities are intended to build a favourable and positive public image of the firm but an adverse message appearing in some media about a product may spoil the image of the company.

6.7 MARKETING MIX – PLACE (DISTRIBUTION)

Place mix involves decisions to be taken in order to make the product available to the customers. Two decisions are required to be taken for this purpose:

1) *Development of channels of distribution*

   Channels of distribution refer to the path taken by the goods in their movement to the customers. It starts with the producer and ends with the consumer. In between there may be a network of inter-dependent organisations or people employed like agents, dealers, wholesalers and retailers, which help in the transfer of product.

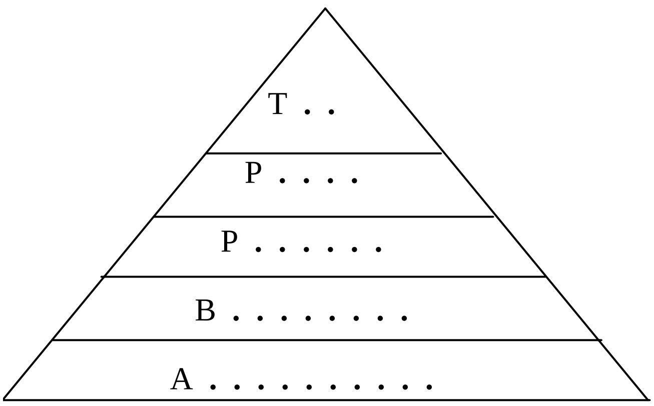
2) *Physical distribution of product*

   Physical distribution involves physical handling of movements of goods from place of production to the place of consumption. Physical distribution fills time (through warehousing) and place (through transportation) gap by providing goods at right place, at right time in the right condition and lowest possible cost.

Check Your Progress Exercise 2

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. On the basis of the given clues fill the following pyramid:



Clues:

i) A package material (3 letters)

ii) Exchange value of a product (5 letters)

iii) A carrier of physical and psychological satisfaction (7 letters)

iv) Assigning name to a product (8 letters)

v) A paid form of non-personal presentation and promotion of goods (11 letters)

2. List the 4 P's of marketing mix.

   i) ……………………………………………………………………...

   ii) ……………………………………………………………………...

   iii) ……………………………………………………………………...

   iv) ……………………………………………………………………...

3. You are a manufacturer of Bikaneri Namkeen. You want to appoint a salesman for door-to-door selling of the product. Name two qualities, which he should possess in order to be a good salesman.

   i) ……………………………………………………………………...

   ii) ……………………………………………………………………...

4. Name the oldest method of selling products.

   ……………………………………………………………………........

   ……………………………………………………………………........

5. Name the non-paid form of communication tool.

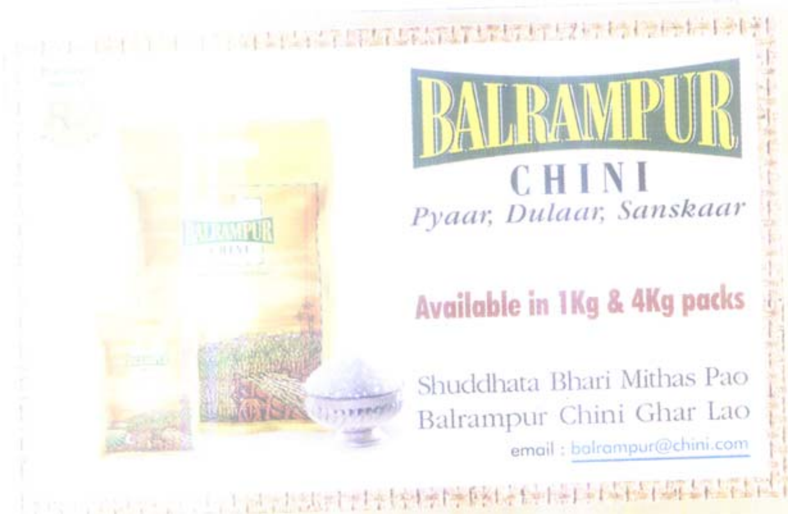
   ……………………………………………………………………........

   ……………………………………………………………………........

6. Observe critically the following advertisement and comment on the basis of information provided in the advertisement whether:

   i) it is attractive to you as a prospective consumer.

   ii) it contains complete information about the product.



(Advertisement No.3*)

6.8 LET US SUM UP

Marketing is the central function of any business. The entire business is a customer satisfying process. Marketing enables a businessman to sell his goods to the consumers. The functions of marketing may be broadly categorised as functions of exchange; functions of physical supply; and facilitating functions. The functions of exchange involve activities associated with buying; assembling and selling. The functions of physical supply include transportation; storage (also called warehousing); inventory management; and order processing. Facilitating functions refer to the activities involved in helping the process of exchange. Important facilitating functions include marketing research, standardisation and grading, financing and risk taking. Marketing mix is a plan designed to analyse the marketing problems. The four areas of marketing mix, known as 4 P's, are product mix, price, place (distribution) and promotion. Product mix involves decisions involving product line, product width, product size, its colour, branding, packaging, labelling etc. In the case of price mix the businessman takes decisions relating to pricing policy, terms of sale, discount, rebates, credit terms, allowances etc. Decisions regarding channels of distribution, transportation, warehousing etc. are related to place mix and finally promotion mix involves decisions regarding advertising, personal selling, sales promotion, publicity etc.

6.9 KEY WORDS

Ex-works price	:	Factory price.
Inventory	:	Stock of goods
MRP	:	Maximum retail price.
Price elasticity of demand	:	Ratio of the percentage change in demand caused by a percentage change in price.
Trade discount	:	Discount allowed by a trader when goods are purchased in bulk quantity.
Warehouse	:	A place where goods are stored.

6.11 SOME USEFUL BOOKS

1. Bhushan, Y.K. (2005) Fundamentals of Business Organisation and Management; Sultan Chand and Sons, New Delhi.

2. Kotler, Philip (2004) Marketing Management – Analysis, Planning and Control, Prentice Hall of India, New Delhi.

3. Varshney, R.L. and Gupta, S.L. (2000) Marketing Management (An Indian Perspective); Sultan Chand and Sons, New Delhi.

6.12 ASSIGNMENTS

1. "It pays to advertise" Justify.

2. Explain how a businessman can promote his sales.

3. "Victoria Foods" have diversified and started processing and packing 'light oven baked porridge (Dalia)'. You are the marketing manager of this firm. What factors will you keep in mind to decide the price of this product?

4. "Bhojan India" wants to transport 50 cartons of 'White wheat Flour' from Chandigarh to Delhi. Which means of transport should they use and why?

5. 'A warehouse serves the function of protecting goods'. Do you agree? Give reasons in support of your answer.

6. What should a businessman do after receiving orders from a customer?

7. How is marketing research done?

8. What are the features of a good brand?

9. Name the material, which a businessman may decide to use for packaging the following products:

   a) Apples

   b) Mango juice

   c) Roasted chana

   d) Mustard oil

   e) Cookies

10. "A good package acts like a silent salesman". Justify this statement on the basis of following specimen of a package.

(Advertisement No.4*)

* (The sample has been used for educational purpose only and not for any other use).

UNIT 7 ANALYSING THE COMPETITIVE SITUATION

Structure

7.0 OBJECTIVES

After studying this unit, you should be able to:

- get a clear view of the competitors who are posing competition in the market;
- comprehend the strengths and weaknesses of the competitors;
- understand the market strategies a businessman is required to develop;
- know about the SWOT expand analysis; and
- understand the special features of the product which makes it attractive.

7.1 INTRODUCTION

You will note that in today's world, every individual is running a race to achieve a certain goal. All of us are in a hurry – either in search of a goal or to reach a goal before anybody else reaches there. In this process, every one has a desire to excel and be at the top. In this era of technological advances and higher levels of mass communication, followers have no place. Respect, prestige and power are only with the leader.

The child who is awarded the prize is the one who gets first rank in the class. The students who get admissions in prestigious colleges are those who find place in the merit list. The same is the case with a businessman too. They are also busy running a race. Some may have won and reached the top whereas there are others who are trying to reach the coveted place. But, what is that coveted place, the destination. It is the hearts of their customers.

(*Competition:* Racing for No. 1 Position to become Market Leader)

It is only when a businessman satisfies his customers and makes them happy and loyal he will slowly and gradually achieve the maximum share of his target market. And the day may come when he will be Rank 1 holder, being adjudged as “market leader”.

But, do you think, in this process of capturing the market share, other followers (i.e. Rank 2, Rank 3, Rank 4 and so on) will keep quiet? No! They will not sit back and see another capturing the market. They will think of various strategies to beat the Rank 1 who has been adjudged as “market leader”. But the game will not stop at this stage. Now, the Rank 1 will make his counter moves to retain his position in the market. Thus there will be moves and counter moves and the players in the market (i.e. various businessmen) will always think of new strategies to defend themselves or confront competition.

7.2 COMPETITORS PRESENT IN THE MARKET

Every industry – whether it is automobiles, textiles, iron and steel, pharmaceuticals, chemicals, or food processing industry – is composed of many firms dealing in the same product. Usually competition prevails within one industry and each firm has to face stiff competition from the others. They compete with each other to gain the top slot, by achieving maximum share of the market as:

1. Market leader

A market leader is the one, who has reached the place where others want to reach. In a way he has gained maximum share in the relevant product market. It leads the other firms in price changes, new product introduction, distribution coverage etc. For example, there are 4 firms in a particular industry with the following market share:

Firm A	60%
Firm B	25%
Firm C	10%
Firm D	5%

Here, Firm A is the market leader with 60% share in the market.

For other businessmen, the market leader acts as a competitor because his strategies and moves will have a direct impact on the turnover and profits of the other firms. Though competition will not be very severe because it will be quite difficult for other firms to confront and attack the market leader by taking advantage of his weakness, if any.

2. Market challenger

The firm that occupies a place next to the market leader in an industry is known as market challenger or runner-up. There may be one such market challenger or more than one. These firms are also very large but smaller than market leader.

Market challengers are a threat to both the market leader and the other competitors. They would try to grab further market share by directly attacking the leader or by attacking other competitors, if not the market leader. For example, there are 4 firms in a particular industry with the following market share:

Firm A	40%
Firm B	35%
Firm C	15%
Firm D	10%

In the above case Firm B is the market challenger. It can easily become a market leader by grabbing only five or six percent of the share from the market followers or 3% from the leader. Market challenger tries to discover the weaknesses of small firms and of the market leader and then builds up its own strategy.

3. Market followers

Market followers are usually small sized firms. They have lower market share than the leader and the challenger. They are actively trying to expand their share through highly aggressive tactics. All the firms who fall in this category act as rivals to one another. They face a threat from the market challenger who is always keen to gobble up some of their share. They have somehow to hold on to their current customers. All the firms coming in this category occupy almost similar position in the market. They may also have similar resources and similar output. For example, there are 4 firms in a particular industry with the following market share:

Firm A	40%
Firm B	35%
Firm C	15%
Firm D	10%

In the above case Firms C and D are the market followers. Both the firms are acting as rivals to one another to retain the existing share. Both have a threat from the side of market challenger i.e. Firm B who is always keen to gobble up part of their share to become market leader. Even market leader may also try to gobble up party some more of the market to make its position more secure against the market challenger.

4. New entrants

A new entrant is one who has just stepped into that industry. This business unit acts as a source of direct competition to the firms which are already in the business. The new entrant can be a resourceful business unit which has entered a new industry because of its expansion and diversification policies. This new entrant may be a leader in his own field.

5. Very small firms

These firms are very small in size. They cannot attack the larger firms. They earn profits from customers, geographic area, or service.

6. Powerful suppliers

When the businessman acts as buyer in the market he must understand the market power of the different suppliers. There may be powerful suppliers in the market. They are so large and powerful that they are in a position to dictate the price and the terms of supply. The power of the suppliers is high when there are very few suppliers in the market. And therefore the businessman has limited option for source of supplies. He will compete with other similar purchasers and will have to put efforts to acquire the supplies at a reasonable price and as per his requirements – quality, time, and quantity etc.

7. Powerful buyers

Similar to powerful suppliers there may be powerful buyers in the market if it is a 'buyers market". Since these buyers are big and powerful they will dictate their prices, terms of purchase, their preferences for packaging, product quality, and delivery terms.

8. Substitute products made available by other competitors

The product supplied by the businessman is to be considered in the light of uniqueness. He has to see whether his product is unique or there exists any substitute for the same. It may also happen that at a later stage a substitute may arise. In case the substitute is or arises later the businessman will have to see how he is to protect his market and customers.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Who is market leader?

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

2. Which kind of competitor is usually called a runner-up?

……………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

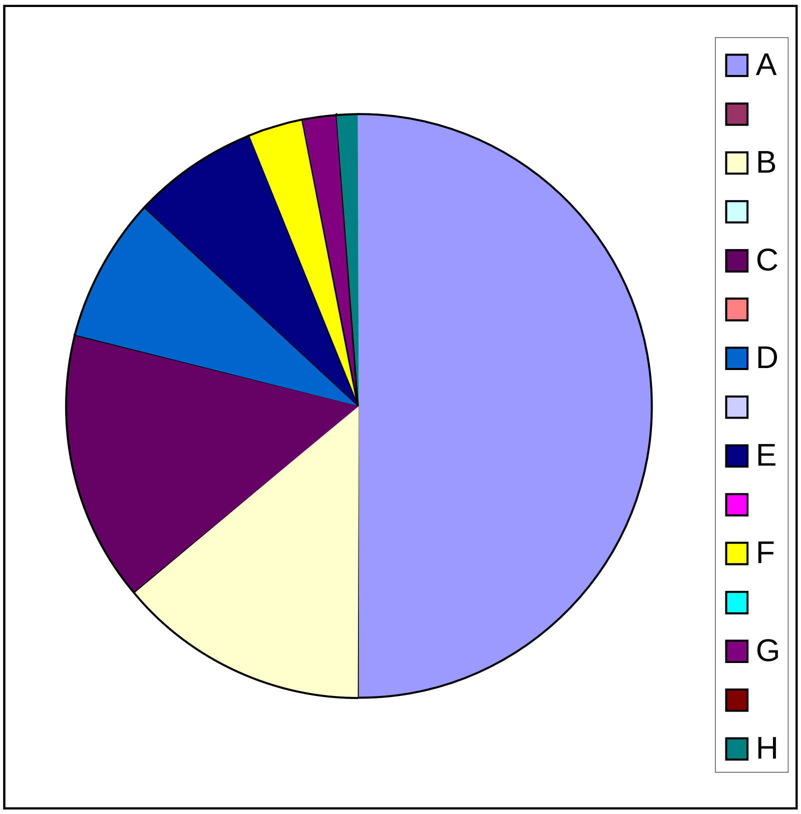
………………………………………………………………………………

3. Following is the hypothetical market share of the various firms:

A) 50%; B) 14%; C) 15%; D) 8%;

E) 7%; F) 3%; G) 2%; H) 1%

Fill in the blanks after analysing the following pie diagram which depicts the market share of above firms:



i) ------------------ is the market leader.

ii) ------------------ are the market challengers.

iii) ------------------ are the market followers.

iv) ------------------ are the small firms.

7.3 MARKETING STRATEGIES VIS-À-VIS COMPETITORS

The businessman has to develop his marketing strategies on the basis of the activities of his competitors. Following are the areas/activities in which the businessman can develop his marketing strategies:

i) Innovations

To beat the competitors the businessman can decide to launch a new product. He can also think of innovative ideas related to customer service, means of distribution etc.

ii) *Prices*

The businessman can keep the prices of his products reasonable in comparison to the price structure maintained by his competitors. At times, the businessman may reduce the prices as well. However, a fear of price war is always associated with this kind of strategy.

iii) *Promotional strategies*

The businessman can adopt promotional strategies by offering discounts, organizing contests, providing free gifts etc. to the customers. But this will also mean sizeable promotional expenditure.

iv) *Quality strategies*

Continuous efforts can be made to improve the quality of the product. At times, we find a slogan 'New and Improved' printed on the package of the product. This is nothing but to beat the competitor that firm's product is now improved as compared to that of the competitor. The firms, now-a-days spend a lot on research and development (R & D) activities. The expenditure is incurred with a view to improving the quality of the product.

v) *Product size*

The businessman can make additions in the size and form of his product. In other words he can bring a product in several sizes and forms, which his competitors may not be having. For example, a ketchup manufacturer may plan to bring his product in many innovation or quality and bottle sizes.

vi) *New brand*

A businessman may launch a new brand of the same product. Each of the brands can be positioned differently in the minds of the consumers.

vii) *Heavy advertisement*

The businessman can undertake heavy advertisement campaign. This will help him to create strong consumer awareness and preferences.

viii) *Competent sales force*

Manpower is an asset for any firm. A good and confident sales force maintained by a businessman may fetch him reputation, good business, loyalty of the customers etc.

ix) *Manufacturing efficiency*

This is another way of facing the competitor. The businessman tries to keep the cost of production low by efficient purchase of material, low labour cost, using modern equipments, etc.

x) *Efficient and extensive dealership system*

A large number of independent dealers can be maintained in the industry. The dealers can be located all over the country and even outside the country also, if the demand arises. An exclusive dealer may focus all of their attention on his product.

xi) Credit policy

In order to increase his turnover in comparison to his competitors the businessman may offer his product on credit terms – instalments, repayment period etc.

xii) Better after-sales services

The businessman may offer better and efficient after-sales service to his customers. A satisfied customer will not only be loyal to him but may bring in more customers through his contacts. Thus, the businessman may expect that the potential customers will not go to his competitors.

Check Your Progress Exercise 2

………………………………………………………………………………

7.4 HOW TO UNDERSTAND THE STRENGTHS AND WEAKNESSES OF BUSINESS

Several functions are carried out in a business enterprise. These are linked with production, research and development, personnel, finance, marketing, etc. The businessman can understand his strength by splitting each function into sub factors. Through this exercise specific factors are identified. Then he tries to zero in on the specific factors, which he can point out and say "Hey, this is my strength".

Business firms have to spot their competitive strengths and nurture them. By studying the competitive strength with respect to the firm's overall strength or weakness in the given area, the firm has to find out – what its distinctive advantages are. For this purpose, internal scanning is to be done. It may relate to –

- Which are the functions the firm does well compared with his competitors.
- Does the firm really excel in them?
- Which are the functions where the firm is weak?
- To what extent does the weakness matter in overall performance?
- Can the weaknesses be made up?

To have a better understanding, the business firm should conduct SWOT Analysis.

SWOT analysis

Just as a doctor needs thermometer or a stethoscope to diagnose an illness, in the same way a businessman needs to do a SWOT analysis to assess the competition he faces in the market. SWOT analysis is an analysis of:

S : Strengths

W : Weaknesses

O : Opportunities

T : Threats

It is a process through which the strengths, weaknesses etc. of a competitor can be assessed. In fact SWOT analysis can be used for any purpose i.e. to evaluate a project; any market opportunity etc.

Strengths: Strengths refers to the strong points a businessman possesses. His strength may lie in the quality of his product or his strategic location or his huge capital base and so on. He should have a firm faith in his internal resources and he should utilise them to their fullest capacity. His strength in a particular area may be the weakness of his competitor.

Weaknesses: The businessman should also always recognise his weak points. He should endeavour to convert his weaknesses into strengths. The weaknesses can be rectified only when they are identified.

Opportunities: There is no dearth of opportunities. The businessman should keep his mind open and make a list of various opportunities, which may be available for him to explore.

Threats: The businessman should be aware of the threats he faces as well. His competitors in the market always pose a threat to him. They may try to divert his customers by offering better product. He should keep on trying to convert the possible threats into opportunities.

In the following way a businessman who is dealing in manufacturing of mango-chutney may conduct SWOT analysis:

S	O
1. Mango chutney goes well with almost every Indian food. 2. Low Investment required for manufacturing chutney.	1. Wide spread market can be captured. 2. Different varieties of chutneys can be introduced.
W	**T**
1. Seasonality of raw material. 2. Seasonality and availability of labour.	1. Presence of a large number of competitors in the market. 2. Tastes of the customers may get changed.

Keeping the points mentioned in the above box (and many more which can be perceived) the businessman has to make continuous efforts to convert his weaknesses into strengths and threats into opportunities to the maximum extent. This way he can thwart competition.

Check Your Progress Exercise 3

Note: a) Use the space below for your answer.

1. Write the full form of SWOT.

……………………………………………………………………………………

……………………………………………………………………………………

2. How can a business man conduct SWOT analysis?

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

7.5 WHAT ARE THE STRENGTHS AND WEAKNESSES OF THE COMPETITORS

Just as an individual has certain strengths and weaknesses, in the same way a business firm possesses certain qualities, which are its strengths and also a few points which are its weaknesses. Big firms generally take the benefit of their size and small firms have the benefit of flexibility and speed of functioning.

The strength of the competitors can emerge in any of the many functions they perform. These functions may be associated with marketing, production, research and development, corporate resources. In the following paragraphs an attempts made to discuss these factors. The presence of these factors may act as strength whereas the absence of these factors may mean weakness.

Product mix

To gain an edge over others, the competitor can shape his product strategy around the technical superiority of his product. The product can be a special product supported by the best technology and its superior quality. He may also be providing attention to quality control and quality assurance. The competitor can be stronger if he has a wide product line. He may also provide maximum possible variety in every product line.

The competitor may also be keeping in mind the tastes and preferences of the customers based on demographic, geographic and psychological factors.

Packaging

The packaging of a product may also serve as a potent strength in the competition. Good packaging adds to the value of the product. An attractive package may lead to increase in turnover. A package contains lot of information as well. It acts as a silent salesman. A good package, therefore, if developed by a competitor may act as a strong point. A new package design, colour, size of the package, material used etc. can all serve as strengths.

Distribution

Some competitors may have a distinctive competence in distribution. They may have a distribution network reaching the remotest rural areas of the country. They may also have a vast chain of showrooms in all metropolitan cities and other big cities of the country. They may have a computerized physical distribution method as well. The other advantage, which the competitors may have, is to have a chain of big stockists who get the supplies directly from the producers. They may also adopt progressive distribution policy, attractive incentives and best margins for dealers.

Service

Providing efficient service to the customers would also be a strength. For example, M/s. A.B. & Co. may assure its customers to provide after-sales service within 24 hours of the receipt of call.

Personnel

A pool of highly talented engineers, technicians and managers and other personnel would be highly motivated and dedicated because of handsome salaries and other perquisites.

Production

A competitor’s strength may lie in the production function. He may come out with large quantity of production within a very short period of time. For example, M/s. Ruchika & Co. may have a high capacity of manufacturing biscuits and other bakery items. Expertise in production planning and scheduling will provide an edge over other businessmen particularly if it matches with the market requirements.

Research and development

This is another area where a competitor may have an edge over the other businessmen. A competitor may possess a competence for making unique products. He may have strong in-house R&D facilities for consistent product augmentation and improvement.

Corporate and finance factor

A competitor may have a reputation in the market. Owing to the goodwill built by him, he is in a position to raise large equity in the capital market. A competitor's strength may also lie in the huge reserves built by his firm. With the help of these reserves he will not face resource crunch when there is depression in the market and it becomes difficult to obtain funds from external sources.

Marketing

A competitor may be well-versed with marketing techniques. His sales forecasting may be very accurate or he may be possessing a highly computerized and high quality Management Information System (MIS). A competitor may be in a position to incur heavy expenditure on advertisement and publicity as well. The price strategy followed by the competitor may be such that it attracts abundance of business.

Check Your Progress Exercise 4

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. How can an attractive package lead to increase in turnover of a competitor?

   ……………………………………………………………………………

   ……………………………………………………………………………

2. "A competitor's strength lies in his production function." Justify.

   ……………………………………………………………………………

   ……………………………………………………………………………

   ……………………………………………………………………………

   ……………………………………………………………………………

7.6 SPECIAL FEATURES OF THE PRODUCT TO ATTRACT CUSTOMERS

Quality of the product is one major factor on which a businessman can count.

Features of the product

i) *Value for money*

   A businessman should develop his product in such a manner that the customer utilizing it should get value for the money spent by him in purchasing the product. For example, if a customer purchases Britannia Cake, it should give him the value, which he thought he will get if he had spent the same money on some other product.

ii) Tangible attributes

- *Size:* The product should be of such size that it can easily be handled.
- *Colour:* The product should be of attractive colour so that it appeals to the customer at the first look.
- *Weight:* A product should not be too heavy to lift. It may be packed in such a way that the customer is in a position to carry it easily. Usually oils are packed in one Kg./one litre packs.
- *Durability:* Most of the products are not meant for one time use. A customer will prefer a product, which can be used for a reasonable period. In other words the product should contain proper preservatives.
- *Packaging:* The product should be packed in such a manner that it remains safe from pests, moisture, rain etc. A good packaging should help in increasing sales and the packed product can be stored easily.
- *Shape:* The shape of the product should be appealing. It may be round, square, rectangle or any other shape. Liquids will of course eatables they can take the shape of their containers.
- *Branding:* The brand name of the product should be such that the customers will find it easier to pronounce and remember. The customer should easily identify the product with its brand name. It should give the customers the assurance of quality.

iii) Augmented attributes

Some additional features can also be added to the product, like:

- Providing after-sales service;
- Providing various finance options like purchasing goods on instalment basis, purchasing goods on zero interest rate etc.
- Providing delivery arrangement like free home delivery;
- Offering warranties.

iv) Product variety

The businessman should try to offer a number of variants in the product. For example a product can come in various flavours.

Check Your Progress Exercise 5

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. List any four tangible attributes of a product.

…………………………………………………………………………………

…………………………………………………………………………………

…………………………………………………………………………………

…………………………………………………………………………………

2. Mahesh is a businessman who manufactures mango pickles. Mention any two quality features which he should try to bring in his product so as to make it preferable to those of his competitors.

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

7.7 LET US SUM UP

Every individual, be it a businessman or any other person is running a race to achieve the No. 1 position. In case of a businessman, however, it is only when he satisfies his customers and makes them happy and loyal he will slowly and gradually achieve the maximum share of his target market. Market comprises a number of competitors. There may be market leader, market challengers, market followers, new entrants, small firms etc. Powerful buyers, powerful suppliers and substitute products are capable of posing competition. As regards marketing strategies to be adopted by a businessman, they are to be adopted based on the activities of the competitors. To understand the strengths and weaknesses of the business, the businessman is required to carry out SWOT Analysis. He has to try his level best to convert weaknesses into strengths and threats into opportunities. A competitor will pose competition to the businessmen due to the presence of certain strengths. The strength of the competitors lies in the level of their functions (like marketing, production, research and development, corporate resources). To thwart competitors, a businessman has to provide quality products to his customers. There are so many features associated with any product that he has to provide a product which gives value to the purchaser for the money spent in purchasing it. The product should have certain tangible attributes. The businessman may also add a few additional features to the product to make it more attractive than that of his competitors.

7.8 KEY WORDS

Market leader	**:**	A business firm possessing largest market share.
Market challenger	**:**	A business firm posing threat to the market leader.
Tangible attributes	**:**	Features of a product perceptible to the senses – sight, smell and mostly taste.

7.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. **Hint:** Market leader is the organisation which has gained maximum share in the relevant product market.

2. **Hint:** The firm that occupies a place next to the market leader in an industry is known as runner-up.

3. i) *Firm A* is the market leader.

   ii) *Firms B and C* are the market challengers.

   iii) *Firms D and E* are the market followers.

   iv) *Firms F, G and H* are the small firms.

Check Your Progress Exercise 2

1. **Hint:** The businessman can make additions in the size and form of his product.

2. **Hint:** Innovations; Price; Product size; New Brand

Check Your Progress Exercise 3

1. Strength, Weakness, Opportunity, Threat

2. **Hint:** By analysing his Strength, Weakness, Opportunity, and Threat.

Check Your Progress Exercise 4

1. **Hint:** Good packaging adds to the value of the product and thereby an attractive package may lead to increase in turnover of a competitor.

2. **Hint:** A competitor may come out with large quantity of production within a very short period of time.

Check Your Progress Exercise 5

1. Size; Colour; Durability; Branding

2. i) Increased durability of the product.
   ii) Attractive packing.

7.10 SOME USEFUL BOOKS

1. David H. Holt (2002) Entrepreneurship – A New Venture Creation, Prentice Hall of India Private Limited, New Delhi.

2. Ramaswamy, V.S. and Namakumari, S. (1998) Marketing Management (Planning, Implementation and Control – The Indian Context), Reprint, Macmillan India Limited, Delhi.

3. Varshney, R.L. and Gupta, S.L. (2000) Marketing Management (An Indian Perspective), Sultan Chand and Sons, New Delhi.

7.11 ASSIGNMENTS

1. Mention any five points relating to the strengths and weaknesses of the competitors.

2. Read the following situation:

   i) Firm I deals in fertilizers.
   ii) Firm G deals in textiles.
   iii) Firm N deals in cosmetics
   iv) Firm O deals in agro-based products
   v) Firm U is a new entrant desiring to manufacture mushroom soup.

Based on the above, identify the competitor for Firm U. Give reasons in support of your answer.

(**Hint:** Firm O)

3. Radha Food Limited manufactures 'ready-to-eat' products. They want to conduct SWOT Analysis in order to guard against the various competitors some of whom are new entrants. They have appointed you as a new market researcher. On the basis of following jumbled up points you are required to group them in the given Table:

i) 14 year old established company.
ii) Low average perception among consumers.
iii) Entry of MNCs on a large scale.
iv) High competition.
v) Both husband and wife form a working couple.
vi) Status symbol.
vii) Use of latest technology by the company.
viii) Low product range.
ix) Huge Capital and dedicated staff.

S	O
1. 2. 3.	1. 2. 3.
W	**T**
1. 2. 3.	1. 2. 3.

(**Hint:** i) S; ii) W; iii) T; iv) T; v) O;
vi) O; vii) S; viii) W; ix) S)

4. Explain the roles of market leader and market challenger in a competitive market.

5. "The strengths of the competitors emerge from the functions they perform" Do you agree? Give reasons.

6. To what matters would "internal scanning" relate?

7. Following is the hypothetical market share of various firms operating in a particular industry:

Firm A	48%
Firm B	42%
Firm C	5%
Firm D	5%

You are required to answer the following questions:

i) Can Firm D act as a threat to Firm B?

ii) Can Firm B act as a threat to Firm A?

iii) Can Firm B act as a threat to Firm C?

iv) Can Firm C act as a threat to Firm A?

v) Can Firm D act as a threat to Firm C?

vi) Can Firm C act as a threat to Firm D?

(**Hint:** i) No; ii) Yes; iii) Yes; iv) No; v) Yes; vi) Yes)

UNIT 8 PREPARATION OF THE BUSINESS PLAN

Structure

8.0 OBJECTIVES

After studying this unit, you should be able to:

- know about the business plan;
- understand the need for business plan;
- identify various inputs of business plan;
- know the challenges faced during the preparation of business plan;
- comprehend the common errors faced in a business plan; and
- understand how to avoid such errors.

8.1 INTRODUCTION

The term ‘business plan’ consists of two words – business and plan. Business is an economic activity. It is associated with buying, selling and manufacturing of goods with a view to earning profit and making a living. The people who engage themselves in a business are known as businessmen or entrepreneurs. Plan is a course of action to achieve a desired result. To plan is to look ahead. It is to assess the future and make provisions for it. Owing to planning a businessman is able to identify various alternatives and after proper evaluation, select the best alternative.

The term business and plan go together. In a business whether small or big a businessman has to plan continuously for one aspect or the other. He needs to know whether his business idea is a promising one or not and he requires a step by step investigation and development of sound business idea. Hence, the need arises for him to make a business plan.

8.2 MEANING OF BUSINESS PLAN

To start with, a businessman goes through the process of identifying various opportunities for the business. He studies the feasibility of various business proposals. He tries to determine the desirability of investing in a particular idea. He tries to establish the viability from different angles such as technical, marketing, financial, economic, managerial etc. If the resulting data show a non-viable project, the various parameters can be adjusted. A particular project can be abandoned if it proves to be not viable despite all alterations. Thereafter, feasibility of a new project should be analysed. If the idea is a promising one then a proper analysis should be done in respect of market, technical, and other aspects. In other words, make a business plan i.e. plan for the business.

A business plan involves step by step investigation and development of a sound business idea. A business plan can be said to be a comprehensive course of action with guidelines for a new venture. It covers the full range of business planning activities. It helps the entrepreneur to make better decisions. A business plan is also called feasibility plan. It is the systematic development of a project idea for the eventual purpose of arriving at an investment decision.

Who will write the Business Plan?

The businessman himself is responsible for planning as no other person will have the same motivation vision or foresight. He is, therefore the best person to draw up a business plan. In case, he is unable make the business plan himself he can take services of counselling organisations who deal in new venture planning. Various State Agencies like the Small Industries Service Institute (SISI), Small Industries Development Organisation (SIDO) etc. which are established to encourage venture development, also help the entrepreneur in this regard. For larger projects, a project team can be set up consisting of experts like industrial economists, market analysts, engineers, management accounting experts etc.

Example

Krishna Kumar has several business ideas in his mind. He can start manufacturing biscuits and cookies at a small level or make plastic refill bottles or simply become a wholesaler. After initial screening, he realises that last two ideas are not feasible and so abandons those ideas. He, then, starts making a business plan for the idea which he thinks is a promising one.

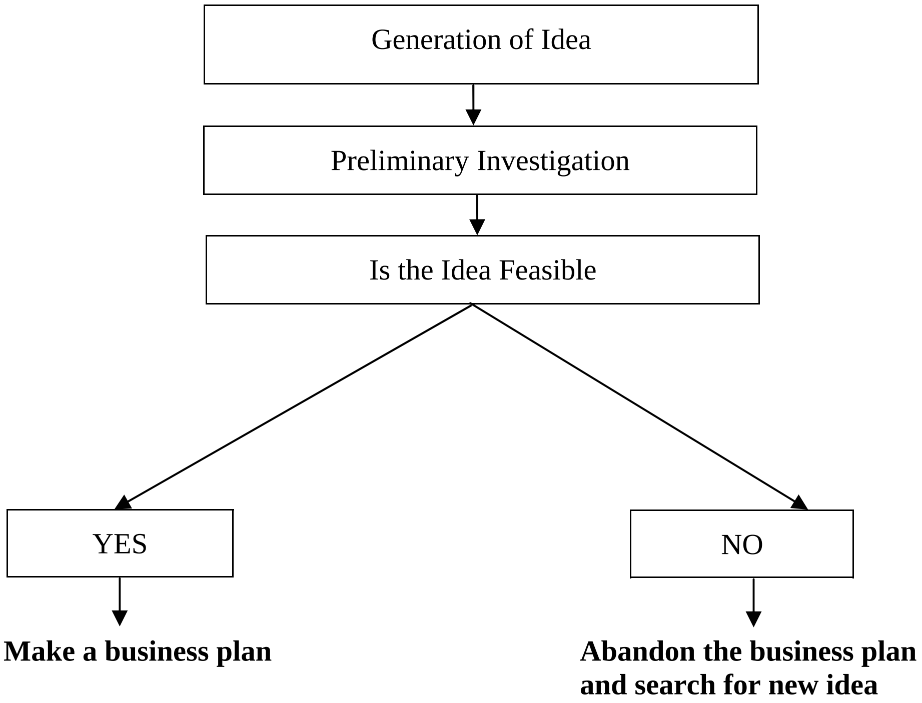

Figure 8.1: Diagrammatic representation of whether to make a business plan or abandon it and search for new idea

8.3 WHY A BUSINESS PLAN IS NEEDED?

A businessman needs a business plan because it serves the following purposes:

1. *Provides framework*

   A business plan provides a framework of future activities of the enterprise. Consequently, it will also shape the future pattern of services. It will provide an initial effort to show that a business idea can be realised and will provide reasons as to why it will succeed.

2. *Initiates development*

   A business plan will initiate the process of development. He can plan his production targets, employment, income generation and so on.

3. *Helps in arranging financial assistance*

   A business plan acts as the best means for obtaining the required assistance from financial institutions. A project report can be prepared on the basis of business plan and after proper analysis the businessman can get the required amount of money in the form of loans.

4. *Helps in selecting appropriate technology*

   A business plan helps the entrepreneur to examine his project idea thoroughly as regards its design, production, and technology to be used etc.

5. *Helps in securing clearances from the government*

   A business plan is also of great help in obtaining necessary clearances from the Government. A businessman can prove his credentials with the help of a well formulated business plan. The procedural formalities can be easily cleared. A business plan will pin point the matters for which Government sanctions have to be obtained.

6. *Provides knowledge about government regulations*

   A business plan helps a businessman in understanding various government directives, import and export policies etc. Scanning the ‘guidelines for industries’ published by the Ministry of Industry, a businessman can obtain information regarding industrial policy, licensing procedure, foreign collaboration, foreign exchange orders etc.

Features of an Ideal Business Plan

Following are the important features of an ideal business plan:

1. It should be written in simple language.
2. It should be informative.
3. It should clearly identify the products, services, markets and promoters of the business.
4. It should be complete and accurate.
5. It should be convincing so that the bankers are able to sanction loans.
6. It should be dynamic in nature.
7. It should have a pragmatic approach.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Fill in the blanks.

   i) A business plan is a broad set of ------------------------ for new venture.

   ii) A plan is to look ---------------.

   iii) An idea which is not feasible should be ---------------------.

   iv) A project report can be prepared on the basis of ---------------------.

   v) A business plan should have a --------------------- approach.

2. Name two organisations from where a businessman can avail services to make a business plan.

   i) …………………………………………………………………………...

   ii) …………………………………………………………………………...

3. State True or False

   i) A business plan should be static in nature.

   ……………………………………………………………….................

   ii) A business plan should be informative,

   ……………………………………………………………….................

iii) The entrepreneur should refer the 'guidelines for industries' before making a business plan.

……………………………………………………………………………..............

iv) A project team is required for small projects.

……………………………………………………………………………..............

v) A banker is the best person to write a business plan.

……………………………………………………………………………..............

8.4 INPUTS REQUIRED FOR A BUSINESS PLAN

A business plan, also known as feasibility plan, comprises several elements which should be taken into account. Following inputs go into the making of a business plan:

I. Information about the Industry
II. Information about the Enterprise
III. Information about Product/Service
IV. Information about Market Research
V. Information about Market Plan
VI. Information about Operation Plans
VII. Information about Finance

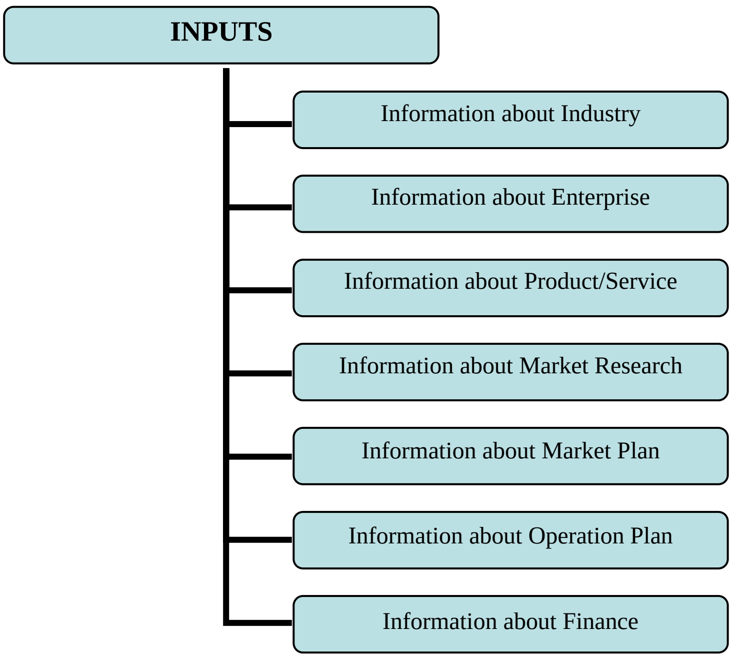

Figure 8.2: Diagrammatic representation of inputs that go into making of a business plan

Let's, now discuss these inputs one by one.

I. Information about the industry

A business plan, to start with, should contain an analysis of the industry. It should contain information like type of industry, its past and present performance, allocation of investment of funds, choice of technique etc.

II. Information about the enterprise

Information about the enterprise includes analysis of past performance, capacity utilisation, profitability etc. The purpose of the new venture (like manufacturing, processing, trading, providing services etc.) should be clearly defined. Forms of business organisation (like sole proprietorship, partnership, company, co-operative etc.) should also be mentioned.

A business plan should describe the entrepreneurial team as well. The skills, qualification, strength, talent etc. of the founding entrepreneur (also known as promoter) and other key personnel which are essential for the success of the firm must be described. The role of each person in the new venture should also be described briefly.

III. Information about product/service

Every business plan should explain its product to be sold or service to be offered. Usually, following points are described:

- Name of the product to be manufactured.
- The stage the business firm has reached to develop the new product e.g. whether such product is at research stage, design stage, testing stage, etc.
- The quality of the product.
- Price of the product.
- Method of using the product
- Material required.
- Cost of the product.
- Method of manufacture (e.g. technology profile).
- Legal protection (e.g. patents, trade mark, copy right etc.).
- Potential of substitute product which may pose competition.
- Licence requirement.
- Diversification plan.

IV. Information about market research

Under this head, the findings of market research should be provided so that it can be proved that a market really exists for the proposed venture. The entrepreneur must provide a summary of the following important points:

i) *Potential customers:* Information about potential customers helps in explaining the market size and likelihood of generating sales. Following factors are analysed under this head:

- Age of the customer
- Gender of the customer
- Family income
- Occupation
- Location

ii) *Market:* A business plan is a forecast for the present and future market. It includes information about market trend etc.

iii) *Competitors:* A business plan should provide information about the potential competitors. This includes:

- Identification of existing competitors.
- Explanation of their strengths and weaknesses.
- Impact of the new venture on the rivals.

iv) *Pricing system:* Under this head the following information should be analysed:

- Price of the product
- Credit Policies
- Discount system
- Pattern of Allowances

v) *Distribution system:* As regards distribution system, methods of distribution should be analysed. These methods include:

- Direct Sales through showrooms, mail etc.
- Distribution through retail houses.
- Distribution through wholesale establishments.
- Distribution through franchising system.
- Distribution through telemarketing.
- Distribution through door-to-door selling.

V. *Information about market plan*

A market plan can be made after proper market research. The purpose of this input is that the reader of the plan (i.e. businessman himself, investor, banker etc.) must be convinced that a viable market exists and the enterprise has a good opportunity to serve this market. It describes the intended strategy of a businessman. Following inputs should be provided:

- Product – quality, use etc. of the product.
- Pricing System – pricing method, discounts, allowances, taxes and duties, quantity, etc.
- Promotion – branding, advertising, demonstration, gifts, coupons, etc.
- Distribution – use of market channels or other approaches.
- Services – after sales service policies, installation and repair services, guarantee and warranty of a product, etc.
- Names and designations of the persons responsible for marketing and sales.

VI. *Information about operation plans*

Under this head the following important aspects shall be covered:

- Choosing a location
- Purchasing property
- Parking and transportation services
- Dealing with legal issues
- Renovations
- Equipment and technologies
- Inventory management
- Human resources
- Quality control

- Insurance
- Patents
- Copy-rights

VII. Information about finance

Money is one of the important measures used to gauge the progress of a firm. Hence, a business plan should include projections of financial statements which are based on operating and marketing assumptions.

A projected profit & loss account is required to show net profit. A projected balance sheet will reveal the financial position by showing the balances in various assets and liabilities accounts. A break-even analysis will reveal when the enterprise shall begin to earn a profit. A projected cash flow statement will show the movements of cash in and out of the firm and its net impact on the cash balance with the firm.

Check Your Progress Exercise 2

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Mention any two points regarding enterprise which should be stated in the business plan.

   i) ……………………………………………………………………………...

   ii) ……………………………………………………………………………...

2. Who can be a part of entrepreneurial team?

   i) ……………………………………………………………………………...

   ii) ……………………………………………………………………………...

3. Match the following:

Column I	Column II
1) Market plan	A) Projected income statement
2) Operation plan	B) Potential customers
3) Financial plan	C) Use of market channel
4) Production	D) Renovation
5) Market research plan	E) Patents

8.5 PREPARATION OF PROJECT REPORT

Meaning of Project Report

A project report is a formal version of a business plan. It gives a complete analysis of inputs and outputs of the project. It enables the entrepreneur to understand at the initial stage whether the project is sound on technical, commercial, financial and economic parameters. On the basis of project reports an entrepreneur takes his decision on whether to proceed on the proposed project or not. The financial institution will also base their decision to extend finance and other support on the basis of the project report. A project report also helps in convincing the investors operating in the money market to invest funds in the business.

It is necessary to prepare a project report according to the format of the loan application of the concerned term lending institutions. The project report can be made either by the entrepreneur himself or by a consultant.

Aspects covered under a Project Report

A project report provides a bird's eye view of all the activities of a business firm. The various aspects of the information have to be systematically estimated and presented mentioning the various opportunities and constraints.

A project report includes information on the following aspects:

i) Economic aspect
ii) Ecological aspect
iii) Marketing aspect
iv) Technical aspect
v) Financial aspect
vi) Managerial aspect

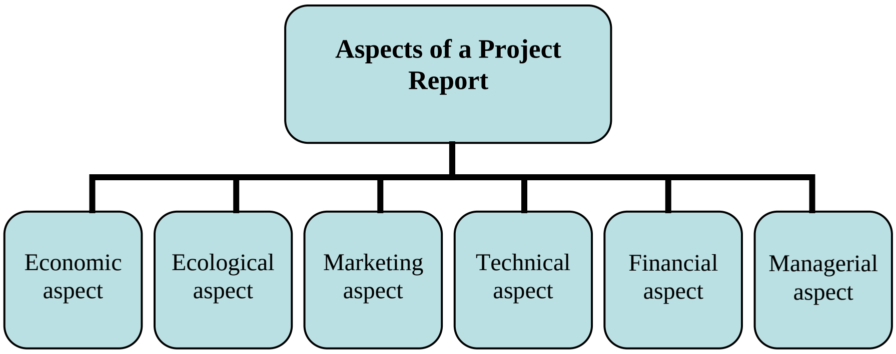

Figure 8.3: Diagrammatic representation of various aspects of a project report

Let's now discuss these points one by one:

i) Economic aspect

It is also referred to as social cost benefit analysis. It is concerned with judging a project from the larger social point of view. Under this, social costs and benefits are analysed. The impact of the project on the distribution of income, level of savings and investments in the society are analysed. It is to be seen that how much employment, self-sufficiency etc. the project will generate.

ii) Ecological aspect

Environmental concerns have assumed a great deal of importance in the present scenario. Ecological analysis is to be done for major projects which have ecological implications like power plants and irrigation schemes and environmental polluting industries. The likely damage caused by the project to the environment is to be seen.

iii) Marketing aspect

The project report should indicate demand for the product and the market share the project under appraisal can obtain. Information regarding consumption trends, structure of competition, elasticity of demand, distribution system, marketing policies, legal constraints, cost, preferences and requirements of consumers, etc. should also be mentioned. In other words a detailed market plan, specification of a proper marketing strategy and the manner in which the marketing process would be undertaken should be stated.

iv) *Technical aspect*

The appropriate report should give details about the techniques and technologies needed, equipments, raw material, machinery, power and other inputs required and the sources of their availability. This aspect covers the optimal scale of operation. Information regarding location and site, size, plant capacity, etc. needs to be mentioned.

v) *Financial aspect*

The report should indicate the amount of capital required. The amount to be contributed by the proprietor should be mentioned and the various other sources of finance should be indicated. Expected rate of return should be specified. Cost of project, projected profitability, break-even point, cost of capital, level of risk, projected financial position should be clearly indicated.

vi) *Managerial aspect*

The report should contain qualification and experience of the entrepreneurs and key personnel i.e. the persons who will be managing the show.

Contents of the Project Report

Following are the various particulars in brief to be given in a project report:

i) General details about the industrial concern, project and financial assistance applied for.

ii) Bio-data of promoters with past history.

iii) Particulars of the industrial concern comprising:

- A brief history.
- Proprietor's/partners' bio-data.
- Full details of revaluation of assets together with the reasons therefor.
- Bio-data of key technical and executive staff.
- Existing long term and short term borrowings.
- Particulars of production and sales.
- Locational advantages.
- Existing requirement of various utilities and services.
- Details of exports and incentives.
- Details of Insurance.

iv) Particulars of the project comprising:

- *Capacity* – Present and proposed installed capacity, maximum production achieved and planned

- *Process* – Details of technical process, labour intensiveness of the process, reasons for choosing a particular process.
- Technical arrangement – Details of the technical arrangement made or proposed, write up on the collaborator, copy of the Government approval for the collaboration etc.
- Management.
- Location of land
- Building
- Plant and machinery
- Raw material
- *Utilities* – Details about power, water etc.
- *Effluents* – Details of the nature of atmosphere, soil and water pollution likely to be created by the project and measures proposed for control of pollution.
- Labour.

ii) Cost of the Project.

iii) Means of Financing.

iv) Marketing and selling arrangement.

v) Government consents.

vi) Requirement of raw material.

vii) Particulars of machinery to be imported.

viii) Margin money for working capital.

ix) Source of funds in respect of expenditure already incurred.

x) Cash Flow Statement.

xi) Projected Balance Sheet.

xii) Projected Income Statement.

xiii) Calculation of wages and salaries at maximum production.

xiv) Unit cost of production.

xv) Declaration that the above particulars are true and correct to the best knowledge and belief of.

Check Your Progress Exercise 3

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. State True or False.

   i) A project report is an incomplete analysis of inputs and outputs of the project.

   …………………………………………………………………………...

   ii) A project report serves as a guide to management.

   …………………………………………………………………………...

iii) A project report can be prepared by anybody.

…………………………………………………………………………...

iv) A project report contains economic and financial aspects only.

…………………………………………………………………………...

v) A project report is needed by an entrepreneur for carrying out expansion or starting a new production line.

…………………………………………………………………………...

2. Read the following paragraph and fill in the blanks with appropriate words given below:

(entrepreneur, financial institutions, analyse, expert, feasibility)

A project report is prepared to ------------------- the extent of opportunity in the contemplated project. It is prepared by the-------------------------- himself or an ------------------- after detailed study and analysis of the various aspects of a project. The ------------------- insist upon such a project report in order to be sure about the ---------------- of the project.

8.6 PROJECT APPRAISAL

In the preceding paragraph we learnt that the entrepreneur has to submit a project report to his bankers in order to avail loan facility from them. The bank/term-lending institutions after receiving the loan application along with project report critically scrutinise it. They intend to ascertain the possibility of generation of funds by the project itself and whether or not it would be substantial enough to repay the amount advanced within the fixed time. The following paragraphs focus on what goes on in the minds of financial institutions while they appraise the proposal.

Let's now discuss the system of project appraisal.

Meaning of Project Appraisal

Project appraisal is the assessment of a project by a bank/term-lending institution. It is a complete and critical scanning of the project. It is the analysis of cost and benefit of the proposed project. It is important for a bank/term-lending institution to appraise a project because the resources are always limited and choice among alternative projects has to be made.

Method of Project Appraisal

The method of analysis of a project report usually varies from project to project i.e. method of analyzing a project by Canara Bank may be different with that of Delhi Financial Corporation. The various aspects that are taken into account by the appraiser are examined below:

i) Economic viability

The larger projects may be critically evaluated by the lending institutions by taking into those factors which have an economic and socio-cultural impact on the society. The appraiser will examine whether the project will lead to increased output, increased employment, larger Government revenues, higher standards of living, increased national income, utilisation of indigenous raw-material, etc.

ii) Ecological viability

Effect of the project on the environment with particular emphasis on the pollution of water and air caused by the project is examined. The arrangement for effective disposal of effluents as per the Government policies is also judged. Energy conservation devices etc. employed for the project are also analysed. This analysis is done for big projects.

iii) Technical viability

All factors relating to infrastructural needs, technology, availability of machines, materials etc. are required to be scrutinised. Following are some of the important points which are usually examined under this head:

a) Size of the available land to meet the present requirements and future expansion plans.

b) Locational advantages in terms of transport facilities, proximity to market, infrastructural facilities like availability of water, power, labour etc.

c) Position of availability of licences, if required from the Central or State Governments.

d) Technology selected and method of manufacture.

e) Technology collaboration, if any.

f) Ready availability of plant and machinery.

g) Arrangements for servicing of the machinery, supply of spare parts etc.

h) Scale of operation.

i) Plant layout and plant capacity.

j) Detailed specification and the quantity proposed to be manufactured for, say, five years.

k) Specifications for raw material and sources of supply.

iv) Marketing viability

Any project can be commercially viable only if it is able to sell its products at a profit. For this purpose, demand and supply pattern of that product is examined. Various methods like trend method, regression method for estimation of demand are employed which are then matched with the availability of particular product. Some of the important aspects which are analysed under this heading are given below:

a) Study of demand forecast.

b) Market potential.

c) Position of other competitors.
d) Distribution channels.
e) After sale-service.
f) Capability of the organisation to survive even under the adverse circumstances.

v) Managerial viability

The background of the founders or promoters of the project is also closely examined by the lending institutions. The project report should also highlight the strengths and weaknesses of the management by commenting on qualification, experience, potential, etc. of the key personnel. Following points are usually critically observed:

a) Organisation Chart clearly defining various ranks and their jobs.
b) Functions assigned to various managers.
c) Communication channels.
d) Delegation of authority and responsibility.
e) Labour relations.
f) Workers' participation in management.
g) Turnover rate.
h) Social security.
i) Working conditions.
j) Fringe benefits.
k) Qualification and experience of the founders/promoters.
l) Training programmes.
m) Internal control systems.

In short, the appraiser wants to be sure that the project is adequately carried out through a well-staffed organisation which is capable of contributing effectively to the success of the project and organisation thereby. The qualification and past experience of the founders is assessed to know their capabilities for implementing the project.

vi) Financial viability

The real objective of the appraisal of the financial aspect of a project report is usually to examine its financial condition for the sound implementation of the project. The financial institution wants to ensure that the business firm is in a position to manage its business in a cost-effective manner as well. Financial viability of the project is also seen to assess whether a project would be in a position to generate enough surplus for timely payment of interest and servicing of debt in a reasonable period of time. The financial aspect of project appraisal covers the following areas:

A) Cost of project

- Cost of land and building
- Cost of plant & machinery
- Furniture and fixtures
- Office equipments
- Interest during construction period

- Margin money for working capital
- Preliminary expenses

B) *Sources of finance*

- Owned Capital
- Unsecured Loans from friends and relatives
- Term Loans from financial institutions/commercial banks
- Deferred Term Credit
- Subsidies and Development Loans

C) *Projected income statement*

Trading account provides net sales figures and details of direct expenses relating to raw material, wages, power, fuel etc.

Profit & loss account provides figures of net profit after taking into account expenses like salary, office expenses, selling and distribution expenses, interest, depreciation etc.

D) *Projected balance sheet*

The lending institution will study the projected balance sheet as well which gives the position of assets and liabilities of the business unit at a particular time. It shows the assets and liabilities of a firm.

E) *Break-even analysis*

A break-even point of a business enterprise is the level of output or sales at which the business enterprise just breaks-even i.e. there is neither a profit nor a loss. The formula for calculating break-even point (BEP) is as under:

$$\textbf{\textit{BEP (in Units)}} = \frac{\text{Total Fixed Costs}}{\text{Selling Price per unit} - \text{Variable Cost per unit}}$$

A unit should always work above the break-even point to earn profit.

F) *Financial ratios*

While analysing the financial aspect of a project, study of financial ratios is quite important. These ratios can apprise the financial institutions about the liquidity position, solvency position of a firm over a period of time. The financial ratios which are usually analysed are:

- Debt-Equity Ratio
- Debt-Service Ratio
- Current Ratio
- Liquid Ratio
- Stock Turnover Ratio
- Debtors' Turnover Ratio
- Return on Investments
- Working Capital Turnover Ratio

G) *Projected cash flow statement*

A projected cash flow statement is a summary of all the sources of cash available (cash inflows) during the course of operation within a period of time and its possible uses (cash outflows) during that period. While appraising the project the banker, with the help of this statement, can find out the total surplus funds created during the operational year for which it is prepared. This information helps to determine the capacity of the project to service its debts and fix the repayment period and moratorium period of loan.

H) *Pay back period*

While carrying out project appraisal the banker considers a project more favourably which has shorter pay back period. This period refers to the length of time which is required to recover the initial cash investment made in a project. A project with a shorter pay back period is always preferred.

I) *Discounted cash flows*

Under pay back period the cash flows are considered without taking into account the time value of money. It may be noted that the value of a particular amount received after five years is not similar to the value of same amount which is received today.

For example, there is a difference between Rs. 10,000 which is received after five years and which is received today. If we compute the present value of Rs. 10,000 which shall be received five years hence, it must be discounted at a particular rate of interest to know its present value.

The banker shall consider the present values of the future cash flows and compare it with the initial investment. If the result is positive i.e. the present values are more the project shall be acceptable.

J) *Internal rate of return*

At the time of appraisal the bankers also consider the internal rate of return (IRR), also known as accounting rate of return. IRR means the discount rate which equals the present value of investment in the project to the present value of future returns earned during the life time of the project. IRR indicates earning capacity and a higher IRR indicates better prospects for the project.

8.7 COMMON ERRORS IN FORMULATION OF BUSINESS PLAN AND REMEDIES THEREOF

Common Errors in Business Plan Formulation and Remedies

Following Table indicates the various common errors which may be committed while formulating a business plan. The Table also contains remedies which will help in avoiding such errors:

Table

Common errors	Remedies
i) The entrepreneur may make heavy investment in land and building in the initial stages which may result in un-economic working due to heavy interest burden on un-productive assets if these are under-utilised.	At the initial stages heavy investment in un-productive assets should be avoided. Such investment may be diverted for purchasing imported machinery and good quality raw material.
ii) Plant and machinery purchased is unbalanced i.e. the capacity at various stages of production is not matched to give the desired output which may result in low production.	A critical analysis of the various technical factors can help the entrepreneur to prevent the unit from getting into difficulties at a later stage.
iii) The management is ineffective in controlling functions like production, marketing, finance etc.	Experienced personnel should be recruited. Their roles should be clearly defined with proper delegation of authority.
iv) The business is more at risk if decision making in all areas is in the hands of one man i.e. one man show.	The businessman should keep important decisions in his hands. Routine business activities should be delegated. Principle of '*management by exception*' should be followed.
v) Promoters are weak in respect to experience, qualification etc.	Experts may be roped in either as partners or employees or consultants.
vi) The project report may not show enough profits to service its debts and for future development.	Avoidable and unnecessary expenditure may be reduced.
vii) A project report when written by the businessman himself may contain mistakes.	The project report may be prepared with the help of experts.
viii) Projections given in the project report are only for short period.	The project report should contain projections for at least five years.
ix) Wrong and unrealistic estimations are incorporated in the project report.	Wrong and unrealistic estimations should be avoided. The estimations should be based on authentic information.
x) Insignificant ratios like Fixed Assets Turnover Ratio, Fixed	Significant ratios like Current ratio, Debtors' turnover ratio, Debt service

asset ratio etc are given in the project report.	coverage ratio, Debt equity ratio etc. should be invariably incorporated.
xi) Wrong estimate of fixed capital are incorporated in the business plan leading to long term adverse effects on the financial position of the enterprise and also on its profitability. It may lead to over/ under capitalisation.	With careful planning the businessman should correctly estimate the fixed capital so that there is no under or over capitalisation in the long run.

Check Your Progress Exercise 4

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Tick the correct option from the following alternatives:

   i) A project report is appraised by:

      a) Banker
      b) Businessman
      c) Central Government
      d) Reserve Bank of India

   ii) The financial projections appraised are:

      a) Projected income statement
      b) Projected financial position
      c) Both of the above
      d) None of the above

   iii) The purpose of project report appraisal is to:

      a) Recruit financial manager
      b) Buy land and building
      c) Sanction term loan
      d) None of the above

   iv) The banker will examine:

      a) Technical viability
      b) Economic and Financial viability
      c) Marketing viability
      d) All of the above

   v) The point which may go against the promoter:

      a) Good Qualification
      b) Wide Experience
      c) Works on whims and fancies
      d) Sharp business acumen

2. Mention any two points which will be examined by the bank at the time of project appraisal.

   ………………………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

3. Mention any two common errors which a project report may contain.

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

……………………………………………………………………………

8.8 LET US SUM UP

Business plan is prepared to assess the future and make provisions for it. A businessman studies the feasibility of various business proposals. He takes up only that idea which is promising one. With this idea in hand, a proper analysis should be done in respect of market, technical, and other aspects. At this stage, the business plan which involves step by step investigation and development of a sound business idea should be prepared. Besides businessman himself, the business plan can be written with the help of experts also. A business plan is required because it provides a framework for the future activities of the enterprise. It helps in initiating development, arranging financial assistance, securing clearances from the Government, selecting appropriate technology etc. The important inputs that go into making of business plan include information about the industry, enterprise, product and service, marker research, market plan, operation plans, and finance. A project report is a formal version of a business plan. A project report includes information about the various aspects like economic aspect, ecological aspect, marketing aspect, technical aspect, financial aspect and managerial aspect. Financial institutions including banks appraise a project report for its viability etc., if any financial assistance is desired by the businessman from such institutions. Common errors like over estimations, heavy investment in unproductive assets, wrong projections etc. should be avoided while formulating business plan.

8.9 KEY WORDS

Cost of capital : It is the rate of return required by the investors on capital provided by them.

Cost of project : It is the total of all items of outlay associated with the project which are supported by long term funds.

Plant capacity : Volume/number of units that can be manufactured during a given period.

8.10 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. i) Guidelines
   ii) Ahead
   iii) Abandon
   iv) Business Plan
   v) Pragmatic

2. a) Counselling Organisations
   b) State Agencies

3. i) False
   ii) True
   iii) True
   iv) False
   v) False

Check Your Progress Exercise 2

1. **Hint:** i) From the business organisation
   ii) Analysis of past performance.

2. **Hint:** i) Promoters
   ii) Experts in the field of finance, Production etc.

3.

Column I	Column II
1) Market Plan	C) Use of market channel
2) Operation Plan	D) Renovation
3) Financial Plan	A) Projected Income Statement
4) Production	E) Patents
5) Market Research Plan	B) Potential Customers

Check Your Progress Exercise 3

1. i) False
   ii) True
   iii) False
   iv) False
   v) True

2. *(analyse, entrepreneur, expert, financial institutions, feasibility)*

Check Your Progress Exercise 4

1. i) a) Banker
   ii) c) Both of the above
   iii) c) Sanction term loan
   iv) d) All of the above
   v) c) Works on whims and fancies

2. **Hint:** i) Financial viability of the project.
   ii) Managerial viability of the project.

3. **Hint:** i) The entrepreneur may make heavy investment in unproductive assets (like land and building) in the initial stages.
   ii) The project report may not show enough profits to service its debts and for future development.

8.11 SOME USEFUL BOOKS

1. Desai, Vasant (1998) Dynamics of Entrepreneurial Development of Management; Himalaya Publishing House, Mumbai, Reprint.

2. Nabhi Publication (2004) How to Borrow from a Baking and Financial Institution; Nabhi Publications, New Delhi, Edition.

3. Bidani, Mitra and Promod Kumar (1998)Bank Finance for Industry; Vision Books, New Delhi, Edition.

4. Chandra, Prasanna (1996) Projects, Planning, Analysis, Selection, Implementation and Review; Tata McGraw-Hill Publishing Company Limited, New Delhi, Fifth Reprint.

8.12 ASSIGNMENTS

1. What is a business plan? Why is it needed?

2. What are the features of an ideal business plan?

3. Explain in detail the various inputs required to be mentioned in a business plan.

4. What is a project report? Why is it prepared?

5. “A business plan comprises several elements”. Name any two.

6. Mention two points relating to product which should find place in a business plan.

7. What is a market plan?

8. What is the purpose of a projected cash flow statement?

9. Explain the various aspects to be covered in a project report.

10. What is the purpose of social cost-benefit analysis?

11. Mention the contents of a project report.

12. What is project appraisal? Who does it?

13. Discuss how the banker will examine technical and financial viability of the project.

14. Mention the various sources of finance which the banker may examine.

UNIT 9 ARRANGING THE INPUTS: FINANCE AND MATERIAL

Structure

9.0 OBJECTIVES

After studying this unit, you should be able to:

- know the meaning and importance of finance;
- understand the various types of capital;
- identify the different sources of finance;
- comprehend the factors involved in selection of appropriate medium of finance; and
- understand the important considerations associated with procurement of material.

9.1 INTRODUCTION

A businessman has innumerable tasks the moment he decides to venture into the line of business. Some tasks out of these may be highly important and crucial for his business to start and gain momentum; while some other tasks may not be so important. The most important task for a businessman is no doubt, to decide 'about what to do'? Should he go into manufacturing line and become a producer or should he divert into a wholesale or retail trade business. Once this important decision is taken then follows the other significant tasks of organizing various resources for his business.

To start with, a businessman needs to assemble five M's i.e. money, material, men, methods and machines for his business. These are the basic inputs required for his business – more so if he plans to be in manufacturing line. In this Unit an attempt has been made to highlight the importance and management of the first two inputs i.e. **money, also known as finance; and material.**

Finance is an important input as no business can function without money and material is important because goods cannot be manufactured without raw material.

9.2 FINANCE: MEANING, NEED AND TYPES

"Finance is the life-blood of any business" – is rightly observed. Finance is required by all types of business – big or small, manufacturing or trading, etc. Finance acts as the lubricant for the wheels of the business to move and to run. No business firm can carry out its work without money. Money is one of the five M's of business – the other four being men, material, machinery and methods. Provision of finance leads to economic development of the country. Past two decades have shown an increase in setting up of SSIs due to availability of finance on easy and better terms. The amount of finance required may be different from one business to another. It depends upon many factors like nature of the business, size of the business, time-period, etc.

A businessman needs money for the following purposes:

i) To start a business;
ii) To expand, renovate and modernize the business.

Types of Capital

Following are two the types of capital required by a businessman:

1. *Fixed capital*

   Fixed capital is required to acquire fixed assets like land, building, plant, machinery, office equipment, furniture and fixtures, erection and installation of machinery, etc. In addition, fixed capital is also required for meeting the cost incurred on insurance, technical know-how etc.

2. *Working capital*

   Working capital is needed to meet day-to-day requirements of a business. For example, amount spent on raw material, wages, hire charges, transportation, interest, etc. It is also known as circulatory capital. Once the raw material is purchased and products are manufactured, the process of selling the goods so manufactured starts. Thereafter, efforts are put in to realise the sale proceeds including that amount of money which gets locked due to the credit sales. The money so realised is once again invested in purchasing raw material and the operating cycle is continued. Hence, the term circulatory capital.

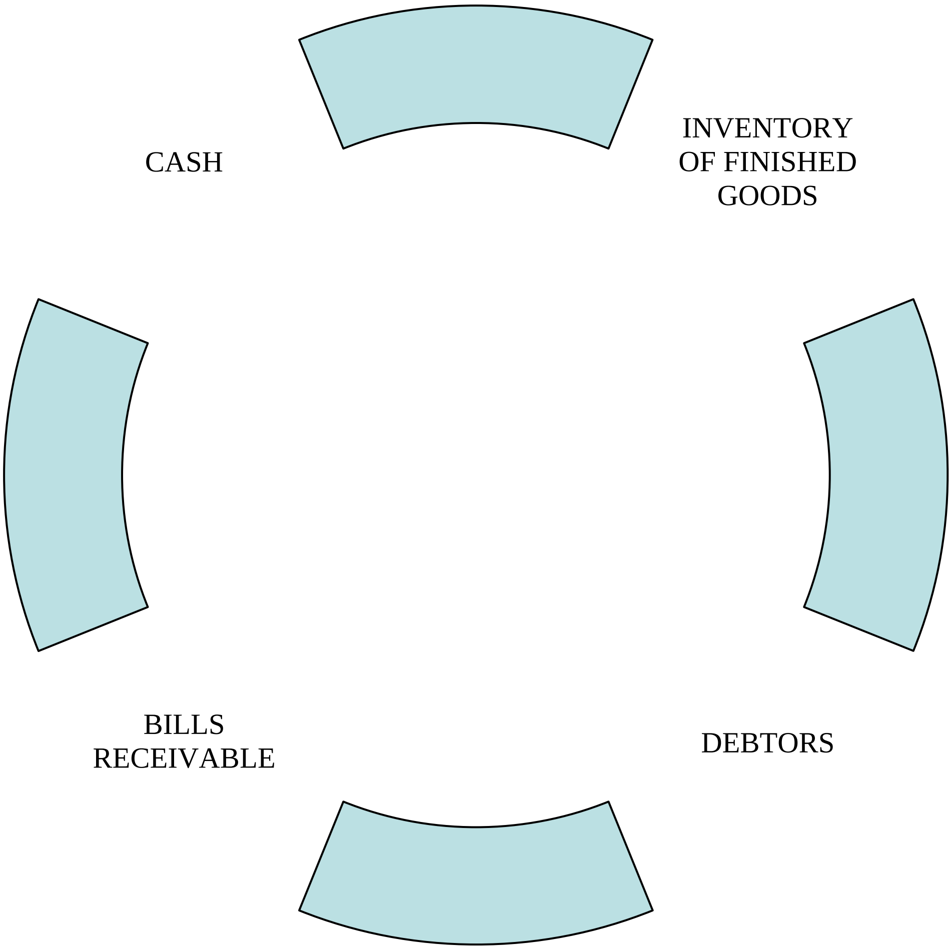

Figure 9.1: Diagrammatic representation of operating cycle in a trading firm selling goods on credit

Types of Finance

For financing fixed capital and working capital a businessman needs long term finance as well as short term finance**.**

1. *Long term finance*

   Long term finance is used for investment in fixed assets such as land and building, plant and machinery etc. It is used to meet the permanent needs of business. It can be raised through owned capital and long term loans. Such finance cannot be withdrawn from the business.

2. *Short term finance*

   Short term finance is used for investment in working capital. It is used to meet the short term needs of the business. For example, purchase of raw material, payment of wages etc. These funds are normally required for a period ranging from three months to two years.

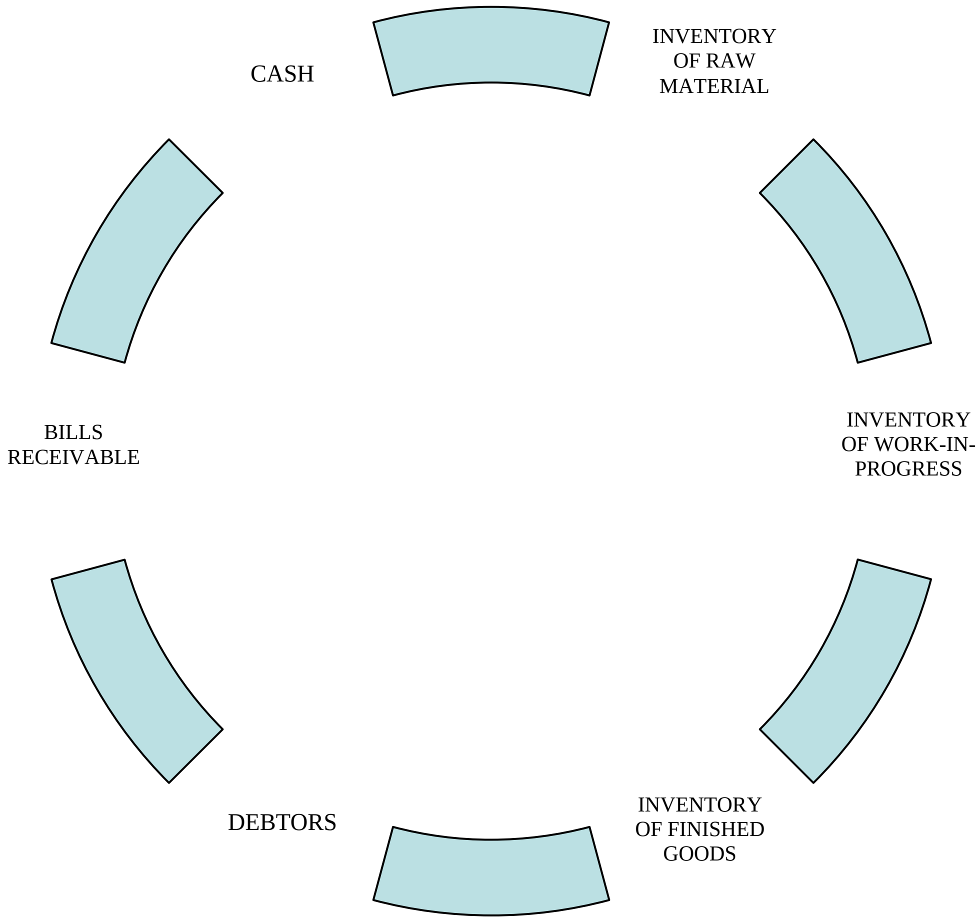

Figure 9.2: Diagrammatic representation of operating cycle in a manufacturing firm selling goods on credit

9.3 SOURCES OF FINANCE

The sources of funds can be broadly divided into:

i) owned capital; and
ii) borrowed capital.

Owned capital is the money brought in by the businessman himself, while borrowed capital is the money advanced by outside agencies. However, sources can also be segregated into long term sources and short term sources. These sources are explained below:

Sources for Long Term Finance

1. Owned capital
2. Retained Profits
3. Funds borrowed from friends and relatives.
4. Loans from Commercial banks
5. Loans from National-level Financial Institutions
6. Loans from various State-level Financial Institutions

Let's now discuss the above sources of finance.

1. *Owned funds*

   Owned funds are the funds provided by the owners. In case of a sole proprietor, the individual himself provides the owned funds from his personal property and past savings. In a partnership firm, the funds contributed by partners as capital are called owned funds. In a joint stock company funds, raised through issue of shares, are known as owned funds.

2. *Retained profits*

The businessman may not withdraw the entire profit from the business. Retained profit represents the amount of profit which remains available in the business after taking out profit for his personal and family affairs. Retained profit serves as a long term source of finance.

3. *Friends and relatives*

Amount can also be collected from the friends and relatives of the businessman. They generally provide this form of assistance at either no or very low rate of interest. The repayment schedule may not be fixed and generally no amount is kept as security. This is provided only due to love and affection.

4. *Loans from commercial banks*

A lot of importance has been put on the role of commercial banks by the successive governments in the development of the economy of our country. It is quite evident that various commercial banks are, therefore, associated with every project of industry/trade irrespective of its size. The banks are catering to the credit needs of a large variety of projects, big or small, in all sectors of the economy including agriculture, trade, industry, services etc. Commercial banks grant term loans for small projects falling under priority sector, small scale sector and also to big units. Long term loans are usually repayable after a period of seven years.

Banks are playing an important role for the upliftment of rural and urban poor. In this direction, they are involved in implementing the various Government sponsored schemes like Swarna Jayanti Gram Swarojgar Yojana (SGSY); Prime Minister’s Rojgar Yojana (PMRY); Swarna Jayanti Shahari Rojgar Yojana (SJSRY); Scheme for Liberation and Rehabilitation of Scavengers (SLRS), etc.

5. *Loans from national-level financial institutions*

Various financial institutions play a significant part in development of big industries. Financial Institutions like Industrial Development Bank of India (IDBI), Small Industries Development Bank of India (SIDBI), Industrial Finance Corporation of India (IFCI), Industrial Investment Bank of India (IIBI), Industrial Credit and Investment Corporation of India (ICICI), Regional Rural Banks (RRBs), National Bank for Agriculture and Rural Development (NABARD) etc. offer financial assistance on long term basis for big projects. These are also known as development financial institutions. They are a major source of finance for forming of new business organisations and expansion of existing concerns. They also provide promotional, technical and managerial services to various new and existing organisations. The rate and repayment procedures are convenient and economical. Loans and guarantees in foreign currency and deferred payment facilities are available for the import of machinery and equipment.

6. *Loans from state-level financial institutions*

   State-level financial institutions were established because the National-level financial institutions were providing finance exclusively to large scale industrial units. The Government, therefore, started establishing development banks at the regional level to provide assistance to small scale industries. These institutions provide long term loans to industries for the purchase of land, building and machinery. They also assist in industrial activities like preparation of feasibility report, identifying entrepreneurs, assisting them in project implementation, etc.

Short Term Sources of Finance

Short term finance is required for meeting the short term requirements of business (like working capital). Short term loans are usually repayable within a period of one to three years. The important sources of short term finance are as under:

1. Bank Overdraft
2. Cash Credit
3. Discounting of Bills of Exchange
4. Short term loans
5. Trade Credit from suppliers
6. Accounts Payable
7. Advances from customers
8. Accruals
9. Factoring
10. Co-operative Credit Societies
11. Indigenous Bankers

1. *Bank overdraft*

   This is one of the most convenient methods of borrowing. Here, a customer having a current account with a commercial bank like Canara Bank is permitted to withdraw more than what he has deposited. The upper limit of what he can overdraw is fixed. Interest is charged on the amount actually overdrawn during a particular period. Some asset is kept as security. Overdraft limits are usually rolled-over limits which are renewed every year.

2. *Cash credit*

   A major part of working capital requirement of any industrial project generally consists of maintenance of inventory of raw material, semi-finished and finished goods, stores and spares etc. Even in trading concerns funds are required to maintain stock-in-trade. Finance against such inventory is granted in the shape of cash credit facility where cash withdrawals are permitted against stock of goods. A running account facility is provided where deposits and withdrawals are permitted to the borrower as frequently as required. Over-drawls are however restricted to an agreed limit and are further subject to availability of drawing power in the account.

3. *Discounting of bills of exchange*

   Commercial banks also extend financial assistance by discounting bills of exchange. Here the customer i.e. the businessman can get the amount of a bill receivable from the bank before the date of maturity. Charges have to be paid by the customer known as discounting charges.

4. *Short term loans*

Loans provided by commercial banks are repayable in monthly/quarterly/half-yearly/yearly instalments. Commercial banks grant short term loans and medium term loans for working capital requirements. Short term loans are repayable in less than three years while medium term loans are repayable in a period ranging from three years to seven years. A loan is granted against security of assets and the personal guarantee of the borrower. Collateral security is also demanded as and when necessary. Interest on loans is required to be paid on regular basis irrespective of the loss suffered by the borrower.

5. *Trade credit from suppliers*

Trade credit is the credit extended by the seller of goods to the buyer as incidental to sale. It is available in the ordinary course of business without any security. An open account credit arrangement is made, the volume of which depends upon the reputation of the buyer, financial position of the seller, volume of purchase etc.

6. *Accounts payable*

Accounts payable is another form of trade credit. Here, the buyer is required to sign a debt instrument e.g. a bill of exchange or a promissory note as an evidence of the amount due by him to the seller. This credit is also made available without creating any charge on assets.

7. *Accrual accounts*

There is usually a time-lag between receipt of income and making payment for the expenditure incurred in earning that income. During this time-lag the outstanding expenditure helps an enterprise in meeting some of its working capital requirement. For example, wages and salaries, taxes due but not paid immediately etc. Wages and salaries are paid in the first week of the month next to the month in which services were rendered.

8. *Advances from customers*

If the businessman is manufacturing a product which is in short supply, he may demand advance money from his customers at the time of accepting their orders. This is a very cheap source of short term finance because either no interest is payable or the rate of interest payable on advance is nominal.

9. *Factoring*

The businessman can obtain short-term finance through factoring. It is an arrangement under which the businessman assigns his book debts to the factoring firm. Against such assignment of debtors' balances the banker advances the money to the businessman. For providing the services of factoring, the factoring firm charges commission known as 'commercial charge'. SBI has opened a subsidiary by the name SBI Factors and Commercial Services Ltd. which provides factoring services. Similarly, Canara Bank has also opened a subsidiary by the name Canara Bank

Factors Ltd. for the purpose of providing factoring services in India. SIDBI has also introduced its own factoring services.

10. Co-operative credit societies

Co-operative Credit Societies are formed by artisans, agriculturists, industrial workers etc. These societies provide financial assistance at reasonably low rate of interest to its members. They also promote the habit of saving and thrift among them.

11. Indigenous bankers

Businessmen can get loans from various indigenous bankers as well. They are known by different names like shroffs, seths, sahukars, mahajans, etc. in different parts of the country. They vary in size from petty money-lenders to substantial shroffs who carry on large and specialized business. They finance the businessmen by means of hundies or bills of exchange. They lend against personal credit of the borrowers. The rate of interest is usually very high. They may not give receipts in most of the cases.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Name the source of finance in the following cases:

   i) Rakesh received Rs. 1,00,000 from his grand parents to start his business.

   ……………………………………………………………………………...

   ii) Shri Ganesh, a neighbour of Mukesh agrees to give Rs. 5,000 to him without any interest.

   ……………………………………………………………………………...

   iii) Suhail Khanna borrows Rs. 25,000 @ 5% p.a. from his brother-in-law.

   ……………………………………………………………………………...

   iv) M/s. Utkarsh & Sons took loan of Rs. 1,00,000 from Canara Bank repayable in three years.

   ……………………………………………………………………………...

   v) Kishore starts his business investing Rs. 50,000 in cash.

   ……………………………………………………………………………...

2. Classify the following expenses into fixed capital and working capital:

   i) Purchase of raw material.

   ……………………………………………………………………………...

ii) Purchase of plant & machinery.

……………………………………………………………………….....

iii) Purchase of land and building.

……………………………………………………………………….....

iv) Rent paid.

……………………………………………………………………….....

v) Purchase of 'Maruti 800'.

……………………………………………………………………….....

3. Name the sources of finance in the following cases:

i) A source of finance where credit is extended by the seller of the goods.

……………………………………………………………………….....

ii) A source of finance where expenses are paid in the first week of the month next to the month in which services were rendered.

……………………………………………………………………….....

iii) A source of finance where 'sahukars' or 'mahajans' grant credit to the business.

……………………………………………………………………….....

iv) A source of finance provided by commercial banks where a customer can withdraw more money than he has deposited.

……………………………………………………………………….....

v) A source of finance where the business can get the amount of a bill receivable from the bank before the date of maturity.

……………………………………………………………………….....

9.4 SPECIALISED FINANCIAL INSTITUTIONS

Specialised financial institutions mainly provide long term financial assistance in various forms. Besides sanctioning loans, the give guarantees for loan raised by the business concerns from other sources.

These institutions are also known as development banks because they provide not only capital but also knowledge and entrepreneurship to the industry. These institutions undertake potential industrial surveys; identify growth projects; provide technical, managerial and other assistance to the entrepreneurs.

These special financial institutions, both at National-level and State-level have been set up upon the initiative of the Central and State Governments respectively.

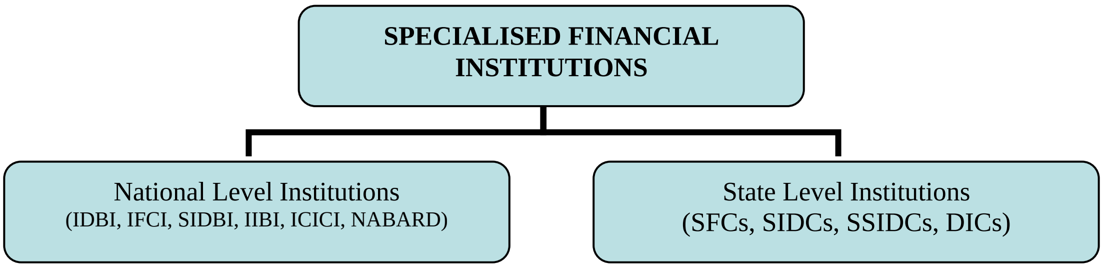

Figure 9.3: Diagrammatic representation of types of specialised financial institutions

Let's now discuss some of the important specialised financial institutions.

1. Industrial Development Bank of India (IDBI)

IDBI was set up as a wholly owned subsidiary of Reserve Bank of India in July, 1964 by an Act of Parliament. It serves as an apex level national institution for providing term finance to the industry. In 1976, the ownership of IDBI was transferred to the Government and it was entrusted with the additional responsibility of acting as principal financial institution for coordinating the activities of institutions engaged in the financing, promotion or development of industry.

Functions of IDBI

i) It provides direct financial assistance to industrial concerns by giving them long term loans.

ii) It provides technical and administrative assistance for promotion and expansion of industry.

iii) It guarantees loans raised by industrial concerns from other financial institutions.

iv) It accepts bills of exchange of industrial concerns and also discounts and rediscounts them.

v) It provides refinancing facilities.

2. Small Industries Development Bank of India (SIDBI)

SIDBI was set up by an Act of Parliament i.e. Small Industries Development Bank of India Act, 1989 as a wholly-owned subsidiary of IDBI for re-financing, bills rediscounting, and equity support to the small scale sector. It started functioning on April 2, 1990. SIDBI was de-linked from IDBI w.e.f. 27th March, 2000. It serves as an apex level national institution for promotion, finance and development of industries in the small sector.

Functions of SIDBI

i) It provides financial assistance through term loans and working capital.

ii) It provides finance through discounting and re-discounting of bills arising from the sale of machinery to small units.

iii) It provides Venture Capital support.

iv) It provides services like factoring, leasing etc.

3. National Bank for Agriculture and Rural Development (NABARD)

NABARD has been set up for the promotion of agriculture, small scale industries, cottage and village industries, handicrafts etc. in the rural sector. It is an apex bank for agricultural finance. It came into existence on July 12, 1982. It provides refinancing facilities. It has initiated Micro Finance programme under which millions of poor people have been provided access to credit. It has created special funds like Watershed Development Fund, Tribal Development Fund, Research and Development Fund, Farm Innovations Fund, and Micro Finance Development and Equity Fund to support innovations in neglected areas.

4. Regional Rural Banks (RRBs)

The object of setting up Regional Rural Banks was to bring the banking services to the doorsteps of rural masses. Initially these banks were providing funds to target groups comprising weaker sections of the society at a concessional rate of interest. However, since 1997 the RRBs have been allowed to lend outside the target group also by classifying their advances into priority sector and non-priority sector.

5. State Financial Corporations (SFCs)

A special law known as State Financial Corporation Act, 1951 was passed by the Parliament to enable all the states except Jammu and Kashmir to set up their own State Financial Corporations. So far 18 SFCs are operating in different States and Union Territories.

The main objective of SFCs is to finance and promote small and medium enterprises and projects costing up to Rs.5 crores for achieving balanced regional socio-economic growth and generating employment opportunities. SFCs operate a number of schemes of refinance and equity type of assistance formulated by IDBI, SIDBI which include schemes for artisans, SC/ST, women, ex- serviceman, physically handicapped etc. and for transport operators, for setting up hotels, hospitals etc.

SFCs can provide financial assistance to proprietary concerns and partnership firms up to Rs. 120 lacs.

Functions of State Financial Corporations

Following are the functions of SFCs:

i) They provide term loans for acquiring land, building, plant and machinery, other miscellaneous fixed assets etc.

ii) They establish polytechnics or training institutes for imparting training to technically qualified persons.

iii) They take up the development of lesser developed parts of the State and engage in infrastructure development like electricity, road, water etc.

iv) They promote self-employment.

v) They provide finance for expansion, modernization and up-gradation of technology in the existing units.

vi) They identify and examine local problems.

vii) They provide seed capital assistance under the schemes of IDBI.

viii) They provide deferred payment guarantees for purchasing plant and machinery.

ix) They provide foreign exchange loans to industrial units under World Bank Schemes.

General Terms and Conditions of Financial Assistance to Small Scale Units provided by SFCs

The general terms and conditions of financial assistance which may be provided to the small scale units are as follows:

1. *Quantum of assistance:* No minimum or maximum quantum of assistance has been stipulated except the upper ceilings.

2. *Debt-equity ratio:* SFCs may approve a Debt-Equity ratio of up to 2.5:1 for providing assistance.

3. *Promoters' contribution:* A minimum promoters' contribution ranging from 12.5% to 22.5% depending upon the location of project and category of enterprise may be accepted.

4. *Repayment period:* SFCs usually fix the repayment period after taking into consideration the profitability and debt servicing capacity of the project. No repayment period is fixed beyond 10 years.

5. *Rate of interest:* The rates are subject to revision from time to time.

6. *Commitment charges:* The commitment charges are payable only after the expiry of 12 months from the date of sanction. However, the rates may again vary from state to state. Usual Commitment Charges are as under:

For loans up to Rs.5 lacs:	*NIL*
For other Projects:	*1% p.a.*

Composite Loan Scheme of SFCs

Generally, SFCs provide assistance for term loan component and the unit has to arrange working capital requirements from a commercial bank of its own choice. SFCs, however, operate a composite loan scheme which meets all the requirements of the unit. Composite loans up to Rs. 50,000 are sanctioned under the Scheme to artisans, village and cottage industries and SSI units in tiny sector. The repayment period of such composite loans is spread from 3 years to 7 years.

Seed Capital Assistance provided by SFCs under the Scheme of IDBI

Under this Scheme maximum assistance per unit is restricted to Rs. 15 lacs. The following categories of entrepreneurs are generally eligible for assistance:

i) Entrepreneurs establishing small scale units for the first time.

ii) Entrepreneurs wishing to undertake expansion, diversification or modernization of small scale units and yet remaining small scale units.

iii) Entrepreneurs wishing to set up a medium scale unit for the first time or wishing to undertake expansion, diversification of existing industrial undertakings for better viability.

iv) Entrepreneurs taking over an existing sick or closed industrial unit.

Application under the Scheme may be made simultaneously along with the main loan application for project finance. The assistance is granted free of interest and a nominal service charge of 1% p.a. is levied on the amount outstanding under the assistance.

6. State Industrial Development Corporations (SIDCs)

SIDCs were set up in 1960s and 1970s. These were established as wholly-owned undertakings of the State Governments under the Companies Act, 1956 or autonomous corporations under specific State Acts. Different States have set up the State Industrial Development Corporations with a view to improving the growth of industry in their States. These corporations operate as per the Guidelines issued by State Governments. There are 28 SIDCs operating in our country. They provide assistance to small and medium units and projects costing up to Rs. 10 crores.

Functions of SIDCs

i) They promote and develop industries by activities like project identification, preparation of project report, selection and training of entrepreneurs.

ii) They provide term loans to industries.

iii) They grant incentives and subsidies on behalf of the Central and State Governments.

iv) They act as agent of IDBI, SIDBI and thereby provide the benefit of seed capital scheme.

v) They provide risk capital to entrepreneurs by way of equity participation.

vi) They develop industrial area by providing infrastructural facilities.

7. State Small Industries Development Corporations (SSIDCs)

SSIDCs are State Government undertakings responsible for catering to the needs of the small, tiny and cottage industries in the States/Union Territories. They undertake a variety of activities for development of the small sector. At present, there are 18 SSIDCs in operation.

Functions of SSIDCs

i) They extend seed capital assistance on behalf of the State Government.

ii) They procure and distribute scarce raw material.

iii) They provide machinery on hire-purchase basis.

iv) They provide assistance for marketing of the products of small scale units.

v) They provide managerial assistance to production units.

8. District Industries Centres (DICs)

DICs have been established in every district. The objective of establishing such centres is to develop small and village industries. They collect information about the availability of raw material and make arrangements for machinery and equipment, marketing research, credit facilities etc. for the development of small units in the district. They identify the potential borrowers in the small sector and sponsor their loan applications to the banks operating in the district. Under the Prime Minister's Rozgar Yojna Scheme (PMRY), DICs are assigned the task of identification of beneficiaries and implementation of the Scheme in the district.

Check Your Progress Exercise 2

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Write the full forms of the following Institutions:

   i) IDBI

   …………………………………………………………………………...

   ii) SIDBI

   …………………………………………………………………………...

   iii) NABARD

   …………………………………………………………………………...

   iv) SFC

   …………………………………………………………………………...

2. Match the following:

Column I	Column II
1. SFC	A) Apex level national institution in small sector
2. SIDCs	B) Delhi Financial Corporation
3. SSIDCs	C) Identification of borrowers in a district
4. SIDBI	D) Small, tiny and cottage industries
5. DICs	E) Twenty Eight

9.5 EVALUATION OF THE SOURCES OF FINANCE

The sources of finance as discussed above can be broadly divided into owned capital and borrowed capital. Both the sources have their own advantages and disadvantages. Even, for availing of borrowed capital the businessman may have to evaluate among the various available options and choose.

Advantages of Owned Capital

i) *Supply of long term capital:* The businessman obtains funds on long term basis. Owned capital provides long term investment.

ii) *Control:* The businessman maintains full control over his business. He has full rights to take decisions without interference from any outside person. Thus, he commands control over his business.

iii) *No charge on assets:* The businessman is not required to keep his assets as security with any institution so long his own capital is used in the business. Consequently, he can offer the assets of the firm to other agencies for raising loan in case he is in need of additional capital besides his own.

iv) *No repayment of liability:* Owned capital is not required to be returned to any body as in the case of loan which is required to be repaid over a period of time.

v) *No fixed cost:* Owned capital does not carry any fixed rate of return as in the case of a loan where interest is required to be paid on periodical basis.

Disadvantages of Owned Capital

i) *Investment of the personal savings:* In case a businessman has invested his own money in the business, a large chunk of his personal savings goes away. Therefore, not much is left for his rainy days.

ii) *Limited scope of expansion:* With his owned capital invested in the business, a businessman has limited scope of expansion. This is so because he can commit his own resources to a certain extent and beyond that he will have to borrow from outside sources.

iii) *Danger of over-capitalisation:* Use of owned capital may lead, at times, to over-capitalisation. This is so because the businessman is free to invest as much capital as he can. At times, the capital invested is more without being put to productive use. In that case the rate of earning is less in comparison to the capital invested.

Advantages of Borrowed Capital

i) *Availability of funds:* The businessman obtains the funds which are not available through owned capital.

ii) Long term source: Outside funds such as long term loans from banks serve as the source for investing in fixed assets.

iii) Scope for expansion: A businessman can think of expanding his business because with the help of borrowed money further resources are available which can be used in modernization and diversification of the business.

iv) Tax Benefit: Interest paid on borrowed capital is an expenditure which is deducted from the profits liable to income tax. The loans thus provide tax benefit to the businessman.

v) Non-interference in the management: The banks generally do not interfere in the management of the business.

Disadvantages of Borrowed Capital

i) *Financial burden:* The businessman is required to pay the interest on the loan regularly at a fixed rate. This results in the creation of financial burden if the enterprise is running at a loss.

ii) *Charge on assets:* The loans are generally secured by pledging the assets as security. Owing to the pledging the assets do not remain free.

iii) *Borrowing capacity:* Ideal debt-equity ratio is 2:1. Excessive borrowing reduces capacity to borrow and therefore the businessman is unable to borrow after a certain limit.

Factors Affecting the Choice of the Source of Loan

Following are the factors which should be evaluated while making a choice about the source of availing loan:

i) *Rate of interest:* Interest is an expense for the firm to be paid on regular basis whether the business earns profit or not. This reduces the profits of the firm. Therefore, the businessman should enquire as to which financial institution is charging the lowest rate of interest before taking a decision to avail of loan from a particular institution. He should opt for that source only where the interest burden is the lowest.

ii) *Repayment period:* The businessman should evaluate the various sources of loan from the point of view of repayment terms. The banker/institution who provides longer repayment period for the similar loan should be preferred.

iii) *Margin requirement:* Every lender insists upon minimum contribution as margin from the side of businessman. However, margin requirement may differ from bank to bank. Thus, a businessman should negotiate the loan proceedings with the bank which offers lower margin requirements.

iv) *Processing charges:* Every financial institution imposes some charges for processing the loan proposal, known as processing charges. It is also one of the factors which should be considered while evaluating a loan. Lower processing charges should be preferred. At the same time, it should be seen that there is no hidden cost involved in a particular loan proposal.

v) *Time-period involved in sanctioning the loan:* The banker who takes lesser time in sanctioning and disbursing the loan should be preferred. In the case of some banks even branch managers are empowered to sanction loans whereas in the case of others, the sanction comes from the higher authority. It is but natural that the branch manager, if empowered, can sanction loan at the earliest whereas if the sanctioning authority is other than the branch manager, the sanction will take much longer time.

9.6 MATERIAL: ITS PROCUREMENT AND IMPORTANT CONSIDERATIONS

Material is one of the five M's of business. With the help of raw material a product can be developed. After the product is sold in the market generation of revenue starts. It is pertinent to note that raw material is the first element in the cost of the product. A proper control over the material is a must right from its procurement till it is consumed in developing the product. In the following paragraphs important aspects relating to materials are discussed.

Principles of Purchasing

Material is procured through the process of purchasing. Therefore, a proper control over purchasing is necessary. Following points, known as five R's of best buy, are the main principles of purchasing material:

1. Right Source
2. Right Quantity
3. Right Quality
4. Right Price
5. Right Time

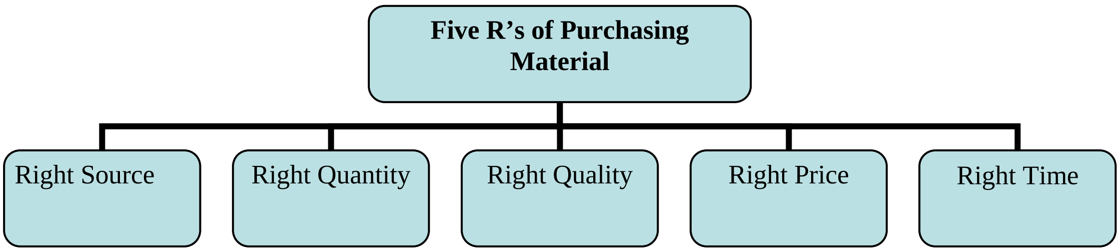

Figure 9.4: Diagrammatic representation of five R's of purchasing material fog

Let's now discuss the five R's in detail.

1. Right source

Right source of procuring raw materials indicates the suppliers/sellers from whom the material can be procured. If the source of procuring material is right we can hope to procure material of right quality in right quantity at right price and at right time. In other words, if there is right source the access to other R's of best buy can easily be made. The following points should be kept in mind while making a choice for the right source:

i) *Location of the supplier:* The businessman should see that the supplier is preferably located near his business site so that heavy spending on transportation is avoided. In fact, geographical location of the supplier has a lot of bearing on the procurement of material.

ii) *Financial position of the supplier:* The businessman should keep in mind that the financial position of the supplier is sound. If the supplier is of sound financial position, he will keep the material always in stock otherwise he may always demand advance payment as and when the order is placed and supply the material after a gap of certain period. In other words, ready supply may be a problem.

iii) *Terms of Supply:* The businessman should procure the material at terms which are beneficial to him. Thus, the ideal supplier will be the one who offers the best terms of supply.

iv) *Production facilities at supplier's end:* In case the supplier is producing the material whether production facilities at his end are capable enough to produce material as and when demanded. The businessman has to keep this aspect also in mind, while making a choice of the right supplier.

2. ***Right quantity***

   Procurement of material in right quantity is another consideration to be kept in mind by the businessman. Right quantity of material to be purchased shall depend upon the (i) raw material required for the production during the year; (ii) time required in getting the supply of the material; and (iii) the quantity of material which the businessman can carry at a particular point of time i.e. average material required. The businessman shall have to decide as to how many orders should be placed in a year so that per order cost is the minimum. Bulk quantity can be purchased at a discount but in that case, the amount of capital invested in bulk purchase shall be more and at the same time the storing cost of the material shall also be more. Thus, a right balance is to be maintained and optimum quantity is to be purchased.

3. ***Right quality***

   Right quality of the material indicates that it will suit the requirements of the product. Quality will relate to the size, shape, appearance, colour, strength etc. of the material. According to the product to be produced, the businessman should decide the right quality of the material.

4. ***Right price***

   Right price of the material indicates that qualitative material is available in right quantity at that price. Right price may not be the lowest one but it should be as near to the lowest side as possible. Right price also means that the supply is available without delay, reasonable services are provided by the supplier and transportation cost in getting the material delivered at the door-steps of the businessman is the minimum. It may happen that though the price of the material is very low but transportation cost of bringing the material to the site is very high. Thus, the overall cost to be incurred is much higher than the cost at which the material is available locally. In this case local price is the right price.

5. ***Right time***

   Material should be available to the businessman at the right time. It means whenever the material reaches the re-order level, the supply should be available before there is stock-out. Further, supply should be available without keeping excessive stock. In other words, right time of purchasing indicates that there is no problem relating to piling up of stock or because of shortage of stock the production is to be stopped for some time.

Purchase Procedure

The job of purchasing material should be done by Purchasing Department under the supervision of Purchase Manager if the size of the concern allows. Purchasing of material involves a series of steps. Let’s now discuss these steps one by one.

1. *Purchase requisition*

   The purchase process begins with the receipt of a purchase requisition by the purchasing department. The requisition contains particulars regarding quantity, quality, date by which the purchase of material is required etc. A specimen of purchase requisition form is given below (Table 9.1):

Table 9.1: Specimen of purchase requisition

ABC Bros.

Address:----------------------

Purchase Requisition

No. **Date-------------**

Please arrange to purchase the following items by ------------2005

Code no. of the article	Quantity to be purchased	Description of the article	Stock in hand	Previous order	
				No. with date	Name of the supplier

Signature--

(Name of the authorised signatory)

Designation

2. *Inviting quotations*

   After receiving the purchase requisition, the purchase department contacts the various suppliers and invites quotations from them. A quotation indicates the price, quantity, quality and other terms and conditions of purchase.

3. *Purchase order*

   The purchase department will scrutinize the quotations received from various suppliers. The person who is willing to supply the material of right quality at the right price should be preferred. A purchase order will then be prepared authorizing the supplier to supply the quality material at the agreed terms and conditions (Table 9.2)

Table 9.2: Specimen of purchase order

ABC Bros.
Address:----------------------

Purchase Order

No. **Date-------------**

Please arrange to supply the following items by ------------2005 as per the agreed terms and conditions stated overleaf:

S. No.	Description of the article	Quantity	Rate per item (in Rs.)	Amount (in Rs.)	Remarks

Signature---
(Name of the authorised signatory)
Designation

4. *Receiving of material*

   The Receiving Department will now receive the goods, unpack them and verify the contents of the packages with the consignment notes sent by the supplier. Discrepancies, if any, are then brought to the notice of the supplier for taking corrective action.

5. *Initiating payment*

   The copies of purchase requisition, purchase order, invoice etc. are sent to the Accounts Department. This Department checks the calculations etc. and thereafter, issues a cheque to the supplier towards payment.

Check Your Progress Exercise 3

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Mr. Gupta, Manager of Receiving Department, on examination finds that out of 100 containers of mustard oil supplied by M/s. Nagpal & Co., five are leaking. Write the appropriate action to be taken by him.

   ……………………………………………………………………………........

   ……………………………………………………………………………........

2. Arrange the following steps of procuring material in proper sequence:

   i) Inviting quotations
   ii) Receiving purchase requisition
   iii) Initiating payment
   iv) Placing purchase order
   v) Receiving of material

9.7 LET US SUM UP

Once the businessman decides as to which line of business he should enter into, the next significant task for him is to organize various resources for his business. Besides other resources, he has to arrange for finance and material. Finance is needed to start a business and to expand, renovate and modernize it. A businessman needs both fixed capital (for purchasing fixed assets) and working capital (for meeting day to day financial requirements of business). Long term finance can be obtained through owned capital and retained profits ploughed back in the business. Further, funds can also be borrowed from friends and relatives and loans can be obtained from Commercial banks, National-level Financial Institutions and various State-level Financial Institutions as well. Short term finance can be obtained through various sources like bank overdraft, cash credit, discounting of bills of exchange, short term loans, trade credit from suppliers, assistance from Co-operative Credit Societies etc. There are certain specialized financial institutions like IDBI, SIDBI, NABARD, various SFCs, SIDCs, DICs which are involved in providing loans to the industries at attractive terms and conditions. A businessman should thoroughly evaluate the various sources of finance before committing funds in the business. Material is needed to develop a product. A businessman has to apply the five R's of the best buy. For procuring material, the businessman should develop and follow the right kind of purchase procedure.

9.8 KEY WORDS

Collateral security : Secondary security demanded for sanctioning loan, in addition to the primary security.

Preliminary expenses : Expenses incurred by a company before its formation.

Commitment charges : Charges levied by the bank for not using the sanctioned limit.

Debt-equity ratio : A ratio which establishes relationship between debt and equity. Normally, loan equivalent to double the equity can be raised.

Deferred payment guarantee : A kind of guarantee given by a financial institution to the supplier of fixed assets like machinery that the payment of instalments shall be made on due dates.

Check Your Progress Exercise 3

1. **Hint:** i) Immediately after examination, informing the supplier (i.e. M/s. Nagpal & Co.) about the leakage of five containers.

   ii) Not to pass the bill for payment till the satisfactory action is taken by the supplier.

2. i) Receiving purchase requisition
   ii) Inviting quotations
   iii) Placing purchase Order
   iv) Receiving of material
   v) Initiating payment

9.10 SOME USEFUL BOOKS

1. Desai, Vasant (1998) Dynamics of Entrepreneurial Development of Management; Himalaya Publishing House, Mumbai.

2. Gupta, C.B. and Khanka, S.S. (2004) Entrepreneurship and Small Business Management; Sultan Chand and Sons, New Delhi; Fourth Ed. Reprint.

3. Maheshwari & Mittal (2002) Cost Accounting, Theory and Problems; Shri Mahavir Book Depot, New Delhi, Twentieth Ed.

4. Mitra, Bidani and Kumar, Promod (1998) Bank Finance for Industry; Vision Books, New Delhi.

5. Nabhi Publication (2004) How to Borrow from a Banking and Financial Institution; Nabhi Publications, New Delhi.

9.11 ASSIGNMENTS

1. Kotak Enterprises wants Rs. Ten lakhs to invest in stock. Under which type of capital his loan application shall be considered by the bank.

2. Explain the various short term sources of finance.

3. Explain the various long term sources of finance.

4. "Working capital is needed because of the existence of operating cycle." Comment.

5. Mention the various functions of State Financial Corporations.

6. How do the commercial banks contribute towards the development of an economy.

7. Should the indigenous bankers be eliminated altogether? If yes, then why are they still existing in our society.

8. Write correctly the following Government sponsored schemes:

   i) Swarna Jayanti Gram Swapan Yojana
   ii) Prime Minister's Rojana Yojana
   iii) Swarna Jayanti Shatabdi Rojgar Yojana

9. M/s. Kohinoor Bros. are interested in purchasing 500 Kgs. of sugar. Explain the purchase procedure which shall be followed by them.

10. Purchase requisition is a first step of purchasing raw material. Mention the remaining steps of procuring the material.

11. Complete the following Specimen of Purchase Requisition Form of Vikalp & Co.

Vikalp & Co.
Address:-----------------------

Purchase Requisition

UNIT 10 UNDERSTANDING THE COMPONENTS FOR MARKETING MIX

Structure

10.0 OBJECTIVES

After studying this unit, you should be able to:

- know about the meaning of marketing mix;
- understand the importance of marketing mix;
- identify various elements of product mix;
- comprehend the pricing of the product;
- understand the various aspects of promotion; and
- know the physical distribution of goods.

10.1 INTRODUCTION

Human needs are unlimited. Human beings need different types of commodities to satisfy their needs. A businessman therefore, engages himself in manufacturing different types of products and services. Marketing can be said to be a process involved in the exchange of goods and services for payment of their cost.

Marketing refers to all those activities which help in directing the flow of goods from the manufacturer to the ultimate user. In other words, the process of marketing leads to the exchange of goods and services through which the needs of the consumers are met.

A businessman has to undergo various activities and to decide upon various issues in order to reach his target. For this purpose, the firm must develop the product, determine its price, inform the potential customers about the product, and make it available to the present and potential customers. All these activities signify that the businessman has to put together all the tools at his disposal in combination so that his objective of selling the goods and services with profitable margins is realised. In the light of this view, a businessman can be thought of as an assembler or mixer of ingredients. The success of the businessman depends on how well these ingredients are assembled.

Marketing mix is nothing but the ingredients or the tools or the variables that the businessman mixes in order to interact with a particular market. Marketing mix has been discussed briefly in Block 2 (Unit 3) – "What does Market Involve", keeping in view the requirements of that Unit. In this Unit, marketing mix has been taken up in detail.

10.2 MEANING OF MARKETING MIX

Meaning and Importance

Marketing mix is a term which is usually used to refer to a particular combination of marketing variables which are controllable by an enterprise. Marketing mix can be regarded as the core of any business firms marketing system. According to Philip Kotler "Marketing mix is the set of controllable variables that the firm can use to influence the buyers' response". In simple words, marketing mix can be said to be the set of marketing tools that the firm uses to pursue its marketing objective in the target market.

Marketing mix comprises decisions taken in the following four important areas:

1. Product
2. Price
3. Promotion
4. Physical distribution i.e. Place

The businessman has to prepare various strategies relating to the aforesaid elements i.e. in the fields of Product, Pricing, Promotion and Physical distribution. The last element i.e. physical distribution is also referred to as 'place'. These four elements are popularly called four P's of marketing mix.

Following diagram depicts the four elements of marketing mix.

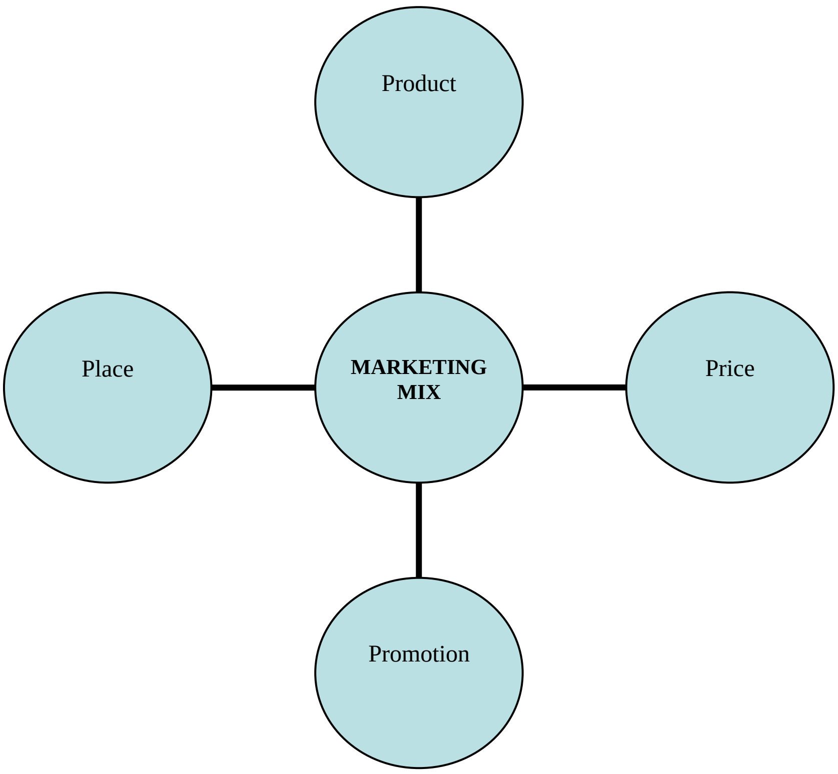

Figure 10.1: Diagram depicting four elements of marketing mix

Importance of Marketing Mix

A judicious mix of the four P's is very important for satisfactory marketing of goods. It will lead to consumer satisfaction, on the one hand and profit maximization, on the other. Marketing mix is thus, the main building block of marketing efforts of a firm. The importance of marketing mix is explained as under:

1. It leads to increase in sales and profits of the business firm.
2. It represents an integrated approach to marketing because a balance is maintained among its inter-related elements.
3. It serves as a linking-pin between the firm and its customers.
4. It helps in maintaining equilibrium between the business firm and its marketing environment.

10.3 MARKETING MIX – PRODUCT

Product mix is one of the important elements of marketing mix. The product element of marketing mix refers to a combination of various features relating to a product which is offered for sale. It signifies the product offered to the customer. It involves decisions concerning:

- Nature of the product
- Features of the product
- Branding
- Packaging
- Labelling
- Guarantees & warranties
- After-sale services

The above are also called sub-elements of product mix. Let's discuss these sub-elements of product mix one by one.

I) The nature of product

The details of nature and character of the product which are contained in the mix are related to:

a) *Product line:* It refers to a group of products within a product class e.g. in the case of Amul Co-operative Society, butter constitutes one product line, cream constitutes another, milk a third one; and so on.

b) *Product width:* The width of the product mix denotes the number of product lines that the businessman offers to the market. For example, Amul has wider product mix whereas MDH (Mahashya Di Hatti) has narrower product mix.

c) *Product length:* It refers to the number of product items that are carried in a product line. The length of product line denotes the number of items in the line e.g. Amul carries a number of product items in butter line – it offers 'white butter' and 'salted butter'. Similarly Amul cheese may be 'cheese spread' or 'sliced cheese'.

d) *Product Depth:* It refers to the total number of variants that are offered of each product item in the product line. In the case of Hindustan Lever Limited the soap Lux may be Pink, white or Lux international.

II) Features of a product

The decisions regarding features of a product are mentioned below:

- *Size:* The size of the product should be easy to handle. It should be convenient to carry and to use. For example, pack of Cadbury chocolate comes in manageable size.

- *Colour:* The colour of the product should be appealing. For example, the yellow colour of Brown & Polson custard.

- *Flavour:* The product should have a wide variety of appealing flavours like Priya Gold Biscuits are found in many flavours – pine-apple, elaichi, orange etc.

- *Weight:* A product should not be too bulky or too heavy. For example Saffola oil comes in one litre pack, Amul butter comes in 100 Gms. packs.

- *Durable:* A product should have a longer shelf life. For example Kissan tomato puree has a shelf life of 12 months.

- *Shape:* Solid products can be round (like Milk Bikis cream biscuits manufactured by Britannia); square (like Krack jack biscuits of Parle); rectangle (like Cadbury's Five Star chocolate) etc. In the case of liquid eatables they take the shape of their containers. For example Pepsi, Coke, Kissan sauce, Kanodia Mustard oil etc.

III) Branding

Branding is a way for an organisation to identify its products and distinguish them from those of the competitors. Branding is naming the product or giving a symbol or mark to identify the product. In other words, a brand is a name, term, sign, symbol, or design or a combination of them, which is intended to identify the goods or services of the seller. A brand distinguishes a product from similar other offerings. A successful brand is a major asset for a company. Following terms are associated with branding:

- *Brand name:* It is that part of a brand which can be vocalized or uttered e.g. Tata tea, Sunfeast cream biscuits, Harvest bread, Frooti, Rasna, Real juice, Haldiram's Navratan etc.

- *Brand mark:* It is that part of a brand that can be recognised. It is not utterable since it is in the form of symbol; design etc. e.g. Nestlé's 'Nest' or Mother Dairy's 'Drop'.

- *Trade mark:* When brand is given legal protection, it is called 'trade mark'. A trade-mark is a legal term protecting the seller's exclusive rights to use the brand name or brand mark. R in circle (i.e.*®)* is used to show that the trademark is registered. A registered trade mark of a product cannot be used by another company. A trade mark is a registered brand name. It may not be pronounceable.

Classification of brands

Brands can be classified as under:

i) *Family brand:*

Family brand is one where a business man uses only one brand name for all his products. Amul, Everest etc. are examples that follow a family brand policy.

When one name is established as a particular brand, other products get easy and instant recognition. This method is simple and economical.

ii) *Individual brands:*

This refers to a brand name given for each individual product. The firm is able to create a distinct image for each of its products. It is a costly method.

iii) *Company name*

In this case Company's name is attached with each product name. Thus, the advantage of family brand and individual branding are combined. For example, Britannia is manufacturing different types of biscuits and in each type, brand name is preceded by the company's name i.e. Britannia like Britannia Cream Treat biscuits, Britannia 50-50 biscuits.

iv) *Separate family brand name*

The firm may follow different brand names or each class of their product i.e. the products are classified in different families and brand names are given to each family.

Selecting a brand name

To develop a brand name is one of the most difficult elements in development of a new product. A good product with a mediocre name may not sell well. Following aspects should be taken into account, while selecting a brand name:

I) It should reflect some benefit and function of the product e.g. Hajmola brand name suggests digestion.

II) It should be distinctive. It should portray status, power etc e.g. Diamond Masale; Jagat Basmati Rice etc.

III) It should be easy to pronounce, spell and remember. One syllable name should be preferred e.g. Tata Tea, Amul butter etc.

IV) It should be capable of being registered and protected legally. It should not be closely linked to an existing brand.

V) It should be short e.g. Lijjat papad.

Advantages of branding

I. Towards producers

a) It creates a new market due to its distinct identity.

b) It becomes easier to advertise the product.

c) New products can be added due to high sales and profits.

d) The price of branded product can be easily increased, once the brand becomes popular.

e) Less commission is offered to the intermediaries.

II. Towards customers

a) It is easy for the customers to recognise the product.

b) A feeling of satisfaction is created due to repeated use of the branded product.

c) The consumers always get a branded product of good quality.

d) Branded products are easily available at the retail outlet.

e) Branded products are made available at a particular price.

IV) Packaging

Packaging refers to all the activities involved in designing and producing the containers or wrappers for a product. For example, rice is packaged in jute bags or plastic bags, ghee is packaged in plastic containers.

A package may be primary package or secondary package. A primary package refers to the products' immediate container. For example, small plastic pouch in which masale are packed. A secondary package is the additional layer of protection. It is generally removed and thrown once the product is ready for use. For example, card-board box of masale on which name of the product and the company is mentioned.

Kinds of packaging

i) Family packaging

A firm may adopt family packaging for all its products. Family packaging gives a common feature of appearance on all packages i.e. packaging will be similar for all the products.

ii) Re-usable packaging

A re-usable packaging can be used again for any other purpose. For example, usually house-wives store spices or pickles in 'Horlicks' or 'Boost' bottles; drinking water in 'Rooh-Afza' bottles etc..

iii) Multiple packaging

Several units of the same product are placed in one container. It is suitable for sale of small items. For example, several biscuits are placed in a single wrapper; several pieces of 'Britannia cakes' are placed in one package etc.

Material used in packaging

Different kinds of products are packaged in different types of material. Some of the examples are given below:

- Fruits are packaged in wooden boxes or card-board boxes or straw baskets.
- Processed food or oil is packaged in metal containers.
- Rice, Ghee, Chocolates etc. are usually packaged in plastic pouches or plastic boxes or plastic wrappers.
- Paper with wax coating is used to package toffees.
- Glass is used to package cold drinks, pickles, sauces, vinegars etc.
- Aluminium foil is used to package tea, coffee, toffees etc.
- Wheat is packaged in jute sacks.
- Tetra pack is used for packaging fruit juices, fruit drinks etc.

Forms of package

A package can take many shapes. Following are the examples:

- Fruit jelly is packaged in a tube form.
- Cold drinks are generally packaged in a bottle form of packaging.
- Tea, spices etc. are generally packaged in small unit packages like 250 gms package, 100 gms package etc.
- Candy, soups, pan masala etc. are usually packaged in sachets.
- Jars are used to package Desi Ghee, edible oil etc.
- Refill packs are used to package coffee, chocolate powder, tea etc.
- Cans are used to package fruit juices, cold drinks etc.
- Bags are used to package flour (atta), rice etc.

Benefits of packaging

- It is an effective advertising medium.
- It provides space in which the product can be contained.
- It helps in keeping the product safe from pests, rodents, moisture, rain etc.
- It helps in storage.
- It helps in product differentiation.
- It helps in increasing sales.
- It increases the shelf life.
- It ensures visibility of the product if the material is transparent.
- It ensures easy handling of the product.
- It makes the product attractive.
- It makes brand of a product popular.

- It protects the goods from pilferage and adulteration.
- It can be re-used.

V) *Labelling*

The term labelling means putting labels on the package or the product. A label is a small slip to provide information to the customers e.g. the name of the product, price etc. A label may be a piece of paper, printed statement, imprinted metal or leather which is attached either to the package or to the product. The label describes the nature of the product, contents of the package and other information like price, date of expiry, batch number, weight etc.

A label is a strong sales tool and an integral part of the point of purchase advertising. Labels are designed to help promoting a product.

Functions of labelling

Labelling serves the following functions:

- Identification of a product is easy for the customer.
- The manufacturer is able to grade the products into different categories, e.g. Hindustan Lever Limited (HLL) sells different types of tea under yellow, red and green label.
- It is a carrier of information.
- It provides information, which is mandatory by law.
- It attracts the buyers and draws them to buy the product.
- It helps in comparing the product.
- It leads to easy trading for retailers.

Features of a good label

- It should supply sufficient information.
- It should be easy to locate and read.
- It should be simple to understand.
- It should be colourful and attractive.
- It should help to make a buying decision.
- It should contain statutory information, if any.

VI) *Guarantees and warranties*

Guarantee is a policy adopted by the manufacturer with regard to his products in case any is found defective. It is an obligation assumed by the seller in which he promises the buyer that he will get certain services in future, including replacement, repairs etc.

Warranty is an assurance of quality, service and performance given by the producer to the consumer. It points out the responsibility of the businessman for repairs, service and maintenance in the case of consumer durables.

VII)After sales service

After-sales service, as we all know, is required after the product has been sold. It is an important aspect of a marketing transaction. After-sales service covers repairs, changing parts at lower charges etc. These services are provided so that the customer is satisfied.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Under which category of branding do the products of 'KISSAN Brand' fall:

   i) Family branding
   ii) Individual branding

2. To which type of packaging 'Tata salt' belongs:

   i) Primary packaging
   ii) Secondary packaging

3. Write the name of the material in which 'Kanodia Brand' 'one kg mustard oil' is packaged:

   i) Plastic; or
   ii) Tin

4. The package of 'red chillies' is an example of multiple package or re-usable package.

5. The label of 'Rex Baking powder' carries information regarding directions for use, net weight, etc.

   i) Yes
   ii) No

10.4 MARKETING MIX – PRICE

The Price element of marketing mix refers to the price to be charged by the businessman. It is the source of revenue for the businessman and cost for the customer. Pricing is one of the most important decision-areas of marketing. This is the only area from where revenue is earned by a businessman. Pricing is crucial to profit as well. Price is the exchange value of a product. A low or a high price may mean success or failure for a businessman. Pricing is the process of translating the value of a product or service in terms of money. Prices not only determine what a businessman will get in return for the goods he has produced but it also has an impact on future production and marketing.

Importance of Pricing

- Price acts as a regulatory mechanism by means of which the buyer and the seller come to a mutually satisfactory understanding.
- Price determines the sales volume.
- Price determines the profit margin.
- Price affects the competitive position.
- Price affects the market share.
- Price determines the purchasing power and standard of living for a customer.

The various decisions taken by a businessman under price mix are as under:

I. Pricing policy

II. Pricing Strategies

III. Discounts and Allowances

Let's now discuss these decisions in detail.

I. Pricing policy

A product has to be priced scientifically. Intuition has no place in this process. Pricing decisions have to be taken taking into account several factors. These factors are discussed as under:

Factors influencing pricing policy

- *Consistency:* Pricing has to be consistent with overall objectives of the firm, e.g. the firm's objective may be profit maximization or to achieve a high turnover. Accordingly, it may be a higher price or lower price.
- *Public image:* If the public image of the product is high the price may be kept high.
- *Purchasing power of the consumers*: If the purchasing power of the consumers is low, the price should be kept low.
- *Ability to postpone purchase:* If the consumer can think of postponing the purchase of a particular product, the price of such product should be kept low.
- *Pricing policy of the competitors*: The businessman should fix the price keeping in view the pricing policy of the competitors.
- *Availability of substitutes:* The price may be kept higher in case there is no substitute for the product available in the market.
- *Cost of production:* The price fixed should be such as would recover all the costs including a fair return to the businessman.
- *Demand and Supply:* If the demand of the product is higher than its supply the price may be fixed at a higher level. In case supply exceeds the demand, the price should be fixed al low level.

- *Current fashion and tastes:* If the product matches the current fashion and tastes, a high price may be fixed.

- *Price control measures:* The prices of certain products are controlled by the government. The businessman should fix the price keeping in mind the prevailing policies of the government.

II. Pricing strategies

Pricing strategies provide a framework within which pricing decisions can be taken systematically to achieve the pricing objective. Following are the different pricing strategies which may be adopted by the firm:

i) Skimming pricing

This is usually adopted to price a new product. A very high price is set in the beginning. The cream of demand may be skimmed and huge profits can be made. In other words, the product is offered to some buyers who are ready to pay much higher price than the others. This may be because the product has high present value to them or they are insensitive to price. Later on price may be reduced to tap other segments of the market.

ii) Penetrating pricing

In this case a low price is fixed to go deep into the market immediately. Due to low price the brand becomes popular and thereby market share can be maximized. It is an aggressive pricing strategy.

iii) Price-discrimination pricing

In this case product is sold at two or more prices. Different customers pay different amount for the same product. Price can be different on the basis of different locations as well.

iv) Going-rate pricing

Under this method, the firm sets its prices on the basis of what its competitors are charging. This system is preferred to keep harmony within the industry.

v) Target pricing

In this method, the businessman tries to determine the price that would give it a specified target rate of return on its total cost at an estimated standard volume.

vi) Cost-plus pricing

Here price is set on the basis of adding some fixed percentage to the unit cost. A cost estimate is done and a margin is added thereto for covering the marketing expenses and profits.

vii) Loss-leader pricing

Here the business firm sells some popular product at a very low price. The aim is to attract the customers to enter the shop. The customers who come to buy that item will stay on and buy other products which are regularly priced. The products which are sold at low price are known as loss-leaders and therefore, the pricing strategy involving the use of loss-leaders is called the 'Loss-leader Pricing'.

viii)Prestige pricing

Under the system of prestige pricing, the price of the product is usually kept high on the basis that a high priced product will be sold better as the customer will think that quality of the product is reflected in the price.

ix) Odd pricing

Under this system of pricing, an odd amount is set for the product e.g. Rs. 599.95 in place of Rs. 600. This pricing gives a psychological feeling that the price is at a lower rung and the buyer is motivated to buy.

x) Marginal pricing

Here price is set to cover the marginal cost only and not the total cost. This method cannot be followed for a long period of time as it ignores the fixed cost.

III. Discounts and allowances

Discounts and allowances are granted by the businessman either to the customer or to the wholesalers and retailers. Discounts and allowances are offered with a view that the other person will provide some benefit by performing some marketing activities the value of which will be equal to the amount of the discount or allowance.

Types of discount

- *Trade discount:* It is allowed by the businessman to the wholesalers and retailers on purchase of goods in large quantity. The amount is deducted from the list price itself.

- *Quantity discount:* It is allowed by the businessman to a customer to encourage him to buy in large amount. It is offered because of a large single purchase.

- *Cash discount:* It is offered by the businessman to the wholesalers and retailers in order to get early payment. For example, when the wholesaler is required to make payment within 10 days of sale, he may be offered that if he makes payment early, say within 5 days, he will be given a cash discount of 5%.

- *Seasonal discount:* This discount is allowed by the businessman who is dealing in seasonal product. For example fans, coolers may be sold during winter season at a discounted price. Thus, he may offer discount if an order is placed during the slack season.

Check Your Progress Exercise 2

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Name the following:

   i) A strategy where a high price is set in the beginning.

   ………………………………………………………………………...

   ii) An aggressive pricing strategy.

   ………………………………………………………………………...

   iii) A strategy where two or more prices are set.

   ………………………………………………………………………...

   iv) A strategy where price ends in odd amounts.

   ………………………………………………………………………...

   v) A strategy where purpose is not to get customers to buy the bargain itself but rather to buy other items as well.

   ………………………………………………………………………...

2. State true or false in Column (3):

Sl. No. (1)	Statement (2)	True/False (3)
1.	Price influences plans for future production and future marketing.	
2.	Pricing is the art of translating into quantitative terms the value of the product to the customers at a point of time.	
3.	Price affects the competitive position.	
4.	Price is used to increase sales volume to the level that matches the organisation expenses.	
5.	Pricing decisions are influenced only by public image.	

10.5 MARKETING MIX – PROMOTION

Promotion is yet another element of marketing mix. The promotion element of marketing mix refers to the activities related to the promotion of the product. The businessman has to take into account this element as well before deciding on any marketing activity. Promotion is a marketing effort done by the businessman to inform about the merits of a product or service and to persuade actual or potential customer to buy.

Promotional strategy concentrates upon letting the product reach the target market through the marketing channels. In this process the businessman needs to communicate to target market and the wholesalers and the retailers so that sales take place as scheduled and his marketing objectives are achieved. Promotion is a communication tool in the hands of a manufacturer.

Promotion mix is the combination of different forms of promotion used by a businessman. The promotion efforts are directed at informing potential customers about the availability of right product and at the right place and at the right price. The core of promotion is communication. The businessman generally chooses a combination of promotional tools to achieve desired communication effect. The various decisions taken under promotion mix are as follows:

I. Advertising
II. Sales promotion
III. Personal selling
IV. Publicity

Let's now discuss the various decisions one by one.

I. Advertising

Advertising is a paid form of non-personal presentation and promotion of ideas, goods and services by an identified sponsor. In other words the communication is directed towards a target audience by the sponsor.

Advertising is spreading the information about an idea, product or service to the people. It is said to be non-personal due to absence of face-to-face contact with the customer. Advertising has mass appeal. It can influence large section of the society. It enables the buyer to know the new product available in the market.

Features of advertising

- It is non-personal in nature.
- It persuades the buyers to purchase the goods.
- It is a paid form of communication.
- It can reach a large section of the people.
- It provides information on the products and services to the customers.

Objectives of advertising

- To inform the customers about the product.
- To build an image of the product in the market.
- To increase sales.
- To support sales promotion measures.
- To build brand loyalty.
- To fight competition in the market.

Benefits of advertising

For consumers:

- It provides information regarding price, availability, quality etc.
- Comparison with other products becomes easier.
- It acts as a guarantee regarding quality.

For manufacturers:

- It increases the sale of the product.
- It helps in easy introduction of new product.
- It establishes contact between manufacturers and consumers.
- It helps build the image of a product.
- It enables them to face competition.

Types of advertising

1. *Product advertising:* The emphasis of product advertising is to inform the customers about the product manufactured by the firm. The purpose is to create a favourable attitude of the product in the minds of the customers. Hence, a desire is created to buy that particular product.

2. *Institutional advertising:* The emphasis of institutional advertising is to build the goodwill of the firm. The aim is to build a positive attitude towards the businessman.

3. *Primary advertising:* It is one of the forms of product advertising. This type of advertising is done to build a demand for a new product.

Media used in advertising

Let's evaluate the important media of advertising.

1. *Newspaper*

   It is a form of print medium. It is a medium through which general public can be reached. The advertisements are inserted in the morning or evening editions or in Sunday edition of the newspaper. The newspaper may be circulating at a local level or state or national level. It can be an English language newspaper like Hindustan Times or Times of India or Asian News or The Hindu or a Hindi newspaper like Navbharat or Hindustan or Dainik Jagran or any other regional language.

   Advantages:

   - Newspapers have a wide circulation as national dailies cover a large geographical area.
   - They offer more flexibility as shape, size, colour and appearance of the advertisement can vary.
   - It is economical as it is cheap in comparison to other media.
   - The response of the consumers is quick.
   - Lengthy message can be transmitted through this medium.

Disadvantages:

- Life of newspaper is short.
- It may not be as attractive, for the paper used is not of good quality and printing may also not be very fine.
- Such advertisements are usually read in a hurry.
- Space allotted to the advertisement in the newspaper may be small.

2. *Periodicals*

Magazines/business journals are purchased for entertainment and information. They are published at periodical intervals like weekly, fortnightly or monthly. The advertisements can be placed in magazines like Woman's era, Femina, Outlook, India Today, Grih Shobha etc.

Advantages:

- It has a strong visual impact as it is colourful and appears on a fine quality paper.
- Such advertisements are read at convenience, in a relaxed mood as the magazine is generally read when the reader has sufficient time in hand.
- Such advertisements have long life as the magazines containing them are generally preserved and read repeatedly.

Disadvantages:

- It is costly to get an advertisement printed in a magazine.
- The advertisement may not appear at the desired time since the magazine is published periodically.
- The magazine has limited coverage.
- Lack of flexibility because changes in the contents of the advertisement may not be possible once the magazine goes for printing.

3. *Television*

As of now, TV is the widest and fastest growing medium. It creates a permanent impression in the mind of the viewers especially children.

Advantages:

- It has audio as well as visual impact.
- It is appealing.
- The advertised product can be demonstrated.
- It has wide coverage.

Disadvantages:

- It is very costly.
- Since the advertisement appears at a time which is not certain a person not watching TV at that time will miss it.

- Lack of flexibility as desired changes may not be incorporated.
- Small-sized companies cannot afford an advertisement on TV.

4. *Radio*

Radio advertising is very popular for the last so many decades. Radio is listened to by rich and poor, old and young, male and female alike.

Advantages:

- The message can reach the remotest place.
- It has wide coverage since all walks of people listen.
- It is a cheap medium of advertisement.

Disadvantages:

- Radio is only audio and has no visual impact.
- There are noise disturbances.
- It has got short message life.

5. *Outdoor advertising*

Outdoor advertising has gained popularity as an important medium in recent times. Its form can be banners, hoardings, billboards, posters, electric poles etc.

Advantages:

- It is attractive and colourful.
- Electric display of the advertisement on roadsides can be very effective.
- It builds awareness quickly.
- It has long life as there is repeated exposure.
- It catches the attention very quickly.
- Low cost.

Disadvantages:

- Limited creativity because such advertisement may contain very limited description of the product.
- The coverage is narrow as it has limited audience.
- It has a short attention span.

6. *Internet*

It is the latest form of advertising medium.

Advantages:

- It is effective.
- It is not costly.
- It is flexible as data can be changed without much difficulty.
- It can be attractive and colourful.
- It may contain lot of information about the product.

Disadvantages:

- Limited reach because advertisement can reach only highly selected audience.
- Problem of connectivity as the server may be down.
- Irregular electric supply may pose a barrier in reaching the advertisement.

7. *Film advertisements*

These types of advertisements are shown in the cinema halls before the main feature film is started or during the interval. In this case, short films or cinema slides are prepared and distributed to the cinema houses for display. The advertisement film contains pictures regarding the product and its uses along with a running commentary.

Advantages:

- It is colourful.
- The advertisement has got life-size pictures.
- It gets attention of the viewers sitting in the cinema hall.

Disadvantages:

- It has limited coverage because a handful of viewers can see the advertisements.
- The advertisement may be missed by those persons who enter the cinema halls a bit late or after the start of the feature film.
- It has short life.
- The preparation and display of advertisement is costly.

8. *Exhibitions and trade fairs*

Businessmen get a nice chance to reach the target market through various exhibitions and trade fairs organised in the cities. Good friendly relations can be built between the businessmen and the customers. Further, the customers get an opportunity to study the product, technical advantages, quality etc. The product can be demonstrated as well. This method is suitable for big manufacturers.

9. *Window display*

The goods are displayed beautifully in the windows at the entrance of the shop. The displays are made more attractive through the use of powerful coloured lights, glitters, show-cards, cut-out displays etc. Window display increases sales. The shopkeeper's time and energy in canvassing about the product are saved.

10. *Showrooms*

Showrooms are separate shops or rooms where the product line of the manufacturer is on display. The customer gets full idea of the product, price etc. A lot of literature in the form of pamphlets, booklets is also freely available. These are maintained in attractive style and goods are displayed in popular style. Showrooms are maintained only by big manufacturers, retailers or wholesalers. Immediate sale can also take place.

Factors affecting the choice of media

Following are the various factors on which choice of the medium will depend:

1. *Coverage*

   Large size of audience can be reached if media like TV, newspaper, magazine, radio are chosen. For selective coverage, film advertising or internet can be selected.

2. *Flexibility*

   A businessman may want to change or modify his advertisement. The medium like TV, magazines may pose problems in changing the advertisement. Radio, newspapers, posters, hoardings are comparatively more flexible.

3. *Cost Factor*

   Cost is an important deciding factor for the medium to be chosen. The benefits of the media should also be evaluated in terms of cost. TV, film advertisements, magazines are costly compared to newspapers or posters.

4. *Life of the advertisement*

   All the media do not have the same life. Media like TV, newspaper, radio have a very short life. People forget the advertisements after looking at it. Magazines, business journals etc. have a long life as they can be preserved by the readers. Usually, people refer to these magazines, business journals etc. even after some gap of time.

5. *Class of people*

   Illiterate people can be targeted through the medium of TV, film advertising, radio where reading is not involved. For literate people, internet, newspapers, magazines etc. are a good option.

6. *Nature of product*

   Consumer goods can be promoted through media like newspaper, magazine, radio, TV etc. whereas industrial goods can be best advertised through business journals, trade fairs, exhibitions etc.

Objections to advertising

- It forces the people to buy goods.
- It leads to extravagance as the people particularly children are induced to buy products which they may not be requiring.
- It increases the cost of the goods.
- It may misrepresent facts.
- It may confuse people.

The above points, however, are not fully valid. The consumers, now-a-days, are very vigilant and alert. They have their own mind to think. Therefore, it is rather difficult to mislead them.

II. *Sales promotion*

Sales promotion is an important communication tool in the hands of the businessman. It refers to short term incentives offered to the consumers. Sales promotion techniques draw a quick response from the target customers. It induces the customers to take the purchase decision. Sales promotion efforts are best suited for new products. In spite of all these benefits, sales promotion lacks permanence because the customer usually goes back to the earlier brand of the product which he was using earlier, after the withdrawal of the sales promotion scheme.

Objectives of sales promotion

- To increase the sales volumes.
- To make the customers try a new product.
- To increase the frequency of use.
- To gain shelf space and display at the point of sale.
- To block competition.

Techniques of sales promotion

At the level of consumers:

- *Samples:* A business firm may distribute samples of the product free of cost to a few customers. It is an expensive method. It is useful to introduce new product in the market e.g. a firm may distribute free samples of tea in a small sachet in a particular colony.

- *Coupons:* A business firm may distribute coupons to the prospective customers. The customers can save money on presenting the coupons to the designated retailers to purchase a specified product within a specified time. The time may be as short as a day or may be as long as six months. The coupons can be distributed through mail, newspapers, magazines or retailers.

- *Premium:* Premium is an offer of a product free of cost on the purchase of another specified product. It is like giving a free gift on purchase of a product e.g. a spoon is gifted along with a glucose pack of 500 gms or a cup is offered along with a beverage.

- *Price-off:* It is an offer to the consumers which promises a certain amount of money off the regular price of a product. In other words, the businessman sells the product below the normal price. There may be 10% to 20% off on the price of a specified product.

- *Contests:* Various contests are organised where a customer is required to write a slogan or complete a sentence with catchy words. For example, the sentence may start with "I like this product because-------------------------" and the prospective customer will be asked to fill in the blanks with suitable words. Attractive prices are offered to the persons chosen by the business firms.

- *Quantity deal:* Quantity deal is a new trend where a unit of product is given free of cost if more number of units are purchased e.g. one Horlicks bottle may be given free on purchase of five Horlicks bottles at a time.

- *Demonstration:* Special shows may be organised where products are demonstrated. Demonstration of a product may be outside the shop as well.

Means of sales promotion

i) *Advertising material:*

Dealers are offered advertising material like attractive pamphlets, banners etc. Due to these attractive and colourful banners on the one hand consumers become aware of the product and on the other hand the shop looks decorated and beautiful.

ii) *Contests:*

Various contests are organised by the manufacturers so that the dealers are prompted to take more interest in the selling of the product. Attractive prizes are offered which include free trip to a foreign country.

iii) *Demonstration:*

The products are demonstrated to the dealers so that they understand the working of the product. This method of sales promotion goes well with electric gadgets and mechanical products.

iv) *Buying allowance:*

The dealer gets discount on the quantity purchased. This sales promotion technique induces the dealer to purchase in bulk.

Sales promotion at the level of salesmen

The aim is to attract the salesmen as they have a direct contact with the customers.

i) *Bonus*

Salesmen may be awarded bonus in case they achieve more than a particular target given to them.

ii) *Contests*

Contests may be organised to boost the performance of the salesmen.

III. Personal selling

The other name for personal selling is salesmanship. Personal selling or salesmanship is an art to persuade people to buy. It is a face to face oral communication with the potential customers to convince them to buy the product. Here, the seller personally or through his representatives (i.e. salesmen) tries to stimulate the needs and wants of the buyer. This way he makes efforts to satisfy the needs by making a sale. In this process the needs of the buyer are met and the seller (i.e. the businessman) earns a profit. Hence, both the parties benefit.

Salesmanship is not aggressive selling. It is, in-fact, winning over. The ultimate objective of salesmanship is creation and stimulation of demand.

Benefits of personal selling

To the consumers:

- The consumers get information about the existing and the new product.
- The product is demonstrated to the consumers.
- The salesman helps the consumers in making a choice.
- The consumers are guided in purchasing and using the product which will give them maximum satisfaction.

To the businessman:

- The salesman identifies the prospective customer for the businessman.
- He helps in creating demand for the new product.
- He helps the businessman in designing a product on the basis of customers responses and the taste, attitude and preferences of the customer.
- He helps in increasing the sales and profits of the businessman.
- He enables the businessman to design or alter the sales policies.

Qualities of a good salesman

A salesman performs a number of different activities in the process of selling a product. The efficient and effective performance of sales activities requires certain qualities in the salesman. Let's discuss these qualities one by one.

I) Physical qualities

- He should possess good and sound health.
- He should possess a pleasing personality.
- He should have an impressive voice.
- He should have energy to work.
- He should have a good posture and clean dress.

II) Mental qualities

- He should be intelligent.
- He should have sharp memory and foresight.
- He should have keen observation.
- He should be imaginative and flexible.
- He should be self-confident and patient.

III) Moral qualities

- He should be honest in his dealings.
- He should be kind and empathetic.
- He should be cheerful and reliable.
- He should be loyal to both the employer and the customers.
- He should be dependable.

IV) Vocational qualities

- He should have sufficient Knowledge about the history of the company, its policies and its goals.
- He should have sufficient Knowledge about the history of the product.
- He should have sufficient Knowledge about the rival products.
- He should have sufficient Knowledge about the consumer, his background and social standing.
- He should have sufficient Knowledge about how to make effective sales promotion.

V) Social qualities

- He should have good manners.
- He should be courteous.
- He should have team spirit.
- He should be co-operative.
- He should be friendly.

Steps involved in the process of personal salesmanship

I) Pre-sale preparation

The salesman should make his foundation strong by obtaining information about the product, company, rival products, sales strategies, social background, income and age bracket of the prospective customers.

II) Locating the potential customer

He then locates the potential buyer and identifies his needs. He should also find out the product used by the customers whom he is trying to contact.

III) Approaching

He should greet the customer warmly, introduce himself politely and then introduce the product.

IV) Presentation

He should show the product to the customer in such a way that the customer feels attracted towards the product. The salesman should also describe the features and uses of the product.

V) Demonstrating

He should then demonstrate the product explaining the method to use it.

VI) Convincing the customer

The salesman should try to convince the customer regarding the quality and usefulness of the product. He should also try to remove the doubts and objections in the mind of the customer.

VII)Closing the sale

After initial negotiations, deal should be made and sale closed in a cordial manner. The product should be handed over to the customer and in return the customer should make the payment to the salesman. He should also assure the customer of service in future.

IV. Publicity

Publicity is a non-sponsored and non-paid form of non-personal presentation of ideas, goods or services by the media voluntarily. The object of publicity is to form a public opinion. It is free of cost. The business organisation is not required to make any payment to the media.

Check Your Progress Exercise 3

10.6 MARKETING MIX – PLACE

The place or physical distribution of marketing mix refers to the various activities which are involved in transferring the ownership of the goods to the customers. Its aim is to make products available in right quantity at the right time and at the right place. Place mix involves decisions to be taken in order to make the product available in the market. Under this concept the decisions relate to transferring of ownership to the customers and to select the channels through which the product should reach the customers. Further, the manufacturer also takes decision regarding development of distribution system for physically handling and transferring of the product through these channels.

The Following decisions are usually taken under place mix:

- Channels of distribution
- Coverage
- Transport
- Warehousing
- Inventory control

Let's discuss these decisions in detail one-by-one.

1. Channels of distribution

It refers to the path taken by the goods in their movement to the customers. It starts with the producer and ends with the consumers. In between there may be a network of inter-dependent organisations like agents, dealers, wholesalers, retailers, which help in the transfer of product.

Levels of channels

The businessman may sell the goods directly to the consumers (i.e. direct sale) or may use various channels in which case services of intermediaries are used for selling the product (i.e. indirect sale). Following are the various levels of channels starting from zero level where no intermediary is involved and ending with three-level where services of number of intermediaries are used.

a) Zero-level channel

Here no intermediary is involved between the producer and the customer. The producer directly sells to the customer. This is the shortest and the simplest channel. Goods can be sold through door-to-door salesmen, direct mail, own retail stores, tele-marketing, etc.

b) *One-level channel*

Here one intermediary is used in between manufacturer and consumer e.g. retailer. This method is popular when the retailers are big and can buy in large quantities.

c) *Two-level channel*

Here the services of wholesalers are taken along with the retailers. This channel is preferred where the producer has limited finance, market is widely scattered and the wholesalers are specialised.

d) *Three-level channel*

Here one more tier is added in way of middlemen like agents. This channel is preferred when the manufacturer cannot directly approach the wholesaler, wide market is to be reached and when the manufacturer carries a limited product line.

Factors affecting choice of channels

i) *Nature of the market:* A manufacturer of industrial products usually prefers a direct sale method whereas a manufacturer of consumer products sells the goods using various channels.

ii) *Size of the market:* A businessman sells the goods indirectly if size of the market is big.

iii) *Unit value:* The products of low unit value are sold through middleman and products of high unit value are sold directly.

iv) *Technically complex products:* A direct sale method is preferred where expert advice is required.

v) *Perishable products:* Such products usually have short channels.

vi) *Financial strengths:* The big and rich businessmen can adopt direct sale method whereas small businessmen sell their goods through middlemen.

vii) *Experience of the businessman:* A direct sale is preferred if the businessman has knowledge and experience of distribution.

2. *Coverage*

Under this the businessman decides regarding how many middlemen should be used in the distribution channel. In this respect the businessman can adopt the following strategies:

a) *Intensive distribution strategy:* Here the aim is to saturate the market. It is adopted where product is inexpensive, frequently purchased and the consumers want it in their vicinity.

b) *Exclusive distribution strategy:* Here the businessman sells his product to a particular middleman in a particular area. Exclusive distribution rights are granted to a particular distributor. This is usually adopted for the goods which may be expensive and to be consumed over a long time.

c) *Selective distribution strategy:* Here the businessman prefers to sell his product in a selected market area or through selected intermediaries. This is useful in branded goods.

3. *Transport*

Transportation helps to widen market and it bridges the distance between production and consumption centres. The various means of transportation used by the businessmen are:

- Roadways;
- Railways;
- Airways;
- Waterways; and
- Pipe-ways

Choice of the mode of transport depends upon relative cost of different modes, their speed, reliability, frequency, etc.

Transportation is a necessary function of marketing as most of the markets are geographically separated from the point of production.

4. *Warehousing*

The businessman stores the goods in the warehouse to protect them against fire, theft, pest, insects, humidity, etc. The businessman may have his own warehouse or may take on rental basis. The warehouse can be located near the place of production or near the market. A regular supply of goods to the customers at minimum possible cost is ensured through warehousing. Modern warehouses provide facilities for packing, blending, grading, labelling, etc. of the stored goods.

5. *Inventory control*

The businessman needs to maintain a particular level of stock to ensure product availability as and when the customers' demand arises. Holding of inventory involves cost of storage, cost of capital tied up in inventory, cost of spoilage, etc. Inventory control implies control over the size of inventory. The management should weigh the benefits of maintaining inventory against the cost and optimum level should be decided.

Check Your Progress Exercise 4

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Name the two functions of modern warehouses.

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

2. Name the channel (direct or indirect) to be adopted by a businessman in the following cases:

   i) Mr. A manufactures big ovens used for manufacturing bakery items, each costing Rs. two lacs and above.

   ……………………………………………………………………...

   ……………………………………………………………………...

   ii) Mr. B manufactures butter and cream.

   ……………………………………………………………………...

   ……………………………………………………………………...

   iii) Mr. C manufacturing spices wants to cover a large number of consumers spread over a large geographical area.

   ……………………………………………………………………...

   ……………………………………………………………………...

10.7 LET US SUM UP

Marketing refers to all those activities which direct the flow of goods from the manufacturer to the ultimate user. The term marketing mix is usually used to refer to a particular combination of marketing variables which are controllable by an enterprise. Marketing mix comprises decisions taken in the four important areas i.e. product; price; promotion; and physical distribution. These four elements are popularly called four P's of marketing mix. Product mix involves decisions concerning nature and features of the product; branding; packaging; labelling; guarantees & warranties; and after-sale services. In the case of price mix, price is to be fixed scientifically. A low or a high price may mean success or failure for a businessman. The various decisions taken by a businessman under price mix relate to pricing policy; pricing strategies; and discounts and allowances. Promotion, another element of marketing mix involves various decisions taken in the areas of advertising; sales-promotion; personal selling; and publicity. Place mix involves decisions to be taken for making the product available to the customers. Decisions taken under place mix usually relate to channels of distribution; coverage i.e. how many middlemen should be used in the distribution channel; transportation; warehousing; and inventory control.

10.8 KEY WORDS

Strategy : A specific plan devised for a campaign and to counter the moves of the competitors.

Transportation : Movement of men and material from one place to another.

Statutory requirement: A requirement which is to be followed compulsorily as per prevailing law.

10.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Family branding
2. Primary Packaging
3. Plastic
4. Multiple packaging
5. Yes

Check Your Progress Exercise 2

1. i) Skimming
   ii) Penetration
   iii) Price discrimination
   iv) Odd pricing
   v) Loss-leader pricing

2. 1. True
   2. False
   3. True
   4. True
   5. False

Check Your Progress Exercise 3

1. i) Advertising
   ii) Publicity
   iii) Premium
   iv) Personal selling
   v) Newspaper advertising

2. **Hint:** Wide coverage; Lower cost as compared to other media of advertisement.

3. **Hint:** i) Having only audio impact but no visual impact.
   ii) There are noise disturbances.

4. **Hint:** Advertisement on TV is appealing; the advertised product can be demonstrated.

Check Your Progress Exercise 4

1. **Hint:** i) Facilities for packing; ii) Facilities for blending

2. i) Direct
   ii) Direct
   ii) Indirect

10.10 SOME USEFUL BOOKS

1. Kotler, Philip: Marketing Management – Analysis, Planning and Control, Prentice Hall of India Private Limited, New Delhi.

2. Mamoria, C.B. and Mamoria, Satish (2003) Marketing Management, Kitab Mahal, New Delhi,

3. Ramaswamy, M.S. (2002) Marketing, Salesmanship and Advertising, Sterling Publishers Private Limited, New Delhi.

4. Ramaswamy, V.S. and Namakumari, S. (1998) Marketing Management (Planning, Implementation and Control-The Indian Context), Macmillan India Limited, Delhi.

5. Varshney, R.L. and Gupta, S.L. (2000) Marketing Management (An Indian Perspective), Sultan Chand and Sons, New Delhi.

10.11 ASSIGNMENTS

1. Mention the various decisions taken under product element of marketing mix.

2. Mention various advantages of branding available to the consumers.

3. Explain various kinds of packaging.

4. What is a label? Mention the qualities of a good label.

5. “Price acts as the regulatory mechanism by means of which buyer and the seller come to a mutually satisfactory understanding”. In the light of this statement explain the importance of pricing.

6. Discuss in brief the various pricing strategies.

7. Explain the factors that influence price.

8. As a publisher you have published a book titled ‘Methods of Value Addition to Various Agricultural Products’. How will you set the price of the book?

9. Why is marketing mix important for a businessman?

10. Explain the various factors which affect the decision regarding the medium of advertising.

11. You are a manufacturer of ‘Noodles’. Which media of advertising would you choose to increase your sales?

12. The life of contests as a sales promotion technique is short-lived. Do you agree? Give reasons.

13. Explain the various qualities of a salesman.

14. Explain the various factors affecting the choice of channels.

UNIT 11 PRODUCT CONSIDERATION

Structure

11.0 OBJECTIVES

After studying this unit, you should be able to:

- explain the concept of a product and its significance for an enterprise;
- identify criteria that can be used in the selecting a suitable product for your enterprise;
- select appropriate value added food products for your enterprise;
- discuss the concept of product mix and apply the same to your enterprise;
- explain how products go through a life cycle of development;
- explain the significance of branding and packaging for value added products;
- select a suitable brand name and an appropriate packaging for your value added food products; and
- identify suitable positioning alternatives for your products.

11.1 INTRODUCTION

Products are the most tangible outcome of an enterprise engaged in manufacturing. They represent the value that manufacturers create and offer to the market for consumption and usage. Product decisions are important decisions for any enterprise because they determine the line of business an enterprise has chosen for itself. This unit introduces the concept of a product and its significance to an enterprise. It also familiarizes you with related terms like the product mix, the product line and product augmentation. Selection of a suitable product line is often a major determinant of the success of an enterprise. The unit also discusses the various criteria that you should use to select appropriate value added food products for your enterprise. Like living organisms, products also go through a life cycle of introduction, growth maturity and decline which need to be managed by the entrepreneur. The Among The decisions that you have to take regarding your product are branding and packaging decisions. The unit discusses the basic inputs that must be borne in mind while considering the branding and packaging alternatives for the value added food products.

11.2 PRODUCT: MEANING AND SIGNIFICANCE

A product is anything that is offered to the market for sale and consumption and has got the potential to satisfy a consumer need or a want. Consumers buy products to satisfy their needs or wants. It is therefore, important for you to think of the product as a solution to the consumer's problem of satisfying his food related needs. When a consumer buys soap, he is looking for a solution to his need for cleanliness and personal hygiene. In addition, he may also be looking for a solution to his problem of dry skin. Among the products available in the market, those that can provide the benefits of cleaning without drying up the skin will have the greatest potential for being selected by the consumer because the consumer perceives such a product as being an ideal solution to his need to stay clean without having a dry, scaly skin. Similarly, when a mother buys a snack for a child; she is looking for the solution to her need for both safety and nutrition for her child. Only a product which provides the benefits of both nutrition and some guarantee of being a safe food product will have the potential of being selected by the mother. A product therefore, represents a bundle of benefits or attributes, which enable it to address a given customer need or want. To conceptualize a product for your enterprise, you will first have to define the need of the consumer that this product is expected to satisfy, and then identify the benefits that a given set of consumers may look for in a value added food product. Such an understanding will help you to focus on the need of the consumer as the starting point for your product idea and product concept. This understanding is important because it enables you to think of a product essentially as a solution to the consumer needs, and therefore must at all times be responsive to the changing needs and requirements of the consumer.

Activity 1

Try to identify the consumer needs that the value added food products may cater to. You may like to do this for the following categories of products

A. Jams, jellies and marmalade
B. Pickles and preserves
C. Branded spice mixes

Ask the existing consumers the reasons for their purchase of these products. In each case describe the needs that were mentioned by these consumers.

A. ………………………………………………………………………………

B. ………………………………………………………………………………

C. ………………………………………………………………………………

(**Hint:** You would find that most people mention reasons like taste and flavour in the first case while adding variety and spice to every day menu may be mentioned as reasons in the second case – All these answers give you an idea as to how new taste combinations and flavours you can actually visualize as new product ideas for the value added food products from fruits and vegetables).

You must have now understood that any given product is actually a bundle of potential benefits that you can offer to a consumer in respect of a given need. These benefits accrue to the consumer as a result of the product attributes which may be physical or psychological in nature. The physical attributes include the product ingredients, its colour, taste flavour, size, weight etc, while the psychological attributes may relate to the brand image and brand positioning in the consumer's mind.

Product classifications also help us understand how consumers behave in relation to different product classes. You may then try to identify in which class you would like to place your value added food product so that you have a general idea of what to expect from the consumers when they consider your product for purchase. Broadly, all products can be classified as consumer products and industrial products. Consumer products are those that are bought and used by ultimate consumers and in such a form that they can be used without much further processing. Industrial products, on the other hand are bought for use in manufacturing other goods or producing some services. Consumer products are further subdivided as:

Convenience goods: These are consumer goods which are frequently purchased and are bought by the consumer without making much effort in making the purchase decision or the act of buying. The consumer often has a brand in mind before he purchases the product as these are the products he may have bought many times over in the past. Common examples include newspapers, household products of daily consumption like tea, coffee, food products like breakfast cereal etc.

Shopping goods: These products are purchased after comparing the products on offer by different manufacturers and retailers. While the consumer has a general idea of what he wants he would like to compare the items on offer in the same product category before deciding what to buy. Common examples of this category are apparel, shoes, furniture etc.

Specialty goods: These are infrequently bought products and bought for their special characteristics and features, with a great degree of buying involvement. The consumer knowledge prior to product search is not very high and the purchase is characterized by fairly intensive consultation with other users and/or dealers. Examples include cars, audio visual systems, residential homes etc.

Consumer durables: These are the products which survive several uses and have a relatively long life. Examples would be products like refrigerators, fans, radio sets etc.

You would, by now, have an idea where the product category of value added food products would fit in as a product class. Being relatively perishable products, value added food products would be in the category of non-durable, speciality or shopping goods which may not relate to a basic necessity but are either part of established food habits of consumers or are bought to add special interest, variety or taste enhancement to basic fare.

11.3 PRODUCT SELECTION

Selection of an appropriate product category for your enterprise would require you to answer these basic questions:

- What is the need this product relates to?
- How is the need being presently satisfied? Are there any gaps in need fulfilment or unfilled demand that can be satisfied by your entering the market with this product? In other words, is there a need in the existing market for the value added food product that you are contemplating?
- What is the type of value that is being offered by your competitors? In what way is your proposed product likely to be different or give the consumer a reason to buy?
- Do you have the necessary skills or competency to produce the product?
- Are the raw materials for your value added food products easily accessible and available?
- What's the potential size of the market for the product; in the area in which you want to operate?
- Are special implements or machinery required for the production process of these products? Do you have the resources or the access to these implements / machinery?
- In what way is the proposed product unique or different from others in the same category already available in the market?

Before embarking upon manufacturing of any value added food product, you must get a very clear idea of the market size, the presence of competition and an assessment of the potential demand that you may be facing for the product / Products. Only if you find that a reasonable demand exists for the product, you should begin with the production of your selected value added food products.

Activity 2

Oranges being abundantly available in your area, you get an idea of selecting orange squash and marmalade as possible products for you to produce. You initially want to market the product in the local area and then go for a statewide market. What are the factors you would consider and measures to get an assessment of the market demand for your proposed product line? Using these factors, assess the local as well as the statewide demand for the proposed products.

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

11.4 PRODUCT MIX DECISIONS

Let us familiarize ourselves with the common terms used in product related marketing decisions.

A single product produced by a manufacturer is termed as **product item**. When the manufacturer produces a group of related products, the terms used to describe this related group of products is **product line.** For example, jams, jellies and marmalade would constitute a product line for the value added food products manufacturer. If however, the manufacturer also decides to manufacture fruit based drinks in several different flavours, this would constitute a separate product line for him.

The term **Product mix** is used to refer to the set of all products and items that a particular manufacturer offers for the market. The *width* of the product mix defines the number of product lines offered by a producer, while the *length* of the product mix defines the number of product items offered. The extent to which the various product lines in the product mix are related in terms of production requirements, end usage and use of distribution channels defines the *Consistency* of the product mix.

Small entrepreneurs usually start their business operations with a single product item and then develop a category of related products as a product line. Their growth strategy then may comprise finding new markets for their existing product line of adding new products / lines to their product mix. It is however, important to understand that the product mix should be an optimum one, enabling you to capitalize on your resources and have a balanced growth strategy. Some of the factors as a small entrepreneur, producing value added food products, you must consider while taking your product mix decisions include the following:

1. Capacity utilization of manufacturing facilities and other resources.
2. Utilization of technical know how.
3. Cost efficiencies.
4. Possibility of improving market position through a more complete offer.
5. Profit and sales growth potential.
6. Overcoming seasonality of demand and ensuring stabilization in sales.
7. Expanding customer base and customer satisfaction.

In the context of value added food products, you may need to identify the specific attributes or features that you would like your products to have. These attributes include features like the taste, flavour, colour, their essential nature as completely natural products or products with some chemical preservatives, convenience of handling etc. You must remember that these attributes need to be responsive to the consumer tastes and preferences in the target segments chosen by you.

Activity 3

Study the product mix of a popular manufacturer of value added food products. Identify the different product lines being offered by him. Comment upon the width, length and consistency of the product mix. What in your opinion is the market advantage that he has been able to get from this offer through his product mix?

………………………………………………………………………………...

………………………………………………………………………………...

……………………………………………………………………………..

……………………………………………………………………………..

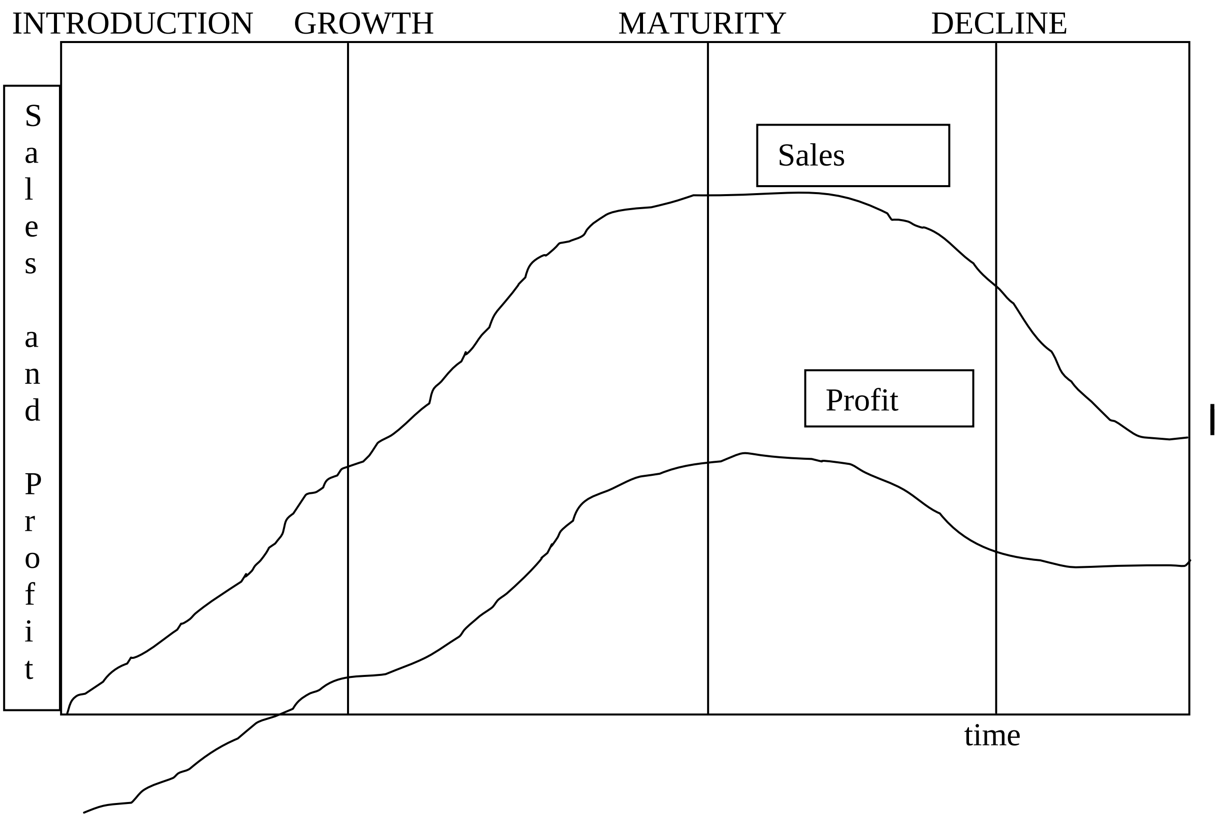
……………………………………………………………………………..

……………………………………………………………………………..

11.5 THE CONCEPT OF PRODUCT LIFE CYCLE

If you observe the profitable life span of products around you, you would often find interesting variations. While some products continue to have long and profitable market existence, others seem to fade away after some time, some very soon after their introduction in the market place. Like living organisms, products also are seen to pass through a life cycle of birth, growth, maturity and decline. What is, however, different is that marketers can often, by carefully planning their product market strategies influence the duration of the growth and majority phases and delay the decline. The stages through which a product passes in its development from introduction in the market to decline and possible discontinuance are referred to as the product life cycle. Figure 11.1 shows the various stages in the product life cycle in terms of the possible sales and profit curve. Let us try to understand the different stages and the way products and markets respond to marketing strategies during these stages

- *Introduction stage:* When you have just introduced the product in the market place relatively a few individuals know about the product, a small number of retailers are willing to carry the product and consequently the sales take time to pick up. If you have managed to understand the consumer requirements well, the sales start showing an upward movement though the rate of growth is slow. This is also the stage when on account of your initial start up costs being high, the profits are almost non-existent or very small. You also need to make a fairly substantial outlay on promotion to create awareness about your product offer, which adds to your introductory costs.



- *Growth stage:* In case the product launched by you is successful, it is said to enter the growth phase which is characterized by a more rapid growth in sales, on account of growing market acceptance. As fixed costs get spread over a larger number of units, the costs per unit go down and your profit position gradually becomes better. From the view of product strategy, this is an important stage because on one hand, your Consumer Franchise is growing and on the other hand, your competitors are also becoming conscious of your presence. They may like to take steps to defend their market position by reducing their prices, or offering products very similar to yours! You need to be prepared to take on the competition by maintaining product quality, attractive prices and providing the consumer a reason to continue to buy from you, on account of the product attributes. This is also the stage, where you may want to add new product variants to counter competitive overtures, and extend the growth potential of your product line.

- *Maturity stage:* As the product becomes more settled in the market, and the competition stabilizes, the sales come to a more stable rate of growth or reach a plateau. The product is in a stage where most of the customers interested in the product have already started using it and the market size is more or less defined, and the demand consists of replacement demand as well as that generated by some new buyers being attracted to the product. Future sales are a function of the population growth and the weaker competitors have exited the market. This is the stage where the entrepreneur prunes his product mix to weed out weaker products and concentrates on the most profitable ones. The maturity stage is usually the longest stage in the product life cycle and is often the most challenging one. You can create opportunities for growth by looking for new markets for your existing products or extend your product line to give a more complete package to your existing customers. Through creative marketing strategies by either market development or product diversification, or even marketing mix modification you can delay the onset of the decline stage.

- *Decline stage:* Sooner or later most products get replaced by new and better products in the consumer preferences and start facing a sales decline. This may happen on account of changing consumer preferences and tastes, improvement in technology or simply by better substitute coming into the market. As noted above the marketers can prevent the onset of decline stage by innovating and preparing themselves to meet these changing tastes and preferences themselves rather than allowing competitors to come out with improved substitutes.

Once sales start declining, it leads to overcapacity and a general inability to meet costs. Unless you can think of strategies to reverse the decline, it is a good move to cut your losses by getting out of a declining market. Some of the strategies used in the declining market include adding new features to the product to give extra benefits to the consumer, improving the incentives to the distribution channels in order to get better support from them, improving product quality or adjusting the price to make the product more suitable to another market segment.

You must however, always bear in mind that the product lifecycle and the duration of the product in different stages of the life cycle is often a result of the product and market strategies used by the entrepreneur rather than a natural progression that every product must follow.

Activity 4

You have only to think of food products which were once popular and are no longer seen in the market, because consumer preferences related to food have changed so drastically. On the basis of the market survey of your local market, try to identify some examples of value added food products which can be said to be in the various stages of the product life cycle. List these examples

Introduction stage…………………………………………………………….

Growth stage………………………………………………………………….

Maturity stage………………………………………………………………...

Decline stage………………………………………………………………….

(**Hint:** Look for some value added food products which have very recently been introduced in the market, some which have been around for some time and some which are now out of consumers favourite brand set-On the basis of what you have studied in this section, try to classify the products in the above stages).

11.6 BRANDING AND PACKAGING DECISIONS

Branding

In order to enable consumers to identify and distinguish between different product offerings, most consumer and industrial products need to have a distinctive name and an identifiable packaging that make them stand apart from other products. An important decision in your product strategy is to have a brand name for your products which is easy to remember and recall when the consumer is planning to buy the products. Let us try to understand the different terms that are used in the context of branding

A **brand** is a word, mark, symbol, or a combination of these used to identify goods or services

A **brand name** is the part of the brand consisting of a word, letter, a group of words or letters comprising a distinctive name which is intended to identify the goods or services of a seller or a group of sellers and to differentiate them from those of competitors. The brand name can be vocalized and therefore, can be used to communicate.

A **brand mark** is that part of the brand which can be recognized but not vocalized.

But **trade mark,** on the other hand, is the part of the brand which enjoys legal protection.

Entrepreneurs prefer to brand their products as branding provides several advantages in marketing. Some of these are

- A well chosen brand name helps invoke some of the desirable features of the product, for example Tang, Dairy Milk, Sunfeast, Shaktibhog etc.

- A brand helps in providing a distinctive image to the product and aids in distinguishing it from competitor's offerings.

- On account of easy identification, the brand helps the middlemen i.e. the wholesalers and the retailers in order booking, inventorying and other distribution functions.

- On account of association of favourable experiences with the brand name, branding makes it easier for consumers to develop brand preferences and ultimately brand loyalty.

- Over a period of time, goodwill of a brand becomes a valuable asset for a producer and is referred to as brand equity

- Brand equity, gives the organization a distinct advantage in future product introductions and market development.

You must therefore, think of a suitable brand name for your value added food products before introducing them in the market place. There are certain costs associated with branding in the sense that you would need to promote the brand name and establish an identity for the product by advertising and creating brand awareness. In view of the advantages already mentioned however, a brand becomes an important tool in the strategy for successful marketing by entrepreneurs.

Selecting a brand name: As the essential function of branding is to help product identification, recognition and recall. There are certain considerations which you must keep in mind when selecting a brand name.

- S*uggestive:* A brand name should suggest something positive about a given attribute of the brand for example the above brand names like Tang and Shaktibhog provide a hint about the product attributes of the drink concentrate being tangy in taste or the flour being an energy providing food.

- *Convenient and memorable:* It should be easy to spell, pronounce and remember (Kissan, Amul).

- *Distinctive:* It should be distinctive enough for people to clearly associate themselves with a given product and should not too closely resemble another brand especially in the same product category.

- *Association value:* The brand name partly on account of its memorability and partly on the basis of its relationship with product attributes, should be able to build up a strong association between the company offerings and the brand. This often happens because while promoting the brand, manufacturers repeatedly use some tag line to focus on the key benefit of the brand; For example the Maggie Brand uses the tag line "Easy to cook, good to eat". Over a period of time, consumers come to associate the value of a time-saving, tasty food product with the brand name Maggie.

Packaging Decisions

Packaging has often been defined as the art, science and technology of producing a container for the product and making it suitable for transportation and sale. A well designed package is an important tool for marketing communication, product differentiation and enhancing the value perception of the product. You have only to look around yourself, to specially in the context of value added food products to appreciate the revolution that has taken place in the area of packaging. The amazing variety of packaging options available today makes it possible for the marketer to use packaging as a strategic advantage in marketing. The choices for value added to products range from the traditional plastic and glass bottles to food grade pet containers, sachets, Tetra packs, aerosol cans and dispensers. The choice available both in terms of material and design is tremendous and it is up to the entrepreneur to select the best possible alternative for gaining the best competitive advantage. While taking packaging decision you must however be conscious of the functions that packaging must perform in order to add value to the product and justify the cost of packaging. The functions that packaging should perform include the following:

1. *Protection:* The most basic function of packaging is protection of the food products from environmental and physical damage to which the product maybe exposed to during transportation, storage and movement from the point of production to the point of consumption and disposal. The various hazards that the product may face during the above stages may include damage due to rough handling, extreme climatic conditions leading to spoilage, contamination, absorption of moisture, loss of fluid and pilferage because of unsafe packing. Your selection of the packaging material and

packaging design must ensure the protection of your product against all these hazards. The cost of packaging must be seriously considered against the cost of possible damage and spoilage during transit and before usage of the product.

2. *Enhancing product appeal:* In the case of food products packaging is being imaginatively used to enhance product appeal. You must understand that in the case of retail situations, the package acts as the silent sales person for the product especially in the self service situations. The package therefore, must *attract attention*, give a *clear idea* of the product; it must *inspire confidence* by looking *clean, hygienic and sturdy*; must be *convenient to handle*, and *to carry and store*

3. *Enabling sales promotion:* Packaging plays an important note in implementing sales promotion schemes as the package can be adapted to give additional benefits to the consumer in several ways For example, Money off package, Premium package, Extra volume for the same price, Benefits given to the consumer for the return of package in the event of a repurchase.

4. *Providing information:* Through labelling, packaging performs the important function of conveying information to the consumer about the product ingredients, prices, shelf life, instructions for use and any special caution that needs to be applied in respect of the product on its storage and usage. In the case of food products, if such information provision is also a legal requirement.

5. *Performance features:* In order to enhance the value for the customer, packages today are also equipped with functional features so that their usage value in the eyes of the consumer goes up. You would have seen ketchup packaged in plastic bottles with dispenser caps, or pickles in spill proof jars or plastic packs with zip lock systems. You may think of innovative ways of adding utility features to your product packaging like creating an aerosol package for salad dressing or a sprinkler cap for masala mixes to provide ease of usage of the product to the consumer. Creative packaging with additional features like these, sometimes results in brand purchase and ultimately brand preference.

Activity 5

A. Try to recall five most popular brand names of value added food products across different product categories. How well these brand names rate on the five qualities of a good brand name suggested above.

Brand 1 (name)……..……………………………………………………...

Brand 2 (name)……………………………………………………………

Brand 3 (name)……………………………………………………………

Brand 4 (name)……………………………………………………………

B. Identify the various functions that packages of value added food products fulfil besides the protection function, by surveying the packages of the value added food products in your local market.

…………………………………………………………………………......

…………………………………………………………………………......

…………………………………………………………………………......

…………………………………………………………………………......

…………………………………………………………………………......

…………………………………………………………………………......

(**Hint A:** You have just seen the criteria which define a good brand name. In respect of the brands selected by you, evaluate to what extent these qualities are displayed by the brand names.

B: Protection is the most basic function performed by packaging, on the basis of what you have studied in the section above, comment on additional functions that product packaging is seen to perform in the products chosen by you).

11.7 DIFFERENTIATING AND POSITIONING PRODUCTS

As a manufacturer of value added food products, it would be easier for you to decide on the various alternatives of your marketing strategy if from the very beginning you had a clear idea as to how you want your products to be perceived by the target consumers of your products. According to Philip Kotler, the designing of your offering and image to occupy a distinctive place in the minds of your consumers is called **positioning**. In the context of the product category offered by you in the market, you can take conscious, planned action to assign a specific image and meaning to your products for your target market. For example, for your value added food products, you can select a position of completely natural food products with no artificial additives or preservatives, or that of a value for money product, offering good nutritive value at economical rates or one that offers a complete range of possible flavours, or one that comes out with new, exciting and innovative taste combinations. Once you decide on a particular positioning to take, your marketing decisions like product attributes to focus on, packaging, promotion, distribution will need to be taken in consonance with the desired position so as to reinforce the desired image in all aspects of marketing activities.

Positioning is based on how you want to differentiate your product offer from your competitors' products. Product differentiation can be created on several bases some of which, relevant to value added products are discussed below:

Product attributes: As mentioned earlier, you can identify product attributes which you would like to focus upon, through which you are offering a distinctive value to the customer. This could be in the form of a particular taste (Maggie Hot and sweet tomato Ketchup) or the most compete range of flavours being offered in fruit juices or jams, or a low calorie variant on account of non-addition of sugar in your range of fruit juices and preserves. When trying to identify the attributes of which you want differentiate your products, you must consult your potential customers to have an idea of the attributes that are important to them.

Product form: Products can be differentiated on the basis of the form in which they are offered. For example, Masala mixes can be offered as a dry powder or a paste, provided this differentiated form offers a distinct advantage to the consumer in terms of usage or storing convenience.

Product packaging: As noted earlier in the section 11.6 on Packaging, we had discussed how packaging can be used to give a differential advantage to the customer. Reusable packages impart a distinctive value to the consumer, as do other convenience factors like dispenser caps, easy to handle bottles, sachet packs etc.

Product quality: You can consciously take the decision to offer a certain level of product quality and use this basis of differentiation to justify your prices. A quality differentiation must be consistently supported by product performance, otherwise it may prove to be counterproductive.

Pricing differentiation: You can differentiate your product on the basis of most economical prices or on a value for money basis. Alternatively, to convey a high quality image, entrepreneurs sometimes follow a high price strategy (e.g. Mothers recipe strawberry preserve) and aim at the high profile of the market.

Product delivery: It is also possible for small entrepreneurs to get an advantage in the market by offering service advantages like free home delivery especially for large buyers. This may specially work for you if you offer a complete range of value added food products rather than just one or two items.

Activity 6

Survey the market around you and study the leading brands of value added food products. Study their marketing communication as well as packaging. What, according to you are the ways in which these brands have been differentiated from their competitors? Try to identify the basis in each case and justify your answer:

Brand 1……………………………………………………………………..

Brand 2……………………………………………………………………..

Brand 3……………………………………………………………………..

Brand 4……………………………………………………………………..

Brand 5……………………………………………………………………..

(**Hint:** You must study the advertisements of all the five brands selected by you and the information provided on their packages. Study the main focus in each advertisement to understand the basis of differentiation being pursued by each brand).

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. What do you understand by the terms product, product mix and product line? Explain by giving suitable examples of value added food products.

…………………………………………………………………………………

…………………………………………………………………………………

…………………………………………………………………………………

…………………………………………………………………………………

…………………………………………………………………………………

…………………………………………………………………………………

2. What are the ways in which products can be classified? How would you classify the following value added food products?

a) Jams, jellies and marmalade.
b) Premium fruit juice.
c) Fruit pulp to be used for manufacture of fruit based confectionery.

Justify your answer by giving reasons for your classification.

11.8 LET US SUM UP

A product represents the offer that an entrepreneur makes to the market in order to satisfy an existing consumer need and earn a suitable return on his investment. In the context of value added food products, this unit tried to define the concept of a product, the product mix and the related terms. The unit also explained the way products can be classified and the criteria that should be applied, while making the selection of a suitable product to manufacture. The concept of product life cycle was covered to enable you to understand the different stages in the market development of a possible value added food product and therefore equip you to identify suitable strategies for various stages in the Product Life Cycle (PLC).

Branding and packaging are important decisions for an entrepreneur as these would enable him to carve out a distinct identity for his products. Advantages of branding and packaging, as well as key considerations that you should bear in mind, while taking these decisions, have been explained.

In the highly competitive market faced by value added food products, product differentiation plays an important role in helping consumers to understand the different values that are being offered by competitive products. The unit also explains the concept of brand positioning and product differentiation to help you apply these important concepts in the successful marketing of your value added food products.

11.9 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. Refer to section 11.2 Product: Meaning and significance and observe the market for suitable examples.

2. Refer to section 11.2 Product: Meaning and significance.

3. Refer to section 11.5 on product life cycle and specially to the decline stage under the PLC.

4. Refer to section 11.6 and look for the inputs given under the heading of branding and brand name selection.

5. Refer to section 11.6 and look for the inputs provided under the heading of packaging.

6. Refer to section 11.7 and look for inputs provided under the heading of product differentiation.

UNIT 12 SETTING THE PRICE

Structure

12.0 OBJECTIVES

After studying this unit, you should be able to:

- explain the various types of costs in an enterprise;
- describe the relationship between cost and price;
- apply the understanding of cost behaviour to price setting;
- define the objective you want to achieve through pricing;
- explain the various methods used by small enterprises for pricing;
- get an understanding of consumers realization to pricing decision; and
- set prices appropriate for your product and market situation.

12.1 INTRODUCTION

As an entrepreneur, pricing is one of the most important decisions you will have to take in respect of your products. You will find that a lot of your decisions become dependent upon the price that you are able to fetch from the market for your value added products. Not only the price set by you should cover your costs, it should also provide you with a reasonable margin as your earning. However, the consumer that you are planning to focus on for your products, must be able and willing to pay the prices that you are planning to set, otherwise the product will not be able to generate the demand that you wish to generate. As you are not the only one offering these products, you will also need to take into consideration what the direct and indirect competitors are charging for similar products. In this unit we will look at the factors that influence the pricing decision, the various cost that you must know, and the possible reactions of consumers to different pricing levels. We would also go through the steps in the price setting process, the various pricing objectives and the inputs you need to have before implementing your pricing decision. These inputs would enable you to take appropriate and ultimately, profitable pricing decisions for your products.

12.2 IMPORTANCE OF THE PRICING DECISION

Pricing is one of the key components of the marketing mix. In order to appreciate the importance of this variable put yourself in the place of a consumer. When you want to buy something, one of the first things you ask for is the price of the product. It often becomes the reason of your deciding to buy or not to buy. Ask yourself the question- why do you decide not to buy if the price does not seem appropriate? The answer is that you do not buy if you think the product in question is not worth the money that is being asked for. The exchange between the buyer and the seller is directly dependent upon the valuation the buyer puts on the product. If his valuation, i.e. his own perception of what the product should be worth, does not match the price that the seller has put on the product, and the exchange will not take place. Pricing as a decision is therefore important because

- It allows the consumer to assess the monetary value that he would need to pay to acquire the product.
- Prices strongly affect the consumer's valuation of the quality of products.
- It is the only source of revenue you would be earning. Your price level becomes the determinant of what revenue will you be able to generate, provided there is demand for your product.
- Pricing decision infringes upon your other decisions in the marketing mix. The price level contemplated by you defines the margin you will be able to make over your costs. Thus margin determines what are the kind of distribution costs you will be able to pay to your distributors and the type of resources you will be able to employ for your product promotion.
- Conversely, you will find that price is also a strong determinant of demand levels. The basic law of demand tells us that the quantity purchased of a given product increases if the price of the same is lowered and vice versa. While it is not true of necessity goods, pries do affect the number of people who will be able to afford the product and therefore is a factor in defining what is the size of the market at a given level of price.
- Your prices also strongly affect the positioning you aim at in the market. The price points enable the comparison of the value offered by you with the value offered by your direct and indirect competitors and allow the consumer to assign a positioning to your product vis-à-vis your competition.

A small entrepreneur is therefore very conscious of the extreme care that he would need to exercise to be able to set the right price for his product, in this case the value added food product that he has chosen for himself. Let us now try to understand the basic foundations of the pricing decision.

12.3 UNDERSTANDING THE BASIC ELEMENTS OF PRICING

At the basic level, you must clearly understand that price determination depends on three fundamentals. These are consumer value, costs and competition. Let us discuss each fundamental element in brief and understand their interplay in the pricing decision.

Costs represent the money value of everything that you will have to spend or utilize in order to create and offer your product for market. You need to be sure, in the short run as well as in the long run that your cost would need to be covered for you to survive in the market. You therefore, cannot afford to price your product below the cost at which you have produced it because you will be incurring losses instead of earning profits. For example, if it costs you Rs. 20,000 to produce 1000 bottles of fruit jam, another Rs. 2000 to package them and Rs. 500 to transport them to the nearby markets, you cannot afford to price one bottle below Rs. 22.50 because then each bottle sold would result in losses. Costs thus represent the floor below which you should not go in taking your pricing decision.

The consumers capacity and willingness to pay a given price is another variable that you will have to consider. In a given market, what is the value that consumers assign to a product like a bottle of fruit jam? How many of them, are willing to buy a bottle of jam, without the guarantee of a known brand name, at a price of, let us say Rs. 35 per bottle ? You will have to make this assessment, because in a given market the number of people, who are able and willing to buy at the price being thought of by you, will determine the demand that exists at that price level. You would need to assess what is the level of price at which the consumers in your chosen market segment are willing to buy your product, simply because above that level you will not be able to find any takers for your bottle of jam. The consumers ability to pay for a product in a given market thus defines the ceiling above which you cannot afford to charge, because a very limited market would result at that level.

It must now be clear to you that there are two limits, lower limit and upper limit that you must consider in your pricing decision, Costs on the one side form the lower limit and the customers ability to pay on the other side, constitutes the upper limit beyond which you should not go warns you while taking the pricing decision. You may have the freedom of charging what you want between these two levels, if you are the only one in that market producing fruit jam. Unfortunately, this is seldom the case because all kinds of value added products like jams, jellies, fruit juices and pickles and the other range of such products, are there always produced by other producers who are your competitors. All the producers who are in the market offering the same product that you are producing or are planning to produce are your competitors. As their prices are also commonly known to your prospective customers, you do not have the freedom of charging prices that are too different from those being charged by your competitors. The third dimension that you would have to study before you set your prices is the dimension of your competitors. To summarise the three basic elements you would need to define the following:

- Who are my customers and what is the value they put on a product like mine? In other words, what is the price at which they will be willing to buy?
- What are my total costs in producing, distributing and promoting my product?
- How do my competitors price the same or similar products?

Activity 1

Talk to about 5 people who are the likely consumers of the value added products and ascertain the possible prices they may like to pay for the following:

A. A bottle of mixed pickle 9250 gms)
B. Tomato (200 gms)
C. Fruit squash (500 ml)

How do these prices compare with the market prices of these products? Comment upon the gap if any.

…………………………………………………………………………………...

…………………………………………………………………………………...

…………………………………………………………………………………...

…………………………………………………………………………………...

12.4 WHAT SHOULD YOU KNOW ABOUT COSTS?

There is a common and widespread belief that costs determine prices. This is on account of the fact that costs are one of the important elements of the pricing decision as you saw in the previous section. You also saw that factors like demand and competition are the other two important factors that help you in finalizing your price. So, while costs continue to be important, their importance cannot be exaggerated you must clearly understand that if your costs are working out to be of a certain level, and covering them results in a price at which there is little or no demand, then you will have to seriously reason out costing and find out ways of minimizing costs in order to survive in the market. In order to clearly understand your costs, let us try to find out the various types of costs and see how they can be combined to give the total cost.

Costing is the way you calculate how much each individual product produced by you will cost you to produce and deliver. In order to realistically price your product, you need to cost the product first because then you will be able to

1. know what is it that you must recover and assess what margin you need to set to earn a reasonable profit;
2. set prices for each product; and
3. match your product offer with the expectation of your chosen set of target customers.

You will find that there are major differences in costs between one producer and another. They may be due to the way they source their raw materials, or utilise their resources or the way they use manpower and utilities like electricity and water. They will also have different cost structures if they have different skill levels and use different grades of raw materials, or different types of packaging. Let us list out the types of costs that may be incurred in the production of value added products.

1. **Direct Costs:** These costs are directly related to the manufacturing activity of the product under consideration and include :

   a) *Direct material cost* **-** Actual costs of raw materials that go into the finished product.

   b) *Direct labour costs* **-** Cost of the labour or manpower that is used to produce the product. Even if you are using the members of your own family, you must assign labour costs. These would be equal to what they would have earned as workers elsewhere if they had not been engaged in the home production activity.

   c) *Other direct costs* **–** Costs of the facilities like fuel, and rent of machines if any, packaging material, transport, storage expenses or tools and equipment etc.

2. **Indirect Costs:** These are the costs that cannot be directly linked to the manufacturing of the product but are required to make production possible. You must also remember that these costs will continue to be incurred whether the production of your value added products is going on or not. These costs include:

- The rent of the building, maintenance of the building, equipment machines etc.
- Power and electricity, water, and other municipal costs like taxes.
- Costs of interest on loans that you may have taken.
- Salaries of people engaged by you who are not directly involved in the production e.g. helper, delivery boy or some consultation fees that you may have paid for general administration or production/marketing of your value added products.
- Stationery postage and telephone if any.
- Costs incurred in providing your product.

You may also look at costs in another way to identify them as fixed and variable costs. All costs that you incur can be classified either as fixed or as variable costs.

Fixed Costs: Costs are those that do not change with the quantity of products produced, i.e. these are costs that cannot be avoided even if no production is being undertaken on a particular day or in a given period. These costs include rent of the building, salaries given to people involved in the production activity, interest on loans, monthly charges of electricity power and water etc.

Variable Costs: on the other hand variable costs are those that vary with the level of output. They directly depend upon the quantity of products being produced. They include the raw material costs, machine operating costs, direct labour costs, packaging, transportation of finished goods etc. You would appreciate that variable costs would arise only when production is going on. On a given day when there is no production activity, the variable costs would be zero.

In order to be able to calculate the total cost per unit of your product, for which the pricing decision is to be taken, you should know the following:

1. Total fixed costs of your organisation
2. Total variable costs for the manufacturing of that product
3. Period over which the fixed costs are being incurred

   ❖ Cost for each product = Total fixed costs + Variable costs of the product

The factors which cause your total costs to rise and make you uncompetitive include the following:

- Your lack of knowledge or uncertainty about the needs of your customers regarding the value added products.
- Inadequate knowledge about the sources of raw materials and availability of others resources.
- Your inability to purchase raw materials in large quantities.
- Uncertainty about the quantity to be produced each day or per period.
- Lack of basic skills relating to introduction or selling of value added products
- Inadequate knowledge about the low cost alternatives for raw materials/ equipments/workers.
- Lack of appropriate standardisation in the production processes, packaging and distribution.
- Inadequate training of labour and other production related staff.

Activity 2: Working out the total cost of the product

Take the following table as an illustration of the various costs associated with the product of a given value added product like jam or fruit preserve. Using the information given above, work out the total cost of the product.

Item/material required	Quantity	Cost/rate per unit	Quantity required per unit	Cost/unit
Unit	30 kg	Rs. 25 per kg	2 kg	Rs. 50
Additive				Rs. 5
Sugar	15 kg	Rs. 8 kg	500 gms	Rs. 4
Packaging		Rs. 2/bottle		Rs. 2
				Rs. 61

………………………………………………………………………………...

………………………………………………………………………………...

………………………………………………………………………………...

In addition there are 2 workers involved per day who produce 300 kg of preserve per month. Their salaries are Rs. 1500/month each. Cost of labour per unit i.e. per kg production is Rs.10.

The direct cost of production = Rs. 71 (=Rs. 61 + Rs. 10 = Rs. 71)
What is the price that you would like to set?

Hint: To the above you will be required to add all the indirect costs divided by the total number of units produced per month, to get the indirect cost per unit. Suppose these costs are Rs. 5/-.

Your total cost of production so therefore = Rs. 71 + Rs. 5 = Rs. 76.

∴ Total direct cost per unit + Total indirect cost/unit = Rs. 76.

Once the goods are produced, you have to incur distribution costs to let the goods reach the hands of the consumer. If you want to sell through dealers i.e. wholesalers and retailers, you will have to incur the cost called distribution margin. If you want to sell directly, you still have to incur delivery costs but these will be in the form of transportation, warehousing and keeping the inventory of the finished goods. Assume, for the sake of simplicity that these selling costs are equal to Rs. 4/ unit. Your total cost of the product is therefore Rs. 80 (Rs. 76 + Rs. 4) = (Cost of production) + (Cost of delivery).

In order to determine your price, you will have to decide the margin you would like to charge to get a reasonable profit margin. The total price per unit, to be charged is given by the simple formula

Price = Total cost/Unit + Markup margin per product

Suppose you decide to earn a 15% margin on your total cost. This works out to Rs. 12. The final price that you would need to charge would be equal to Rs. 92 per kg. In case you want to sell in500 gm bottles, the price should be around Rs. 46.

Activity 3

Based on your information of the market price of raw materials and an assessment of labour costs involved, try to work out the possible margins being charged by 2 branded value added products of your choice.

……………………………………………………………………………….....

……………………………………………………………………………….....

……………………………………………………………………………….....

……………………………………………………………………………….....

……………………………………………………………………………….....

We have in the above example used the direct cost, indirect cost classification to work out the total cost and estimate the final price.

You may also use the classification of fixed and variable costs for the same exercise for calculating the total cost.

In order to work out the total cost, you would need the following information.

1. Fixed cost of the Production Unit

   a) Cost of total machines & equipment
   b) Cost of rental of the building
   c) Cost of furniture and fixtures
   d) Cost of installation transport etc.

2. Monthly payments of the unit

   a) Payment of electricity/water/telephone
   b) Salaries of the workers if any
   c) Salary of self
   d) Office costs if any
   e) Cost of production

3. Variable cost of raw materials and labour used.

Using the above information, work out the total cost/unit of any value added product of your choice.

12.5 WHAT SHOULD YOU KNOW ABOUT YOUR CUSTOMERS?

The basic objective of the pricing decision is to set it at a level where exchanges will take place i.e. the price at which a large number of consumers will be willing to buy.

You must also appreciate that in a country like ours, your potential consumers can also be your competitors in the sense that they can produce most of the value added products you intend to offer, by themselves. While evaluating pricing options, you must keep in mind that if the prices are too high, consumers may simply not consider the products worth the money.

From the point of view of the consumer, prices become barriers to purchase in both circumstances, when they are too low or too high. Above a particular price, the product is perceived as being too expensive and below a particular price, it is perceived as being of too low a quality to be considered desirable. Looking at the consumer group you wish to cater to, you must get an appropriate idea of these two limits. These limits constitute the range above which or below which you should not set your price. It is a good idea to get an assessment of the prices that consumer will be willing to pay for your type of value added product through discussion with consumers or a survey of the prevailing market prices for similar products,

Another assessment that you would need is the price elasticity of demand. This price elasticity of demand is a measure of what is the responsiveness of consumer to small changes in price. Is the product of that type where the price consciousness of the consumer is very high and any small change in price by other producers, will shift the demand in favour of the competing product? You can protect your product from direct price competition by differentiating it on the basis of quality, freshness, taste, flavour, low sugar content or any other value that you may choose to include. To summarise, the different factors that you would need to know about your consumers include:

- What are the prices that your consumers are willing to pay for your product?
- What is the approximate demand that is likely to result at different price points?
- How sensitive are consumers to changes in prices for your type of product?
- What are the factors other than price, that consumers assign value to when they select value added production?

Activity 4

For a product like pickles, find out from different sections of your prospective consumers the prices they are willing to pay for a 500 gm bottle of good quality pickle. Based on the assessment of costs as in activity 1, what type of margins will these prices enable you to get ?

……………………………………………………………………………...

……………………………………………………………………………...

……………………………………………………………………………...

……………………………………………………………………………...

12.6 WHAT SHOULD YOU KNOW ABOUT YOUR COMPETITORS AND TRADE PRACTICES?

At any given point of time, wherever you contemplate putting a value added product on offer, you must be aware that there are several competitive products already on the market. People who fulfil the same need of consumers, that you are trying to fulfil through your product, are your competitors. As noted in the earlier section, value added products represent a category where the consumer himself may also be a competitor.

While pricing your product, you need to be aware of the prices that your competitors are charging. A casual survey of the retail market would give you a clear idea of the final price that the existing consumers are paying for your competitors' product. In order to give them a reason to buy, you need to either price the product a little below that of the competitor while keeping similar levels of quality, or include some other value in the product for which the consumers are willing to switch their brands at the same price or even slightly higher prices. You must clearly understand that the competitors' prices create what is called a reference point for the consumers against which they assess all new offers. You, therefore, cannot afford to have prices that are radically different or unsupported by a reasonable value proposition.

In the next unit, you will study in detail about the distribution practices that emerge to bridge the gap between points of production and points of consumption. It is, however, relevant here for you to understand that distribution costs also have to be absorbed in the final price of the product. When you develop value added products, in order to take them to the point where consumers can access them, you will need to use the services of middlemen like wholesalers and retailers. These distribution agencies operate on the bases of margins that they earn on the products they help to sell. In common parlance, the terms on which you share the distribution of your products to the markets selected are known as terms of trade. These include the quantum of margins (in terms of percentage) payable to the distributors, the types of services performed in return, the type of warehousing and promotional support provided and the terms of payment i.e. cash or credit, terms of credit etc.

As distributors are independent businessmen in their own right and provide the essential services of creating access for the customers to your products, for a new manufacturer there is seldom any choice but to follow and abide by the existing terms of trade. You should, while taking the pricing decision, be aware of what are the costs generated by the different types of channels of distribution you can select. These costs will also become a factor in the total costs that would need to be recovered through your pricing decision.

12.7 UNDERSTANDING PRICING OBJECTIVES

For your enterprises, you may have several objectives at a given point of time. Your pricing goals would reflect what you want to achieve as an entrepreneur. For example, a new entrepreneur in a highly competitive environment has the primary objective of survival and therefore, his pricing objectives would reflect the need to be able to merely survive in the market place for the time being. The various pricing objectives that entrepreneurs seek include:

- Survival
- Maximising current profit
- Maximising market share
- Market entry objectives
- Product quality leadership

Survival as an objective is followed if the enterprise is faced with more capacity than the demand, intense competition and changing preferences of the buyers. The prices are set at a level which will enable the entrepreneur to stay in the market as long as possible. The entrepreneur, in such conditions fixes the price at a level which covers his variable and fixed cost and he tries to stay in business. This is a very short term objective and soon the entrepreneur will have to decide how to add value to his offer or be prepared to exist in the market.

Another short term objective that many small entrepreneurs follow is that of maximising current profits. When you understand that there are different demand levels that will result at different prices, and you are interested in whatever maximum you can get from the market, you would select a price level that produces, for a given demand level, the highest current profit for you. You must however, know that under this objective the entrepreneur may be ignoring the long term objectives of his organisation.

Some entrepreneurs, specially those who have attained a certain size of business are interested in increasing their share of the market because they believe that a larger customer base will allow them to cut their costs and in the long run allow them to have higher profit. Their pricing objective is to maximise market share, and they will select the lowest possible price, if the market is price sensitive. You are all familiar with the example of Nirma washing powder. Indian consumers of detergent are very price sensitive. At the time when established detergents like surf and sunlight were being sold for Rs. 30-35 per kg. Nirma was introduced at a price of Rs. 6 per kg. It continued with similar price levels for quite some time because the objective was to take a large share of the market.

This strategy is also termed as particular pricing because this enables you to penetrate the market, in a competitive but price sensitive situation sometimes, where the entrepreneur is able to create a unique or an innovative product which is new to the market and therefore has a great novelty value, he is in a position to charge extra for the novelty value of the product. The pricing objective that is selected in such circumstances is called market skimming. The product is initially priced very high, so that the customers with higher paying capabilities and with current desire for the product will be attached and will give initial high profits to the entrepreneur. As the novelty wears off and the product gets more well established, the prices are reduced to a level where the larger population can afford to pay. The sales margin will go down but the higher volume will still allow the entrepreneur to make profits.

Sometimes, entrepreneurs may wish to present their products as the highest quality products and charge high prices. In this case, he is conscious that his prices limit the total size of his market, but pursues that objective in the hope that his product quality leadership will be established and in the long run it will be able to create a reputation for high quality.

As an entrepreneur, you need to select an appropriate pricing objective based on what are the overall business objectives you are seeking at a given point of time.

Activity 5

From among the above pricing objectives, what are the objectives you would like to select for yourself?

a) At the introduction stage
b) At the business growth stage

…………………………………………………………………………………...

…………………………………………………………………………………...

…………………………………………………………………………………...

…………………………………………………………………………………...

12.8 ALTERNATIVE PRICING POLICIES THAT ENTREPRENEURS FOLLOW – RELATIONSHIP BETEWEEN PRICE AND QUALITY

Variable Price Policy

Under this policy, different price are charged for different customers depending on the situation prevailing in the market. Some situations under which variable price policy is adopted are:

1. Difference in the size of the customers (e.g. bulk customers may be offered lower price);
2. Difference in the anticipated business from different customers;
3. Difference in the bargaining power of the customers;
4. Difference in the demand and supply position at various locations;
5. Difference in the customers' ability to pay; and
6. Ignorance of the customers.

Some entrepreneurs adopt variable price policy in their effort to maximise profits. They determine the minimum price to be charged by the total cost of the product, and the maximum price by the customers' ability to pay. Bargaining is usually resorted to in finalizing a deal. As such, this policy may be detrimental to the long-term interest of a firm.

Base Price and Discounts Policy

Under this policy, a base price or least price is used and varying price discounts are offered to different categories of customers. Under the variable price policy, the price is charged according to the particular situation. However, under the base price and discounts policy, discounts are offered uniformly to all customers and each one of them can avail these on satisfying the stipulated conditions. Discounts are of several kinds: **Trade discount** is given to a trader to cover his costs and provide him with a margin as incentive to deal in the product. **Quantity discount** is offered to bulk purchasers because of their value to the seller. **Cash discount** is given to the customer making cash down or immediate payment. **Seasonal discount** is given to boost the sale of a product during slack season. Electric fans, woollen garments, and cooler pumps are typical examples where seasonal discounts are offered.

Market Rate Policy

Prevailing market rate, many times is the basis on which an entrepreneur determines the price of his product. If the nature of the product is such that it is largely indistinguishable from those of the competitors, or if it is found that all manufacturers are charging more or less the same price for their products, the market rate policy of pricing is usually adopted. In case the entrepreneur finds that the prevailing market rate is not economical for him, he has to lower down his costs somehow rather than increasing the price unilaterally. This method is commonly used in the case of unbranded products like oils and chemicals, and services like courier, tailoring and car or scooter servicing. One advantage of this policy, especially for new small enterprises, is that they get some immunity from the vagaries of price wars.

Market Skimming Pricing Policy

Under market skimming pricing strategy, a very high price is charged in the beginning with the objective of recovering the investment in a short period. High price is usually supported by heavy product promotion. This strategy is seldom possible except when the product is an innovative one and is expected to command good reception from the customers. One cannot continue with such a strategy for a long period of time as high price acts as an incentive to the competitors to enter the field. The price is permitted to fall as the competition sets in.

Market Penetration Pricing Policy

Market penetration pricing strategy calls for a very low initial price in order to penetrate into the market. The strategy puts emphasis on creating a mass market for the product at low margins. This strategy can be adopted when the demand is expected to be price elastic, i.e. customers are price sensitive, and when the economies of large scale production are substantial.

12.9 PUTTING PRICING IN PRACTICE – WHAT SHOULD YOU KNOW BEFORE IMPLEMENTING THE PRICING DECISION

When you decide upon a particular price, there are important aspects of buying behaviour that you should be aware of before implementing the price decision.

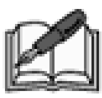
- For the consumer prices are a quantitative value, while quality, branding and promotion are qualitative and difficult to assess. Your price point becomes a reference point for them to make assessment about the product.

- As said earlier, price must be viewed by your target group as being affordable, in the consumers below it should offer good value for money.

- However, if the price is too low in comparison to similar products, the consumers may tend to think that it is of inferior quality. You must carefully assess, that for food products consumers may not like to compromise on essential quality, so even if you are offering reasonable quality, too low a price may give a low grade quality usage to your product and will turn away consumers who are quality conscious.

- Packaging and labelling add to the cost and therefore, result in higher prices. Some entrepreneurs may try to economise economies on these costs but please remember, inferior packaging may allow you to set lower prices but will also interfere with the quality of the product as and when the product reaches the consumer.

12.10 LET US SUM UP



Pricing constitutes one of the most important decisions of the entrepreneur. It often affects the growth and survival of the enterprise. In this unit, you have been given inputs on factors which influence the pricing decision, pricing objectives and the importance of costs consumers and competition in the pricing decision.

Entrepreneurs may like to pursue different objectives at a given point of time and consequently follow different pricing polices. The unit discusses different pricing polices that small entrepreneur may implement, in view of their objectives.

The unit also introduces you to possible buyer reactions to price related decisions and may help you in taking the same into action while you set your prices.

12.11 SELF ASSESSMENT QUESTIONS

1. Why are pricing decisions so crucial for the entrepreneur in marketing value added products?

2. What are the different types of costs you will incur while making

   a) Jams
   b) Pickles
   c) Fruit juice concentrate

   Explain how their costs will affect your pricing decision.

3. Carry out a survey of the prices of the value added products being considered by you for production. What are the different prices ranges that are offered by your competitors?

12.12 SOME USEFUL BOOKS

UNIT 13 DEVELOPING AND MANAGING DISTRIBUTION

Structure

13.0 OBJECTIVES

After studying this unit, you should be able to:

- explain the importance of distribution decisions for the marketing of value added food products;
- identify the various options available for distribution of value added food products;
- make appropriate selection from among the distribution choices available to you;
- evaluate the advantages and disadvantages of selling through retailers and wholesalers;
- assess the margins that you need to pay to your distributors and measure the impact of distribution margins for the pricing of your value added products;
- demonstrate an understanding of the processes involved in the distribution of goods; and
- evaluate the performance of the channel members used by you.

13.1 INTRODUCTION

As a manufacturer of value added food products, you need to make your products available to the customers who can then decide to buy and consume them. In the previous unit, you have gone through the processes through which manufacturers promote their goods and create demand for their products. In order to be able to consume the products, the consumers require the product to be made accessible at places near them. As the consumers of your products are scattered in large geographical areas it may not be possible for them to approach you directly. Similarly, it may be difficult for you to reach the individual consumers on a direct basis. The decisions that you need to take in order to make your products available for consumption to the final customer are referred to as distribution decisions and form the fourth "P" of the marketing mix for products and services. We will explore the various options that you may like to consider in order to make your value added food products available to the final customers of your products. This unit enables you to identify and select between channel options, evaluate whether direct or indirect distribution is a viable option for you and explore the various tasks that are required to be undertaken to enable the physical transfer of goods from the point of production to the point of consumption.

13.2 DIRECT OR INDIRECT DISTRIBUTION

As a manufacturer of value added food products, you are aware that the conversion of these products into revenue for you would not take place unless customers buy these products and continue to do so. For them to be able to do so, it is important that the Products are made accessible to them at places that are convenient to them. Consumption does not take place unless the goods are available at the right place, at the right time, in the right quantity and at an appropriate price. The term distribution refers to the process of moving the products from the point of production to the point of consumption so that the products become accessible to the people who may like to consume them. When a manufacturer establishes direct linkages with his consumers and sells directly to them without using any intermediaries, this option is called direct distribution. This option is usually possible when the customers are few in number and an individual customer is large enough to give you sufficient sales volume, as in the case of organizational customers. As a producer of value added food products, for example, if you are able to secure large orders from restaurants, canteens or hotels; you can easily supply the products directly to these customers as this will enable you to economize on your distribution margins and establish a direct rapport with your clients. Direct distribution as an option offers several advantages. Direct distribution would involve using your own sales force and arranging the delivery of goods through your own resources. Alternatively, direct selling can also be done by obtaining your orders through direct mail or telephone.

- It allows you to save on distribution margins of commission which are required to be paid to the intermediaries like retailers and wholesalers.
- This saving can be often utilized to offer very competitive prices to your customers; The low selling price can give you a competitive advantage vis-à-vis your competitors
- Your direct contact with your important clients can enable you to customize your value added food products in accordance with the needs, tastes and requirements of the customers.
- You can have a greater control on the final price and the terms of sale offered to your customers.

There are, however, certain disadvantages of using direct distribution. Your initial investment in creating facilities for storage, warehousing, transportation and handling of material becomes substantial. When you use direct distribution as an option your working capital requirements on account of salaries to the sales force as well as delivery related expenditures are higher. The geographical area that you can cover on your own is often limited and therefore, your market becomes limited to local markets or a few large organizational customers. In such cases, your dependence on a single or over a few organizations is so high that discontinuance of orders from any one of them could seriously affect the profitability of the business.

On the other hand, if your customers are individual household consumers, the economics of direct distribution does not work out. Individual consumers may be scattered geographically, and the individual order size per household will be small . In such cases it is difficult, if not impossible for you to reach all your customers on your own. To reach a large number of individual customers, producers use intermediaries like wholesalers and retailers. These intermediaries are independent organizations that enable you to reach your final customers by providing distribution related services to you for an agreed trade margin. When you use intermediaries to reach your final customers, the mode of distribution is called indirect distribution. The advantages of using indirect distribution include the following:

- Low initial investment in distribution facilities.
- Relatively lower working capital requirement in relation to the distribution function.
- Large coverage and access provided to a far larger number of customers.
- Benefits of specialization accruing from the intermediaries.

Your choice of direct vs. indirect distribution is determined by the composition of your customers. As mentioned above, if your customer base is composed of organizational customers direct distribution is a better option. Indirect distribution is a more viable option when your customer base is composed of individual households. These are choices that you need to make at the beginning of setting up of your business and selecting your target customers. You may like to work with a few organizational customers or may like to address the needs of individual households. This decision in turn will determine your choice of direct or indirect distribution.

Activity 1

Make a survey of about ten retail shops in your neighbourhood to collect information on the type of value added food products carried by them. List these products. Try to identify products that do not come from large multinational or national providers. Your list will tell you that quite a few small entrepreneurs today use the indirect channel of distribution for their value added products. Discuss with the retailers to find out the type of retail margins that have been paid for these value added products by the small and medium entrepreneurs.

13.3 TYPES OF INTERMEDIARIES

The set of organizations, outside your own firm, selected by you to enable your final customers to access your products is known as channel of distribution. A channel of distribution essentially enables the movement of products from the point of production to the point of consumption as well as the transfer of title from the manufacturer to the ultimate consumer. Looking at the market and the type of organizations engaged in the distribution of products, you would find that there are a wide variety of such organizations performing different kinds of distribution related functions, with varying terms of trade. Let us look at different types of intermediaries that if you may need to consider in order to to form your own channel of distribution.

Broadly, all intermediaries can be divided into two categories: Agent middlemen and Merchant middlemen. The agent middlemen are brokers and commission agents who negotiate purchase and sale of goods on behalf of other parties for a certain percentage of commission. Because agent middlemen work on behalf of other parties they do not take title to goods. Quite a few new entrepreneurs find it useful to appoint agents when they first get into the business of producing value added food products to help them find appropriate clients and avenues of selling their products. If you are starting with a small operation and your production is not too large, agent middleman may not find it profitable to act on your behalf.

Merchant middlemen, on the other hand, are those intermediaries who buy the goods from the producers and then sell them on their own behalf. In other words, they take title and possession of goods in order to resell them further. The merchant middlemen can be of several types viz. wholesalers, retailers, cooperatives and supermarkets, multiple shops or chain stores and department stores. In order to establish your channel of distribution, you will need to decide a specific combination of these intermediaries. Let us look at the main functions performed by these intermediaries so that you can accordingly take your channel decision.

Wholesalers: The term wholesalers includes all establishments and businesses engaged in purchase of goods from the producers for the purpose of reselling them to retailers or industrial, commercial, institutional or professional users or to other wholesalers. The principal business of wholesalers is buying goods in bulk and reselling them for a profit to (a) retailers who then resell the goods to the final customers or (b) utilize the goods in the course of operating an enterprise or business. In performing the distribution related activities, the wholesalers perform the following functions:

a) Taking possession of goods, maintaining storage facilities and maintaining adequate stocks in terms of both variety and quantity on a regular basis.

b) Delivering goods to customers (You must appreciate that the customers of wholesalers are retailers, industrial or professional enterprises and other, smaller wholesalers).

c) Taking ownership or title of goods from the producer and passing it on to the customer when the sale is made.

d) Participating in promotional activities for trade promotion initiated by the producer.

e) Negotiating on prices, terms of trade and terms of sale with both the producer and the customer.

f) *Taking risks:* Risk taking is a major function performed by the wholesalers. By taking the ownership of the goods, they assume the risk of obsolescence, pilferage and damage to the goods as the goods are now owned by them. In the case of new untried products or unknown products they also take the risk of being left with stocks of unsold goods, if the goods are not accepted in the market.

g) *Ordering:* The flow of ordering moves from the final consumers via retailers and wholesalers to the manufacturers. Wholesalers, order the supplies of goods from various manufacturers in anticipation of the order flow from the retailers and final customers.

h) *Financing:* Wholesalers, by selling the goods on credit to the retailers and collecting the payment after an agreed time period, provide a vital financing support to the retailers.

Retailers: The term retailer includes all establishments and businesses engaged in selling goods for personal or household consumption. The distinction between the wholesalers and retailers is that the retailers sell primarily for ultimate use by the final consumer. You will find a variety of retail establishments existing in our country, ranging from consumer stores, multipurpose retail stores to sophisticated departmental stores. In terms of distribution activities, retailers perform the following functions:

a) Taking possession of goods from wholesalers, maintaining storage and desired stocks in order to fulfil the requirements of the final consumer.

b) Passing the delivery of the goods to the final consumer for price.

c) Taking ownership from the wholesaler to retailer and passing it on to the final consumer.

d) Participating in the promotion programmes of the manufacturer by organizing store displays and acting as final deliverers of sales promotion schemes directed at the final consumers.

e) *Risk taking:* Like wholesalers, retailers also take the risk associated with ownership. Their risk in the case of unsold merchandise may be partially offset if the wholesaler or manufacturer agrees to accept the returned unsold stocks.

f) *Information flow:* As they are in touch with the final consumer, retailers are a source of valuable information about the consumers' tastes and preferences, buying habits and paying capacities. Retailers participate in information flows backwards to the manufacturer so as to improve services to the final customer.

You would by now have noticed that the functions performed by the wholesalers and retailers are quite similar except for the fact that the scale of operations by wholesalers is much larger as they buy and sell in bulk for the purpose of reselling. The retailers, on the other hand, sell for the purpose of consumption by the final consumer. Their distribution related activities are directed mainly towards the ultimate consumer. There can be several types of retail establishments as we have noted earlier, some of the common ones being departmental stores, cooperative stores and chain stores.

Departmental stores usually located at a central location, provide a great shopping convenience to the modern customer who is short of time, by providing them a range of products under one roof. Being able to attract a large number of customers they are able to manage a large turnover even though their margins maybe small. Their large size enables them to buy directly from the manufacturers and avail bulk discounts thereby saving the wholesalers' margins and passing the benefit on to the consumer in the form of lower prices. As a producer of value added products, you may consider departmental stores as an option because your products can get a large exposure to your target customers in such locations.

Cooperative stores or consumer cooperatives are run by societies formed by consumers themselves. The basic purpose of the cooperative store is to eliminate the middlemen and obtain the goods for their members at a low price. Like departmental stores, cooperative stores also obtain their supplies in bulk and enable the consumers to get the benefit of low selling prices. Some of the common examples of consumer cooperative stores are super bazaar and the Central Government Employees' Consumer Cooperatives.

Chain stores or multiple shop systems represent a concept where a number of stores are managed by one common ownership and management. The various stores can be located in different cities or at different locations in one large city. The chain stores usually deal in similar types of goods for example the Bata Shop, and the Phillips appliances shop. Food based chain stores are becoming very common in metropolitan cities, named as food bazaars or food courts. They have become a good outlet for the introduction of new food products and availing a larger variety of food products in one location. Such food bazaars may be a good outlet for the value added food products for you to consider.

Haats and weekly markets: Rural consumers, on account of the absence of organized markets in the villages, carry out a lot of their buying activity at haats and weekly markets held around their villages. As the purchasing power of the rural customers has grown, marketers have found that these weekly markets provide a lot of access to a large number of customers in the non-urban markets. You must realize that the rural market in India is a large one, with high potential for development. Though the market for value added food products may at present be very limited, the potential for developing this market cannot be ignored.

Activity 2

Make a visit to the following types of retail outlets in your locality:

A. A super bazaar or cooperative store.
B. A departmental store.
C. A general provision store in your own colony.
D. A weekly market organized near your colony.

Make a list of the type of value added food products you find at these retail establishments. How do you think your own proposed value added food products will fit into the product assortment being offered by these stores? Which type of retail outlets will be most suitable for your value added food product and why?

13.4 IMPLICATIONS OF USING INTERMEDIARIES: CHANNEL LEVELS

By selecting an appropriate channel, you as a producer of value added products are trying to bridge the gap between you and your final consumers. Now that you have looked at different types of intermediaries operating in the market place, you can decide in terms of the levels or the number of channel intermediaries you want to mobilize to reach the final customers. Your choice would be strongly dependent on the market coverage you want and the scale at which you want to operate. Since you are a producer of consumer goods, the following channel options are available to you as diagrammatically shown in the figure below:

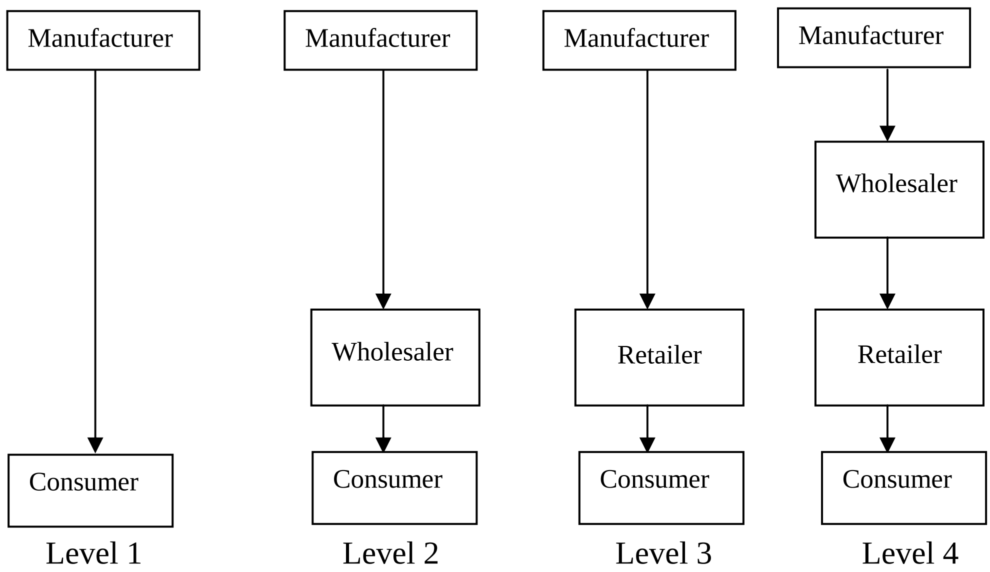

Fig.13.1: Levels of intermediaries

Level 1 represents the direct distribution situation explained earlier in section 13.2; where you choose to sell directly to your customers without using any intermediaries. Levels 2 and 3 represent situations where the manufacturer chooses to sell through wholesalers or retailers directly to a large number of consumers. Level 4 represents multilevel distribution situation where owing to the large market coverage desired, the manufacturer accesses the market through a network of wholesalers who then sell to their respective network of retailers. The retailers then reach out to the final consumers in their respective areas.

13.5 SELECTING AN APPROPRIATE CHANNEL

The channel selection decision is one of the most important decisions that you would be required to take. This is on account of two reasons. One, channel decisions bind you in relatively long term commitments which are usually difficult to undo. Secondly, the costs involved in distribution affect the final price the customers are to pay and therefore, has a bearing on the type of market you will be able to attract at that price. The channel decisions also strongly affect your promotion, pricing and product line extension decisions. These decisions therefore, are taken after a lot of deliberation and consideration .The selection of an appropriate channel design would depend upon:

a) *The market coverage desired:* Your choice of channel design is strongly dependent upon whether you want to operate in the local market only or you desire to operate in regional and national markets as well. As your intended coverage grows, it is difficult and uneconomical to operate only through your own direct channels. Level 3 or level 4 channel systems become more prevalent as the market coverage desired by an entrepreneur grows to regional or national markets.

b) *The resources available at your disposal for production and marketing:* In the initial years, your capacity and resources to produce large quantities of value added products and to market them effectively is rather limited. Direct distribution or shorter channel systems (level 1 or levels 2) to distribute the limited lot sizes being produced by you are more suitable in such circumstances. As the market acceptance grows, entrepreneurs find it more economical to use longer and multilevel channel systems.

c) *The cost of distribution:* In respect of each of the channel systems that you want to use is an important criterion of selection between channel alternatives. As distribution costs form a large percentage of the total cost of goods sold, comparison of different combination of participants in channel systems and the total cost each alternative system should be carried out once you have decided to use intermediaries for the distribution of your value added products.

d) *The type of services that the intermediaries are able to provide to you:* Intermediaries differ in the extent and types of services they are willing to offer to the entrepreneurs. These services range from promotional support to favourable shelf space, refrigeration facilities, cold storage facilities, warehousing, credit support to retailers by wholesalers etc. Depending upon the requirements of your product and marketing effort, you may like to select the channel alternative that best complements your product and marketing needs.

e) *The nature of the product and its shelf life:* Product characteristics often become the starting point in your search for suitable channel alternatives. The nature of the product in terms of its perishability, packaging requirements, shelf life, type of handling required etc are important determinants of what kind of channels or intermediary partners would be most suitable to you . For example, if your value added products are jams or jellies which need to be sold in glass bottles and have a shelf life of about three months, you can afford to be more flexible in your choice of intermediaries but if you are dealing in fruit juices packaged in tetra packs, your choice would be restricted to channel members who can provide refrigeration facilities to ensure that the product to reach the customers in an unspoiled and fresh condition. Similarly, in the cases of products which are equally substitutable by similar competitive products, and have low brand loyalty, entrepreneurs have to resort to intensive distribution to ensure that the consumer does not switch to a competitive product on account of non-availability to their brands.

f) *Buying habits of the customers:* Every marketer needs to study the buying habits of the customers in terms of their shopping preferences, store selection, volume of purchase and frequency of buying. Preferred store choices for food products would be a key input in your choice of the retail level outlets because a new product would get maximum exposure to consumers if it is placed in the outlets frequented by them.

g) *The trade practices followed by your competitors:* When you are in a competitive business like marketing of value added food products, you cannot afford not to be present where your competitor is present in the store outlets, neighbourhood shops, or periodic markets like haats and weekly bazaars. On the other hand, if there are some markets which are overly occupied by a competition, as a new entrant you may find it easier to access other markets where the intensity of competition is lower. In either case, your choice of intermediaries is dictated by the trade practices followed by your competitors.

Typically as new organizations, small firms begin to sell through getting themselves accepted by the existing intermediaries in the local markets; beginning from a limited market access, and by gradually capturing larger markets by diversifying their channel options. You may find that as a new entrepreneur, your problem is often not of selecting appropriate channels but that of being selected by existing intermediaries. Wholesalers and retailers also take the risk when they agree to stock and sell products from unknown new manufacturers especially when the products are eatables like value added food products. You may find that in the initial years you may not have too much of a choice in the selection of your intermediaries. As you get established in the market and your brand starts getting accepted by the consumers, your discretion and flexibility in choosing your own intermediaries will increase.

Motivating the channel members: Once the channel members have been selected and a distribution channel put in place, every manufacturer expects the channel members to provide the best possible support to his products and brands. You would appreciate however that while business from you may be important to the channel intermediary, yours is just one of the brands that he carries. Intermediaries are independent businessmen, engaged in providing distribution support to the manufacturers in lieu of the margins that they can earn from distribution of goods to the final customer. At any given point of time they need to cater to a large number of manufacturers in the same product category, most of them competitors to each other. As an entrepreneur, therefore you would often find that you may need to motivate the channel participants so that there is no laxity in their efforts to push your brands and to create the desired awareness at the point of sale especially when your brand is new. Several approaches are followed by the manufacturers, chief among them being the cooperative approach where the entrepreneur and the channel members get into an agreement whereby the entrepreneur agrees to provide promotional support and assistance, the display materials and equipment if any, commission on extra sales in return for extra efforts by channel members in pushing his products. Use of power, granting of exclusive selling rights, attractive sales promotion schemes directed at the intermediaries, dealer contests etc. are other approaches that used to keep the channel members motivated.

Whether you are conducting your distribution function yourself or following the indirect distribution alternatives through wholesalers and retailers; it is a good idea for you to define the outputs that you want from your distribution network in terms of the service levels that you want to offer to your customers. These outputs could be defined in terms of timeliness of delivery, freshness of stock, information on product and product line, maintenance of complete product line, prevention of stock out conditions etc. Defining these outputs in physical terms will enable you to measure the performance of the distribution effort.

Activity 3

Visit some retail outlets selling value added food products. For the different categories of food products, find out the commission being charged by the retailers from the manufacturers. Also discuss with them to find out the various kinds of support that is being provided by the manufacturer for these products in terms of promotional material, sales display support, sales promotion schemes etc. How in your view the commission given and the support provided affect the selling efforts of the intermediaries?

13.6 PHYSICAL DISTRIBUTION TASKS: DISTRIBUTION ACTIVITIES AND LOGISTICS

The physical movement of finished products from the point of production to the point of consumption and the associated decisions of maintenance and movement of stocks, handling of material and transportation are included in the physical distribution function, is often called the market logistics function. Physical distribution is an important area of decision making for entrepreneurs who are shocked to often find that it can amount to 30 to 40 percent of the total product cost. Poor functioning of physical distribution activities can lead you to lose customers if you fail to supply goods on time, and create situations where your money is tied up in unsold stocks. The various decisions that you will need to take as a manufacturer of value added food products within the Physical distribution function are the following:

- *Order processing decisions:* The order processing system defines the way your order- to- payment cycle is planned i.e. what is the processing system you would like to put in place once an order is received to the stage where payment for the supply of the order is received. This process may include several steps, from receiving in order to filing it, checking it against available inventory, putting a production schedule in operation if it is a large order, order and invoice shipment, information to the customer for and collection of payment. In case you are selling through the intermediaries, your orders would be received from the intermediaries and the payments in turn would be received from them. Computerization of inventory processes and an order tracking system help in cutting down the order- to- payment cycle considerably and help in saving costs as well as improving the efficiency of the system.

- *Warehousing decisions:* You will find that as a manufacturer of value added products, because of the gap between the time of production and the time of consumption you would need to store finished goods until they are sold. Depending upon whether you are selling only in the local markets or in regional or national markets, you will need to decide on the number and location of warehouses or stocking places where finished goods can be stocked till they are ordered and sold. Small entrepreneurs usually hire space in public warehouses rather than building up their own warehouses. While on one hand more stocking locations mean that that the delivery time to customers will be shorter, it also means that the inventory costs and the warehousing costs would be higher. You could alternatively choose to have a single warehousing location centrally and use quicker transportation modes to deliver the shipments to your various customers.

- *Inventory decisions:* Inventory decisions are important because they represent major cost component of the total cost of distribution. Your inventory decisions include decisions on when to stock and how much to stock of each item. The manufacturers would like the distributors or stocking locations to hold enough stocks of all their value added food products so that the customer orders can be promptly fulfilled. If it is, however, found that holding sufficient stocks of all the items in the product line at all locations is not cost effective. Depending upon the different levels of demand for different items of the product line at different locations in the market, economic order quantities and reorder points are worked out so that overall inventory costs can be minimized.

- *Transportation decisions:* Since goods need to be physically transferred from the point of production to the point of consumption or demand, one of the important physical distribution decisions is that of selecting the mode of transport. In trying to transport your value added food products to your warehouses, your dealers or large customers, if you will be faced with a variety of options like trucks, railways, container services, waterways and airways. The criteria used to selection include cost, speed, reliability, availability and possibility of tracking in- transit information, depending upon their own product based needs, requirements of timeliness of delivery and the weightage they wish to assign to the other criteria, entrepreneurs make their transportation mode selections.

13.7 ISSUES IN THE PHYSICAL DISTRIBUTION PROCESS

There are certain issues that you may need to consider, while taking your physical distribution decisions. Some of the important issues are discussed below:

- The physical distribution objective is often defined as making the goods available in all the places that they are desired in the least possible time at the lowest possible cost. While this looks good on paper, it is something almost impossible to achieve. If you want to make goods available in all possible places where they are needed, and do so in the least possible time you would find that the cost of fast distribution is indeed and not the lowest cost. You will, therefore, have to choose the type of speed of delivery that you desire at the costs that you can afford.

- You will find that there is a certain inter-relationship among the various components of the physical distribution process. A faster transportation mode would mean higher costs of transportation but may result in lower inventory costs. Similarly, higher costs of warehousing may result in lower transportation costs but mean higher inventory costs. Trade offs are therefore, available between different components within the physical distribution function .The relevant cost to look for therefore, is the overall physical distribution cost rather than clicking to minimize the cost of individual components of the physical distribution function.

- In addition to the criteria of cost and timeliness of delivery based on the nature of your product, to which in this case is of semi perishable nature, you may also need to consider competitive criteria- what are the speed and delivery parameters that are being used by the other manufacturers in this business. These parameters sometimes define the trade practice in a given trade

13.8 LET US SUM UP

Distribution performs the vital function of linking the manufacturers with their consumers, by making the goods available at the time at which they are needed by the consumers and at the places at which they are needed. As a manufacturer of value added food products, an entrepreneur has the choice of undertaking the various tasks of distribution himself (Direct distribution) or identifying a suitable combination of intermediaries like wholesalers agents for retailers who will undertake the distribution function for this products in return for the trade commission(indirect distribution). The choice of a suitable channel structure depends upon criteria like the nature of the product, cost, competition, the type of market coverage desired etc. The entrepreneur, in addition, has to decide upon the various components of the physical distribution aspects which include order processing, warehousing, inventory decisions and transportation selection. These decisions are important and need to be taken with serious consideration as physical distribution forms a significant proportion of the total cost of distribution. In this unit you have been exposed to the need and scope of the distribution function, the factors affecting choice between direct and indirect distribution, types of intermediaries and their functions as well as the levels of channels. You have also been exposed to the decisions and issues involved sell for Sussman in the physical distribution function.

13.9 KEY WORDS

Direct distribution : The distribution situation where the entrepreneur chooses to undertake all the distributions functions by himself and sell directly to his customers without involving any intermediaries.

Indirect distribution : The distribution situation where the entrepreneur chooses to sell his value added food products through a network of wholesalers, retailers or agents or a combination of one or more of these intermediaries to form a channel of distribution to reach his customers.

Channel of distribution : A combination of institutions which perform all the activities needed to move a product and its ownership from the point of production to the point of consumption.

Wholesaler : The intermediary who buys from the manufacturer in bulk for the purpose of reselling to the retailers.

Retailer : The intermediary who buys from the wholesalers or directly from the manufacturer for the purpose of selling directly to the consumers.

Physical distribution : The function involved with physical movement of finished goods from the point of production to the point of consumption.

13.10 SELF ASSESSMENT QUESTIONS

1. For the list of products given below, suggest whether direct or indirect distribution channels would be appropriate. Give reasons for your answer.

   a) Fresh fruit juice
   b) Packaged or tinned fruit juice
   c) Jams, jellies or marmalade
   d) Vegetables preserves

e) Pickles
f) Packaged ready to eat vegetables
g) Soup powders

2. As an entrepreneur you have developed a line of fruit based products to suit the health requirements of the present generation. These include a complete range of fruit juices, preserves, jams and jellies without artificial sweeteners or extra sugar. As chemical preservatives have not been used the products have a relatively short shelf life. What are the criteria that you would apply to select appropriate channels for your product line?

3. What are the important decisions within the physical distribution function that an entrepreneur dealing in value added food products will need to take? Explain with the help of suitable examples

UNIT 14 UNDERSTANDING AND MANAGING PROMOTION

Structure

14.0 OBJECTIVES

After studying this unit, you should be able to:

- discuss the role of promotion in effective marketing of value added products;
- describe the components of the promotion mix;
- decide upon the components that you should use in your promotion effort;
- set up your promotion budgets;
- develop appropriate advertising for your products;
- identify suitable media for your advertising; and
- evaluate your promotion effort.

14.1 INTRODUCTION

Once you have identified what you intend to produce, you also would need to inform the potential customer about the existence and availability of your product, interest them in your product through information about the features of the product, and give them a reason to buy. The entire function of informing the potential and existing market about your offerings, encouraging them to buy your products is referred to as promotion. Promotion is one of the most important elements in the marketing mix. It encompasses all the means of communication with the customers. In accordance with your target market, you need to decide who should inform about the product and what should you tell them. Also, how should you reach these people who may be your potential customers. Promotion is important because it contributes to the consumers' knowledge about the various products available in the market and makes it easier for them to make informed decisions. Promotion is also important because it establishes your product image and brand in the mind of the customer and facilitates the process of remembering and recalling the brand name at the time of decision making. Promotion enables consumers to understand the differences between different product offers and allows you to create an identity distinct from your competitors. For the consumers, it helps them to understand how one brand is different from others, so that they can choose something which most ideally suits their requirements.

14.2 WHAT IS PROMOTION AND HOW ADVERTISING WORKS?

All the processes used by the manufacturers to influence the customer in favour of their products by various means of communication are collectively termed as promotion. Essentially, all products are solutions to the needs of the consumers. At any given time, however, there are several alternative solutions that the customers may have for a given need. The different brands of value added products represent the alternative solutions that the customers may like to choose from. As a marketer, you would need to tell the potential benefits of your product over other competing products. The promotional efforts undertaken by the small entrepreneur can take the form of advertising, publicity, sales promotion or personal selling or a combination of two or more of these. Together these functions constitute the promotion mix for an organisation. Let us try to understand how promotion works.

1. *Creating awareness:* The primary task of promotion or advertising is to create awareness of the product in question for the purpose of increasing the likelihood of purchase of value added products being contemplated by your potential customers. For a new product the marketer's challenge is to create the recognition of the brand name, with simple messages and building recognition of the name over time.

2. *Build knowledge:* Not only is it important for consumer to know your product name, but it is also required that they know what are the features of the product. For example, that it is a quality product with natural ingredients and with no chemical preservatives. Only on the basis of what they know about the product, your consumers will be able to distinguish it from the other products on offer, and decide whether the product would suit their requirements.

3. *Creating liking:* It is the job of the marketer to find out what their potential consumers like in products like jam, marmalade, pickles or juices, incorporate them in the products and then highlight the same in the promotion.

4. *Building preference:* Due to their exposure to your promotion some of the consumers may like the product, but still not prefer it to others. The promotional process, by highlighting features like quality, freshness, taste purity and standardisation of process, attempts to develop a preference for the advertised or promoted product.

5. *Creating conviction:* Through reinforcing the product superiority and making sure the product fulfils the promise created through

communication, promotion also seeks to build up conviction among the target audience over a period of time. You must therefore ensure that the promotion undertaken by you is believable and credible.

6. *Promoting purchase:* Finally, by giving consumers a reason to buy now, or buy a larger quantity or undertake a product trial, either by giving an introductory offer by a promotional discount or a quantity discount promotion aims at influencing purchase of the product.

The above model of how promotion works is called the hierarchy of efforts model. According to another, popular model the AIDA model, promotion works by attracting attention, creating interest, initiating desire and finally buying action.

Activity 1

Make a list of 3 popular brands of juices and fruit preserves. Taking the list with you, ask at least 10 consumers how they first came to know about each brand. Try to learn what they know about the brands, even if they are not using the brand Study this information. What does the information tell you about the role of promotion?

…………………………………………………………………………………...

14.3 COMPONENTS OF THE PROMOTION MIX

In your daily life you are exposed to a variety of promotional efforts by organisations television commercials and print ads, billboards on the road, employment announcements in the paper, 'sale' and discount offers, promotional fliers in your letter box or your e-mail and sales persons knocking at your door are all examples of the promotional efforts being made by the marketers to inform, create awareness, build up preferences and ultimately promote the purchase of their products. To understand different forms of promotion, so that you can utilize them effectively for your own promotional activity, let us define the various components of the promotion mix. As noted earlier, the promotion mix consists of four components i.e. advertising, personal selling, sales promotion and publicity. Each is explained below:

Advertising: It is any paid form of non-personal, mass presentation and promotion of ideas, goods, services by a known sponsor. Advertising may be through any media like newspapers, magazines, posters, bill boards, handbills, television and radio commercials, cinema commercials, direct mailers and e-mail based mailers, catalogues and message on buses, trams, trains etc. Depending upon your budget and the type of audience you want to reach, you may select any combination of forms of the media described above. One basic purpose of advertising is to increase the possibility of purchase and this is sought to be accomplished by imparting information, developing brand awareness and belief, developing favourable attitudes and to influence buying action. You as the marketer would like to inform your potential customers of the availability, prices and the benefits associated with your product so that this information facilitates their selection between various brands. In addition to this basic purpose, you may also use advertising for

a) to announce a special promotion scheme
b) to counteract moves made by your competitors
c) to build up motivation of the retailers to sell your product
d) to encourage and build up the morale of your sales team
e) to build up the image of your company.

Personal selling: In contrast to non-personal mass promotion (i.e. advertising), personal selling is person to person communication between the potential buyer and the seller. It is the oral presentation or oral presentation supported by other media like reports or audio visual slides to one or more potential buyers for the purpose of making a sale. Personal selling as a mode is more flexible than advertising because the salesman can mould his method of presentation and persuasion according to the needs of the customers that he is facing at a given time. In addition to persuading people to buy, personal selling can be used to perform the following functions:

a) Booking orders
b) Generating inquires about the product
c) Answering consumers queries about the use and attributes of the product
d) Price negotiation
e) Collection of payment
f) Collecting market information about customers, competitors and dealers.

Because personal selling uses personal contact as a mode of communication, this is also one of the most expensive methods of promotion specially for low unit value products.

Sales promotion: All marketing activities, other than personal selling, advertising and publicity that are used to stimulate consumer buying and dealer motivation such as incentives, sales displays, shows and exhibitions, coupons, contests, discounts, free sample offers and gift schemes and other non-routine selling activities are included in sales promotion. The purpose of sales promotion is to stimulate the sale of a product by offering some specific incentives which may be directed either at the consumers or the traders. You may also create incentives directed at your own salesmen, stimulating them to sell higher quantities of the product. Generally sales promotion offers give customers a reason to buy now, as the offers are open for a limited period of time. They perform the function of creating an immediate interest and inducing trial of the product. The marketer hopes that once the consumer has tried the product, he will stay with the product since the product is good. There are several types of sales promotion tools. The tools directed at the customer include:

a) Price discounts for a specific period or for a certain package size.
b) Free samples or Subsidised samples.

c) Pack in premium – which is a free gift along with the pack.
d) Quantity offer which allows people to buy extra quantity at no extra cost.
e) Coupons which allow consumers a saving on next purchase or a cash refund.
f) Contests which encourage consumers to enter contest and benefit through games or schemes.

Marketers also use sales promotion directed at their wholesalers and retailers to encourage them to stock sufficient quantities of the product and put in special efforts to sell the product. These sales promotion tools include quantity discounts, display materials, allowances for local advertising, dealer contests and gifts etc.

Publicity: Publicity is defined as non-personal stimulation of demand for a product, service business by generating commercially significant news about it in published media or getting favourable presentation on public media like radio or television. This form of promotion is not by an identified sponsor and is also not paid for by the sponsor.

Today, other elements of the marketing mix are also used as promotional tools. Packaging is an important tool of promotion which can, through distinctive colouring and designing become a special aid in brand recognition and identification. Information on the package and label can play a useful role in creating consumer awareness and knowledge. Attractive package design can stimulate consumer interest. Reusable packages like glass jars and pet bottles add to utility value of the product and add another incentive to purchase.

Public relation, the function of maintaining good relations with general public, customers, press and society at large can contribute to the promotional activity by establishing a favourable image of your organisation.

All these elements together constitute the promotion mix for an organisation. You would need to decide which element or combination of elements you would like to use for your own products, keeping in mind the costs to be incurred, the need for creating awareness and interest and the specific objectives you want to attain through the promotional effort. In the next section, we would discuss the considerations you must keep in mind for deciding on your promotion mix.

Activity 2

Take the example of a few value added products like

a) Branded masala blends (Chat masala, Chana masala etc.)
b) Squashes
c) Fruit juice concentrate

Go through the various media like radio, television and newspapers and identify the types of promotion that is being used for each of these categories. Prepare a brief note on the same, why do you think these elements have been included in the promotion mix?

14.4 DECIDING UPON THE PROMOTION MIX

While attempting activity 2, you would have noted that marketers seldom use only a single element in their promotional efforts. They usually utilize a combination of four elements, depending upon their marketing objectives and resources. If you consider a sample product like Maggie, Noodles, you will find that a combination of television and print advertising, displays in shops, danglers and bill boards, gift schemes and quantity discounts is being used to promote the product. Several considerations affect the type of promotion tools that would be required for a particular product. Let us look at these considerations:

1. *Product considerations:* The type of promotion task to be formed is strongly influenced by the type of product involved. For a low priced, repetitively purchased item like toothpaste or food products, the promotional message would need to be repeated frequently so that consumers are reminded. It would need to reach a large number of consumers so that new consumers can be attracted to the product. As large number of potential customers have to be addressed, person to person methods like personal selling would be unsuitable. You would require elements like advertising and sales promotion to address your promotion needs, newspapers, handbills, posters, free samples radio spots and if you can afford audio visual ads are sources of the alternative you may consider.

2. *Market consideration:* The choice of elements in your promotion mix will also depend upon where your customers are located, are they very widely dispersed, how many target customers do you want to reach, is your target area local, regional or national? How many competitors are already operating in the market place and what are the ways they have chosen to communicate with the consumers? When the target consumer groups are both poor and distributed over a vast geographical area, advertising and sales promotion are more economical and cost effective; as the cost of reach per customer is low. You will find that while personal selling plays a more central role in cultivating customer for industrial goods and even for consumer durable goods, for non-durable low price per unit consumer goods like value added food products, the role of personal selling often gets limited to servicing the wholesalers and retailers.

3. *Resources available:* As an entrepreneur, you would need to set aside resources for promotion. The money you decide to allocate for promotion constitutes your promotional budget. Each of the alternatives studied by you, has its own cost. The extent to which you want to use each element, and the number of elements you want to use at a given point of time, depend upon the size of promotion budget that you have decided for the effect. You will realise that initially your relatively modest budget may allow you only to have localized advertising in the vernacular press, distribution of handbills and displays at the retailer shops. As you grow and develop and are able to assign higher budgets, your choice of elements and the extent to which you want to use them widens.

Product life cycle consideration: All products go through a life cycle of introduction, growth, maturity, saturation and decline. The duration of the stages and the time taken to attain the next stage varies widely with the type of market and the type of marketing strategies applied by the marketers. At each stage, the role of promotion differs. At the introductory and early group promotion has the role of informing the potential customers, creating maximum awareness and building up an interest in the product. The promoting task would require lots of publicity, consumer sales promotion through samples and introductory discounts, informative and creative advertising and promotion directed at the trade. During the late growth and maturity stage, informative advertising is not required, your advertising would be targeted at sustaining consumer preference and building brand loyalty. Looking at your marketing objectives framed, development, growth, stabilisation and survival at different points in the life cycle of your product, you will need to vary the composition of your promotion mix.

Activity 3

Select 5 value added products one each in the product life cycle stages described above. Carefully study the promotional efforts used by them and identify what are the tools used at each stage? Can you reason why this variation exists?

14.5 SETTING THE ADVERTISING OBJECTIVES

A large number of users of advertising feel that the ultimate objective of advertising is to sell. Advertising seeks to do this though persuasive communication, creating awareness building familiarity and brand recognition and informing consumers from time to time about the comparative advantages of your product over other competing products. Advertising thus has both communication and sales objectives. At any given point of time you may choose to assign more than one communication and sales objectives to your advertising activity. However, for focused effort and effectiveness; it is advisable to define objectives as measurable goals. This is referred to as the DAGMAR approach (defining advertising goals for measured advertising results). The approach suggests that advertising goals should be defined as specific and well defined communication tasks, in measurable terms, which should be stated to be achieved within a specific time period, with respect to a particular set of customers. For your own potential customers, for example, advertising goals could be defined as "to create awareness levels of my brand of Jams and Jellies from the present 0% levels to about 20% among 50% of the target customers in the city of Nagpur and Aurangabad within the next 3 months".

You would appreciate and that when you are about to start your business, the main objective of advertising would be informing your target customers about your products and their features. At the initial stages of the business advertising is designed to create a business and knowledge of your range of products among potential customers. Advertising is essentially a persuasive communication and another objective that is used in the initial stages is to build up the liking, preference and belief in the product and its characteristic in order to motivate customers to initiate purchase. At the later stages when there are several competitors for your products, the objective of advertising would be to compare your product favourably with those of the competitors and getting the customers to learn how to differentiate between your product and the competitors' product. This is known as comparative advertising and the focus is to show the comparison, the advantages of the advertised product over its closest competitors.

Once the product has been accepted in the market, advertising is used to remind people again and again (Reminder advertising) so that the product may remain in the memory of consumers and promote repeat purchases. At subsequent stages in the product life cycle when your objective is to retain the customer your advertising should take the form of reinforcement advertising, and because your goal is to convince the customer that he has indeed made the wise choice by selecting your product.

Your selection of the advertising goals should clearly reflect a clear understanding of your current market situation. If you are in a competitive market and are introducing a new product, the advertising aim would obviously be to create market awareness and give your customer a reason to buy. If you find that the product is getting established but the usage is low then your advertising objectives should be directed at increasing usage.

Your promotional activity is an investment in establishing you in the market by getting you to become known and bringing in the required sales. In order to maximize this investment however you need to be very clear about what exactly you want your advertising to do for you. This clarity will help you in directing your advertising investment towards yielding the most profitable results.

To summarize the objective of the promotion exercise for popularizing your value added products could be the following:

- To inform the market and build awareness of your products.
- To create brand knowledge and help the consumers to differentiate your products.
- To reinforce the positive attitude about your products.
- To motivate consumers to take buying action.
- To build up interest among the dealers and retailers to carry your product.
- To build the image and recall of your product.

14.6 DECIDING UPON THE PROMOTIONAL BUDGET

How does a small business decide how much to spend on promotion? As you have just noted, advertising and promotion are your investments in establishing you in the market. You must set a promotional budget based on your own resources and the objectives of the promotional activity that you have decided for yourself. Some of the methods of deciding promotional budgets used by small businesses include the following:

The affordable method: Small businessmen using this method base their budget on whatever they can afford at a given point of time. While this method is simple, it ignores the reality that when you plan to set up a business to make and market value added products. Your resources are often limited and basing a decision on what you can afford can often leave you with very meagre resources for promotion; whereas your requirements for spending on promotion may be very high because you are new to the market.

Competitive parity method: Some people try to take what their competitors are spending for their own promotion and make this a basis for deciding on their promotional budgets.

Objective and task method: This method allows you to estimate the size of your promotional budget by looking at the tasks and objectives that you have kept for your promotional activity. This method has the advantage that it allows you to adapt your promotion budget according to the tasks that you have assigned to your promotional activity at any given point of time. This is among the most rational methods of arriving at your promotional budget.

Fixed sum per unit method: Under this method the promotional budget is determined by the allocation of fixed rupee amount per unit of product, depending upon the expectation of future sales of the product. This method is also easy to calculate but is arbitrary because it does not take into account the variations needed under given competitive or market circumstances.

Percentage of sales method: In the case of an ongoing business activity, promotional budgets are often decided on the basis of a fixed percentage of sales that you may like to set aside for promotional activity. For example, if you are selling vegetable soup concentrate and your targeted sale for the year is Rs. 2 Lacs, you may decide to spend 5% of your sales for your promotional activities which will give you a budget of Rs. ten thousand. This method also has the advantage of being simple. If you are selling a number of value added products, this five percent may be used as a general guideline for arriving at the promotional budgets for different products, or your overall sales figures may be used as the basis of the total promotional budget for your entire product line. This budgeting method has the advantage of being simple to calculate and easy to administer, but it ignores the market realities and specific requirements that a particular product may have, which may require a different kind of budget than suggested by a standard percentage of sales.

Activity 4

Assume that you are planning to enter the market with a product line of fresh fruit juices and tinned fruit slices. While the fresh fruit juices have a very competitive market, the fruit slices are a relatively new product and there are no major producers in the market. Looking at the methods that you have just studied, how will you decide upon your promotional budget? Identify the method you use and suggest why?

………………………………………………………………………………...

………………………………………………………………………………...

………………………………………………………………………………...

………………………………………………………………………………...

………………………………………………………………………………...

14.7 SELECTING APPROPRIATE ADVERTISING MESSAGE

The primary purpose of advertising is to help sell your products. Any promotional activity which does not bring the customer nearer to the act of buying is a waste of money. Through your promotion, you should be able to offer a distinctive and attractive proposition by which you can attract your customers to pay attention to what you are saying and ultimately to buy your product. This proposition is called the unique selling proposition (USP) in advertising language. It represents a specific proposition which is distinctive and gives unique information about the attributes of your product which can pull the customers to the advertised product. In the case of value added products, the USP could relate to:

- The freshness of the product.
- The non-use of chemical preservatives.
- The purity of ingredients used.
- The unique flavours developed by you.
- The tamper-proof packaging being offered.
- The unique taste offered by you.
- The pricing advantage offered to the customers.
- Or anything about the product which gives you a uniqueness or a distinctive advantage over your competitors.

In addition, the message in the promotion should be presented in a way that it is able to attract the potential customers to go through the message and help them remember the features of the product. Use of simple language, interesting headlines and attractive visuals showing the product, go a long way in creating effective messages.

14.8 SELECTING SUITABLE MEDIA

There are a variety of media options available for you to take your message across to your targeted customers. Newspapers, radio, television and billboards are some of the most common media used while selecting your media, you should have a clear idea of the media habits of your potential customers – Do they watch Television or listen to the radio and which papers do they read, (most of the literate)? The other factors you would need to consider include the cost of the medium, the reach of the medium, availability of the medium and suitability to your message design. For value added food products, you may like to consider the following media, described below along with their chief characteristics:

Press (including all types of newspaper and magazines): Wide circulation, limited life, is good for mass circulation and reminder messages. You could initially choose local newspapers to cut down on your initial costs and later expand to more regional or national press.

Door to door distribution of pamphlets: Controllable circulation, limited life, and inexpensive and flexible usage are good for mass circulation. These pamphlets can be manually distributed or inserted along with newspapers, with a commission paid to the distribution agents of newspapers.

Direct mail: Restricted circulation, flexible usage and high impact, need prior identification of potential customers. This medium is used by sending promotional letters to identified customers, and is usually applied for high value added customized products.

Outdoor media: Localized circulation is relatively durable and inexpensive and good value reminder as media. Outdoor media include holdings, billboards, posters, neon signs, display cards on buses etc. and wall writings.

Radio: It has wide reach , accessibility across literacy barriers, high flexibility and possibility of quick reminders within no possibility of visual demonstration. On account of its wide reach, radio gives among the lowest cost per listener and is a popular medium among small and new entrepreneurs.

Television: Combines the advantages of both audio and video but expensive medium with limited reach and high degree of viewer involvement. It is very suitable for product demonstration.

Cinema: Reach is limited to the cinema going population not all of whom maybe your potential customers. It reaches literate, neo literate, and illiterate audience.

Miscellaneous media: Media like exhibitions, fairs, haats and weekly bazaars offer good opportunities for promoting low unit value products like value added fruit and vegetable products.

For promoting your value added food products, you can select one or a combination of some of the above media on the basis of their effectiveness in reaching your promotion messages to your target audience. Due to the cost constraints, some of the expensive media like television or national dailies maybe unaffordable at the initial stages of the business. In fact, if in the initial stages you are catering primarily to the local markets, more localized media like outdoor media, pamphlets, local bazaars and radio may be more suitable as your media choices to begin with.

14.9 COORDINATING WITH THE ADVERTISING AGENCY

As you would have realized, most of the promotional activity is a specialized one. It is therefore, advisable to engage an advertising agency to design and release your advertisements and organise other promotion as per your requirements. An advertising agency is an independent business organization comprising creative and business people to design, develop, prepare and place advertisements in media for their clients seeking to find customers for their products. Copy writing for ads, buying media space, planning media schedules, conducting marketing research to know the consumers better, public relations etc are all highly specialized activities, and are better left to specialized functionaries in the agency itself.

In order to get the best work out of the agency; you need to work closely with the agency. It is a good practice to get your requirements and ideas regarding your product and the way you want them to be promoted, across very clearly during the first meeting with the agency. At the initial stage you may have to set aside a lot of time and information to help the agency to have a complete understanding of your business, your marketing targets and the precise way in which you want your products to be presented to the customers. Usually the work of a specific client is entrusted to a given executive called the account manager for, who handles all the activities related to that account. It helps if close communication can be setup with this account manager so that your coordination with the agency can be easy and effective.

14.10 ROLE OF PUBLICITY IN PROMOTION

As noted earlier in the beginning of this unit, publicity is the non-personal stimulation of demand for a product or business unit by placing commercially significant news about it in a published medium or by obtaining a favourable presentation on it on radio, television or stage, which is not paid for by the sponsor of the promotion.

Publicity is essentially aimed at building up a favourable image, creating goodwill and getting a positive visibility which helps the business in its marketing efforts. Publicity is specially useful in creating a favourable information dissemination about new products, special features introduced, special R&D efforts made in value addition, promotion of new trademarks and brand images.

Publicity is also used to counter any misinformation misgiving or negative information in the market about a particular product or a brand or the business. As publicity is not paid for, and is seen to emanate from a neutral and impartial source, it can be an extremely powerful tool and should be used carefully for maximum impact.

Activity 5

Identify, by reading newspapers or magazines some publicity releases about value added food products. Explain how the printed material which has come out as an article on news item would help the product in question.

……………………………………………………………………………………...

……………………………………………………………………………………...

……………………………………………………………………………………...

……………………………………………………………………………………...

……………………………………………………………………………………...

……………………………………………………………………………………...

……………………………………………………………………………………...

14.11 ROLE OF PERSONAL SELLING

While advertising and publicity are impersonal methods of mass communication, personal selling uses face to face personal communication with target customers. As a manufacturer of value added food products, you may need to personally convince large dealers and big retailers to carry your product line. The scope of the personal selling activity for consumer goods includes obtaining periodic orders, ensuring timely supplies, helping dealers with desired style of display and building up a personal network of dealer relationships over time. If you decide to use personal selling as part of your promotional activity, you could often find that while it is costly in terms of time & effort, it helps to get valuable feedback and market information about your customers and competitors. You are also able to monitor the movement of your goods and assess the relative performance of the various products in your product line.

In order to perform the PERSONAL selling function well, you need to

- know your own product extremely well, specially in terms of how it is better or different from the competitor's product;
- know your competing products well;
- know the trade practices regarding margins to be paid and credit to be allowed to the distributors and retailers;
- listen carefully to what your customers need;
- collect information about what is the consumption pattern shown by your distributors;
- address your customers with due courtesy and regard;

- highlight the advantages of your product compared with your competitor's products;
- be persuasive and make persistent efforts to get the orders; and
- always highlight your unique selling proposition, if any.

14.12 ROLE OF SALES PROMOTION

As explained in the initial part of this unit, sales promotion refers to all promotional activities which are designed to stimulate the features of a product by offering some kind of incentives. The incentives may be directed at the target customers or the dealers. Sales promotion is usually of a short duration and the schemes announced have a fixed time within which they will be operational. By using sales promotion, you not only provide the customer a reason to buy, but also a reason to buy now or buy a far larger quantity than he or she would otherwise have bought. You may, as the producer of value added food products, need to some times offer incentives to move your products fast into the market. Let us identify some of the sales promotion methods that can be used by you. The sales promotion methods directed at the consumers include the following:

- *Price off schemes:* These offer a price discount for a specific period. You may use the scheme as an inaugural discount or as a discount on large purchases.
- *Samples:* Samples involve free distribution or subsidized distribution of small quantities of your products to your potential customers to let them have an idea of what the product is like. Samples enable customers to taste the product and check the quality by themselves.
- *Pack in premium:* Such schemes involve the offer of a free article along with the product for example, a free teaspoon or a bowl along with a jar of fruit preserve.
- *Quantity off:* These schemes offer extra quantity at no extra cost.
- *Coupons:* Coupons entitle the buyer to a stated saving on the purchase or the future purchase of the product.
- *Cash refund offers:* These offers are also like coupons except that in this case the refund in cash form is made after the purchase
- *Contests and games:* Such schemes invite the customers to participate in a contest or a game and some are given prizes through a lucky draw or some other objective method. Such contests get very popular among children and are an excellent device to popularize a new product or gain wide awareness among consumers.

Sales promotion schemes may also be directed at your dealers or sales persons. Buying allowances, free goods, display material, and sales contests are some of the common trade promotions used by small businessmen and entrepreneurs.

Activity 6

Make a quick survey of recent newspaper advertisements or TV advertisements to identify some of the sales promotion schemes that are used for food products. In your view, what are that types of schemes that are most common in the case of such products? What do you think is the impact of such schemes on potential customers?

…………………………………………………………………………………...

…………………………………………………………………………………...

…………………………………………………………………………………...

…………………………………………………………………………………...

…………………………………………………………………………………...

14.13 EVALUATING THE EFFECTIVENESS OF YOUR PROMOTIONAL EFFORT

As a manufacturer of value added products, who has put in effort and resources towards promoting his products, you may like to find out whether your promotional effort has been effective or not. One of the most common indicators that people try to use is the increase in sales, but you would agree that there is always a time lag between advertising effort and sales results. Let us understand how can you evaluate whether your promotion has been effective?

While discussing the objectives of promotion in the beginning of this unit, it was pointed out that promotion could have two types of objectives, the communication objectives and the sales related objectives. Under the same section the DAGMAR approach to promotion objectives was also explained. Your task of measuring the effectiveness of your promotion would be strongly dependent upon the precise objectives that you defined for the promotional activity. You can therefore, measure the effectiveness of promotion by

- Measuring the communication effectiveness of promotion.
- Measuring the sales effect of promotion.
- Measuring the relative impact of different media used by you.

The communication effectiveness of promotion is measured by testing the awareness levels of your target customers about your product before and after the promotion campaign, or recall and recognition levels of your brand, based on the objectives defined by you.

Sales are a result of both promotion as well as other elements of your marketing effort. It is therefore, usually difficult to isolate the effect of only the promotional inputs. The fact that there is a time lag between the effort made and the resulting sales, makes the situation even more complicated. The sales effect of advertising is measured by the regression analysis over time. However, sales effect of specific schemes used is easier to calculate. For example, if you have used direct mail as your promotion method, the sales orders received as a response would let you judge the effectiveness of your promotion in terms of sales effect. Again, if you have used coupons as a sales promotion method, the number of coupons received by you becomes a direct measure of the sales resulting on account of the coupons

Manufactures also use different levels of promotional effort or different kinds of appeals in different market territories to compare and measure the sales effect of these efforts.

14.14 LET US SUM UP

In this unit, an effort has been made to introduce to you the basic components of the promotion mix that can be used by you to promote the sales of your product in the market and establish your market identity among your customers. The role of each of these components has been discussed. The important decisions in your promotional activity, right from deciding upon the promotion mix and setting up the promotion budgets to evaluating the effectiveness of your promotion have been discussed at length. The unit also tries to give you an idea of the different media that can be used for low units value items like food products.

14.15 SELF ASSESSMENT QUESTIONS

1. What is the significance of promotion in the effective marketing of value added food products? Explain with the help of suitable examples.

2. How do advertising and promotion work? What is the kind of effect that these may have on consumers of your products?

3. What do you understand by the term promotion mix? What are the components of the promotion mix?

4. What are the factors that help you decide upon the design of your promotion mix? Assume that you are a manufacturer of several types of sauces and spice blends. While spice blends from other manufacturers are also available, your sauces are unique and innovative. They are targeted at the high end market. Explain the factors you would consider while selecting your promotion mix. Also specify what type of components would you use in your promotion and why?

5. How would you decide your promotion Objectives? Discuss with reference to the product you want to promote in the market place.

6. What are the media options available to producers of value added food products who want to promote their products?

   a) On our nation-wide basis?
   b) In the local markets?
   c) In the export market?

   Explain with reference to specific product examples chosen by you.

7. How can the effectiveness of promotion be evaluated? Explain with the help of suitable examples.

UNIT 15 PERFORMANCE MEASUREMENT AND CONTROL

Structure

15.0 OBJECTIVES

After studying this unit, you should be able to:

- understand the relationship between planning and controlling;
- comprehend the meaning and need for measuring performance;
- get a clear view of the performance measures;
- understand the concept of controlling and its procedure;
- know about the procedure of controlling; and
- have an insight into the important tools and techniques of controlling.

15.1 INTRODUCTION

A businessman has always to look ahead in terms of production, sales, expenses, profitability, customers, etc. In the process of looking forward and assessing his future he should be mindful of various activities happening in his firm. He should occasionally, stop and review his previous activities to see whether his business is running on the right track as he desired or not. Planning is important but review of measurement of performance and its control is also equally important. Both of them are in fact complementary and supplementary to one another. Controlling is effective only when there is proper planning, and planning is fruitful only when there is effective control. The inter-dependency of planning and control can be shown through the following diagram.

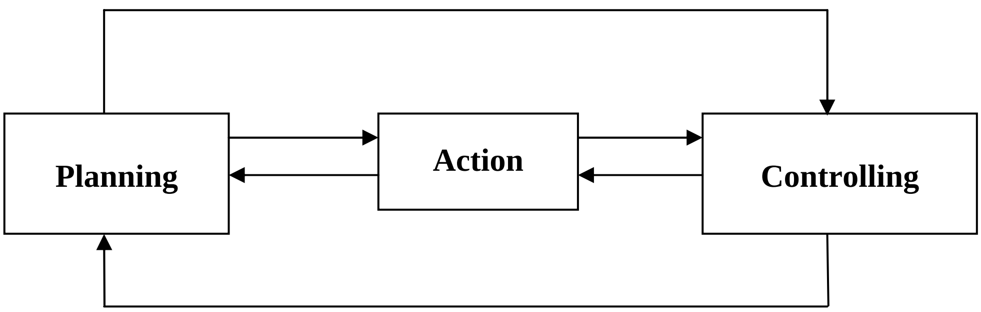

Figure 15.1: Diagram showing inter-dependency of planning and control

Performance Measurement

In this Unit you will learn the importance of performance measurement and control.

Meaning

Performance measurement is a management function. It helps in detecting, preventing or eliminating distortions in the process or product. The aim is to match the product to the customer's requirements. Performance measurement makes the organization capable of taking sound decisions about the action to be taken to ensure appropriate processes and products.

Need for Measuring Performance

If an activity cannot be measured, its effect cannot be seen and suitable correctives cannot be applied. The activity cannot then be controlled and managed.

What are performance measures

A performance measure is composed of a 'number' and a 'unit of measure'. The number gives us a magnitude (how much) and the unit gives the number a meaning (what). Performance measures are always tied to a goal (the target). These can be represented by hours, meters, number of reports, units of product manufactured etc. They can show the variation from the standards set.

Two types of unit of measures are used:

i) single-dimensional unit of measure;
ii) multi-dimensional units of measure.

In case of single dimensional units, performance measures can be represented by units like hours, meters, rupees, number of reports, etc. They can show the variation in a process. Single-dimensional units of measure usually represent basic measures of some process or product.

In case of multidimensional units of measure, performance measures are expressed as ratios of two or more basic units. These may be units like number of bottles of jam produced per month, number of hours worked to produce a packet of papads, etc. Performance measures expressed this way convey more information than the single-dimensional or single-unit performance measures.

Foundation for a Performance Measurement System

Successful performance measurement systems are based on the following principles:

1. A businessman should focus on customer needs and based on that measure what is needed to be measured.

2. A businessman should measure only that which is important and will affect customers' satisfaction.

3. A businessman should involve employees/workers in the design and implementation of the measurement system. He should give them a sense of purposeful control, which will lead to improvement in the quality of the measurement system.

Benefits of Performance Measurement

1. *To ensure that the decisions are based on facts*

   The businessman can ensure that his decisions are based upon well-documented facts and figures and not on intuition and gut feelings.

2. *To show the areas of improvements*

   Performance measurement can show the areas where improvements need to be made. The businessman can come to know where he can do better or how he can improve.

3. *To reveal the clear picture of improvements*

   Based on measurement of performance the businessman can have a clear picture whether the improvements have actually occurred or not.

4. *To reveal incorrect assumptions*

   If the businessman has been doing his business for a long time, he might have been assuming incorrectly that things are going well, whereas in actuality that may not be the case. Thus, without measurements there is no way to tell whether the business cannot do better.

Performance Measures

Performance measures are generally expressed in terms of quantity. They provide useful information to the businessman so that he may make intelligent decisions about his business. They tell him something important quantitatively about the processes with the help of which products are manufactured. In a nutshell, performance measures tell him:

- how well he is doing;
- if he is meeting his goals;
- if his customers are satisfied;
- if his processes are well in control;
- if and where improvements are necessary.

Features of an ideal unit of measure

Following are the features of an ideal unit of measure:

1. It should be understandable.
2. It should reflect the needs of the business.
3. It should reflect the customer's needs.
4. It should be capable of wide application.
5. It should be interpreted uniformly.
6. It should be precise in interpreting the results.
7. It should be economical to apply i.e. its should be cost effective.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Fill in the blanks:

   a) Performance measure can be used for exercising ____________.

   b) A performance measure is composed of a number and a ___________.

   c) 'Hours' is an example of ______________________ dimensional unit of measurement.

   d) Performance measures are generally expressed in __________________.

   e) A performance measure should reflect the needs of the ______________ and the business.

2. State True or False:

   a) A businessman should measure only important activities of the firm.

   b) A businessman should involve the employees in the formulation of measurement system.

   c) An ideal unit of measurement should be expensive to apply.

   d) Single-dimensional unit of measure conveys more information than multi-dimensional unit of measure.

   e) Measurement of performance does not provide a clear picture whether the improvement has actually taken place or not.

3. Name any two performance measures.

   ………………………………………………………………………………………

   ………………………………………………………………………………………

15.2 MEANING AND FEATURES OF CONTROLLING

Let's go down the memory lane. Think of those days when you were in Class XII studying for your first terminal examination. You decided to secure 75% marks in aggregate and started studying accordingly. When you received your Report Card you were shocked because you could manage to get only 60% instead. After certain hue and cry you must have sat down and thought that where you went wrong –

- Whether your scheduling was incorrect; or
- Whether your syllabus was too heavy; or
- Whether you got nervous right at time of examination; or
- Whether you had not revised the lessons thoroughly.

Lastly, you must have made fresh plans to do better at the next terminal examination by making a proper timetable, by revising the lessons thoroughly and by streamlining your study pattern.

In the above process you have unknowingly applied the controlling procedure.

Controlling Defined

Controlling is nothing else but to set standards, measure the performance, compare the performance with the standards set and take corrective measures if deviations are found. In other words controlling is comparing operating results with the plans and taking corrective action when result deviates from the plan. Thus, controlling is an 'action oriented' process.

Control process can be illustrated with the help of an example of automatic iron, which is fitted with thermostat. As soon as the iron is switched on the bulb lights up – it means that the current is passing in the iron. The current goes on passing as long as the temperature does not reach the level at which the thermostat is set. Immediately after the temperature reaches that level, the thermostat starts functioning and the current is disconnected, thereby causing the bulb to go off. When the temperature becomes low than the level set, the thermostat allows again the current to pass and the bulb lights up. Here, the thermostat is acting like a controlling device, which compares the actual performance with the standard set. It starts functioning and disconnects the electric current when the actual deviates from the standard.

Features of Controlling

- It is the last function of management process, the first function being planning.
- It is a dynamic process, adapting itself to the changes in the environment.
- It is a continuing process.
- It is pervasive in nature i.e. it is found at all the levels of management.
- It is backward looking because it involves feedback and responses. It is linked with – what has happened in the past.

Check Your Progress Exercise 2

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Why is controlling referred to as 'backward looking'.

…………………………………………………………………………………
…………………………………………………………………………………
…………………………………………………………………………………
…………………………………………………………………………………

2. Mention two features of controlling.

…………………………………………………………………………………
…………………………………………………………………………………
…………………………………………………………………………………

3. If controlling is said to be the last function of management process then which one is the first function?

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

………………………………………………………………………………

15.3 PROCEDURE OF CONTROLLING

Let's now discuss the control process. It embraces the following steps:

i) Fixing standards

Standards serve as a test of performance. It is a criterion against which results are measured. Standards can be expressed in physical terms and monetary terms. If we say that the firm is required to manufacture 1000 packets of tomato puree in a week, this is expressing standards in physical terms. In case the standard set is to increase the sales by Rs. 10,00,000 by the end of the current financial year, this is expressing standards in monetary terms.

The standards should be easily understandable, result-oriented and attainable. They should be scientifically set with the help of time and motion studies. Workers should also be consulted in order to involve them in achieving the standards set.

In general, good performance standards should have the following attributes:

- *Understandable:* Standards should be expressed in simple and clear terms, so as to avoid misinterpretation or vagueness. Similarly, instructions for their use should be specific and complete.
- *Attainable:* Standards should be such that they can be attained with reasonable efforts under the given conditions.
- *Economical:* Cost of setting and administering the standards should be low in relation to the activity covered and the benefit to be derived.
- *Applicable:* Standards should be such that they can fit the conditions under which they are to be used. If conditions vary, they should contain built-in flexibility to meet these variables.
- *Consistent:* Standards should help to unify communication and operations throughout all functions of the company.
- *Stable:* Standards should have a fairly long life to provide comparability.
- *Adaptable:* Standards should be designed in such a way that elements can be added, changed, and brought up-to-date without much complexity.

- *Equitable:* Standards should be accepted as a fair basis for comparison by the people who have been assigned the responsibility of meeting the goals.

- *Customer-focus:* Standards should address areas, which are important to the customer (internal/external) such as cycle time, quality, cost schedule performance, and customer satisfaction.

ii) Measurement of performance

Performance can be measured through inspection, observation, measurement and reporting. Uniform reports should be prepared at regular intervals. Performance measurement should be an ongoing process. It is easier to measure the standards if they are tangible in nature. For example, Rahul & Co. sets the standard to reduce the advertisement expenses by Rs. 50,000 in the next six months. This standard being tangible can be easily measured with the actual performance by looking at the figures of actual advertisement expenses. But, in cases where standards are not tangible like result expected from a training programme for salesmen, measurement of results becomes complicated.

iii) Comparison with actual performance

The actual performance should be measured with the standard set. If deviations are found exceptionally wide then only should be concentrated upon. It helps in conserving time and effort of the businessman. For long-run standards (like increase in return on investment) annual comparison may not at all be appropriate. But in case of short-run standards (like to maintain a minimum cash balance of Rs. 1000) comparison can be on daily basis. For certain short-run standards comparison can be on weekly or monthly basis e.g. to reduce the selling and distribution expenses by 2% within a period of 4 months.

iv) Finding the cause of deviation

A very wide range of deviation is analysed at this stage. It is done so to find out the various reasons of its occurring. This analysis should be promptly done to make control effective.

v) Taking corrective actions

Remedial action is to be taken so that deviations may not occur again and objectives are properly achieved. Corrective action may involve:

- *Let the situation remain as it is:* This is applicable if the deviation is insignificant i.e. within tolerable limits (which should be set in advance).

- *Correct the deviation:* This can be done by improving the performance e.g. defective tools to be repaired, generators to be installed, close supervision, incentives to be provided, appointing more salesmen, good training provided etc.

- *Revision of standards:* The standards may need to be revised if they are not effective for required control.

Check Your Progress Exercise 3

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Write any two examples of standards which can be easily measured and compared.

……………………………………………………………………………………

……………………………………………………………………………………

2. What will be the consequence if the standards fixed are on higher side?

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

3. Why the reporting should be quick?

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

15.4 TOOLS AND TECHNIQUES OF CONTROLLING

1. Ratio Analysis

Ratio analysis is a study of relationship among various financial factors in a business like sales, gross profit, net profit, stock, debtors, fixed assets etc. It is a technique of analysing the financial statements by computation of ratios. Ratio analysis acts as an important and effective control device in an organization. It is the process of establishing a significant relationship between the items of financial statements to provide a meaningful understanding of the performance and financial position of a firm. Ratio analysis focuses attention on relative figures which should be significantly related. For example, figure of sales when related to the figure of gross profit will indicate gross margin earned on sales. This means both the figures in the ratio are significantly related. Ratio analysis seeks to measure the effectiveness and profitability of the various functions.

Controlling process starts when the accounting ratios are compared with their own past ratios or with the ratios of similar firms in the same industry. For example, a Fruit Jelly manufacturer measures that his gross profit ratio for current year is 18% whereas in the immediate past year it was 22%. Thus, on comparing the gross profit ratio he finds the deviation. Now he has to take remedial action to improve the ratio.

Some of the important ratios used in controlling the affairs of a business are:

i) Return on Investments (ROI)
ii) Net profit to Sales (Net Profit Ratio)
iii) Sales to Capital employed (Capital Turnover Ratio)
iv) Gross profit to Sales (Gross Profit Ratio)
v) Sales to Working Capital Ratio (Working Capital Turnover Ratio)
vi) Stock Turnover Ratio
vii) Operating Ratio
viii) Current Ratio
ix) Debtors' Turnover Ratio

Let's now discuss these ratios.

i) Return on Investments (ROI)

This ratio shows the relationship between net profit (before interest and tax) and capital employed. It indicates how efficiently the capital employed in the business has been used. In other words it shows the firm's ability to generate profit per rupee of capital employed. It is a measure of overall profitability of an enterprise. Higher the ratio the better it is.

Formula: $\text{Return on Investments (ROI)} = \frac{\text{Net profit (before interest and tax)}}{\text{Capital employed}} \times 100$

where Capital employed = Fixed assets + Working capital

For example, a company manufacturing various bakery items has earned a net profit (before interest and tax) of Rs. 4,00,000 during the current financial year. The company has Rs. 16,00,000 as capital employed. The ROI works out to 25%. In the same industry ROI is 20%. This means the company has used its capital efficiently.

ii) Net Profit to Sales (Net profit ratio)

This ratio shows the relationship between net profit and net sales. It measures the rate of net profit on net sales. It helps in ascertaining the efficiency with which the affairs of the firm are being managed particularly its marketing. In case the ratio increases, it indicates improvement whereas if it declines, it reveals inefficiency in the management of the affairs of the firm.

Formula: $\text{Net Profit Ratio} = \text{Net Profit/Net Sales} * 100 = \frac{\text{Net profit}}{\text{Net sales}} \times 100$

For example, the net profit of a firm is Rs. 1,00,000 and the net sales is Rs. 4,00,000. In this case, the Net Profit Ratio is 25% as calculated below:

$$\text{Net Profit Ratio} = 1{,}00{,}000 / 4{,}00{,}000 * 100 = 25\% = \frac{1{,}00{,}000}{4{,}00{,}000} \times 100 = 25\%$$

In the corresponding next year, if the Net Profit Ratio works out to 30% it will show efficiency in the management of the affairs of the firm.

iii) *Sales to Capital Employed (Capital Turnover Ratio)*

This ratio shows the relationship between net sales and capital employed. It indicates the firm's ability to generate sales per rupee of capital employed. Higher the ratio the better it is.

Formula: $\text{Capital Turnover Ratio} = \dfrac{\text{Net sales}}{\text{Capital employed}}$

where Capital employed = Fixed assets + Working capital

For example, net sales of a company is Rs. 8,00,000. The company has Rs. 2,00,000 as capital employed. The Sales to Capital employed (Capital Turnover Ratio) works out to 4 times. i.e.

$$\frac{8{,}00{,}000}{2{,}00{,}000} = 4$$

iv) *Gross Profit to Sales (Gross Profit Ratio)*

This ratio shows the relationship between gross profit and net sales. It indicates the gross margin earned on sales.

Formula: $\text{Gross Profit Ratio (GP Ratio)} = \dfrac{\text{Gross profit}}{\text{Net sales}} \times 100$

For example, a spices manufacturing unit earns a gross profit of Rs. 5,00,000 during the current financial year. Its net sales (i.e. gross sales – sales returns) are Rs. 25,00,000. In this case the GP ratio works out to 20%. Higher the ratio the better it is.

v) *Sales to Working Capital Ratio (Working Capital Turnover Ratio)*

This ratio shows the relationship between net sales and the working capital. It indicates the efficiency with which the firm has utilised its working capital. In other words it signifies the ability of the firm to generate sales per rupee of working capital. Higher the ratio the better it is.

Formula: $\text{Working Capital Turnover Ratio} = \dfrac{\text{Net sales}}{\text{Working capital}} \times 100$

where Working capital = Current assets – Current liabilities

For example, a grocery dealer's sales during the current financial year are Rs. 18,00,000. His working capital is Rs. 6,00,000. In this case Sales to Working Capital Ratio (Working Capital Turnover Ratio) works out to 3 times.

vi) *Stock Turnover Ratio*

This ratio shows the relationship between cost of goods sold and the average stock. It indicates the efficiency with which the firm has utilised its stock. In other words it signifies the speed with which stock is converted into sales. Higher the ratio the better it is.

Formula: $\text{Stock Turnover Ratio} = \dfrac{\text{Cost of goods sold}}{\text{Average stock}}$

where (i) Cost of goods sold = Opening Stock + Purchases + Direct Expenses – Closing Stock and (ii) Average Stock = (Opening Stock + Closing Stock) / 2.

For example a mango juice manufacturer's cost of goods sold during the current financial year amounted to Rs. 10,00,000. His average stock during this period was Rs. 2,00,000. In this case Stock Turnover Ratio works out to 5 times.

vii) Operating Ratio

This ratio measures the relationship between operating cost and net sales. It indicates the operational efficiency with which the production or purchases or selling operations are carried on. Lower the ratio the better it is.

Formula: $\text{Operating ratio} = \dfrac{\text{Operating cost}}{\text{Net sales}} \times 100$

where (i) Operating Cost = Cost of goods sold + other operating expenses like administrative expenses, selling and distribution expenses etc.

For example a tomato puree manufacturer's cost of goods sold during the current financial year amounted to Rs 10,00,000 and other operating expenses were Rs. 75,000. His sales during this period were Rs. 25,00,000 whereas sales returns were Rs. 50,000. In this case the operating ratio works out to 43.88% as calculated below:

Operating Ratio = 10,75,000/24,50,000*100 = 43.88%.

viii) Current Ratio

This ratio measures the relationship between current assets and current liabilities. It indicates the ability of the firm to meet its short term obligations. In other words it shows short term financial solvency of the firm. Ideal current ratio is 2:1.

Formula: $\text{Current Ratio} = \dfrac{\text{Current assets}}{\text{Current liabilities}}$

where (i) Current assets = Cash and bank balance, marketable securities, debtors, bills receivables, stock, prepaid expenses etc. and (ii) Current liabilities = creditors, bills payable, bank overdraft, short term loans etc.

For example a ginger and garlic paste manufacturer's current assets as on 31st March 2004 were Rs. 6,00,000 and current liabilities were Rs. 3,00,000. In this case the current ratio works out to 2:1.

ix) Debtors' Turnover Ratio

This ratio measures the relationship between net credit sales and average debtors. It indicates the ability of the firm to collect its trade debtors. In other words it shows the speed with which the debtors are collected. A high ratio indicates shorter collection period i.e. debtors are repaying promptly.

Formula: $\text{Debtors' Turnover Ratio} = \dfrac{\text{Net credit sales}}{\text{Average debtors}}$

Where Average Debtors = Opening Debtors (including opening bills receivable) + Closing Debtors (including closing bills receivable) / 2.

For example a 'sarson' oil manufacturer's net credit sales for the year 2004 were Rs. 90,00,000 and average debtors were Rs. 15,00,000. In this case the Debtors' Turnover Ratio works out to 6 times.

2. Cost Analysis and Control

This analysis is associated with various costs of the firm. Cost control is important because all the businessmen – whether operating on a small scale or large scale – always try to contain their all types of costs. For a successful analysis, the businessman should himself have a very clear idea of all the costs. He should also have an effective system to measure and analyse them systematically. Various costs may include – cost of production; cost of credit sales; selling and distribution costs; inventory costs; channel costs; marketing research costs; advertising costs; sales promotion costs etc.

These costs should be measured against the results produced by incurring them. The results may take the form of sales revenue generated, gross profit achieved etc. The efficiency of each product, channel, customer-class, and salesmen should be analysed by measuring their respective contribution to profit of the firm on the one hand and to the overheads on the other.

Cost analysis should also include standard costing for various management functions. It is not enough that costs should be compared with the budgeted costs only. The firm should develop standard costs for each function of market and measure actual cost with the standards set.

Cost analysis helps the businessman in the following ways:

- It helps to control and reduce all types of costs.
- Cost reduction leads to savings.
- It leads to alternate ways of performing functions to reduce the costs.
- Prices can be kept at competitive rates if costs are reduced.
- The businessman can drop unprofitable customers, products, dealers etc. from the list.

3. Credit Control System

A businessman generally prefers to sell his goods on cash basis. It is because of the following reasons:

- No risk of bad debts.
- Less working capital required because of continuous cash generation.
- Short operating cycle.

Despite above advantages of selling goods on cash basis, the businessman may still be forced to sell goods on credit basis on instalment basis to achieve higher turnover. There may be number of problems attached to the selling of goods on credit or instalment basis like:

- Interest on money involved.
- Money blocked for longer period of time.
- Legal hassles i.e. court cases if money is not realized.
- Loss due to insolvency of debtors.
- More accounting work involved.

Despite these problems a businessman sells his goods on credit or instalment basis because he has to survive in the market, and higher turnover may offset losses and such sales.

In case he sells his goods on credit basis, he should frame a clear credit policy. The businessman should also have a proper credit control system on the following lines:

i) Credit should be extended to the customers and dealers after a proper credit rating is made. A credit rating analysis would reveal the soundness of the customers and dealers. No-risk customers may be extended large credit limits. High-risk customers could be given credit only if bank guarantee or collateral security is made available.

ii) The businessman should also adhere to the prescribed credit limits.

iii) As a part of credit control system he should analyse the accounts receivables and bad debts. The number, type, extent and integrity of the debtors or the reason for a debt to become bad must be brought out by the analysis. The age of debtors outstanding should be determined (i.e. 15 days old debts, 30 days old debts, 45 days old debts, 180 days old debts, 365 days old debts etc.) from time to time and based on this analysis corrective action should be taken.

iv) A proper credit control system will ensure that the cost of credit is built to the price itself.

v) Strategies like offering cash rebates in lieu of credit can be thought of. Cash discounts may be offered for quick recoveries.

4. Budgetary Control

A budget is a plan for some specific future period. It is based on objective to be attained. It is expressed in monetary or physical units. A budgetary control is a system in which all operations are forecast and planned and the actual results are compared with the forecast and the planned ones for reviewing policy are programme for the balance period or for next period.

Budgetary control can be applied to every function of the business i.e. production, finance, human resources, marketing etc. It corrects the deviations from pre-planned path through observation, research, reporting, planning and decision making. The future activities of the business can thus, be performed in an orderly way.

The procedure of budgetary control involves the following steps:

i) Establishing the budgets.

ii) Continuous comparison of actuals with budgets by preparing control statements which will show:

- Budgeted figures
- Achieved figures
- Variances

iii) Placing the responsibility for failure to achieve the budgeted figures.

iv) Revision of budgets.

Advantages of budgetary control.

Following are the advantages of budgetary control:

i) It helps in bringing efficiency and economy in the working of the business enterprise.

ii) It fixes responsibility on every division or department of the enterprise.

iii) It coordinates the various divisions of a business i.e. production, marketing etc.

iv) It serves as an automatic check on the decisions of the management.

v) Credit agencies favour that organisation which operates through a well-ordered budget plan.

5. Break-even Analysis

Break-even analysis is yet another controlling device which can be used by a businessman. It is an important tool of profit planning. It is also called cost-volume-profit (CVP) analysis. It facilitates cost control by measuring operational efficiency. At break-even point the businessman neither makes profit nor incurs losses. For calculating break-even point we need to understand the following concepts:

i) Fixed costs (FC): Fixed costs are those costs which remain constant whether there is increase or decrease in production over a given period of time. These costs are fixed in nature and are incurred as soon as the business is started. This concept of fixed costs remains valid up to a particular level of operation.

Examples of fixed costs are – rent of the premises, salaries of the employees, depreciation, interest charges on long term debts, insurance premium, property tax etc. Even if there is no production, these fixed costs will be incurred. Suppose, a jam manufacturer incurs Rs. 40,000 towards fixed costs for manufacturing jam bottles. In this case fixed costs are Rs. 40,000 which shall be considered for calculating break-even point.

ii) Variable costs (VC): Variable costs are those costs which vary according to the level of production attained. They will increase if the production is increased even by one unit or decrease when there is decrease in production.

Such costs are – raw material costs, wages to the workers, water charges, oil and fuel etc.

For calculating break-even point, generally we consider variable cost per unit of production. Suppose variable cost incurred for manufacturing 1000 jam bottles is Rs. 55,000. In this case per unit variable cost works out to Rs. 55.

Note: For the purpose of calculating total cost of production we have to add fixed cost and variable cost. Thus,

Total Cost = Fixed cost (FC) + Variable cost (VC)

iii) *Selling price:* Selling price is that price at which the goods are sold. Usually, we consider selling price per unit for calculating break-even point. For example, a jam bottle is priced at Rs. 75. It means that it will be sold to the consumers at this price. Thus Rs. 75 is the selling price per unit of the product.

iv) *Contribution margin:* Contribution margin is the difference between selling price per unit and the variable cost per unit. In other words:

Contribution Margin = Selling Price per unit – Variable cost per unit

Considering the figures given above contribution margin is Rs. 20 (i.e. Rs. 75 - Rs.55)

It may be noted that for calculating contribution margin, fixed cost is not considered.

After understanding the above concepts, we can move on to calculate break-even point (BEP) with the help of following formula:

$$\text{BEP (in units)} = \frac{\text{Fixed costs}}{\text{Contribution margin per unit}}$$

BEP (in units) = 40,000/20 = 2,000 units

BEP (in value) = 2,000 units * Selling price per unit i.e. Rs.75 = Rs. 1,50,000.

At the level of 2,000 units the manufacturer does not incur any loss nor earn any profit. This is verified as below:

Selling price of 2,000 units = 2,000*Rs.75 = Rs. 1,50,000

Variable cost of 2,000 units = 2,000*Rs.55 = Rs. 1,10,000

Fixed cost = Rs. 40,000

Total cost = (VC+FC) = Rs. 1,10,000 + Rs. 40,000 = Rs. 1,50,000.

The manufacturer does not earn or lose anything by selling 2,000 jam bottles because at this level both sales revenue (i.e. Rs. 1,50,000) and total cost (i.e. Rs. 1,50,000) are the same. Beyond this level he will start earning profit and below this level he will incur losses.

From controlling point of view the manufacturer has to understand whether he can operate above the level of break-even point. If he can do so in a shorter span, it is better for him. He must understand that the lower BEP denotes lesser risk.

6. Internal Audit

Internal audit is another effective tool of managerial control. It involves appraisal of operations i.e. weighing actual results in the light of planned results. It is a regular appraisal which is done by trained staff of internal auditors of the accounting, financial and other operations of a business.

It is concerned with long term business interest. It aims at evaluating the entire system of an organisation. It can be said to be a continuous, systematic and bias free study of total efficiency of the firm. It tries to measure and evaluate the effectiveness of all other control devices employed by the firm.

Internal audit is advantageous for the departmental managers as well. They get proper advice from the internal auditors on policies and plans of the firm. The auditors also suggest solutions to managerial problems.

The limiting factors for internal audit are two-fold – first, the business firm should be able to afford an internal audit and secondly, specialized persons should be available who can do a broad type of internal audit.

For making the internal audit successful, full support of subordinates is also required.

Check Your Progress Exercise 4

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Does ratio analysis technique have an edge over Budgetary Control methods of appraising the performance of an enterprise? If so in what respects?

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

2. Below is the performance measurement of Firm A and Firm B in terms of Gross Profit and Sales. You are required to make a comparison and state which of the firms has performed better.

	Firm A	**Firm B**
Gross profit (Rs.)	50,000	1,28,000
Sales (Rs.)	5,00,000	6,00,000

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

3. Based on the following figures you are required to ascertain whether the performance of Firm A is improving or not:

	Year 1	Year II
NP ratio	12.21%	10.32%

…………………………………………………………………………………

…………………………………………………………………………………

…………………………………………………………………………………

4. Which technique aims at a total evaluation of the entire system of an organisation?

…………………………………………………………………………………

…………………………………………………………………………………

…………………………………………………………………………………

5. Give one word for the following.

   a) Certain costs which remain constant over a period of time.

      a) ……………………………………………………………………

   b) Costs which vary according to the level of production.

      b) ……………………………………………………………………

   c) A specialized person who evaluates various controlling techniques adopted by a firm.

      c) ……………………………………………………………………

   d) A monetary or physical plan meant for a specific future period.

      d) ……………………………………………………………………

   e) An effective controlling tool which establishes relationship between items of financial statement.

      a) ……………………………………………………………………

15.5 LET US SUM UP

Measurement of performance and its control is quite important because substantial benefits are realized by organizations which implement performance measurement programmes. Being a function of management, performance measurement makes the organization capable of taking sound decisions. Performance measures are generally expressed in terms of quantity. A performance measure is composed of a 'number' and a 'unit of measurement'. Single-dimensional and multi-dimensional are two types of units of which are generally used. An ideal unit of measurement should reflect needs of the customer and business; should be understandable, capable of being applied over a wide area and interpreted uniformly. Performance measurement is associated with controlling. Controlling is nothing else but to set standards, measure the performance, compare the performance with the standards set and take corrective measures if deviations are found. Some of the important tools and techniques of control are ratio analysis, cost analysis and control, credit control system, budgetary control, break-even analysis and internal audit.

15.6 KEY WORDS

Quality : The degree to which a product or service meets customer's requirements and expectations.

Control : The set of activities employed to detect and correct variation in order to restore a desired state of conformance with quality goals.

Remedial action : Measures taken to rectify conditions adverse to quality.

Unit of measurement : A quality feature that permits evaluation of that feature in numbers.

15.7 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. a) control
   b) unit of measure
   c) single
   d) quantity
   e) customer

2. a) False
   b) True
   c) False
   d) False
   e) False

3. i) Hours ii) Metres

Check Your Progress Exercise 2

1. It is based on feedback.

2. i) It is the last function of management.
   ii) It is a continuing process.

3. To plan the objectives of the firm.

Check Your Progress Exercise 3

1. **Hint:** i) Reduction in advertisement expenses by Rs. 50,000 in next 6 months.

   ii) Increasing the production by 5,000 units in next one month.

2. Standards will not be met leading to wastage of time, money and efforts as well as de-motivation for the concerned person.
3. To take remedial action quickly.

Check Your Progress Exercise 4

1. **Hint:** Ratio analysis focuses attention on relative figures which are actual. These figures are significantly related. Ratios help in judging solvency, profitability and liquidity of an organization. However, in case of Budgetary Control methods the budgets are prepared bases on estimated figures (future estimates) which are not actuals. Based on budgets solvency, profitability and liquidity of an organization can not be judged.
2. Firm B's performance is better because its GP ratio is high.
3. Firm A has not improved.
4. Internal audit
5. a) Fixed costs
   b) Variable costs
   c) Internal auditor
   d) Budget
   e) Ratio analysis

15.8 SOME USEFUL BOOKS

1. Bhushan, Y.K. (2001) Fundamentals of Business Organisation and Management, Ed., Sultan Chand and Sons, New Delhi.
2. Chandra, Prasanna — Projects-Planning, Analysis, Selection, Implementation & Review, 1996 Reprint, Tata McGraw Hill Publishing Company Limited, New Delhi.
3. Gupta, R.L. & Gupta, V.K. (2001)Principles & Practice of Accountancy, Ed., Sultan Chand & Sons, New Delhi.
4. Koontz, Harold and Cyril O'Donnell — Principles of Management: An analysis of Managerial Functions – McGraw-Hill Inc.
5. Maheshwari, S.N. and Mittal, S.N. (2001-02) Cost Accounting, Theory and Problems, Ed., Shree Mahavir Book Depot (Publishers), Delhi.
6. Ramaswamy, V.S. and Namakumari, S. (1998) Marketing Management (Planning, Implementation and Control-The Indian Context), Reprint, Macmillan India Limited, Delhi.
7. Varshney, R.L. and Gupta, S.L. (2000) Marketing Management (An Indian Perspective), Ed., Sultan Chand and Sons, New Delhi.

15.9 ASSIGNMENTS

1. Why should a businessman measure his performance?
2. 'Planning and controlling are inter-dependent.' Justify.

3. What is control?

4. Explain the procedure of control.

5. Name the accounting ratios which can be calculated using the following financial factors as the basis:

   i) Turnover and average debtors
   ii) Turnover and net profit

6. Explain briefly any four benefits of measuring performance.

7. A businessman wants to apply budgetary control in his firm. He has already established the budgets for the current financial year. What according to you should he do next?

8. Why should a businessman analyse his costs?

9. What are performance measures? Explain its types briefly with examples.

10. Explain the features of controlling.

11. The following data relates to Evergreen Products Ltd.

Particulars	**March 31, 2003**	**March 31, 2004**
Sales	20,00,000	26,00,000
Cost of Goods Sold	15,00,000	21,20,000

The manager claims that he has worked more efficiently during 2004 because the sales and gross profit have increased and should get reward for his efficiency. The management of the company has sought your advice on the Manager's claim. Please advise.

(**Hint:** Calculate GP ratio)

12. What is internal audit?

13. Write the meaning and the formula of the following:

   i) Net Profit Ratio
   ii) Debtors' Turnover Ratio.

14. The following table gives actual and standard ratios for the year 2004-05 in case of Ganga Masale Di Hatti. Examine these ratios and suggest remedial action which the businessman should take.

Particulars	**Actual ratio**	**Standard ratio**
Current assets / current liabilities	6	2
Cash/current liabilities	5	1
Debtors/sales	9	12

(**Hint:** 1. The funds are lying idle and they can be invested.
2. Short term planning of funds should be improved by investing idle funds in income-yielding investments.
3. It indicates that the debtors are collected promptly.)

UNIT 16 MANAGING GROWTH

Structure

16.0 OBJECTIVES

After studying this unit, you should be able to:

- know about the growth of a business;
- understand the need of growth for a business;
- identify various measures of growth;
- comprehend the type of growth strategies used by business firms;
- understand the various stages of growth; and
- know the challenges faced by a businessman during the various stages of growth.

16.1 INTRODUCTION

What is Growth? What does this term mean? Haven't all of us grown from small children to adults? In fact, we find 'growth' all around us. Does not the small rose bud in our backyard grows and blooms into a beautiful flower? Does not a small mango sapling grow into a big mango tree? Does not a small kitten grow into a lovely cat? So, we find that growth is everywhere around us – whether it is a bud plant, an animal or a human being. In their growth process, human beings pass through the stages of infancy, childhood, adulthood and old age. Thus, in each and every case whether it is the question of survival of human beings or of a business, growth is a must. In the following Unit we will discuss the various aspects of growth of a business firm.

16.2 MEANING OF GROWTH AND ITS MEASURES

Meaning of Growth

The growth of a businessman is quite similar to that of a human being. It is a positive phenomenon. It is gradual. A businessman grows from the very initial stage – the day he starts the business and struggles hard to survive in the market – but slowly and gradually he finds himself in a stable and comfortable position. There are a large number of business firms, cottage industries etc.

which started in a small way and now have been transformed into big organisations, e.g. MDH, Amul Co-operatives, etc.

Measures of Growth

There are various parameters through which a businessman can come to know whether his business is growing or not. Some of the important measures of growth are as follows:

1. An increase in total net worth of the firm i.e. capital + reserves.
2. An increase in the size of total business of the firm.
3. An increase in the total number of employees.
4. An increase in the volume of output.
5. An increase in the monthly or yearly sales of the firm.

For better understanding, let's read the following Table 16.1:

Table 16.1: Growth in business

Particulars	**First year**	**Second year**
Revenue (Rs.)	1,00,000	5,00,000

Looking at the table it is clear that the sales revenue has increased by Rs. 4,00,000 in the second year i.e. the businessman has attained growth in his business.

16.3 NEED FOR GROWTH

A business man is motivated to grow for more than one reason. The various factors which drive him to grow are discussed in the following paragraphs.

1. *Forces of competition*

   A businessman needs to grow if he wants to survive in the market. Acute competition usually forces a businessman to grow in order to maintain his existence. In other words, a businessman has to be creative or he should innovate new things so that he is able to retain his present position.

2. *Economies of bulk*

   A businessman can avail certain benefits if he increases his volume of production. Large scale production provides several economies not only in the field of production but also in the areas of marketing, finance, management etc. Such economies of scale may include strong bargaining power, lower overheads, availability of finance at lower rates etc. The per unit cost of operation gets lowered due to the above mentioned economies.

3. *Better returns*

   The motive of the businessman to obtain more and more profits leads him to grow. He ensures growth of his organisation through continuous ploughing back part of profits instead of distribution of entire earnings .The size of the business thus gets expanded.

4. *Modern technology*

Business firms try to expand the size of the business in order to take advantage of modern or latest technology. Only large firms can take full advantage of hi- tech machines.

5. *Goodwill*

At times business firms prefer to expand in order to command power and respect. People take pride in owning business of large size. Business firms grow to achieve reputation. With reputation and size, power is not far behind. Big companies, no doubt, have more economic and social power compared to small business units.

6. *Personal factors*

Personal factors comprise individual organizational abilities, ambition etc. These factors also drive businessmen towards growth of their business firms. Certain businessmen may be highly ambitious or they may be endowed with special organizational skills. They may want to be independent too in respect of, say, marketing of raw materials or finished products.

7. *Trade cycles*

Trade cycles also influence the decision of growth of a business firm. During a period of boom businessman generally reaps high profits due to high production and high sales. The problem arises when at the time of depression economic activities come to the lowest level. The demand for the products goes down and so do the prices and profits. At this point of time when the businessmen are faced with the problem of closing down the business, they think of joining with other firms. They combine their businesses and grow.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Mention any two economies of scale which a businessman may avail in the process of expansion.

………………………………………………………………………………….

………………………………………………………………………………….

2. Name two measures of growth.

………………………………………………………………………………….

………………………………………………………………………………….

3. Name the need of growth in the following cases:

i) Mr. Khanna wants to make use of baking machine which has some added features of speed, volume etc.

i) ……………………………………………………………………….

ii) Mr. Ram Vilas has a desire to own and control a big business house.

ii) ……………………………………………………………………….

16.4 GROWTH STRATEGIES

A strategy is a well- planned course of action designed to achieve a specific objective. A growth strategy is a strategic plan meant to expand the operations of a business firm. A strategy which a firm may adopt will depend upon the fact whether the businessman wants to develop internally or externally.

Following are the main strategies which are usually followed by the businessmen for the growth of their enterprise.

A) **Internal Growth Strategies:** Internal growth strategy can be sub-divided into:

1. Expansion; and
2. Diversification

B) **External Growth Strategies:** External growth strategy can be sub-divided into:

1. Joint ventures; and
2. Mergers.

A) Internal Growth Strategies

Internal growth implies that the business firm expands its business without seeking help from other firms. Involvement of other firms is absent. The business firm grows from within. It is also called aggregative growth strategy.

A case study of Lizzat papad

Seven housewives in a small colony (Shankar Badi Lane, Mumbai) in 1957 sat together and discussed ways to use their spare time in a good and positive manner. They planned to make papads. They had their own doubts and apprehensions. Almost daily they discussed – 'How would we able to make papads?'; 'Who would buy from us?'; 'Would we have to go to each shop to sell the product, etc.?' Since their determination and will-power to venture into a new business was very strong, they persevered and began their business with a very modest amount. Today, as we all know they have a vast network. Their turnover, production, profits, employees, machines, net worth etc. all have increased. This is the story of growth of a business from within. Hundreds of other such organisations have also grown in a similar way.

Another case study of Everest masale

Some 40 years ago, Vadi Lal Shah, founder of "Everest Masale" started his career as a shopkeeper in a two hundred sq. ft. shop by manufacturing milk masala. Slowly and gradually his business started growing as he added some basic spices too. In 1968, he launched three blended spices – Everest Garam Masala, Kesri Milk Masala and Tea Masala. Today there are thirty four blends under the Everest brand name. For example, Pav Bhaji Masala, Subzi Masala, Sambhar Masala, Meat Masala, Chat Masala, etc.

The basic spices list also became longer and longer. It now includes turmeric powder, red chilli powder, coriander powder, black pepper powder etc.

At present, his business has grown to such an extent that approximately 1850 million packets of Everest Masale are sold each year. Within a span of forty years the company has captured a 30% market share in Indian food condiments segment. Its blends are available in over three lakhs outlets across a thousand towns and cities. This is another example of internal growth.

A firm may grow internally through:

i) Expansion
ii) Diversification

Let's discuss these ways of growth one by one.

i) Expansion

A businessman may start looking for opportunities for expansion as his business concern starts moving forward. Expansion is one way of internal growth. A firm may expand by increasing the sales, exploring new markets, developing new products and the like. It may plough back its profits for expansion or it may take loans or advances from financial institutions to increase its production capacity. The business unit will always retain its original character when it expands from within. Expansion may take the following forms:

a) Market Penetration
b) Market Development
c) Product Development

These forms of expansion are discussed below:

a) Market penetration

Under market penetration, a businessman tries to increase the sale of his existing products in the existing market. The businessman may try to increase the sales of his existing products in the same market. In other words, there is no change either in the firm's product or in its market. The entrepreneur generally tries to increase the sales by launching sales-promotion techniques e.g. Brook bond offered a glass bowl free with every 250 grams pack of tea to increase the sales of its product. Market penetration can also be achieved by selling goods at reduced prices.

b) Market development

Market development is different from market penetration. Under market development the businessman tries to explore new markets for existing products. A businessman dealing in rural areas may try to expand by catering to urban markets. A big manufacturer may on the other hand increase his sales by exploring rural areas as well, e.g. ready–to-eat food packs or fast food item being sold in rural areas. The businessman can also develop his market by crossing the boundaries of the country and start exporting the goods to the foreign traders or customers in foreign countries. Market development strategy is usually used by a businessman when existing markets are stagnant or when increase in market share is difficult because of powerful competitors.

c) *Product development*

Product development is yet another strategy adopted by a businessman who has a burning desire to grow and expand his business. Under this method, he plans either to develop a new product or modify the existing product. A product is modified by adding new features or value to it. The point to be noted is that creation of new product or modification of existing product is done for sale in the existing market. Development of new product is usually done to meet the changing needs and wants of the customers, to match new competitive advantage, to get the advantage of new technology etc.

Advantages of expansion

1. The businessman usually does not face any problem of funds as he may be a position to invest his previous years' profits and/or he may also borrow.
2. The businessman still remains at the top of the management ladder as there is no major change in the organisation structure.
3. The businessman may avail of economies of scale.
4. It opens up opportunities for competition.
5. The businessman is in a position to use the existing resources in a better way due to large scale production.

Disadvantages of expansion

1. Growth is slow and gradual. It is not instant.
2. The businessman may have paucity of funds if he does not have enough of his own resources to invest in various assets. In that case if he wants to carry out expansion programme he will have to knock at the doors of financial institutions for availing loans.
3. The businessman may hesitate to expand and increase the volume of output because he may not have that much strength to counter-act the moves of his competitors.
4. There may be limited scope of expansion in the present product market.

ii) Diversification

By now, we all know that growth is natural and gradual. A businessman in order to grow may increase the sale of existing products and may explore new markets for existing products or modify his products. These efforts will lead him to better utilisation of existing resources and more of profits. After some more time, he may reach a point where it is no longer possible to expand in the present product market. A better option for him would be to add new products or markets. This method of growth is known as diversification.

Diversification is nothing but trying new areas and new products i.e. entering new fields of business. For example, a tea manufacturer may diversify by entering sugar industry, or hotel industry.

Advantages of diversification

1. The businessman can utilise his resources in a better way.
2. He can balance the decline of sales in his present product.
3. There can be reduction of risk by developing a balanced portfolio of business.
4. Cash surplus of one business can be used to finance another business.
5. There is an increase in competitiveness of a firm.

B. External Growth Strategies

A business unit can grow by joining hands with another business firm. This is how a businessman grows externally. It is also called as integrative growth strategy.

A firm may grow externally through:

i) Joint Ventures
ii) Mergers

These external growth strategies are detailed below:

i) Joint ventures

Joint venture is another form of partnership between two business units. Here, two or more independent business firms join hands by contributing to total equity capital and by participating in the business operations together. It is usually for a specific purpose. It may also be called as temporary partnership meant for a limited purpose.

Advantages

1. When two business units join hands, it may result in the end of wasteful competition.
2. Reduction in production and marketing costs through more sales.
3. Risk is divided among the co-venturers.
4. Amount of investment is shared by two or more firms.
5. Better utilisation of resources.
6. Better control over market.
7. Economies of scale.

Disadvantages

1. Changes in organisation structure and management.
2. Lack of co-ordination among co-venturers.
3. Large amount of funds may be required.

ii) Mergers

Merger is another type of growth strategy. Integration/Combining of two or more firms into one is known as merger. It may be through take-over of one company by another or by creating a new company by full consolidation of two or more separate companies.

There may be a combining or merging of two or more firms engaged in the same production (e.g. Brooke Bond and Lipton merged together and formed a new company known as "Brooke Bond Lipton India Limited") or there may be a combination where combining units are complementary to each other.

In the process of merger two firms engaged in dissimilar lines may also combine. But this is not common.

Check Your Progress Exercise 2

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Read the following extract given in the box and answer the questions given thereafter:

Hindustan Milk Food Manufacturers Limited was incorporated in 1958 to manufacture health food drinks. In the following decades the company underwent successive rounds of name changes following merger of associating companies. In December 2000, the associate company SmithKline Beecham Pic. merged globally with Glaxo Wellcome and formed Glaxo SmithKline Pic. In 2002, the brand created history by re-launching "Boost" with "power boosters™", a product completely different from any other health food drink. The company is working on products with further value addition, enlarging its presence in rural markets and developing a sizeable export plank.

a) Mention the names of the two companies which have been merged.

………………………………………………………………………….......

………………………………………………………………………….......

b) The name of the merged company is:

………………………………………………………………………….......

c) Name of the product which was re-launched is:

………………………………………………………………………….......

d) Which new market is the company trying to enter?

………………………………………………………………………......

e) Is the company trying to make its presence feel in the international market?

………………………………………………………………………......

f) Name the strategy adopted by the companies to grow.

………………………………………………………………………......

2. State True or False:

a) Expansion can be financed from the firm's own funds.
b) Growth is always fast.
c) Expansion involves additional risk.
d) Market penetration and market development are the same.
e) Development of new product is to meet the needs of the customers.

3. Mention any two advantages of diversification.

………………………………………………………………………......

………………………………………………………………………......

4. Fill in the blanks

a) ………………………. strategy aims at increasing sales of existing products in the current market.

b) ………………………. involves development of new product for existing market for new competitive advantage.

c) The ……………………………. strategy represents an effort to bring existing product into new market.

16.5 STAGES OF GROWTH AND CHALLENGES FACED BY THE ENTRPRENEURS

Every organisation follows some pattern of growth. Some businessmen may experience no growth at all and may have to leave the arena soon. On the other hand there may be a few who experience slow growth while there may be others who feel that their business is expanding at a very fast rate. Usually, at the commencement of the business, the rate of growth is slow. Gradually, as the business gains momentum the rate of growth quickens. The businessman at this time plans to expand the customer base and product line. As time passes, the entrepreneur may face sharp competition which may reduce the rate of growth. Market may become saturated as well. Some entrepreneurs may be forced to think that the period of decline is not far away and they would be ousted if certain revival measures are not taken. The businessmen are faced with new challenges and responsibilities as and when their venture transits from one phase to another.

In the following paragraphs let's now try to understand the different stages of growth and the various challenges which the businessman has to face at every stage.

Various Stages of Growth

Various stages of growth are as under:

1. Inception
2. Growth
3. Maturity
4. Decline

These stages of growth are discussed below:

1. Inception

The first stage starts with the discovery of an idea by the entrepreneur. He i.e. the entrepreneur is also known as the founder or the pioneer as he is the one who takes the lead. Here he is just like a sprinter who plans, trains, develops strategies and gets prepared both physically and mentally to run. Similarly, an entrepreneur does the spade work before starting the business. He may undertake the following kinds of studies during this period:

i) Study regarding the product

- Feasibility of the product.
- Designing of the product.
- Investigation regarding development costs, etc.

ii) Study of the market

- Who will buy the product?
- What can be the price?
- Will there be scope for the long term growth, etc.

iii) Study of finance

- Amount of personal savings.
- Availability of short term and long term loans, mortgage of property etc.
- Amount of seed capital required.

iv) Implementation

- Decide business location.
- Obtain licences from various agencies.
- Purchase machinery.
- Appoint employees.
- Sign agreements etc.

At this stage the sales are at the lowest; profits may or may not be earned; the firm may run out of cash; the rate of growth will be very slow and also it will be inconsistent, competition is uncertain. Usually a businessman offers only a single product at this stage and may cater only to a single market. The product is usually targeted to narrow market niches.

Many businesses come to an end during the stage of inception itself. In other words they do not reach the next stage of expansion at all. Can you think of the reasons? Well, it can be due to 'no planning' or 'wrong planning'; no feasibility plan made; lack of confidence; lack of vision; lack of business qualities; lack of capital; lack of market research, etc.

To avoid such failures, at the stage of inception, he should try to keep the price as low as possible, to cover the bare cost of the product. He should make a proper feasibility plan. He should also be very clear about the purpose of the project. He should try to build selective distribution system and try to build product awareness among early adopters and dealers. The psychological characteristics of the founder will largely determine how the venture will progress through this stage. The founder should have proper business plan. He should not rely on intuitions, he should be optimistic, energetic, and have the vision and foresight to wade through this initial stage which is full of problems and difficulties.

The businessman may also use heavy sales promotion schemes to attract trial.

2. *Growth*

A company can grow at a slow pace or at a very rapid rate. There may be business units which may have great potential for growth but the businessman himself may not be interested in further expansion. For example, a grocery-store owner may have no desire to expand beyond his capacity to own and manage a store personally.

In this stage the business can be transformed from a single-line enterprise operating in a limited market to a multi-line company penetrating new market. At this stage sales have a fast growth, profits are generally at the peak level, the competition is moderate, the product line is widened through innovation and development. Enterprises are enlarged. Due to expansion departments are created and authority delegated. There is decentralization.

To cope with this stage of growth the businessman requires effective leadership and vision. He should make well defined plans and should expand through strategic implementation of the plans. The business must be positioned to achieve long term objectives. He may launch new products or may enter new markets or may do both. He may have to provide better services, offer warranties, adopt penetrating price strategies, build intensive distribution system, and create interest in their product on a mass scale.

As the organisation expands the personal skills of the founder alone may not be sufficient. The organisation needs business related skills, functional expertise, marketing and operational skills etc. These decisions are beyond the scope of one person. Therefore, the personally managed firm may have to take the shape of professionally managed companies. The new activities will include marketing, cash flow management, inventory control, credit management, human resource development, logistics and distribution, management accounting etc. Decisions at this stage have to be based on systematic plans and through competitive evaluation and industry, market and the company. In a nutshell the businessman should be an able planner and he should be able to accept leadership roles which would be quite different from his role as a founder manager.

3. *Maturity*

Rapid growth cannot continue indefinitely. There will come a time when the market may become saturated. Competition is intensified; the businessman would be faced with marginally smaller incremental share of market. This is the period where maturity sets in.

The rate of growth is slowed down, capital becomes scarce, sales growth continues but at a diminished rate, profits start declining, many competitors enter the field. The weaker companies at this stage may fail or may be sold of. The businessman may reduce his product line or retreat from marginally profitable market. There may be a need to reduce the staff to streamline the distribution system and to withdraw from high risk market. The businessman may try to revise his business through innovative products. Re-positioning of product can also be tried. The company can utilise its resources towards research and development programmes.

4. *Decline*

If revival efforts are short-lived or ineffective the last stage i.e. decline sets in. Successful businessmen will not complete the life cycle because they will avoid decline. At this stage of decline, the sales will be very low and so the profits. There will be few new customers and no growth of business. The reasons for this decline can be many. The product of the businessman may have gone obsolete, the management may be inefficient. Ineffective leadership and lack of vision can be yet another reason for this disaster. For small business units, this phase is very difficult to handle due to very limited resources. Re-allocation of limited resources is the need of the hour. The businessman may have to take the help of professional managers who will identify the focal activity on which the future of the unit can be built. The stage of decline can be reversed through discovery of new uses of the product, appearance of new users, introduction of new features in a product etc. Decline may also occur if there is no successor to seen the show. The life of the venture is limited to the working life of its founder businessman. For example, a retail store or a small manufacturing firm may be sold or closed down for want of competent successors.

Check Your Progress Exercise 3

Note: a) Use the space below for your answer.

b) Compare your answers with those given at the end of the unit.

1. Fill in the following table:

Variable/stages of growth	Inception	Growth	Maturity	Decline
Sales	Slow	-----	Slow	------
Product	-----	Multiple product	------	Obsolete product
Market	Single Market	----------	High potential market	----------
Profits	---------	Peak	-------	Low
Competitors	Few	Growing	-------	Declining

2. Choose the odd one out:

i) At the inception stage, the businessman will –

(a) design the product;
(b) investigate development cost;
(c) decide location of the plant;
(d) create various departments.

i) ……………………………………………………………………...

ii) At the growth stage, the businessman will –

(a) penetrate new market;
(b) delegate authority;
(c) obtain licences from various Government agencies;
(d) provide leadership to his employees.

ii) ……………………………………………………………………...

iii) At maturity stage the businessman will –

(a) face paucity of funds;
(b) reduce product line;
(c) encourage research and development programme;
(d) close down his business.

iii) ……………………………………………………………………...

iv) At decline stage the businessman will –

(a) streamline distribution system;
(b) have obsolete product;
(c) will have inefficient management;
(d) will have lack of vision.

iv) ……………………………………………………………………...

3. Match the following:

Stages	Challenges
i) Inception	A. To allocate limited resources.
ii) Growth	B. To reposition product line.
iii) Maturity	C. To plan organizational structure.
iv) Decline	D. To do break-even analysis.

16.6 LET US SUM UP

Growth is universal in nature. It is found everywhere around us. As human beings pass through the stages of infancy, childhood, adulthood and old age, similarly a business firm also passes through various stages of growth. Business growth is a natural and ongoing process. A businessman can judge the growth of his business through various parameters like increase in net worth; increase in total assets; increase in volume of output, etc. A businessman is motivated to grow so that he can survive in the market. He can avail several economies of large scale production like lower overheads, strong bargaining power, etc. He can earn more profits and can make use of modern technology if his business keeps on growing. The growth strategies which the businessman usually follows may be categorized as internal growth strategies and external growth strategies. The former includes expansion and diversification while the latter includes joint ventures and mergers. The business firm usually follows some pattern of growth. Some businessmen may experience no growth at all while others a slow growth. Still there may be others who may experience that their business is expanding at a very fast rate. Various stages of growth of a business firm include inception, growth, maturity and decline. It is not necessary that every business will experience decline stage. Much depends upon the vision and foresight of the persons managing the organisation.

16.7 KEY WORDS

Trade cycles : Business cycles i.e., a period of boom followed by a period of depression.

Seed capital : Amount required for product development, market research, initial operating expenses before sales begins.

Market niches : A carefully defined segment of a broader market.

Cash flow statement : A financial statement that accounts for actual cash received and spent in the course of doing business.

Feasibility plan : An initial written plan comprising all the elements of a good business plan with the objective of determining whether a new venture is expected to succeed.

Innovation : Transformation of creative ideas into useful application by combining resources in new or unusual ways to provide value to society for new or improved products, technique or service.

16.8 ANSWERS TO CHECK YOUR PROGRESS EXERCISES

Check Your Progress Exercise 1

1. i) Strong bargaining power
   ii) Economy in freight

2. i) Increase in net worth of the firm
   ii) Increase in the volume of output

3. i) Modern technology
   ii) Personal factor

16.10 ASSIGNMENTS

1. Mention any two challenges which a businessman may face at the first two stages of growth.

2. Mention the various stages of growth.

3. Why does the businessman try to widen his product line through innovations while expanding?

4. Is decline of a business inevitable? Give two reasons to support your view.

5. What could be the various reasons for closure of a business firm:

   i) at inception stage;
   ii) at decline stage.

6. What is a joint venture? How is it different from mergers?

7. "Growth is slow and steady". Discuss.

8. Mention four advantages of diversification of business.

9. "Market development is different from market penetration". How?

10. A businessman is motivated to grow due to multiple factors. Discuss the various factors.

UNIT 17 INTERNATIONAL MARKETS: SCOPE FOR SMALL ENTERPRISES

Structure

17.0 OBJECTIVES

After studying this unit, you should be able to:

- understand the distinct characteristics associated with international marketing;
- get an insight into the target market;
- identify various business opportunities, offered by the international markets;
- describe the various routes through which international markets may be accessed;
- understand the various export incentives; and
- comprehend export pricing and export documentation.

17.1 INTRODUCTION

When a businessman crosses national boundaries for purchase and /or sale of goods and services, he enters international markets. Purchase of goods from international markets is called 'import' and sale of goods thereto is called 'export'.

All the activities, which take place in the domestic market, are also associated with international marketing. Thus, a businessman operating in international market shall have to identify correctly, assess and interpret the needs of the buyers in the foreign country and make marketing effort to satisfy those needs. However, there are certain distinct characteristics, which are associated with the international marketing only. These are:

Rules and regulations framed by the Government: A businessman desiring to enter the international market has to follow complex formalities relating to customs, foreign exchange etc. He should have full knowledge of rules and regulations governing foreign trade. Documentation part of foreign trade is much more complicated. All these formalities require expense of time and money.

Different languages and customs: There may be some communication barriers because each nation has its own language and customs. Though English is the common language used yet in certain countries people use their own language.

Transit risk: Trading in international market implies that the goods have to undergo long transportation route before they reach the destination. An all-proof packing is a must for the exportable goods. Modes of transport used, in the case of foreign trade is land air or sea. In these modes of transport transit risk is always on the higher side. The goods must be insured before despatch.

Problem of foreign exchange: The currency circulating in the importing and the exporting country is not the same. The currency of one country is considered as a commodity in the other country. Thus, in the case of foreign trade there always remains the problem of exchange of currency. There is a risk associated with the exchange rates, which are always fluctuating. Settlement of accounts between the exporter and the importer may create certain difficulties.

Creditworthiness of the customers: Due to the distances involved the exporter and the importer hardly meet physically. In the absence of any meeting exporter has to depend upon the references for ascertaining the creditworthiness of his customers. The exporter is not certain whether he has obtained the correct picture of his customer.

Blocking of capital: The capital of the businessman remains blocked for comparatively longer period of time because payments are not realized immediately. A number of intermediaries are involved in the case of foreign trade. This results in longer time gap between dispatching of goods and ultimate realisation of payments from the importers.

17.2 KNOWLEDGE ABOUT THE MARKET

Knowledge of the product in which the businessman wants to deal is important but at the same time knowing the target market (in this case the foreign market) is equally important. It has been observed that the most successful exporters remain in constant touch with the market.

Defining the Market

A businessman has to define the geographic location of his potential market. It may be just across the border i.e. neighbourhood or a far off city or a particular region or the whole country. If the businessman knows his market clearly he may be in a position to focus his marketing efforts. Following points need attention of a prospective exporter:

- Potential customers of the product and why they need the product.
- In which way the product is now to the market or different from the product available to it.
- In which way the product is more desirable.
- What are the chances that the product will be accepted or rejected in the prospective market?
- Prepare a list of prospective market areas. These should be the areas where the exporter thinks that his sales programme for the product may find support.

- A testing of prospective market areas may be done with a view to determine where marketing efforts will be more productive.

Initially, it will be more appropriate to deal in a small, geographic locality and thereafter extend the market to keep the cost of operations reasonable.

What Constitutes the Prospective Market

The businessman should find out what? before exporting his product the type of customer and the business. For example:

- Does the target customer belong to a particular age, social or economic group?
- Is the target customer more interested in quality and durability of the product?
- Is the target customer already buying a similar product, which is offered for sale or he is to be educated regarding the uses of product?
- Which of the needs of the target customer will be fulfilled by the product offered for sale?
- Is the target customer likely to haggle/bargain?

Keeping Track of Movements of Exportable Product

The businessman should know beforehand as to when demand for his product arises in the international market. Knowledge of seasonality of demand is very important. If the businessman knows the timing when his product is needed, say near a particular festival time, he should schedule his operations backwards from that date so that supplies are made available well before that festival. The following movements of merchandise may take several weeks (and even months) for completion:

- Movement of goods from importer's warehouse to retailer's warehouse in the importing country.
- Clearance of goods through foreign customs.
- Transporting of goods from the point of manufacture to the port of export.
- Manufacturing time required for producing the goods.
- Preliminary research, planning etc.

All the above tasks may take much longer time than expected and therefore a track of movement of merchandise must be kept.

Conducting Market Research

The businessman should conduct market research in one form or the other on a continuous basis. Good business planning is not possible if no market research is conducted on regular basis. At present it is a buyers' market and not a sellers' market. There is always a need to secure information on the needs and preferences of consumers. It must be the endeavour of the exporter constantly to analyse what is happening in the market place.

Contacting Potential Customers

The businessman needs to know his potential customers. If he knows his market and the customers well, he will be in a position to offer what they need rather than what he wants to sell. In other words a rapport with customers is a must. He may ask his potential customers in the foreign market:

- What is your requirement?
- What is selling well? What features will make for good sales?
- What price would the market bear?
- What terms of sale would you require?

The exporter should find out the stores and businesses they are already interested in goods from his country or are dealing with products in the same line on his intended exports as his potential customers one likely to be found among them.

Check Your Progress Exercise 1

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Fill in the blanks:

   i) Purchase of goods from international markets is called ------------.

   ii) Sale of goods to international markets is called ---------------------.

   iii) Modes of transport used for foreign trade include ---------------- and ----------------------.

   iv) ------------------- should be conducted on regular basis for good business planning.

   v) In foreign trade capital invested remains blocked for comparatively longer period of time due to number of ---------------- involved.

2. Mention two distinct characteristics of foreign trade.

   ……………………………………………………………………………………

   ……………………………………………………………………………………

3. Why does an exporter need to know his potential customers?

   ……………………………………………………………………………………

   ……………………………………………………………………………………

   ……………………………………………………………………………………

17.3 OPPORTUNITIES OFFERED BY THE INTERNATIONAL MARKETS

International markets offer a number of opportunities to a businessman. They are listed as below:

i) Scope for bulk sales

Usually export orders are much larger than those emerging from the domestic markets. Sometimes a single export order may far exceed the total supply made by the firm in a year in the domestic market. The businessman has, thus, the opportunity to go for bulk sales.

ii) *Scope for full utilisation of installed capacity*

Sometimes it may happen that the businessman has got the installed capacity but the same cannot be utilised fully because there is no sufficient demand in the domestic market. Export business provides a suitable opportunity to use the installed capacity to its full extent.

iii) *Scope to overcome recession in the domestic market*

The businessman may face recession in the domestic market for his product. To overcome recession international markets provide a golden opportunity. Recession serves as a stimulus to various export opportunities. The businessman can venture to enter the international markets and create a place for his products.

iv) *Scope to overcome legal restrictions in the domestic market*

Sometimes it may happen that the Government might impose certain restrictions in the domestic market on sale of certain products or on the further growth of particular firms. However, this problem may be sorted out by resorting to exports i.e. accessing international markets. Even the exports may help the businessman to earn export incentives from the Government.

v) *Scope for technological advancement*

A businessman opting for international market might be enabled to pick up new product ideas and to add to the existing product line. Exports provide the chance to go for technological advancement, which may help the businessman to improve his product. Improvement in products will help in reducing costs and also discovering new uses of the product. This can even help in capturing more share of domestic market.

vi) *Scope for diversifying business risks*

Entry into the international market provides an opportunity to the exporter to diversify his risks. At times, domestic market may show downward fluctuation in sales resulting in low turnover and profits. This may be offset if the businessman opts for exports and targets international market to boost his sales. This is nothing but geographical diversification. The businessman can attain growth in his business by adopting this kind of diversification because a single market may not give adequate profits.

vii) *Scope for increase in production*

Survival needs of a business require increase in production. The firm will go for increased production if there is scope for absorption of its product. International markets present an opportunity for absorbing increased production if it is up to the international standards. The businessman may opt for markets in developed and developing nations for supplying his product. Production at large scale helps the firm to derive economies of scale and reduce the cost of production.

Check Your Progress Exercise 2

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. State True or False against each:

   i) There is no scope for bulk sales in case of foreign trade.

   ii) Export business helps in utilizing installed capacity to its full extent.

   iii) Recession in the domestic market does not serve as a stimulus to various export opportunities.

   iv) International markets enable a businessman to pick up new product ideas.

   v) Risks can be diversified by entering international markets.

2. Mention two opportunities available if the businessman enters international markets.

   i) ………………………………………………………………………...

   ii) ………………………………………………………………………...

3. "International markets present an opportunity for absorbing increased production". Comment.

   ……………………………………………………………………….........

   ……………………………………………………………………….........

   ……………………………………………………………………….........

17.4 HOW TO ENTER INTERNATIONAL MARKETS?

A businessman can enter international markets by following any of the following routes mentioned below:

I. Indirect Route
II. Direct Route
III. Other Miscellaneous Routes

Let's now discuss these routes in detail.

I. Indirect Route

In this case the businessman does not enter international markets on his own. He takes the help of merchant exporters for exporting his products. These merchant exporters are usually recognised as star export houses (categorised as one star export house, two star export house, three star export house, four star export house and five star export house – in terms of Foreign Trade Policy 2004-2009).

Export houses are also interested in promoting the exports of goods originating from units in small-scale industry, Tiny sector, cottage industry sector and units registered with KVICs or KVIBs. This is so because, for being recognised as star export houses, these merchant exporters are required to achieve certain export performance. In case they export goods originating from above type of units, they are entitled for double weightage of such exports in calculating their export performance. Further export of agro-products also entitles them to double weightage.

- *Benefits of Exporting Products through Star Export Houses*

  i) *Gain from wide knowledge and experience:* These merchant exporters have wide knowledge and experience about the products, which have an export market. Similarly, they know the international markets, trends prevailing there much better.

  ii) *Availability of finance:* The manufacturers can obtain pre-shipment finance from the export houses as in deserving cases they extend financing facility to their supporting manufacturers. Similarly, the manufacturer can obtain pre-shipment and post -shipment finance from banks on the guarantee of merchant bankers.

  iii) *Less financial risk:* There is less financial risk involved while exporting goods through export houses because generally they (i.e. export houses) make payment to the businessman as soon as he delivers the exportable goods to them.

  iv) *Invaluable advice regarding characteristics of international markets:* Merchant exporters can advise the manufacturers regarding production pattern, packing standards, quality requirements and other important characteristics of international markets. Based on the advice, the manufacturer can bring out a product acceptable in the overseas market.

  v) *Dealers' network:* Most of the merchant exporters have a dealers' network and sales organisations operating in many international markets. Through these organisations and the network they can provide exporting opportunities to the businessman.

  vi) *Valuable guidance regarding product development:* Merchant exporters can provide valuable guidance to the businessman with regard to product development so that exportable products match the international standards. At times they may even give samples of exportable products.

  vii) *Better terms for shipping and insurance:* Shipping and insurance play a major role in exports. The merchant exporters can secure better terms from shipping and insurance companies as compared to the businessman if he wants to act on his own. This is so because the merchant exporters have their own arrangements with these companies and therefore they are in a position to obtain better deals for their clients. At times, merchant exporters combine several shipments from various firms and the goods are shipped that way. This helps in reducing transporting charges considerably.

  viii) *Professional handling of export documentation:* In case of exports, lot of shipping and documentation work is involved, which the merchant exporters can handle more professionally.

II. Direct Route

Export of goods through merchant exporters may not always be beneficial. The main drawback is that the businessman does not get the chance to create goodwill for his our product and brand name. Also he gets less net return on sales to allow for the profit of merchant exporter. He is not recognised in the international market though his product is exported. You will note that success in the international market as exporter may help him in boosting his image in the domestic market also. Keeping these facts in view the businessman may opt for direct exporting. In this respect he may take the following steps:

i) *Try to establish contacts with big departmental stores*

The businessman should try to establish contacts with the big departmental stores in the developed as well as developing countries. Departmental stores keep a variety of products like grocery items, ready-made garments, electronic gadgets, leather goods, jewellery items etc. The key persons to be contacted there may be few. If the product to be exported is of good quality, the businessman may use his personal selling techniques and be in a position to convince one or two such departmental stores to purchase his product. If he succeeds in his endeavour and his product finds way into such departmental stores and the sales of that product at that end picks up it will boost his performance and reputation. There are chances that other departmental stores may also come to know of that product and may place orders for supply. Thus, he will get more and more business.

ii) *Try to establish contacts with institutional buyers*

In every country there are institutional buyers like hospitals, government establishments, hotels, educational institutions etc. In every such institution there is a particular department or key person who purchase the supplies. Here, the businessman has to use his personal selling techniques and thereby establish contacts and persuade the persons concerned to purchase his product. If he succeeds he may secure large export business.

iii) *Direct exporting through co-operative societies*

Forming of co-operative societies by persons having common interest is quite usual in various countries. The members of these co-operatives try to secure better terms for purchasing their requirements. Here also, the key persons to be contacted may be few. In case the businessman is good at personal selling with additional requirement that he produces a qualitative product, he may hope to secure large export orders.

iv) *Overseas sales agents*

Overseas sales agents play an important role in establishing contacts with the importers. They are always near the international markets. A sales agent may be a commission agent or a distributor. In case of commission agents, they secure export orders for the exporters. For their services, they receive an agreed rate of commission from the exporters. In case of distributors, they purchase the exportable products from the exporters. Thereafter, they sell the products on their own through the sale outlets owned by them. Overseas sales agents are very useful to the exporters inasmuch as they provide latest information for adopting right market strategy and guide the exporters in choosing a proper channel of distribution.

Note: It is advisable for a small-scale entrepreneur to undertake export through merchant exporters (i.e. indirect exporting) initially. After gathering enough experience regarding international markets, packaging of exportable products, export documentation, dealing with shipping companies etc. he could go for direct exporting.

III. Other Miscellaneous Routes

Besides indirect and direct exporting there are certain other options available through which entry into international markets may be made. These are stated as below:

a) *Opening a branch office or subsidiary abroad:* The businessman may take steps to open a branch office in a foreign country or even subsidiary at that end. The work to be undertaken there may include processing of the product including assembly and packaging. In the course of time, as the business develops, even complete manufacturing may also be undertaken.

b) *Going for joint ventures:* This is another option available and the businessman may go for joint ventures in foreign countries. Through the joint ventures he may undertake marketing of the product in that country. Manufacturing activities may also be undertaken depending upon the purpose for which the joint venture has been formed. In India a number of joint ventures where foreigners are involved, are operating successfully.

c) *Providing consultancy services:* Another way of entering international markets is to provide consultancy services. A person having expertise in agricultural activities may offer expert advice to the foreigners in increasing the agricultural output. Consultancy services can be provided in other fields of business also. Persons providing consultancy services are known as consultants.

d) *Technology transfer:* The businessman may enter into contract with the foreigners for supply of technology. A franchising agreement may be entered into in this respect. Similarly patents, trademark etc. of the exporting firm may also be used by the overseas buyers.

Check Your Progress Exercise 3

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Name the following:

i) a merchant exporter who helps the businessman in exporting his products.

ii) a person who works on commission basis in the international markets.

iii) a person offering consultancy services to the foreigners.

iv) a person who purchases goods from the exporters and sells them on his own in the international market.

v) A store which keeps a variety of products and which can be contacted by the exporter.

2. Explain the other miscellaneous routes of entering into international markets.

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

……………………………………………………………………………………

17.5 EXPORT CONCESSIONS, INCENTIVES AND PROMOTIONAL MEASURES

In India, the Government has encouraged exports to a considerable extent. A number of export concessions and incentives are available to the exporters – no matter whether they are working on a small scale or large scale. Till 2004, Government had operated EXIM Policy for promotion of exports. Now it is Foreign Trade Policy 2004-2009, which will provide export promotion measures. In the following paragraphs we will study about these concessions, incentives and export promotional measures.

i) Export Finance

Banks have been authorised to provide export finance to exporters at concessional rates. Finance is needed both for the manufacture of exportable goods and after the shipment of the goods. These are termed as pre-shipment finance or packing credit, and post shipment finance. Under pre-shipment finance facility, the exporter obtains finance for purchase, processing, manufacturing, or packing of goods for export purposes. Under post-shipment finance facility, the exporter obtains finance to cover the time to receive payment after the shipment of goods.

ii) Duty Exemption/Remission Schemes

These schemes facilitate import of goods for export production. *Duty exemption schemes* enable duty free import of inputs required for export production. The process starts by issue of an advance licence for duty free import of inputs. The advance licence is issued subject to the actual user condition. Therefore, advance licence and material imported thereunder shall not be transferable even after completion of export obligation. The licence can be issued for physical exports, intermediate supplies and deemed exports.

A *duty remission scheme* enables post export replenishment / remission of duty on inputs used in the export product. These schemes consist of Duty Free Replenishment Certificate (DFRC) Scheme and Duty Entitlement Pass Book (DEPB) Scheme. DFRC permits duty free replenishment of inputs used in the export product. DEPB allows drawback of import charges on inputs used in the export product.

iii) Export Promotion Capital Goods (EPCG) Scheme

Under this scheme import of capital goods is permitted. These capital goods are to be used for export production. New capital goods including computer software systems can be imported under EPCG scheme. The import is permitted at a concessional customs duty rate of 5%. However, export obligation equivalent to 8 times of customs duty saved on capital goods imported under the EPCG scheme shall be fulfilled over a period of 8 years. The period for fulfilling export obligation shall be increased to 12 years if the duty saved is Rs. 100 crores or more. For exports of agricultural products and their value added variants, import of capital goods would be allowed at 0% duty.

iv) *Duty Drawback (DDB) Scheme*

For the production of export goods raw materials and components are used on which excise duty/customs duty is paid. Under *Duty Drawback Scheme* excise and customs duties paid on raw materials and components used for producing export goods are refunded to the exporters once the exports materialise.

v) *Deemed Exports*

In case of deemed exports, goods supplied or sold do not leave the country. This is possible when the goods are supplied to some particular establishments like units located in EPZ, 100% EOUs, projects funded by United Nations Agencies or multilateral or bilateral agencies, power projects and refineries, etc. in India. Payment for these supplies is received either in Indian rupees or free foreign exchange. Deemed exports are eligible for following benefits:

a) Advance licence for intermediate supplies/deemed exports/DFRC/ DFRC for intermediate supplies.
b) Deemed export drawback.
c) Exemption / refund of terminal excise duty.

vi) *Market Development Assistance (MDA)*

Under MDA scheme, assistance is provided to the exporter for marketing his products in the international markets. You know that export marketing requires heavy investments. Exporters on their own may not be in a position to market the products. To help them out in marketing of export products, MDA has been devised. As per the revised Guidelines effective from April, 2004 assistance under MDA is available to exporters with annual export turnover up to Rs. 5 crores. The marketing development assistance is provided for the following purposes:

a) Individual sales-cum-study tours/trade delegations abroad.
b) Individual participation in trade fairs, exhibitions and buyers-cum-sellers meets abroad or in India.
c) For conducting Export promotion seminars.
d) Publicity and advertisement.
e) Other specified activities.

vii) *Taxation Relief*

For promoting exports income tax exemption is available. However, the income tax exemption scheme is going to be phased out over a period of five years by 2004-05. It is provided that the scheme shall remain operational for the units located in EPZs and in case of 100% EOUs. As regards sales tax, the same is not to be levied in case of export sales. Goods meant for export can be purchased without payment of sales tax against issue of Form H. Further excise duty is not leviable on and if paid is refunded to the exporters.

viii)Export Processing Zones (EPZ)

With a view to provide an internationally competitive duty free environment for production of exportable goods, EPZs have been set up. Units located in EPZs get infrastructural facilities for manufacturing products at lower cost. They need not obtain import licence for importing capital goods, raw materials etc. Excise duty is exempted on capital goods and raw materials purchased from the domestic market.

ix) 100% Export Oriented Units (100% EOUs)

A businessman can set up these types of units anywhere in the country. 100% EOUs are required to export their entire production except some permitted portion, which can be sold in the domestic market. Similar facilities which are available to units located in EPZs are also available to 100% EOUs. An EOU engaged in agriculture, floriculture or horticulture may be permitted to remove specified goods in connection with its activities for use outside the bonded area.

x) Special Agricultural Produce Scheme (Vishesh Krishi Upaj Yojana)

This Scheme has been announced in the Foreign Trade Policy 2004-2009. The objective of the Scheme is to promote export of fruits, vegetables, flowers, minor forest produce, and their value added products. Exporters of such products shall be entitled for Duty Credit Scrip equivalent to 5% of the FOB value of exports for each licensing year commencing from 1st April 2004. The exporters can freely transfer the scrip and the items imported against it. Further, the Duty Credit may be used for import of inputs or goods including capital goods.

Check Your Progress Exercise 4

Note: a) Use the space below for your answer.
b) Compare your answers with those given at the end of the unit.

1. Write full forms of the following abbreviated schemes:

   i) DEPB Scheme ---

   ii) DFRC Scheme ---

   iii) EPCG Scheme ---

   iv) MDA Scheme ---

   v) DDB Scheme ---

2. Following paragraph, which relates to 'Export Finance', contains certain blanks. You are required to fill in the blanks with appropriate words:

   'Banks have been authorised to provide export finance to exporters at ------------- rates. Finance is needed both for the manufacture of ------------ goods and after the shipment of the goods. These are termed as -------------- finance or packing credit, and ------------- finance. Under the facility, the exporter obtains finance for purchase, ------------, manufacturing, or --------- of goods for export purposes. Under post-shipment finance facility, the exporter obtains finance for the purpose that it may take sometime to receive --------------- after the shipment of goods.'

17.6 EXPORT PRICING AND EXPORT DOCUMENTS

Export Pricing

Export pricing is the most important factor, which a businessman must consider for success in the international markets. There are some specific issues associated with export pricing which are not present in the domestic pricing of a product. These are as under:

i) Currency for export pricing

In India, the businessman can quote the price of his product in rupees but when he goes into the international market there arises a question – in which currency he should quote the price. Exchange rate fluctuations can increase or decrease the export profits to a significant extent. A stable currency should be considered for export pricing.

ii) Consideration of inflation

Every country in the world is in the grip of inflation. Prices of the products are affected by the inflationary conditions. Therefore, to counteract the inflation, pricing policy should be so designed that it takes into account the measures, which help in decreasing the impact of inflation. If the businessman faces high inflation rates, he may follow NIFO (Next in First Out) system.

iii) Quoting of export price (Price quotations)

In case of international marketing there are many ways in which export price may be quoted. These are as under:

- *Loco price:* Loco price, also known as ex-factory price includes the cost of production and the normal profit margin. In case of this type of quotation the foreign importer has to collect the goods from the seller's warehouse. The other expenses incurred for taking the goods to importer's place are to be borne by the importer.
- *F.O.R. (Free on Rail):* In this type of quotation, the exporter quotes the export price, which includes the cost of goods, profit margin and the cost of carrying the goods to the railway station and loading them.
- *F.A.S. (Free along side ship):* In this type of quotation, the exporter quotes the export price, which includes the cost of goods, profit margin, cost of carrying the goods to the railway station and loading them, and charges for placing the goods near the ship.
- *F.O.B. (Free on Board):* In this type of quotation, the exporter quotes the export price, which includes the cost of goods, profit margin, cost of carrying the goods to the railway station and loading them in the wagons, and charges for loading the goods into the ship.
- *C. & F (Cost & Freight):* This type of price quotation includes the F.O.B. price and the freight payable to the shipping company for transporting the goods to the importer's country.
- *C.I.F. (Cost Insurance & Freight):* In this type of quotation, the exporter quotes the export price, which includes C&F price and the premium paid for marine insurance.

- *Ex-ship price:* In this type of quotation, the exporter quotes the export price, which includes all the expenses until the ship arrives at the port of destination.
- *Landed price:* In this type of quotation, the exporter quotes the export price, which includes ex-ship price and also the cost of unloading the goods from the ship.
- *FRANCO:* This type of price quotation includes all the expenses for delivering the goods at the warehouse of the importer.

Export Documents

There are certain principal export documents, which are required for transferring ownership of the goods from the exporter to the importer. There are certain other documents, termed as auxiliary export documents, which are required for the preparation of principal export documents. These export documents are stated below:

Principal export documents

i) Commercial Invoice

ii) Packing List

iii) Bill of Lading

iv) Certificate of Inspection

v) Letter of Credit

vi) Marine Insurance Policy

vii) Certificate of Origin

viii) Bill of Exchange

Auxiliary export documents

i) Proforma Invoice

ii) Intimation for Inspection

iii) Shipping Instructions

iv) Insurance Declaration

v) Shipping Order

vi) Mate's Receipt

vii) Application for Certificate of Origin

viii) Letter to the Bank for negotiation or collection of documents

17.7 LET US SUM UP

Doing business after crossing national boundaries means entering into international markets. Purchase of goods from international markets is called ‘import’ and sale of goods thereto is called ‘export’. Before going for exports the businessman needs to know the target market. His should understand his customers, what type of product they need, whether the product he is offering fits into the category, which is in demand and so on. He is required to keep a track of the movements of his product, which he desires to export so that it is placed in the target international market at the right time. In this connection he should schedule operations backwards. A market research on regular basis is a must because at present it is a buyers’ market and not a sellers’ market. The businessman should remain in constant contact with his customers. International markets offer a number of opportunities like scope for bulk sales, full utilisation of installed capacity, overcoming of any legal restrictions or recession in the domestic market, diversification of business risks, increase in production etc. International markets may be approached either through indirect exporting or direct exporting but it is always better if a small entrepreneur initially adopts the route of merchant exporters for exporting his goods. Other routes of entering international markets include opening a branch office or subsidiary in the foreign country, going for joint ventures with foreign nationals providing consultancy services and transfer of technology. In India, a number of concessions, incentives and promotional measures are available for boosting exports. They include availability of export finance at lower rates of interest, duty exemption/remission schemes, EPCG scheme for import of capital goods, duty drawback scheme, deemed exports, market development assistance scheme, taxation relief, duty credit scrip to the exporters of horticulture produce, etc. Export pricing should be done keeping in view the specific issues associated with it. Depending upon the agreement reached between the exporter and the importer, export price quotation may be loco price, F.O.R., F.A.S., F.O.B., C. & F., C.I.F., ex-ship price, landed price or FRANCO. In the export of goods a number of documents are involved which may be categorised as principal export documents and auxiliary export documents.

17.8 KEY WORDS
